Release Notes for Creo Toolkit

Technical Summary of Changes for Creo 12.4.0.0.....	7
Technical Summary of Changes for Creo 12.4.1.0.....	11

Technical Summary of Changes for Creo 12.4.0.0

This section describes the critical and miscellaneous technical changes in Creo 12.4.0.0 and Creo TOOLKIT. It also lists the new and superseded functions for this release.

Critical Technical Changes

This section describes the changes in Creo Parametric 12.4.0.0 and Creo TOOLKIT that might require alteration of existing Creo TOOLKIT, Creo Elements/Pro TOOLKIT, and Pro/TOOLKIT applications.

Updates to the Error Type

The error type `PRO_TK_SUPPRESSED` is added to the header file `ProToolkitErrors.h`. This error type indicates that the object is suppressed.

Quarterly Release Cadence

In and later, Creo releases will be versioned as per quarterly cadence. For example, the first quarterly release for Creo will be versioned as 12.0.0.0, second as 12.1.0.0 and so on. To avoid any confusion with the point release 12.0.0.0, 12.1.0.0, 12.2.0.0, the external major version string is modified from Creo 12.0 to Creo 12.

New Functions

This section describes new functions for Creo TOOLKIT for Creo Parametric 12.4.0.0.

Annotation Features

New Function	Description
<code>ProAnnotationelemReferencesInherit-Get()</code>	Checks if a child annotation element inherits references from its parent.
<code>ProAnnotationelemReferencesInherit-Set()</code>	Sets the semantic inherit references flag in a child annotation element to inherit references from its parent.
<code>ProDrawingViewAnnotDispStatusGet()</code>	Gets the display status of all annotations of a drawing view.
<code>ProDimensionTangentAttachGet()</code>	Retrieves the dimension to take tangent as minimum, maximum, or center.
<code>ProAnnotationReferencesInheritGet()</code>	Checks whether a child annotation

New Function	Description
	element inherits references from its parent.
ProAnnotationReferencesInheritSet()	Sets a child annotation to inherit references from a parent.
ProAnnotationReferenceIsInherit()	Checks whether the specified reference is an inherited annotation reference.

Cross Section

New Function	Description
ProXSectionItemXhatchScaleUp()	Doubles the hatch scale of xsec_item.
ProXSectionItemXhatchScaleDown()	Scales down the hatch of xsec_item in half.
ProXSectionItemXhatchScaleSet()	Sets the hatch scale value of xsec_item.
ProXSectionItemXhatchRotate()	Rotates the hatch of xsec_item.
ProXSectionItemXhatchRotateClockwise()	Rotates the hatch of xsec_item clockwise using the config hatch_pattern_rotation_interval.
ProXSectionItemXhatchRotateCounter-Clockwise()	Rotates the hatch of xsec_item counter-clockwise using the config hatch_pattern_rotation_interval.
ProXSectionItemXhatchRotateAngle-Set()	Rotates the hatch of xsec_item to rotate_val.
ProXSectionItemXhatchTranslateHorizontal()	Translates the hatch horizontally using the translate_by object.
ProXSectionItemXhatchHorizontalOffsetSet()	Sets the hatch horizontal offset to the horizon_offset.
ProXSectionItemXhatchTranslateVertical()	Translates the hatch vertically by translate_by.
ProXSectionItemXhatchVerticalOffsetSet()	Sets the hatch vertical offset to the vertical_offset.
ProXSectionItemXhatchColorSet()	Sets the color of the hatch pattern.

Appearance States

New Function	Description
ProApprnrstateIsActive()	Determines if the given appearance state is active.

Drawings

New Function	Description
ProDrawingViewXhatchDependentGet()	Checks if the section hatching is dependent on the parent view.
ProDrawingViewXhatchDependentSet()	Sets the section hatching dependency on the parent view.
ProDtlsyminstSurffinGet()	Gets the owner surface finish from the symbol instance cosmetic.
ProDrawingViewSegmentedLeaderGet()	Returns the leader view of a segmented (total unfold) view.

Holes

New Function	Description
ProSketchedHoleMembersCount()	Counts number of holes created by sketched placement hole.
ProSketchedHoleGeomitemVisit()	Visits all the geometry items created by the sketched placement hole.

Fundamentals

New Function	Description
ProToolkitApplDisplayVersionGet()	Returns the version on which the application was built.

Model-based Definition Tables

New Function	Description
ProTableCellMergeGet()	Gets the merge information of a specified cell.
ProTableCellBlankGet()	Gets the blank border information for the specified cell.
ProTableBorderStyleGet()	Gets the line style of the table borders.

New Function	Description
ProTableCellFillColorGet()	Get the color of the specified cell.
ProDwgtabledataFree()	Free the memory allocated for the ProDwgtabledata structure.

Models

New Function	Description
ProMdlHasNoConflict()	Checks if the specified model does not have a storage conflict at the time of saving the modifications.
ProMdlsAreModifiable()	Checks if the specified models are modifiable.
ProMdlsHaveNoConflict()	Checks if the specified models do not have a storage conflict at the time of saving the modifications.

User Interface: Tab Operations

New Function	Description
ProUITabItemInsert()	Inserts a new item after an existing one in the tab.
ProUITabItemDelete()	Deletes an item from the tab.

Miscellaneous Technical Changes

The following changes in Creo Parametric 12.4.0.0 can affect the functional behavior of Creo TOOLKIT. PTC does not anticipate that these changes cause critical issues with existing Creo TOOLKIT, Creo Elements/Pro TOOLKIT, or Pro/TOOLKIT applications.

Support for the New Dimension Type

In Creo Parametric 12.0.0.0 and later, the value `PRODIMTYPE_IPAR_INT` is added to the enumerated data type `ProDimensiontype`. You can now retrieve the `IPAR_INT` dimension type of a user-defined feature that includes patterns.

Support for Solidify Plies Feature

In Creo Parametric 12.4.0.0 and later, the element tree for Solidify Plies feature is added in the header file `ProSolidifyPlies.h`. Solidifying plies is the creation of solid geometry from laminate objects. You can create only one solidify plies feature in a composite feature. The feature is updated automatically when the laminate is updated.

Updates in the Connected Body in the Generative Design Application

In Creo Parametric 12.4.0.0 and later, the value `PRO_SIMULATION_GD_CONNECTED_BODY` is added to the enumerated data type. In a Generative Design application, when you create contact between an undesignated body and a generative body, the undesignated body becomes classified as a connected body.

Updates in `ProMfgOptions.h` header file

In Creo Parametric 12.4.0.0 and later, the following enumerated data types are added to the header file `ProMfgOptions.h`.

- `PRO_NCSEQ_MW_UNDERCUT_MACHINING`—The new NC sequence of type Undercut Machining is added.
- `PRO_TM_TYPE_MW_UNDERCUT_MACHINING`—The new tool motion type for the Undercut Machining NC sequence.

Cabling Data Object for a Composite Part

For a composite part, specify the type of cabling data object `ProMdlsubtype` as `PROMDLSTYPE_CBL_DATA_OBJ`.

Technical Summary of Changes for Creo 12.4.1.0

This section describes the critical and miscellaneous technical changes in Creo 12.4.1.0 and Creo TOOLKIT. It also lists the new and superseded functions for this release.

Critical Technical Changes

This section describes the changes in Creo Parametric 12.4.1.0 and Creo TOOLKIT that might require alteration of existing Creo TOOLKIT, Creo Elements/Pro TOOLKIT, and Pro/TOOLKIT applications.

Updates to Error Types

The following functions have updates to the error type:

- The error type `PRO_TK_CANT_MODIFY` is added to the following functions. The functions that do not support read-only or locked models return the error type `PRO_TK_CANT_MODIFY` when a read-only or locked model is passed as the input model.
- `ProTableCreate()`
- `ProTableTextEnter()`
- `ProTableDelete()`
- `ProTableDisplay()`
- `ProTableErase()`
- `ProTableRowAdd`
- `ProTableColumnAdd()`
- `ProTableCellsMerge()`
- `ProTableCellMergeGet()`
- `ProTableCellsRemesh()`
- `ProTableRowDelete`
- `ProDwgtableColumnDelete()`
- `ProTableRotate()`
- `ProTableColumnWidthSet()`
- `ProTableRowHeightSet()`
- `ProTableRowheightAutoadjustSet()`
- `ProTableReferencesAdd()`
- `ProTableReferenceDelete()`

New Functions

This section describes new functions for Creo TOOLKIT for Creo Parametric 12.4.1.0.

Material Types and Properties

New Function	Description
<code>ProMaterialUsageParametersCollect()</code>	Collects all usage parameters for the specified material.

Models

New Function	Description
ProMdlLayersVisit()	Calls the specified filter and action functions for each layer in the model.

Solids and Parts

New Function	Description
ProLayerstateDefaultPropagateSet()	Controls whether layer statuses propagate from the top model to sub-models by default.

2

Get Started

Creo TOOLKIT Concepts	15
Installing and Testing the Creo TOOLKIT Development Environment	16
Using Extended Resources	24

Creo TOOLKIT Concepts

Creo TOOLKIT is the customization toolkit for Creo Parametric. Customers and partners can expand the capabilities of Creo Parametric by writing C or C++ programming language code using Creo TOOLKIT and then seamlessly integrating the resulting application into Creo Parametric. PTC provides new releases of Creo TOOLKIT concurrently with releases of Creo Parametric.

Creo TOOLKIT uses an object-oriented design. A library of C functions provides safe and controlled access to the Creo Parametric database and applications. Many data structures for transfer of information between Creo Parametric and the application are not directly visible to the application. Contents of these data structures are accessible only with Creo TOOLKIT functions. The sections in this chapter describe the capabilities and modes of communication of Creo TOOLKIT.

What Can You Do with Creo TOOLKIT?

With Creo TOOLKIT you can:

- Automate modeling for derived or single-use models driven by geometric or parametric constraints
- Monitor the state of the user's interactive session to enforce company rules or offer design advice
- Integrate external applications requiring access to Creo Parametric data or operations
- Extend the Creo Parametric user interface with custom processes seamlessly embedded into the interface
- Automate tedious or difficult Creo Parametric operations with applications designed to save design time and prevent mistakes.
- Create processes to run automatically without a user interface on demand or at designated times.

Communication Modes for Creo TOOLKIT

Creo TOOLKIT supports synchronous applications that are invoked from commands within a session of Creo Parametric. Modes of communication for synchronous applications may be:

- **DLL mode**—A dynamically-linked library (DLL) is loaded by the Creo Parametric executable at runtime. Communication between the DLL and Creo Parametric is as fast as possible and hence the DLL mode is the preferred mode for application development.
- **Spawn (multiprocess) mode**—A separate executable is spawned by Creo Parametric. Spawn-mode applications interact with Creo Parametric through

interprocess communications and hence are slower than the DLL mode. This mode is typically used as a part of asynchronous mode applications, where the external application starts or connects to external sessions of Creo Parametric as needed.

Another mode available is asynchronous mode applications, where the external application starts or connects to external sessions of Creo Parametric as needed.

Installing and Testing the Creo TOOLKIT Development Environment

This section discusses the process to install Creo TOOLKIT and to test the development environment. The test application and other sample code described in this guide assume the use of a Windows environment.

Installing Creo Toolkit

The next sections describe how to install Creo TOOLKIT.

Overview

Creo TOOLKIT is on the same DVD as Creo Parametric, so you do not need to arrange a special delivery from your supplier. When Creo Parametric is installed using PTC.Setup, one of the optional components is *API Toolkits*. This includes Creo TOOLKIT, Pro/WebLink, J-Link, VB, and Creo Object TOOLKIT C++ and Creo Object TOOLKIT Java.

If you select Creo TOOLKIT, it is installed under the loadpoint of Creo Parametric at the location `<creo_loadpoint>\<datecode>\Common Files\protoolkit`. The `protoolkit` directory contains all the headers, libraries, example applications, and documentation specific to Creo TOOLKIT.

The following figure shows the tree of directories found under the Creo TOOLKIT loadpoint after installation.

Creo Toolkit Installation Directory Tree

The directory `protk_appls` contains sample Creo TOOLKIT applications. For more information regarding the sample applications refer to the Appendix on Sample Applications.

Setting Up the Development Environment

Before you build your first Creo TOOLKIT application, set up the supported compilers, sample make files, and the appropriate licensing for your application development environment.

Platform and Compiler Support

Creo TOOLKIT runs on the same platforms as Creo Parametric. The Platform Support notes at [Creo Future Platform Support Summary](#) describes the compilers supported by PTC.

Licensing for Creo TOOLKIT

Creo TOOLKIT requires a license for developing and testing applications. To check if you have the Creo TOOLKIT license option, run the `Ptcstatus` utility from the Creo Parametric load point. Check for the license option `TOOLKIT`. You can check the license option in Creo Parametric user interface. Click **File** ► **Help** ► **System Information**. In the **INFORMATION WINDOW**, under **Configured Option Modules** check for the license option `TOOLKIT`. In case the license is not available please contact your system administrator.

When you first build an application using Creo TOOLKIT, the application is considered "locked." The application requires the Creo TOOLKIT development license when you test it in Creo Parametric. Loading a locked application into a session of Creo Parametric that lacks the Creo TOOLKIT license causes an error as the application starts.

Before you distribute an executable for a Creo TOOLKIT application to your end user, you must unlock it. Unlocking allows the end user to run the application without having the Creo TOOLKIT license.

The unlock process is initiated with the following command:

```
<creo_loadpoint>/<version>/Parametric/bin/protk_unlock  
<filename>
```

In the previous command, `filename` is the full path to the Creo TOOLKIT application.

Testing the Creo Toolkit Installation

After your system administrator has installed Creo TOOLKIT, you should compile, link, and run a simple Creo TOOLKIT application as soon as possible on each machine you intend to use for development. This provides an independent test of the following items:

- The installation of Creo TOOLKIT is present, complete, and visible from your machine.
- The version of Creo Parametric you plan to use during development has the Creo TOOLKIT license option added to it.
- The machine you will use for development has access to all the necessary C program development tools, in versions supported by Creo TOOLKIT (especially, of course, the C compiler and linker).

Makefiles

PTC provides sample makefiles for each platform. These makefiles:

- Document the compiler and linker flags to be used for each platform
- Serve as templates for structuring your own application makefiles

Refer to these makefiles when creating a new application. Update the flags in your application makefiles when moving to a new release of Creo Parametric.

Using the Microsoft Visual Studio Solution

PTC provides a ready-to-use Visual Studio solution on the Windows platform to create and test Creo TOOLKIT applications by using a makefile or by setting up the Visual Studio development environment. For the version of Visual Studio compatible with the release of Creo TOOLKIT, refer to the hardware notes at [Creo Future Platform Support Summary](#).

This ready-to-use Visual Studio solution has the following advantages:

- Provides an effective way to build and test sample applications provided by PTC.
- Provides a pre-configured Visual Studio development environment for use with Creo TOOLKIT.
- Supports **Intellisense** for Creo TOOLKIT functions.

Note

- The supported version of Visual Studio changes with every release of Creo TOOLKIT, and hence the compiler flags and libraries also change. For every release, you must download the latest version of the ready-to-use solution from the Creo TOOLKIT load point.
- In Creo Parametric 11.0.0.0 and later, Creo TOOLKIT supports Visual Studio 2022. The compiler flags and libraries are available for Visual Studio 2022. Creo TOOLKIT no longer supports Visual Studio 2019.

All Creo TOOLKIT applications on 64-bit Windows platforms built using the Microsoft Visual Studio 2022 compiler must set the configuration property Platform Toolset as Visual Studio 2022 (v17.6.5).

When you install Creo TOOLKIT, the file `protk_install_example.zip` is installed under the `<creo_toolkit_loadpoint>` at `<machine_type>/obj`. To use this solution:

1. Unzip `protk_install_example.zip`. The following directories and files are available:

Directory or File	Description
<code>make_install</code>	Contains the makefile project and the <code>creotk.dat</code> file.
<code>make_install.sln</code>	Specifies the ready-to-use Visual Studio solution file.

2. Open Microsoft Visual Studio.
3. Click **File ► Open ► Project/Solution**. The **Open Project** dialog opens.

-
4. Browse the `protk_install_example` directory and select `make_install.sln`.
 5. Click **Open** to access the solution file. The `make_install` makefile project is available in Visual Studio.

Running the Makefile Project

1. Click **Build ► Build make_install**. The application should build without errors. This creates the Creo TOOLKIT DLL file called `pt_inst_test.dll`. If the application fails, check that the environment variable `PROTOOL_SRC` is set correctly.
2. Modify the `exec_file` and `text_dir` fields in the `creotk.dat` file located in the `make_install` directory to specify the full path to `pt_inst_test.dll` and `\text`, respectively. For example,

```
exec_file <full_path>\pt_inst_test.dll
text_dir <full_path>\text
```
3. Unlock the application, using the following command:
`<creo_loadpoint>/<datecode>/Parametric/bin/protk_unlock.bat <path to executables or DLLs to unlock>`.
4. Start Creo Parametric.
5. On the **Tools** tab, in the **Utilities** group, click **Auxiliary Applications**. The **Auxiliary Applications** dialog box opens.
6. Click **Register** to register the updated `creotk.dat` file. The **Register auxiliary application** dialog box opens.
7. Browse to the `<full_path>` and select `creotk.dat`.
8. Click **Open**. The Creo TOOLKIT application adds the command **Install Test** under the **Tools ► File** menu in the **TOOLKIT** group in the **Home** tab on the Creo Parametric ribbon user interface.

Note

Refer to the Creo Parametric Help for more information on customizing the Ribbon.

9. Click **Tools** and then click **File ► Install Test**. The Creo TOOLKIT **Install Test Results** message window opens, indicating that the installation test has succeeded.

10. Click **OK**.

To run other sample applications provided by PTC, follow these steps:

1. Copy the required makefile from `<creo_toolkit_loadpoint>\$<machine_type>\obj` to the `make_install` directory of the ready-to-use Visual Studio solution.

If you are working on a 64-bit Windows platform, copy the file from `<creo_toolkit_loadpoint>\x86e_win64\obj`.

2. Copy the text directory associated with the sample application from `<creo_toolkit_loadpoint>\protk_appls\<app_name>\text` to the `make_install` directory.
3. Open Visual Studio and set the values of the following variables in the makefile:
`PROTOOL_SRC = ../../../../../../protoolkit`
`PROTOOL_SYS = $(PROTOOL_SRC)/$(PRO_MACHINE_TYPE)`
4. Click **Project ► Properties** to update the **NMake** properties of the project.
5. Click **Build ► Rebuild make_install**. The application builds and creates a new `.dll` file.
6. Update the `creotk.dat` file located in the `make_install` directory with the name of the sample application and the DLL file.
7. Modify the `exec_file` and `text_dir` fields in the `creotk.dat` file to specify the full path to the `.dll` file and `\text` directory, respectively.
8. Start Creo Parametric.
9. On the **Home** tab, in the **Utilities** group, click **Auxiliary Applications** or click **Tools ► Auxiliary Applications**. The **Auxiliary Applications** dialog box opens.
10. Click **Register** to register the updated `creotk.dat` file. The **Register auxiliary application** dialog box opens.
11. Browse to the full path and select `creotk.dat`.

12. Click **Open**. The Creo TOOLKIT application runs.

Creating Your Own Microsoft Visual Studio Project

The Creo TOOLKIT load point includes the source of a simple application called `pt_install_test` designed specifically to help you test the installation. The steps to build and run the test application follow.

1. Open Microsoft Visual Studio.
2. Create a project named `ProTOOLKITInstall` in an empty directory. Set this project to be a makefile project.

3. Set the **Debug Configuration Settings** to run the Creo Parametric makefile as shown in the following table and figure:

Setting	Value
Command line	<code>nmake /f make_install dll</code>
Output	<code>pt_inst_test.dll</code>
Clean all commands	<code>del pt_inst_test.*</code>
Rebuild all commands	<code>nmake /f make_install dll</code>
Include search path	<code><creo_loadpoint>\<version>\Common Files\protookit\includes</code>

4. Set the **Release Configuration Settings** to the same settings as the **Debug Configuration Settings**. Click **Finish**.
5. Copy the file `make_install` from `<creo_toolkit_loadpoint>/<machine>/obj` to your project directory, that is, the directory `ProTOOLKITInstall` that also contains `ProTOOLKITInstall.vcproj`. If you are working on a 64-bit Windows platform, copy the file from `<creo_toolkit_loadpoint>/x86e_win64/obj`.
6. Click **Project ► Add Existing Item** to add the makefile to the project. In the **Add Existing Item** window, view all files and select the file `make_install`.
7. Edit the setting for `PROTOOL_SRC` (EXTERNAL USE – DEFAULT) in `make_install` to point to the Creo TOOLKIT installation directory, that is, `<creo_loadpoint>/<version>/Common Files/protokit`.

Note

If the Creo Parametric load point is in a directory containing spaces, use the DOS short names.

8. On the Windows 64-bit platform select the platform as follows, else go to the next step:
 - a. Click **Build ► Configuration Manager**.

-
- b. Under **Active Solution Platform**, select **New**. The **New Solution Platform** dialog box opens
 - c. Type x64 as the platform and click **OK**.
 9. Click **Build ► Rebuild Solution**.

The application should build without errors. This creates the Creo TOOLKIT DLL file called `pt_inst_test.dll`. If it fails, check that the path to the Creo TOOLKIT installation directory is set correctly in the makefile in step 7.
 10. In the `install_test` directory, create a text file called `creotk.dat`. This registry file provides Creo Parametric information about the Creo TOOLKIT application. The `creotk.dat` file should contain the following lines:

```
name install_test
startup dll
exec_file pt_inst_test.dll
text_dir <creo_toolkit_loadpoint>/protk_appls/pt_install_test
end
```
 11. Run Creo Parametric from the directory that contains the `creotk.dat` file. The Creo TOOLKIT application adds the command **Install Test** under the **File ► Tools** menu in the **TOOLKIT** group in the **Home** tab on the Creo Parametric ribbon user interface.

If you encounter an error, or if the Creo TOOLKIT command does not appear in the Creo Parametric **TOOLKIT** group, verify if the Creo Parametric version that you ran has the Creo TOOLKIT license included.
 12. Click **Tools** and then click **File ► Install Test**. The Creo TOOLKIT **Install Test Results** message window opens, indicating that the installation test has succeeded.

Using Extended Resources

This section provides the resources for support in working with Creo TOOLKIT for the following areas:

- Example code provided
- Technical Support
- PTC User Community

As you become more familiar with these resources, you'll find that they overlap in areas of expertise. A PTC online account is required to access PTC documentation from the Web. Register for an account at <https://www.ptc.com/appserver/common/account/basic.jsp>.

Locating Example Code

PTC provides many sample applications with Creo TOOLKIT in directories under the path `protoolkit/protk_appls`. This section describes some of the sample applications. You can refer to the APIWizard and the `protoolkit/protk_appls` directory for other sample applications.

pt_userguide

Location	Makefile
<code><creo_toolkit_loadpoint>/protk_appls/pt_userguide</code>	<code>make_userguide</code>

The sample application `pt_userguide` consolidates examples that access the User Interface.

pt_examples

Location	Makefile
<code><creo_toolkit_loadpoint>/protk_appls/pt_examples</code>	<code>make_examples</code>

The sample application `pt_examples` consists of Creo TOOLKIT application examples. It provides a user interface to access many areas of Creo TOOLKIT. This application covers Creo TOOLKIT functions and modules, including ProMenuBar and ProMenu based UI functions. The directory `pt_examples` includes sub-directories containing useful utility functions.

pt_async

Location	Makefile
<code><creo_toolkit_loadpoint>/protk_appls/pt_async</code>	<code>make_async</code>

The sample application `pt_async` provides an example for the full asynchronous mode.

Other Sample Applications

The following table lists all the sample applications available with the Creo TOOLKIT installation. Please refer to the *Creo TOOLKIT User's Guide* for more information.

Sample Application	Location	Makefile
<code>pt_af_examples</code>	<code>protoolkit/protk_appls/pt_af_examples</code>	<code>make_af_examples</code>
<code>pt_autoaxis</code>	<code>protoolkit/protk_appls/pt_async</code>	<code>make_async</code>
<code>pt_basic</code>	<code>protoolkit/protk_appls/pt_basic</code>	<code>make_basic</code>
<code>pt_geardesign</code>	<code>protoolkit/protk_appls/pt_</code>	<code>make_geardesign</code>

Sample Application	Location	Makefile
	geardesign	
pt_inst_cxx	protoolkkit/protk_appls/pt_install_cxx	make_install_cxx
pt_install_test	protoolkkit/protk_appls/pt_install_test	make_install
pt_mech_examples	protoolkkit/protk_appls/pt_mech_examples	make_mech_examples
pt_mfg_proctable	protoolkkit/protk_appls/pt_mfg_proctable	make_mfg_proctable
pt_simple_async	protoolkkit/protk_appls/pt_simple_async	make_simple_async
pt_udf_examples	protoolkkit/protk_appls/pt_udf_examples	make_udf_examples
pt_wc_server	protoolkkit/protk_appls/pt_wc_server	make_wc_server

Contacting PTC Technical Support

Technical support for Creo Parametric and Creo TOOLKIT is available 24 hours a day, 7 days a week. You can contact Technical Support by phone, fax, e-mail, or FTP. For resources and services to help you with PTC software products, please visit the Customer Support Guide in the eSupport Portal at:

<http://support.ptc.com/appserver/support/csguide/csguide.jsp>

You must have a Service Contract Number (SCN) before you can receive assisted technical support. If you do not have a service contract number please contact PTC Customer Care by clicking the [Contact](#) tab on the Customer Support Guide page.

Joining the PTC/USER Community

PTC/USER Community provides education and communication services for users of PTC software. This nonprofit corporation offers an annual international conference and connects you to more experienced PTC software users, including Creo TOOLKIT developers. Visit <http://www.ptcuser.org> for more details.

Fundamentals

Fundamentals

This section describes fundamental Creo TOOLKIT concepts and functions.

Introduction to Creo Toolkit

Creo TOOLKIT is the customization toolkit for Creo Parametric from Parametric Technology Corporation (PTC). It gives customers and third-parties the ability to expand Creo Parametric capabilities by writing C programming language code and then seamlessly integrating the resulting application into Creo Parametric.

Creo TOOLKIT provides a large library of C functions to provide the external application safe and controlled access to the Creo Parametric database and applications. Creo TOOLKIT is the primary PTC application programmer's interface (API) for Creo Parametric.

Creo Toolkit Style

Creo TOOLKIT uses an object-oriented programming style. Data structures for the transfer information between Creo Parametric and the application are not directly visible to the application. These data structures are accessible only with Creo TOOLKIT functions.

Objects and Actions

The most basic Creo TOOLKIT concepts are objects and actions.

Each Creo TOOLKIT library C function performs an action on a specific type of object. The Creo TOOLKIT convention for function names is the prefix “Pro” the name of the object type, and the name of the action it performs, for example:

```
ProSectionLocationGet()
```

A Creo TOOLKIT object is a well-defined and self-contained C structure used to perform actions relevant to that object. Most objects are items in the Creo Parametric database, such as features and surfaces. Others, however, are more abstract or transient, such as the information resulting from a select action.

In Creo TOOLKIT, each type of object has a standard name consisting of a “Pro” plus capitalized word that describes the object. Simple examples of Creo TOOLKIT object types and their Creo Parametric equivalents are as follows:

- `ProFeature`—A feature
- `ProSurface`—A surface
- `ProSolid`—An abstract object created to exploit the commonality between parts and assemblies

- ProWcell—A workcell feature in a manufacturing assembly

Creo TOOLKIT provides a C typedef for each object used for variables and arguments that refer to those objects. Creo TOOLKIT objects have a hierarchical relationship that reflects the Creo Parametric database. For example, a ProFeature object can contain objects of type ProSurface (among others).

For example, the following functions have actions that are single verbs:

```
ProSolidRegenerate()
```

```
ProFeatureDelete()
```

Some Creo TOOLKIT functions require names that include more than one object type. The function names have the object types first, then the action. For example:

```
ProFeatureParentsGet()
```

```
ProWcellTypeGet()
```

The action verbs indicate the type of action being performed, as shown in the following table.

Action Verb	Type of Action
Get	Read information directly from the Creo Parametric database.
Eval	Provide the result of a simple calculation.
Compute	Provide the result of a computation that typically involves numerical analysis of the model geometry.

Examples are:

- ProEdgeLengthEval()
- ProSurfaceAreaEval()
- ProSolidRayIntersectionCompute()

To illustrate further, function ProSolidOutlineGet() reads from Creo Parametric the currently stored solid outline, but ProSolidOutlineCompute() invokes a recomputation of that information. Use ProSolidOutlineCompute() to compute an accurate outline of a solid.

Note

Do not use ProSolidOutlineGet() to calculate the outline of a solid. It will not return a properly calculated outline.

Other Creo TOOLKIT function conventions are that the first argument identifies the object, and input arguments come before output arguments.

Function Prototyping

Each Creo TOOLKIT function has an ANSI function prototype. (The C compilers on platforms supported by Creo TOOLKIT provide at least the option of function prototype checking.) All function prototypes for a particular Creo TOOLKIT object reside in a header file named for that object. For example, the prototype for function `ProEdgeLengthEval()` is located in the header file `ProEdge.h`.

Note

PTC strongly recommends that you use prototyping. Make sure you include the appropriate header files in your Creo TOOLKIT application.

Function Error Statuses

The return type of most Creo TOOLKIT functions is `ProError`. `ProError` is an enumerated type with a value for each common case where Creo TOOLKIT functions succeeds or fails.

The normal value for success is `PRO_TK_NO_ERROR`. The other “failure” statuses occur when there is a genuine problem, or for more benign reasons. For example, these error statuses denote genuine problems:

- `PRO_TK_BAD_INPUTS`—The Creo TOOLKIT program called the function incorrectly.
- `PRO_TK_OUT_OF_MEMORY` or `PRO_TK_COMM_ERROR`—System failure.

The following statuses are more benign:

- `PRO_TK_USER_ABORT`—A function that supports user interaction was aborted by the Creo Parametric user.
- `PRO_TK_E_NOT_FOUND`—A function attempted operation on an empty object list.

Users must pay careful attention to how their program reacts to a Creo TOOLKIT function error status—there can be several types of failure and success, each requiring different handling.

The subset of `ProError` values that a particular Creo TOOLKIT function can return is described in the browser under that function. Possible errors are also included in a comment under each function prototype in the corresponding Creo TOOLKIT header file.

Installing_Creo_Toolkit

Overview

The next sections describe how to install Creo TOOLKIT.

Creo TOOLKIT is on the same DVD as Creo Parametric, so you do not need to arrange a special delivery from your supplier. When Creo Parametric is installed using PTC.Setup, one of the optional components is API Toolkits. This includes Creo TOOLKIT, Pro/WebLink, J-Link, VB, and Creo Object TOOLKIT C++ and Creo Object TOOLKIT Java.

If you select Creo TOOLKIT, it is installed under the loadpoint of Creo Parametric at the location `<creo_loadpoint>\<datecode>\Common Files\protoolkit`. The `protoolkit` directory contains all the headers, libraries, example applications, and documentation specific to Creo TOOLKIT.

The following figure shows the tree of directories found under the Creo TOOLKIT loadpoint after installation.

Creo Toolkit Installation Directory Tree

The directory `protk_appls` contains sample Creo TOOLKIT applications. For more information regarding the sample applications refer to the Appendix on Sample Applications.

Add or Update Creo Toolkit Installation

Add a Creo TOOLKIT installation to an existing Creo Parametric installation using the Update option in PTC.Setup. For a description of using PTC.Setup, refer to the *Creo Parametric Installation and Administration Guide*.

Be sure your system administrator reinstalls Creo TOOLKIT each time they update your Creo Parametric installation from a new CD. PTC recommends that, when possible, you use a Creo TOOLKIT from the same build number as Creo Parametric.

 Note

The Creo Parametric library functions work by invoking functions inside the Creo Parametric executable, so an update to Creo TOOLKIT often involves a change to Creo Parametric rather than Creo TOOLKIT itself. So when you receive a Creo Parametric DVD that contains an update to Creo TOOLKIT, always reinstall Creo Parametric from that DVD.

In many situations it will be inconvenient or impossible to ensure that the users of your Creo TOOLKIT application will use the same build of Creo Parametric that you used to compile and link the Creo TOOLKIT application. Refer to [Version Compatibility: Creo Parametric and Creo Toolkit on page 45](#) for the rules to mix versions of Creo Parametric and Creo TOOLKIT.

Testing the Creo Toolkit Installation

After your system administrator has installed Creo TOOLKIT, you should compile, link, and run a simple Creo TOOLKIT application as soon as possible on each machine you intend to use for development. This provides an independent test of the following items:

- The installation of Creo TOOLKIT is present, complete, and visible from your machine.
- The version of Creo Parametric you plan to use during development has the Creo TOOLKIT license option added to it.
- The machine you will use for development has access to all the necessary C program development tools, in versions supported by Creo TOOLKIT (especially, of course, the C compiler and linker).

Running the Microsoft Visual Studio Solution

PTC provides a ready-to-use Visual Studio solution on the Windows platform to build and test Creo TOOLKIT applications by using an appropriate makefile. For the version of Visual Studio compatible with the release of Creo TOOLKIT, refer to the hardware notes at [Creo Future Platform Support Summary](#).

This ready-to-use Visual Studio solution has the following advantages:

- Provides an effective way to build and test sample applications provided by PTC.

- Provides a preconfigured Visual Studio development environment for use with Creo TOOLKIT.
- Supports Intellisense for Creo TOOLKIT functions.

Note

- The supported version of Visual Studio changes with every release of Creo TOOLKIT, and hence the compiler flags and libraries also change. For every release, you must download the latest version of the ready-to-use Visual Studio solution from the `creo_toolkit_loadpoint`.
- In Creo Parametric 11.0.0.0 and later, Creo TOOLKIT supports Visual Studio 2022. The compiler flags and libraries are available for Visual Studio 2022. Creo TOOLKIT no longer supports Visual Studio 2019.

All Creo TOOLKIT applications on 64-bit Windows platforms built using the Microsoft Visual Studio 2022 compiler must set the configuration property Platform Toolset as Visual Studio 2022 (v17.6.5).

When you install Creo TOOLKIT, the file `protk_install_example.zip` is installed under the `<creo_toolkit_loadpoint>` at `$<machine_type>\obj`. To use this solution:

1. Unzip `protk_install_example.zip`. The following files and directories are available:

Directory or File	Description
<code>make_install.sln</code>	Specifies the ready-to-use Visual Studio solution file.
<code>make_install</code>	Contains the makefile project and the <code>creotk.dat</code> file.

2. Open Microsoft Visual Studio.
3. Click **File ► Open ► Project/Solution**. The **Open Project** dialog opens.
4. Browse the `protk_install_example` directory and select `make_install.sln`.
5. Click **Open** to access the solution file.

The `make_install` makefile project is available in Visual Studio.

Running the Makefile Project

1. Click **Build ► Build make_install**. The application should build without errors. This creates the Creo TOOLKIT DLL file called `pt_inst_test.dll`. If the application fails, check that the environment variable `PROTOOL_SRC` is set correctly.

-
2. Modify the `exec_file` and `text_dir` fields in the `creotk.dat` file located in the `make_install` directory to specify the full path to `pt_inst_test.dll` and `\text`, respectively. For example, `exec_file <full_path>\pt_inst_test.dll text_dir <full_path>\text`
 3. Unlock the application, using the following command:

```
<creo_loadpoint>/<version>/parametric/bin/protk_unlock.bat<path to executables or DLLs to unlock>.
```
 4. Start Creo Parametric.
 5. On the **Tools** tab, in the **Utilities** group, click **Auxiliary Applications**. The **Auxiliary Applications** dialog box opens.
 6. Click **Register** to register the updated `creotk.dat` file. The **Register auxiliary application** dialog box opens.
 7. Browse to the `<full_path>` and select `creotk.dat`
 8. Click **Open**. The Creo TOOLKIT application adds the command **Install Test** under the **Tools ► File** menu in the **TOOLKIT** group in the **Home** tab on the Creo Parametric ribbon user interface.

 Note

Refer to the Creo Parametric Help for more information on customizing the Ribbon.

9. Click **Tools** and then click **File ► Install Test**. The Creo TOOLKIT Install Test Results message window opens, indicating that the installation test has succeeded.
10. Click **OK**.

To run other sample applications provided by PTC, follow these steps:

1. Copy the required makefile from `<creo_toolkit_loadpoint>\$<machine_type>\obj` to the `make_install` directory of the ready-to-use Visual Studio solution.

If you are working on a 64-bit Windows platform, copy the file from `<creo_toolkit_loadpoint>\x86e_win64\obj`.
2. Copy the text directory associated with the sample application from `<creo_toolkit_loadpoint>\<protk_appls>\<app_name>\text` to the `make_install` directory.
3. Open Visual Studio and set the values of the following variables in the makefile:

```
PROTOOL_SRC = ../../../../protookit
```

-
- ```
PROTOOL_SYS = $(PROTOOL_SRC) / $(PRO_MACHINE_TYPE)
```
4. Click **Project ► Properties** to update the **NMake** properties of the project.
  5. Click **Build ► Rebuild** `make_install`. The application builds and creates a new `.dll` file.
  6. Update the `creotk.dat` file located in the `make_install` directory with the name of the sample application and the DLL file.
  7. Modify the `exec_file` and `text_dir` fields in the `creotk.dat` file to specify the full path to the `.dll` file and `\text` directory, respectively.
  8. Start Creo Parametric.
  9. On the **Home** tab, in the **Utilities** group, click **Auxiliary Applications** or click **Tools ► Auxiliary Applications**. The Auxiliary Applications dialog box opens.
  10. Click **Register** to register the updated `creotk.dat` file. The **Register auxiliary application** dialog box opens.
  11. Browse to the full path and select `creotk.dat`.
  12. Click **Open**. The Creo TOOLKIT application runs.

## Building a Sample Application

The Creo TOOLKIT loadpoint includes the source of a simple application designed specifically to test the Creo TOOLKIT installation. The steps required to build and run the test application are described in the following sections.

In this explanation, `<creo_toolkit_loadpoint>` refers to the directory that forms the loadpoint of Creo TOOLKIT, and `<machine_type>` refers to the name of the type of platform you are using (for example, `i486_nt`).

### Step 1—Compile and Link

Compile and link the Creo TOOLKIT installation test application using the `makefile` `<creo_toolkit_loadpoint>\$<machine_type>\obj\make_install`

The `makefile` is designed to be run in that location, and creates a Creo TOOLKIT application file in the directory from which it is run. If you do not have root privileges, you probably need to copy the `makefile` to a directory of your own so the output file can be created. If you do this, you also need to edit the `makefile` to correct the macro that refers to the Creo TOOLKIT loadpoint.

If you copy the `makefile` to another directory, replace the line:

```
PROTOOL_SRC = ../..
```

with:

```
PROTOOL_SRC = <creo_toolkit_loadpoint>
```

In this line, `<creo_toolkit_loadpoint>` is the loadpoint for your Creo TOOLKIT installation.

---

To run the makefile, type the following command:

```
nmake -f make_install
```

This creates a file called `pt_inst_test.exe`.

If you experience any error messages at this stage, it might be due to the Creo TOOLKIT installation being incomplete, or, more likely, the C compiler and linker being unavailable or unsupported by Creo TOOLKIT.

## Step 2—Register

In the same directory, create a text file called `creotk.dat`. This file is the “registry file” that tells Creo Parametric about the Creo TOOLKIT application. Refer to the [Registering a Creo Toolkit Application on page 43](#) and [Sample Registry Files on page 2038](#) sections for syntax requirements for this file. The `creotk.dat` file should contain the following lines:

```
name install_test
exec_file pt_inst_test.exe
text_dir <creo_toolkit_loadpoint>/protk_appls/pt_install_test
end
```

### Note

Use the delimiter character `\` in `creotk.dat`.

---

## Step 3—Run Creo Parametric

Run Creo Parametric from the directory that contains the `creotk.dat` file; Creo Parametric starts the Creo TOOLKIT application in multiprocess mode (see the section [How Creo Toolkit Works on page 40](#) for more information on multiprocess mode). You should see that the **Install Test** command has been added in the **TOOLKIT** group in the **Home** tab on the Creo Parametric ribbon user interface. Click **Tools** and then click **File ► Install Test**. The Creo TOOLKIT application displays a custom dialog indicating whether the installation test has succeeded:

## Install Test Results Dialog Box

Failure or error messages at this stage could be due to the following reasons:

- You made a mistake when creating the `creotk.dat` file. If the syntax or contents are wrong, you should see a self-explanatory message in the window from which you started Creo Parametric.
- The Creo Parametric you ran is not licensed for Creo TOOLKIT. This also causes an explanatory message to be displayed in the startup window.
- The Creo TOOLKIT executable you created in Step 1 is wrong in some way: it is for the wrong platform, for example, or might not have execute access. You can check this by trying to execute the file directly by typing its name. If the file is correct, the program prints the following messages and then terminates:

```
pt_inst_test: insufficient arguments; need 2
arguments:
(1) own RPC program #
(2) root directory path for Pro/TOOLKIT
text files.
```

If the file is incorrect, the exact message will depend on which platform you are using, but should explain the cause of the problem.

## Step 4—Repeat the Test in DLL Mode

To build for DLL mode, use the same makefile, but use the following line instead of the line `nmake -f make_install`:

```
nmake -f make_install dll
```

This creates a file called `pt_inst_test.dll`, which is the library to be dynamically linked.

Next, make these two changes to the `creotk.dat` file:

Add this line after the first line:

```
startup dll
```

---

Change the `exec_file` statement to reference the new Creo TOOLKIT file. Use the executable name `pt_inst_test.exe` in the second line, and the Windows directory syntax in the third line.

You can run Creo Parametric and look at the behavior of the Creo TOOLKIT application exactly as in Step 3.

See the section [How Creo Toolkit Works on page 40](#) for more information on DLL mode.

## Developing a Creo Toolkit Application

This section describes how Creo TOOLKIT works and the steps you need to take after installing Creo TOOLKIT to create a Creo TOOLKIT application. The topics are as follows:

- [How Creo Toolkit Works on page 40](#)
- [Compiling and Linking a Creo Toolkit Application on page 42](#)
- [Registering a Creo Toolkit Application on page 43](#)
- [Version Compatibility: Creo Parametric and Creo Toolkit on page 45](#)
- [Stopping and Restarting a Creo Toolkit Application on page 47](#)
- [Structure of a Creo Toolkit Application on page 54](#)
- [User-Supplied Main on page 59](#)
- [Creo Toolkit Techniques on page 60](#)

## How Creo Toolkit Works

The standard method by which Creo TOOLKIT application code is integrated into Creo Parametric is through the use of dynamically linked libraries (DLLs). When you compile your Creo TOOLKIT application C code and link it with the Creo TOOLKIT library, you create an object library file designed to be linked into the Creo Parametric executable when Creo Parametric starts up. This method is referred to as DLL mode.

Creo TOOLKIT also supports a second method of integration: the “multiprocess,” or spawned mode. In this mode, the Creo TOOLKIT application code is compiled and linked to form a separate executable. This executable is designed to be spawned by Creo Parametric and runs as a child process of the Creo Parametric session. In DLL mode, the exchanges between the Creo TOOLKIT application and Creo Parametric are made through direct function calls. In multiprocess mode, the same effect is created by an inter-process messaging system that simulates direct function calls by passing the information necessary to identify the function and its argument values between the two processes.

---

Multiprocess mode involves more communications overhead than DLL mode, especially when the Creo TOOLKIT application makes frequent calls to Creo TOOLKIT library functions, because of the more complex method of implementing those calls. However, it offers the following advantage: it enables you to run the Creo TOOLKIT application with a source-code debugger without also loading the whole Creo Parametric executable into the debugger. See the section [Using a Source-Code Debugger on a Creo Toolkit Application on page 49](#) for more details.

You can use a Creo TOOLKIT application in either DLL mode or multiprocess mode without changing any of the C source code in the application. (The methods of setting the mode are described in detail later in this section.)

It is also possible to use more than one Creo TOOLKIT application within a single session of Creo Parametric, and these can use any combination of modes.

If you use multiprocess mode during development of your application to debug more easily, you should switch to DLL mode when you install the application for your end users because the performance is better in that mode. However, take care to test your application thoroughly in DLL mode before you deliver it. Any programming errors in your application that cause corruption to memory used by Creo Parametric or Creo TOOLKIT are likely to show quite different symptoms in each mode, so new bugs may emerge when you switch to DLL mode.

Although multiprocess mode involves two processes running in parallel, these processes do not provide genuine parallel processing. There is, however, another mode of integrating a Creo TOOLKIT application that provides this ability, called “asynchronous mode.” (Asynchronous mode is described in detail in the section [Core: Asynchronous Mode on page 277](#).) The DLL and multiprocess modes are given the general name “synchronous mode.” An asynchronous Creo TOOLKIT application is fundamentally different in its architecture from a synchronous mode application, so you should choose between these methods before writing any application code. As a general rule, synchronous mode should be the default choice unless there is some unavoidable reason to use asynchronous mode, because the latter mode is more complex to use.

---

 **Note**

- All Creo TOOLKIT calls running in either synchronous (DLL or multiprocess) mode or asynchronous mode always clear the Undo/Redo stack in the Creo Parametric session. The Creo Parametric user interface reflects this by making the **Undo** and **Redo** menu options unavailable.
  - When you invoke the Creo TOOLKIT application, ensure that no dialogs are open in Creo Parametric session. If Creo Parametric dialog is open, the results may be unpredictable.
-

---

## Compiling and Linking a Creo Toolkit Application

This section describes compiling and linking Creo TOOLKIT applications.

### Makefiles

The C compiler options and system libraries needed to compile and link a Creo TOOLKIT application are different on each platform. To ensure that the makefile you use for building your Creo TOOLKIT application uses the correct options, you should base your makefile on one of the makefiles located under the `<creo_toolkit_loadpoint>`. These are designed for building the various Creo TOOLKIT applications whose source is included in the Creo TOOLKIT installation.

An example of one of the Creo TOOLKIT applications provided is the installation test, whose source code is under the directory `<creo_toolkit_loadpoint>\protk_appls\pt_install_test`, where `<creo_toolkit_loadpoint>` is the loadpoint directory of the Creo TOOLKIT installation. The makefile for the installation test application is `<creo_toolkit_loadpoint>\$<machine_type>\obj\make_install`.

To use this as the model for your own makefile, copy it to the directory that will contain your Creo TOOLKIT source code, then make the following changes to it:

- Change the macro `MAKEFILENAME` to refer to the makefile by its new name.
- Change the macros `EXE` and `EXE_DLL` to define output file names more suitable for your own application.
- Change the macro `PROTOOL_SRC` to refer to the loadpoint of Creo TOOLKIT.
- Change the macro `OBJS` to refer to the object files that will result from compiling your Creo TOOLKIT source files.
- Add targets for those object files. These contain instructions for
- compiling your C source files. The form of these target definitions can be copied from the ones in the original makefile. They generally take the following form:

```
myfile.o: myfile.c
 $(CC) $(CFLAGS) myfile.c
```

---

#### Note

The second line must start with a tab character.

---

If you want to use a debugger with your Creo TOOLKIT application, you can also add the appropriate compiler switch (usually “-g”) to the `CCFLAGS` macro.

---

If you are rebuilding an existing Pro/TOOLKIT application with a new version of Creo TOOLKIT, remember to repeat these steps to set up a new makefile—do not continue to use a makefile created for the previous version. You must do this in case the compiler switches or system libraries needed to build a Creo TOOLKIT application have changed in the new version.

## Registering a Creo Toolkit Application

Registering a Creo TOOLKIT application means providing Creo Parametric with information about the files that form the Creo TOOLKIT application. To do this, create a small text file called the Creo TOOLKIT registry file, that Creo Parametric will find and read.

Creo Parametric searches for the registry file as follows:

- In the absolute path specified in the `creotkdat`, `protkdat`, `prodevdat`, and `toolkit_registry_file` statements in the Creo Parametric configuration file.
- For the files named `creotk.dat`, `protk.dat`, or `prodev.dat` in the following locations:
  1. The starting directory
  2. `<creo_loadpoint>\<datecode>\Common Files\<machine_type>\text\<language>`
  3. `<creo_loadpoint>\<datecode>\Common Files\text`
  4. `<creo_loadpoint>\<datecode>\Common Files\text\<language>`

In the preceding locations, the variables are as follows:

- `<creo_loadpoint>`—The Creo Parametric loadpoint (not the Creo TOOLKIT loadpoint).
- `<machine_type>`—The machine-specific subdirectory, such as `i486_nt` or `x86e_win64`. Set the environment variable `PRO_MACHINE_TYPE` to define the type of machine on which Creo Parametric is installed.

If more than one registry file having the same filename exists in this search path, Creo Parametric stops searching after finding the first instance of the file and starts all the Creo TOOLKIT applications specified in it. If more than one registry file having different filenames exist in this search path, Creo Parametric stops searching after finding one instance of each of them and starts all the Creo TOOLKIT applications specified in them.

---

### **Note**

- Option 1 is normally used during development, because the Creo TOOLKIT application is seen only if you start Creo Parametric from the specific directory that contains the registry file.
  - Option 3 is recommended when making an end-user installation, because it makes sure that the registry file is found no matter what directory is used to start Creo Parametric.
- 

The registry file is a simple text file, where each line consists of one of a predefined set of keywords, followed by a value.

The standard form of the registry file in DLL mode is as follows:

```
name YourApplicationName
startup dll
exec_file $LOADDIR/$MACHINE_TYPE/obj/filename.dll
text_dir $LOADDIR
end
```

The fields of the registry file are as follows:

- `name`—Assigns a unique name to this Creo TOOLKIT application.
- `startup`—Specifies the method Creo Parametric should use to communicate with the Creo TOOLKIT application. The example above specifies the DLL mode.
- `exec_file`—Specifies the full path and name of the file produced by compiling and linking the Creo TOOLKIT application. The example above shows a typical use of environment variables to make the reference to the executable file more flexible.
- `text_dir`—Specifies the full path name to text directory that contains the language-specific directories. The language-specific directories contain the message files, menu files, resource files and UI bitmaps in the language supported by the Creo TOOLKIT application.

---

### **Note**

The fields `exec_file` and `text_dir` have a character limit of `PRO_PATH_SIZE-1` wide characters (`wchar_t`).

---

- `end`—Indicates the end of the description of this Creo TOOLKIT application.

---

If you want to run the application in multiprocess mode, make the following changes to the registry file:

- Change the startup statement to:  
startup spawn
- Make the `exec_file` statement refer to the Creo TOOLKIT program executable.

---

 **Note**

For all Creo TOOLKIT plugins, the registry file `protk.dat` is located inside the `%ProgramData%\PTC\<Creo Toolkit version>\Plugins` subdirectories. All registry files located in this location must use the absolute path in all their entries.

For more information about the registry file, refer to the appendix [Creo Toolkit Registry File on page 2037](#).

---

## Limit on the Number of Loaded Applications

Previous versions of Pro/ENGINEER limited the number of applications that could be specified in the registry files; there is no such limit for Pro/ENGINEER Wildfire 2.0 onwards. However, most platforms do have limits for the size of a process, the total size of all processes, and the number of processes that a single process can spawn. PTC recommends that you combine related applications into the same binary file wherever possible to avoid running into these limits.

## Version Compatibility: Creo Parametric and Creo Toolkit

In many situations it will be inconvenient or impossible to ensure that the users of your Creo TOOLKIT application use the same build of Creo Parametric used to compile and link the Creo TOOLKIT application. This section summarizes the rules for mixing Creo TOOLKIT and Creo Parametric versions. The Creo TOOLKIT version is the Creo Parametric CD version from which the user installed the Creo TOOLKIT version used to compile and link the application.

Functions Introduced:

- **ProToolkitMajorVersionGet()**
- **ProToolkitApplDisplayVersionGet()**

Superseded Functions

- **ProEngineerReleaseNumericversionGet()**

---

The function `ProToolkitMajorVersionGet()` returns the version number of the Creo Parametric executable to which the Creo TOOLKIT application is connected. This number is an absolute number and represents the major release of the product.

The function `ProToolkitApplDisplayVersionGet()` returns the version on which the application was built. The output argument *display\_version* is a version. You can use the function `ProStringFree` to free the memory.

The function `ProEngineerReleaseNumericversionGet()` is deprecated. Use the function `ProToolkitMajorVersionGet()` instead.

---

 **Note**

From Pro/ENGINEER Wildfire 4.0 onwards applications built with libraries older than Pro/ENGINEER 2001 will not run. You must recompile these applications with later versions of the Pro/TOOLKIT libraries.

---

The following points summarize the rules for mixing Creo Elements/Pro TOOLKIT and Creo Elements/Pro versions.

- Pro/ENGINEER release older than Pro/TOOLKIT release:  
Not supported
- Creo Parametric release newer than a Creo TOOLKIT release:  
This works in many, but not all, cases. The communication method used to link Creo TOOLKIT to Creo Parametric provides full compatibility between releases. However, there are occasional cases where changes internal to Creo Parametric may require changes to the source code of a Creo TOOLKIT application in order that it continue to work correctly. Whether you need to convert Creo TOOLKIT applications depends on what functionality it uses and what functionality changed in Creo Parametric and Creo TOOLKIT. PTC makes every effort to keep these effects to a minimum. The Release Notes for Creo TOOLKIT detail any conversion work that could be necessary for that release.
- Creo Parametric build newer than Creo TOOLKIT build  
This is always supported.

---

## Application Compatibility: Creo Parametric and Creo Toolkit on Different Architecture

In some situations it will be inconvenient or impossible to ensure that the users of your Creo TOOLKIT application use a machine with the same operating system and architecture as the machine on which it was compiled. An example might be an application integrating with a third party library which is only available as 32-bit architecture, but needs to be run with Creo Parametric on a 64-bit architecture machine with the same operating system. Creo TOOLKIT provides limited capability to support these situations in spawn and asynchronous mode only. DLL applications must always be compiled on machines with the same operating system and architecture as the Creo Parametric executable.

The following situations might occur:

- Creo TOOLKIT application compiled on the same architecture and operating system as Creo Parametric. This is always supported.
- Creo TOOLKIT application compiled on a machine with a smaller pointer size (native data size) than the machine on which the application is run. For example, a Creo TOOLKIT application built on Windows 32-bit running on an Windows-64 bit installation of Creo Parametric. This is supported for spawn and asynchronous mode only.
- Creo TOOLKIT application compiled on a machine with a larger pointer size (native data size) than the machine on which the application is run. For example, a Creo TOOLKIT application built on Windows-64 bit machine running on an Windows-32 bit installation of Creo Parametric. This is not supported.

## Stopping and Restarting a Creo Toolkit Application

Creo TOOLKIT supports the ability to stop and restart a synchronous application within a single session of Creo Parametric. This is particularly useful during development of an application because it enables you to make changes to your source code and retest it without having to restart Creo Parametric and reload your test models. Use the **Auxiliary Applications** dialog box to stop and restart applications.

To make this option available, the registry file (default name `protk.dat` should contain one of the following lines:

```
Multiprocess mode:
 startup spawn
DLL mode:
 startup DLL
```

If you want to be able to stop and restart your Creo TOOLKIT application within Creo Parametric, you must also add the following statement to the definition of the application in the registry file:

---

```
allow_stop TRUE
```

To access the **Auxiliary Applications** dialog box, on the **Home** tab, in the **Utilities** group, click **Auxiliary Applications** or click **Tools ► Auxiliary Applications**. The dialog box displays a list of Creo TOOLKIT applications identified by the name defined in the `name` statement in its registry file. Only applications that a user can start or stop are displayed. This dialog box also shows the current state of an application and allows an application to be started or stopped.

When a user starts an application from the **Auxiliary Applications** dialog box, Creo Parametric freezes the user interface until the application connects to it.

If you use the `allow_stop` option, you might also set Creo Parametric to not start the Creo TOOLKIT application until you explicitly request it. To do this, you must add the following statement in your registry file:

```
delay_start TRUE
```

To start your application in Creo Parametric, choose **Auxiliary Applications** from the **Tools** tab, select your application from the list, then click the **Start** button.

In addition to **Start**, **Stop**, and **Close**, the dialog box includes the following buttons:

- **Register**—Enables you to register a Creo TOOLKIT application whose registry file was not present when Creo Parametric was started.
- **Info**—Reports the following information about each currently registered Creo TOOLKIT application:
  - The names of the executable file and text directory
  - The version number used to build the application
  - Whether the application is currently running

There are a few other, less commonly used options in the registry file. All the options are described fully in the [Creo Toolkit Registry File on page 2037](#) appendix.

---

### **Note**

You can delete registration information on any application that is not running.

---

When stopping an application, make sure that no application-created menu buttons are current. To do this, before you exit an application you must choose a command that interrupts the current menu command.

---

## Using a Source-Code Debugger on a Creo Toolkit Application

For a full description of how to debug Creo TOOLKIT applications, see section appendix [Debugging Creo TOOLKIT Applications on page 2093](#). This section also describes optional methods of debugging a Creo TOOLKIT application.

### Unlocking a Creo Toolkit Application

Before you distribute your application executable to the end user, you must unlock it. This enables the end user (your customer) to run your applications without having Creo TOOLKIT as an option. In Creo Parametric 6.0.0.0 and later you can digitally sign your application.

To unlock your application, enter the following command:

```
<creo_loadpoint>/<datecode>/Parametric/bin/protk_unlock [-c]
[-cd] <path to executables or DLLs to unlock>
```

---

#### Note

- The Creo TOOLKIT application is unlocked even if you do not specify the `-c` option.
  - To unlock and digitally sign your application, specify the `-cd` option. Note that it is mandatory to sign your application if you use the `-cd` option. See the section [Digitally Signing the Application on page 52](#), for more information on digitally signing your application.
- 

More than one Creo TOOLKIT binary file may be supplied on the command line.

---

#### Note

Once you have unlocked the executable, you can distribute your application program to Creo Parametric users in accordance with the license agreement.

---

Using `protk_unlock` requires a valid Creo TOOLKIT license be present and unused on your license server. If the Creo Parametric license server is configured to add a Creo TOOLKIT license as a Startup option, `protk_unlock` will cause the license server to hold only the Creo TOOLKIT option for 15 minutes. The license will not be available for any other development activity or unlocking during this period.

If you use `-cd` option to unlock your application, a message appears asking you to digitally sign your application before using it in Creo.

---

If the only available Creo TOOLKIT license is locked to a Creo Parametric license, the entire Creo Parametric license including the Creo TOOLKIT option will be held for 15 minutes. PTC recommends you configure your Creo TOOLKIT license option as startup options to avoid tying up your Creo Parametric licenses.

---

 **Note**

Only one license will be held for the specified time period, even if multiple applications were successfully unlocked.

---

Unlocking the application may also require one or more advanced licensing options. The `protk_unlock` application will detect whether any functions using advanced licenses are in use in the application, and if so, will make a check for the availability of the advanced license option. If that option is not present, unlocking will not be permitted. If they are present, the unlock will proceed. Advanced options are not held on the license server for any length of time. For more information refer to the [Advanced Licensing Options on page 2048](#) section.

If the required licenses are available, the `protk_unlock` application will unlock the application immediately. An unlocked application does not require any of the Creo TOOLKIT license options to run. Depending on the functionality invoked by the application, it may still require certain Creo Parametric options to work correctly.

---

 **Note**

Once an application binary has been unlocked, it should not be modified in any way (which includes statically linking the unlocked binary with other libraries after the unlock). The unlocked binary must not be changed or else Creo Parametric will again consider it "locked".

---

## Unlocking a Creo Toolkit Application

Before you distribute your application executable to the end user, you must unlock it. This enables the end user (your customer) to run your applications without having Creo TOOLKIT as an option. In Creo Parametric 6.0.0.0 and later you can digitally sign your application.

To unlock your application, enter the following command:

```
<creo_loadpoint>/<version>/Parametric/bin/protk_unlock [-c]
[-cd]
<path to executables or DLLs to unlock>
```

---

 **Note**

- The Creo TOOLKIT application is unlocked even if you do not specify the `-c` option.
- To unlock and digitally sign your application, specify the `-cd` option. Note that it is mandatory to sign your application if you use the `-cd` option. See the section [Digitally Signing the Application on page 52](#), for more information on digitally signing your application.

---

More than one Creo TOOLKIT binary file may be supplied on the command line.

---

 **Note**

Once you have unlocked the executable, you can distribute your application program to Creo Parametric users in accordance with the license agreement.

---

Using `protk_unlock` requires a valid Creo TOOLKIT license be present and unused on your license server. If the Creo Parametric license server is configured to add a Creo TOOLKIT license as a Startup option, `protk_unlock` will cause the license server to hold only the Creo TOOLKIT option for 15 minutes. The license will not be available for any other development activity or unlocking during this period.

If you use `-cd` option to unlock your application, a message appears asking you to digitally sign your application before using it in Creo.

If the only available Creo TOOLKIT license is locked to a Creo Parametric license, the entire Creo Parametric license including the Creo TOOLKIT option will be held for 15 minutes. PTC recommends you configure your Creo TOOLKIT license option as startup options to avoid tying up your Creo Parametric licenses.

---

 **Note**

Only one license will be held for the specified time period, even if multiple applications were successfully unlocked.

---

Unlocking the application may also require one or more advanced licensing options. The `protk_unlock` application will detect whether any functions using advanced licenses are in use in the application, and if so, will make a check for the availability of the advanced license option. If that option is not present,

---

unlocking will not be permitted. If they are present, the unlock will proceed. Advanced options are not held on the license server for any length of time. For more information refer to the [Advanced Licensing Options on page 2048](#) chapter.

If the required licenses are available, the `protk_unlock` application will unlock the application immediately. An unlocked application does not require any of the Creo TOOLKIT license options to run. Depending on the functionality invoked by the application, it may still require certain Creo Parametric options to work correctly.

---

 **Note**

Once an application binary has been unlocked, it should not be modified in any way (which includes statically linking the unlocked binary with other libraries after the unlock). The unlocked binary must not be changed or else Creo Parametric will again consider it "locked".

---

## Digitally Signing the Application

In Creo Parametric 6.0.0.0 and later, you can digitally sign your application. Use the standard Microsoft utility SignTool to digitally sign your application. See the Microsoft documentation for more information on this utility and to create the digital certificate.

In Creo Parametric 7.0.0.0 and later, Creo checks signatures of Creo TOOLKIT applications at load time.

The following configuration options control whether to always allow the users or administrator to determine whether signed or unsigned Creo TOOLKIT applications should be allowed to always run, to never run, or to prompt the user before running:

- `open_prot_k_unsigned_apps`—Controls whether unsigned applications can be loaded in a Creo session. It can have the following values:
  - Always—Always loads unsigned applications.
  - Never—Never load unsigned applications.
  - Prompt—Asks the user whether to load unsigned applications.
- `open_prot_k_signed_apps`—Controls whether signed applications can be loaded in a Creo session. It can have the following values:
  - Always—Always loads signed applications.
  - Never—Never load signed applications.
  - Prompt—Asks the user whether to load signed applications.

## Unlock Messages

The following table lists the messages that can be returned when you unlock a Creo TOOLKIT application.

| Message                                                                                | Cause                                                                                                                                                                                        |
|----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <application name>:Successfully unlocked application.                                  | The application is unlocked successfully.                                                                                                                                                    |
| Usage: protk_unlock <one or more Creo TOOLKIT executables or DLLs>                     | No arguments supplied.                                                                                                                                                                       |
| <application name>:ERROR: No READ access<br><application name>:ERROR: No WRITE access  | You do not have READ/WRITE access for the executable.                                                                                                                                        |
| <application name>:Executable is not a Creo TOOLKIT application.                       | The executable is not linked with the Creo TOOLKIT libraries, or does not use any functions from those libraries.                                                                            |
| <application name>:Executable is already unlocked.                                     | The executable is already unlocked.                                                                                                                                                          |
| Error: Licenses do not contain Creo TOOLKIT License Code.                              | A requirement for unlocking a Creo TOOLKIT application.                                                                                                                                      |
| ERROR: No Creo Parametric licenses are available for the startup command specified     | Could not contact the license server.                                                                                                                                                        |
| <application name>:Unlocking this application requires option TOOLKIT-for-3D_Drawings. | The application uses functions requiring an advanced option; and this option is not available.<br><br>The license option 222, that is, the TOOLKIT-for-3D_Drawings license is not available. |
| <application name>:Unlocking this application requires option TOOLKIT-for-Mechanica.   | The application uses functions requiring an advanced option; and this option is not available.<br><br>The license option 223, that is, the TOOLKIT-for-Mechanica license is not available.   |

## Checking the Status of the Creo Toolkit Application

You can use the command `protk_unlock` along with the option `-readall` to check or verify if the Creo TOOLKIT application is locked or unlocked.

- If your application is non-digitally signed, use the following command:  

```
<creo_loadpoint>/<datecode>/Parametric/bin/protk_unlock.
exe -readall <path to executables or DLLs to unlock>
```

The status of the application is shown as UNLOCKED.
- If your application is digitally signed, use the option `-d` along with the `readall` option.  

The status of the application is shown as UNLOCKED.
- If you are trying to unlock a digitally signed application using the option `-cxxd`, you will see the following message:  
The application is digitally signed.  
You can not unlock this application which is digitally signed.  
Please rebuild the application, unlock and then digitally sign.

---

## Structure of a Creo Toolkit Application

The contents of this section refer to the use of synchronous mode. For information on asynchronous mode applications, see section [Core: Asynchronous Mode on page 277](#).

### Essential Creo Toolkit Include Files

The only header file you must always include in every source file of your Creo TOOLKIT application is `ProToolkit.h`. This file must always be present, and must be the first include file because it defines the value of `wchar_t`, the type for characters in a wide string, referenced from many other include files.

`ProToolkit.h` also includes these standard include files:

- `stdio.h`
- `string.h`
- `stddef.h`
- `stdlib.h`

Therefore, you do not need to include these header files explicitly in your application.

When you use functions for a particular Creo TOOLKIT object, you should always include the header file that contains the function prototypes for those functions. If you do not do this, or omit some, you lose the benefit of function argument type-checking during compilation. The header file `ProObjects.h`, which contains the declarations of the object handles, is included indirectly in each of the header files that contains function prototypes, and so does not need to be included explicitly.

For example, if you are using the function `ProSurfaceAreaEval()`, you should include the file `ProSurface.h`, which contains the prototype of that function, but you do not need to include `ProObjects.h` in order to see the definition of `ProSurface`, because `ProObjects.h` is included in `ProSurface.h`.

### Core of a Creo Toolkit Application

Functions Introduced:

- **`user_initialize()`**
- **`ProEngineerDisplaydatecodeGet()`**
- **`user_terminate()`**

A Creo TOOLKIT application must always contain the functions `user_initialize()` and `user_terminate()`. These functions have the prefix “user\_” because they are written by the Creo TOOLKIT application developer, but they are called from within Creo Parametric at the start and end of the session.

---

The function `user_initialize()` initializes a synchronous-mode Creo TOOLKIT application. This function must be present in any synchronous mode application in order for it to be loaded into Creo Parametric. Use this function to setup user interface additions, or to run the commands required for a non-interactive application. `user_initialize()` is called after the Creo Parametric application has been initialized and the graphics window has been created. It should contain any initializations that your Creo TOOLKIT application needs, including any modification of Creo Parametric menus (such as adding new buttons).

---

 **Note**

- `user_initialize()` must contain at least one Creo TOOLKIT API call. Failure to do so causes the Creo TOOLKIT application to fail and return `PRO_TK_GENERAL_ERROR`.
  - When coding a Creo TOOLKIT application in C++ you must declare the function `user_initialize()` as `extern "C"`.
- 

The `user_initialize()` function is called with a number of optional arguments that can add to your function definition. All input and output arguments to this function are optional and do not need to be in the function signature. These arguments provide information about command-line arguments entered when Creo Parametric was invoked, and the revision and build number of the Creo Parametric in session. Refer to the section [user\\_initialize\(\) Arguments on page 57](#) for more information on the function arguments.

The initialization function must return 0 to indicate that the Creo TOOLKIT application was initialized successfully. Any other return value will be interpreted as a failure, and the system will notify the Creo Parametric user that the Creo TOOLKIT application failed. Use the optional output argument to `user_initialize()` to specify the wording of this error message.

The call to Creo TOOLKIT application using the function `user_initialize()` is delayed until Creo Platform Agent is loaded. When you install a Creo application, an appropriate version of the Creo Platform Agent also gets installed. The Platform Agent is used for all browser-related functionalities, which includes interaction with Windchill. So, to run a Creo TOOLKIT application which interacts with Windchill using functions, Creo Platform Agent must be initialized first before running the Creo TOOLKIT application.

The Creo Platform Agent is always initialized first by default. The Creo TOOLKIT applications are delayed until the Platform Agent is fully initialized. The Platform Agent must load in a maximum of 60 seconds, beyond which the agent will time out. If the Platform Agent fails to load, the Creo TOOLKIT application will not start and an error message is displayed. You can override this

---

behavior and start the Creo TOOLKIT application, even if the Platform Agent has not loaded using the following environment variables. The valid values for these variables are true and false.

- `PROTK_DELAYINIT_NO_DELAY`—Initiates Creo Platform Agent. However, Creo TOOLKIT applications are initiated, without waiting for Platform Agent to load.
- `PROTK_DELAYINIT_ALWAYS_INIT`—Waits for Creo Platform Agent to load. However, it initiates the Creo TOOLKIT application even if Creo Platform Agent fails to load or times out.

---

 **Note**

If both the variables are set, then the environment variable `PROTK_DELAYINIT_NO_DELAY` takes precedence.

---

---

 **Note**

The Creo Parametric visible datecode format has changed. `user_initialize()` continues to receive the classic format based on the year and week of the Creo Parametric build.

---

The function `ProEngineerDisplaydatecodeGet()` returns the user-visible datecode string from Creo Parametric. Applications that present a datecode string to users in messages and information should use the new format for the Creo Parametric displayed datecode.

The function `user_terminate()` is called at the end of the Creo Parametric session, after the user selects **Yes** on the **Exit** confirmation dialog box. Its return type is void.

---

 **Note**

When coding a Creo TOOLKIT application in C++ you must declare the function `user_terminate()` as `extern "C"`.

---

The following example is the empty core of a Creo TOOLKIT application. This code should always be the starting point of each new application you develop.

```
#include "ProToolkit.h"
int user_initialize()
{
 return (0);
}
```

```

void user_terminate()
{
}

```

If you use the options to start and stop a multiprocess-mode Creo TOOLKIT application within a Creo Parametric session, `user_initialize()` and `user_terminate()` are called upon starting and stopping the Creo TOOLKIT process only. However, any menu modifications defined in `user_initialize()` will be made, even if this involves repainting menus that are already displayed. All of these modifications will be reset when the Creo TOOLKIT application is stopped.

## user\_initialize() Arguments

`user_initialize()` is called with a number of input and output arguments. As always in C, if you don't need to use an argument, your function does not need to declare it, provided that it declares all the arguments up to the last one used.

The input arguments are:

| <code>int arg_num</code>   | Number of command-line arguments.                                                                                                                                                                                                                                        |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>char *argc[]</code>  | Command-line arguments passed by Creo Parametric. (See further explanation below.)                                                                                                                                                                                       |
| <code>char* version</code> | Release name of the Creo Parametric being used.<br><br>Note: From Pro/ENGINEER Wildfire 4.0 onwards applications built with libraries older than Pro/ENGINEER 2001 will not run. You must recompile these applications with later versions of the Pro/TOOLKIT libraries. |
| <code>char* build</code>   | The build number of the Creo Parametric being used.                                                                                                                                                                                                                      |

The output argument is:

|                                   |                                                                                                                                                                                                                                   |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>wchar_t err_buff[80]</code> | The text of an error message passed to Creo Parametric if the Creo TOOLKIT fails to initialize. Creo Parametric displays this text when it reports the Creo TOOLKIT failure (if <code>user_initialize()</code> returns non-zero). |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

The first command-line argument passed to Creo TOOLKIT is the same one seen by Creo Parametric; that is, it is the name of the Creo Parametric executable. The remaining command-line arguments passed to `user_initialize()` are a subset of those given on the command line that invoked Creo Parametric. The rule is that Creo Parametric passes on to `user_initialize()` any command-line argument that starts with a “+”, or with a “-” followed by an upper-case character.

For example, these command-line arguments will be passed to Creo TOOLKIT:

```

+batch=mybatchfile.txt
-Level=expert

```

---

Command-line arguments such as `-g:no_graphics` are interpreted by Creo Parametric but not passed on to Creo TOOLKIT.

## Threading in Creo Toolkit Applications

Calling Creo TOOLKIT applications from within multiple threads of any application in any mode is not supported. Extra threads created by the application are to be used only for completion of tasks that do not directly call the Creo TOOLKIT functions.

Multithreading is now always supported in Creo TOOLKIT applications, without the need to call the multithreading function, when the application creates additional threads for processing.

## Using Creo Toolkit to Make a Batch Creo Parametric Session

Function Introduced:

- **ProEngineerEnd()**

If you want to use your Creo TOOLKIT application to perform operations on Creo Parametric objects that do not require interaction with the user, you can make all the necessary calls to Creo TOOLKIT functions in `user_initialize()`. When your operations are complete, call the function `ProEngineerEnd()` to terminate the Creo Parametric session.

A useful technique when designing a batch-mode Creo TOOLKIT application is to use command-line arguments to Creo Parametric as a way of signaling the batch mode and passing in the name of a batch control file. Consider the following command to start Creo Parametric:

```
pro +batch=<filename>
```

In this example, the option will be ignored by Creo Parametric, but will be passed as an input argument to `user_initialize()`. Inside that function, your code can recognize the switch, and get the name of the file that could contain, for example, the names of Creo Parametric models to be processed, and operations to be performed on each one.

A batch-mode operation should also run without displaying any graphics. To ensure that the Creo Parametric main Graphics Window and Message Window are not displayed, you should use either the command-line option `-g:no_graphics` (or the configuration file option “`graphics NO_GRAPHICS`”) to turn off the Creo Parametric graphics. See the Creo Parametric Help for more details of these options.

---

## Example 1: Batch Mode Operation

The sample code in `simple_async.c` located at `<creo_toolkit_loadpoint>\<datecode>\Common Files\protoolkit\protk_appls\pt_simple_async\pt_sasync_src` shows how to use the arguments to `user_initialize()` and the function `ProEngineerEnd()` to set up a batch mode session of Creo Parametric. The application retrieves a part specified in the Creo Parametric command line, performs an action on it (using the dummy function `UserAddHoles()`), saves the parts, and terminates Creo Parametric.

## Creo Toolkit Support for Creo Applications

Creo TOOLKIT applications in synchronous and asynchronous modes are supported only with the Creo Parametric application. They are not supported with the other Creo applications, such as, Creo Layout, Creo Simulate, and so on.

In the asynchronous mode, the functions `ProEngineerConnect()` and `ProEngineerStart()` return an error when the Creo TOOLKIT application attempts to connect to a Creo application other than Creo Parametric.

For Creo TOOLKIT applications in synchronous mode, the non-Creo Parametric applications ignore the Toolkit registry files without any warnings. The **Auxiliary Applications** dialog box is also not available within the non-Creo Parametric applications.

## User-Supplied Main

Function Introduced:

- **ProToolkitMain()**

In synchronous mode, the `main()` function of the Creo TOOLKIT program is not written by you, the application developer. In DLL mode, the `main()` is the root of the Creo Parametric program itself; in multiprocess synchronous mode, the `main()` is taken from the Creo TOOLKIT library, and its job is to set up the communication channel with the separate Creo Parametric executable.

If you are using a language such as C++ in your Creo TOOLKIT application, it can be advantageous to compile the `main()` function with the C++ compiler to ensure that the program structure is correct for C++. In DLL mode, you cannot do this because you do not have access to the Creo Parametric `main()`. But in multiprocess mode, you can substitute the Creo TOOLKIT `main()` with your own, if you observe the following rules:

- Your `main()` must call the function `ProToolkitMain()` as its last statement. This function contains all the necessary setup code that needs to be run when the Creo TOOLKIT application starts up in multiprocess mode.

- 
- You must pass on the *argc* and *argv* arguments input to `main()` as the input arguments to `ProToolkitMain()` without modifying them in any way.
  - You cannot make calls to any other Creo TOOLKIT functions before the call to `ProToolkitMain()`, because the communications with Creo Parametric have not yet been set up. You may, however, make other non-Creo TOOLKIT function calls before calling `ProToolkitMain()`.

The following example shows a user-defined `main()` for use in multiprocess mode.

```
#include "ProToolkit.h"
main(
 int argc,
 char *argv[])
{
 .
 .
 .
 ProToolkitMain (argc, argv);
 /* The program exits from within ProToolkitMain().
 Any code here is not executed. */
}
```

## Asynchronous Mode

For more information on the asynchronous mode, see section [Core: Asynchronous Mode on page 277](#).

## Creo Toolkit Techniques

This section describes the basic techniques you use when writing Creo TOOLKIT applications. The topics are as follows:

- [Object Handles on page 60](#)
- [Expandable Arrays on page 63](#)

Also see section [Visit Functions on page 67](#) for information on techniques used when writing Creo TOOLKIT applications.

## Object Handles

Each object in Creo TOOLKIT has a corresponding C typedef, called a “handle”, whose name is always the name of the object itself with the prefix “Pro.” The handle is used as the type for all variables and arguments that refer to an object of that type. For example, any Creo TOOLKIT function that performs an action on a solid has an input argument of type `ProSolid`.

---

Handles are classified into two types, depending on the way in which they are defined and have to be used. The two types are opaque handle (OHandle) and database handle (DHandle). The following sections describe these handles in detail.

## OHandles

The simplest way to reference an object in Creo Parametric is to use the memory address of the Creo Parametric data structure that describes that object. To prevent the Creo TOOLKIT application from accessing the content of the data structure for the object directly, the declaration of the structure is not provided. For example, the object handle `ProSurface` is defined as follows:

```
typedef struct geom* ProSurface;
```

The structure `struct geom` is used to describe a surface in Creo Parametric, but the declaration of the structure is not included in Creo TOOLKIT. This type of handle is called an opaque handle or opaque pointer for this reason.

Opaque handles have the advantage of simplicity and efficiency—they can be directly dereferenced inside the Creo TOOLKIT function without any searching. They can also reference items that are transient and not in the Creo Parametric database at all, such as the surfaces and edges that result from an interference volume calculation.

Other examples of Creo TOOLKIT objects that are given OHandles are as follows:

```
typedef void* ProMdl;
typedef struct curve_header* ProEdge;
typedef struct sld_part* ProSolid;
typedef struct entity* ProPoint;
typedef struct entity* ProAxis;
typedef struct entity* ProCsys;
typedef struct entity* ProCurve;
```

Because opaque handles are just memory pointers, they suffer the disadvantage of all pointers in that they are volatile—they become invalid if the database object they refer to moves to a different memory location. For example, a `ProSurface` handle (a pointer to a Creo Parametric surface) may become invalid after regeneration of the owning part (because its memory has been reallocated).

However, most of the Creo Parametric structures referenced by opaque handles contain an integer identifier that is unique for items of that type within the owning model. This identifier retains its value through the whole life of that item, even between sessions of Creo Parametric. Creo TOOLKIT provides functions such as `ProSurfaceIdGet()` and `ProAxisIdGet()` that enable your application to use these identifiers as a persistent way to reference objects. These integer identifiers are also used in DHandles, described in the following section.

---

In the case of models, it is the name and type that are persistent. The functions `ProMdlMdlnameGet()` and `ProMdlTypeGet()` provide the name and type of a model, given its opaque handle.

## DHandles

A further limitation of opaque handles is that they can be too specific in cases where the action you want to perform is more generic. For example, a function that provides the name of a geometrical item should, ideally, be able to act on any of the geometry objects (`ProSurface`, `ProEdge`, `ProCsys`, and so on). However, the opaque handles for those different geometry items are not mutually compatible, so the Creo TOOLKIT function would also need to know the type of the object before it could internally de-reference the opaque pointer.

To solve this problem, Creo TOOLKIT defines a new, generic object type in these cases and declares it using a data handle, or `DHandle`. A `DHandle` is an explicit data structure that carries just enough information to identify a database item uniquely: the type, integer identifier, and handle to the owning model. Because the `DHandle` must contain the integer identifier (not the too-specific opaque handle), it also has the advantage of being persistent.

The most important examples of `DHandles` are `ProGeomitem`, which is the generic type for the geometry items previously mentioned, and `ProModelitem`, which is an even more generic object that includes `ProGeomitem`.

The declaration is as follows:

```
typedef struct pro_model_item
{
 ProType type;
 int id;
 ProMdl owner;
} ProModelitem, ProGeomitem;
```

---

### Note

Although the field `owner` is defined using the `OHandle` `ProMdl`, and is therefore strictly speaking volatile, this handle is guaranteed to remain valid while the Creo Parametric model it refers to remains in memory.

---

The generic object `ProGeomitem` can represent any of the geometrical objects in a solid model, such as `ProSurface`, `ProEdge`, `ProCurve`, and `ProCsys`. The specific object types are said to be “derived from” the most generic type, and also to be “instances” of that type. The object type `ProGeomitem` is in turn an instance of `ProModelitem`, which can represent database items other than geometrical ones.

---

The generic object types such as `ProModelitem` and `ProGeomitem` are used as inputs to Creo TOOLKIT functions whose actions are applicable to all of the more specific types of object that are instances of the generic type. For example, the function `ProGeomitemFeatureGet()` has that name because it can act on any type of object that is an instance of `ProGeomitem` `ProSurface`, `ProEdge`, `ProCsys`, and so on. The function `ProModelitemNameGet()` is applicable to a wider range of database objects, not just geometrical ones.

If you have the `OHandle` to an object, such as `ProSurface`, and you want to call a generic function such as `ProGeomitemFeatureGet()`, you need to convert the `OHandle` to the more generic `DHandle`. Functions such as `ProGeomitemInit()` and `ProModelitemInit()` provide this capability. Similarly, you can convert a `ProGeomitem` to a `ProSurface` using the function `ProSurfaceInit()`. These techniques are illustrated in [Example 3: Listing Holes in a Model on page 68](#), in the [Visit Functions on page 67](#) section.

## Workspace Handles

When you use Creo TOOLKIT to create an object in Creo Parametric that contains a lot of information, such as a feature, it is important to be able to set up all of that information before adding the object to the Creo Parametric database. The object-oriented style of Creo TOOLKIT does not allow explicit access to the contents of such a structure, however. Instead, you must use a special workspace object that is allocated and filled by the Creo TOOLKIT application using functions provided for that purpose.

The “workspace” is a memory area in Creo Parametric that contains data structures not yet part of the design database.

The workspace object is identified by a handle that contains the address of the memory for the object, which is therefore similar to an `OHandle`. To distinguish this from handles that refer to objects in the Creo Parametric database, such handles are called workspace handles (WHandles).

## Expandable Arrays

Functions Introduced:

- **`ProArrayAlloc()`**
- **`ProArrayFree()`**
- **`ProArraySizeGet()`**
- **`ProArraySizeSet()`**
- **`ProArrayMaxCountGet()`**
- **`ProArrayObjectAdd()`**
- **`ProArrayObjectRemove()`**

---

The functions in this section enable you to access a set of programming utilities in general use within Creo Parametric. The utilities fill a need that is common in C and Pascal programming—to provide a storage method that provides the advantages of an array, but without its limitations.

When you use an array for storage for a group of items, you have the advantage over a linked list in that the members are contiguous in memory. This enables you to access a given member using its index in the array. However, if you need to make frequent additions to the members in a way that cannot be predicted (a common situation in MCAE applications), you must reallocate the memory for the array each time.

A common compromise is to allocate the memory in blocks large enough to contain several array members, then reallocate the memory only when a block becomes full. You would choose the size of the blocks such that the frequency of reallocation is significantly reduced, while the amount of unused memory in the last block is acceptably small. The difficulty of this solution is that you would normally need a new set of utilities for each item you want to store as an array, and additional static data for each array to keep track of the number of blocks and the number of members.

The “expandable array” utilities provide a set of functions that can be applied to items of any size. The utilities do this by keeping a private header at the start of the array memory to which the “bookkeeping” information (the number and size of its members, and of the blocks) is written. The pointer your application sees is the address of the first block, not the address of the preceding header.

The importance of the expandable array utilities in a Creo TOOLKIT application is not only that you can use them for your own arrays, but that you must use them for arrays of data passed between your application and the internals of Creo Parametric through the Creo TOOLKIT functions.

Note that because the array pointer is not the start of the contiguous memory claimed by the array utility, this pointer is not recognized by the operating system as a valid location for dynamic memory. Therefore, you will cause a fatal error if you try to use the memory management library functions, such as `realloc()` and `free()`.

The basic type used for referring to expandable arrays is `ProArray`, declared as `a void*`.

The function `ProArrayAlloc()` sets up a new expandable array. Its inputs are as follows:

- The initial number of members in the array
- The size, in bytes, of each array member
- Number of objects added to `ProArray` at each memory reallocation. A higher number means more memory is preallocated and fewer reallocations of the `ProArray` are required.

---

The function outputs a pointer to the contiguous memory that will contain the array members. You can write to that memory to fill the array using the usual memory functions (such as `memcpy()` and `memset()`). If you increase the array size beyond the limit returned by `ProArrayMaxCountGet()`, this function returns an out-of-memory message.

The maximum memory allocated is 2 MB, except for 64-bit platforms where the maximum is twice that.

The function `ProArrayFree()` releases the memory for the specified `ProArray`.

The function `ProArraySizeGet()` tells you how many members are currently in the specified array.

The `ProArraySizeSet()` function enables you to change the number of members in the expandable array. This function is equivalent to `realloc()`.

Function `ProArrayMaxCountGet()`, when given the specified structure size in bytes, returns the maximum number of structure elements a `ProArray` can support for that structure size.

The function `ProArrayObjectAdd()` adds a contiguous set of new members to an array, though not necessarily to the end of the array. The function also sets the contents of the new members. If you increase the array size beyond the limit returned by `ProArrayMaxCountGet()`, this function returns an out-of-memory message.

The function `ProArrayObjectRemove()` removes a member from the array. The member does not necessarily have to be the last member of the array.

Functions `ProArraySizeSet()`, `ProArrayObjectAdd()`, and `ProArrayObjectRemove()` change the size of the array, and might therefore also change its location.

The Creo TOOLKIT functions use expandable arrays in the following circumstances:

- The function creates a filled, expandable array as its output.
- The function needs a filled, expandable array as its input.
- The function needs an existing expandable array to which to write its output.

An example of the first type of function is the geometry function `ProEdgeVertexdataGet()`, which provides a list of the edges and surfaces that meet at a specified solid vertex. When you have finished using the output, you should free the arrays of edges and surfaces (using the function `ProArrayFree()`).

---

An example of the second type of function is `ProSolidNoteCreate()`, which creates a design note in a solid. Because the text lines to add to the note are passed in the form of an expandable array, your application must create and fill the array using the functions `ProArrayAlloc()` and `ProArrayObjectAdd()` before you call `ProSolidNoteCreate()`.

An example of the third type of function is `ProElementChildrenGet()`, which gets the number of feature elements that are the children of the specified compound element. The feature elements form a tree that contains all the necessary information about a particular feature. (This function is therefore used in both feature analysis and feature creation.) Before calling `ProElementChildrenGet()`, you must call `ProArrayAlloc()` to create an empty array. You can then use `ProArraySizeGet()` to find out how many elements were added to the array.

There is a fourth case, which is a variation of the first, in which a Creo TOOLKIT function creates an expandable array as its output the first time it is called in an application, but overwrites the same array on subsequent calls. An example of this is `ProSelect()`, whose output array of `ProSelection` structures must not be freed using `ProArrayFree()`. You must also make sure to copy the contents of the array if you need to use it to make another call to `ProSelect()`.

The conventions are chosen for each function according to its individual needs. For example, `ProElementChildrenGet()` is typically called in a recursive loop to traverse a tree, so the fourth method of allocation would be inconvenient.

The rules for each Creo TOOLKIT function are documented in the browser.

## Example 2: Expandable Arrays

The sample code in `UgFundExpArrays.c` located at `<creo_toolkit_loadpoint>\protk_appls\pt_userguide\ptu_fundament` shows how to use expandable arrays, not as input or output for a Creo TOOLKIT function, but to create a utility that provides an alternative to a Creo TOOLKIT visit function. To use Creo TOOLKIT to access all the features in a solid, you call the function `ProSolidFeatVisit()`. However, you might prefer to use a function that provides an array of handles to all of the features, then traverse this array. This kind of function is called a “collection” function, to distinguish it from a visit function. Although Creo TOOLKIT does not provide collection functions, you can use the technique demonstrated in the example to write your own.

The utility function `UserFeatureCollect()` passes an empty, expandable array of feature handles as the application data to `ProSolidFeatVisit()`. The visit function `FeatVisitAction()` adds the handle to the visited feature to the array using `ProArrayObjectAdd()`.

---

## Visit Functions

In a Creo TOOLKIT application, you often want to perform an operation on all the objects that belong to another object, such as all the features in a part, or all the surfaces in a feature. For each case, Creo TOOLKIT provides an appropriate “visit function.” A visit function is an alternative to passing back an array of data.

You write a function that you want to be called for each item (referred to as the “visit action” function) and pass its pointer to the Creo TOOLKIT visit function. The visit function then calls your visit action function once for each visited item.

Most visit functions also provide for a second callback function, the filter function, which is called for each visited item before the action function. The return value of the filter function controls whether the action function is called. You can use the filter function as a way of visiting only a particular subset of the items in the list.

For example, the visit function for visiting the features in a solid is declared as follows:

```
ProError ProSolidFeatVisit (
 ProSolid solid,
 ProFeatureVisitAction visit_action,
 ProFeatureFilterAction filter_action,
 ProAppData app_data);
```

The first argument is the handle to the solid (the part or assembly) whose features you want to visit.

The second and third arguments are the visit action function and filter function, respectively.

The type of the final argument, `ProAppData`, is a typedef to a `void*`. This argument is used to pass any type of user-defined application data down to the `visit_action` and `filter_action` functions through the intervening Creo TOOLKIT layer. You might want to use this as an alternative to allowing global access to the necessary data.

Although you write the visit action and filter functions, they are called from within the Creo TOOLKIT visit function, so their arguments are defined by Creo TOOLKIT. To enable the C compiler to check the arguments, Creo TOOLKIT provides a typedef for each of these functions.

For example, the type for the action function for `ProSolidFeatVisit()` is as follows:

```
typedef ProError (*ProFeatureVisitAction) (
 ProFeature *feature,
 ProError status,
 ProAppData app_data);
```

It takes three arguments:

- The handle to the feature being visited

- The status returned by the preceding call to the filter function
- The application data passed as input to the visit function itself

The type for the filter function is as follows:

```
typedef ProError (*ProFeatureFilterAction) (
 ProFeature *feature,
 ProAppData app_data);
```

Its two arguments are the handle to the feature being visited and the application data.

The filter action function should return one of the following values:

- `PRO_TK_CONTINUE`—Do not call the visit action for this object, but continue to visit the subsequent objects.
- Any other value—Call the visit action function for this object and pass the return value as the status input argument.

The visit action function should return one of the following values:

- `PRO_TK_NO_ERROR`—Continue visiting the other objects in the list.
- `PRO_TK_E_NOT_FOUND`—For visit functions, this value indicates that no items of the desired type were found and no functions could be visited.
- Any other value (including `PRO_TK_CONTINUE`)—Terminate the visits. Typically this status is returned from the visit function upon termination, so that the calling function knows the reason that visiting terminated abnormally.

### Example 3: Listing Holes in a Model

The sample code in `UgFundVisit.c` located at `<creo_toolkit_loadpoint>\protk_appls\pt_userguide\ptu_fundament` demonstrates several of the principles used in Creo TOOLKIT, including visit functions, the use of `Ohandles` and `Dhandles`, and the `ProSelection` object.

The example shows the function `UserDemoHoleList()`, which visits the axes in the current part that belong to features of type `HOLE`. It then writes the axis names and feature identifiers to a file, and highlights the hole features.

The top function, `UserDemoHoleList()`, calls `ProSolidAxisVisit()`. The function uses the `ProAppData` argument to pass to the visit action function, `UserDemoAxisAct()`, a structure that contains the file pointer and handle to the owning solid.

---

## Support for Creo Model Names and Files Paths

Creo Parametric supports a maximum length of 31 characters for file names of native Creo models. This excludes the file extension. The local file paths can contain a maximum of 260 characters. File paths support some multi-byte characters.

From Creo Parametric 4.0 F000 onward, file names support multi-byte characters.

The file names and file paths support the following multi-byte characters:

- All characters from Unicode number 0800 onward.
- The following characters from Unicode numbers 0000 to 0070F are supported. All the other Unicode characters between 0000 to 0070F are not supported.
  - A to Z
  - a to z
  - 0 to 9
  - \_ Underscore
  - – Hyphen

All the Creo TOOLKIT functions support multi-byte characters in file names and file paths of the models.

## Wide Strings

Creo TOOLKIT, like Creo Parametric, has to work in environments where character strings use codes other than ASCII, and might use a bigger character set than can be coded into the usual 1-byte char type, for example, the Japanese KANJI character set.

For this reason, Creo TOOLKIT uses the type `wchar_t` instead of `char` for all characters and strings that may be visible to the Creo Parametric user. This includes all text messages, keyboard input, file names, and names of all dimensions, parameters, and so on, used within a Creo Parametric object.

## Defining `wchar_t`

Although most platforms supported by Creo TOOLKIT provide a definition of `wchar_t` in a system include file, not all do. Those that do use definitions of different lengths; some provide definitions that are not suitable for all the character codes supported by Creo Parametric. Therefore, Creo Parametric takes considerable care to make sure it uses a suitable definition of `wchar_t` on each supported platform.

It is essential to make sure your Creo TOOLKIT application is using the same definition of `wchar_t` as Creo Parametric on each platform your application supports. To make this easier, Creo TOOLKIT supplies the include file `filepro_wchar_t.h`. This file ensures that, if a definition of `wchar_t.h` has not

---

already been made in an earlier include file, one is provided that is consistent with the Creo Parametric definition of the type. Because this file is included by the file `ProToolkit.h`, you should include `ProToolkit.h` as the very first include file in each source file.

## Setting the Hardware Type

To make the handling of the wide character type `wchar_t` across different platforms simpler and more reliable, the include file `pro_wchar_t.h` is hardware dependent. It knows which platform is being used from the setting of the environment variable `PRO_MACHINE`; the recognized values are listed in the include file `pro_hardware.h`, included by `pro_wchar_t.h`.

You must make sure that the environment variable `PRO_MACHINE` is set to indicate the type of hardware you are using. Set it to same value used for the makefile macro `PRO_MACHINE` in the makefile taken from the Creo TOOLKIT loadpoint.

## Checking Your Declaration of `wchar_t`

Function Introduced:

- **ProWcharSizeVerify()**

The function `ProWcharSizeVerify()` checks to make sure you have the correct declaration of `wchar_t`. PTC recommends that you always call this function at the beginning of the `user_initialize()` function (or `main()` in asynchronous mode).

You pass as input the size of your `wchar_t` definition, in bytes, and the function outputs the correct size. It returns `PRO_TK_NO_ERROR` if your size is correct, and `PRO_TK_GENERAL_ERROR` otherwise. You can check for correctness as follows:

```
int proe_wchar_size;
int protk_wchar_size = sizeof (wchar_t);

if (ProWcharSizeVerify (protk_wchar_size, &proe_wchar_
size) !=
 PRO_TK_NO_ERROR)
{
 ProMessageDisplay (msgfil, "USER wchar_t size is %
0d,
 should be %ld", &protk_wchar_size, &proe_wchar_
size);
 return (1);
}
```

---

## String and Widestring Functions

Creo Parametric provides many functions taking as inputs a fixed-length character or wide character array as a string. Due to some platform-specific behavior, PTC recommends that you do not use string literals in lieu of fixed length arrays. Always copy the literal strings to the full size array that the functions accepts as the input.

For example the following function will get warnings on certain platforms because the code expects that the arguments can be modified.

```
ProEngineerStart("proe_path", "text_path");
```

```
where ProCharPath proe_path="proe_path";
```

```
ProCharPath text_path="text_path";
```

To overcome this error, it is recommended that you replace the literal strings in the function with defined arrays as follows:

```
ProEngineerStart (proe_path, text_path);
```

Functions Introduced:

- **ProStringToWstring()**
- **ProWstringToString()**
- **ProWstringLengthGet()**
- **ProWstringCopy()**
- **ProWstringCompare()**
- **ProWstringConcatenate()**

Wide character strings are not as easy to manipulate in C as ordinary character strings. In general, there are no functions for wide strings that correspond to the standard C `str*()` functions. `printf()` does not have a format for wide strings, and you cannot set a wide string to a literal value in a simple assignment. Because of this, it is frequently convenient to convert wide strings to character strings, and vice versa. This is the purpose of the functions `ProStringToWstring()` and `ProWstringToString()`.

The function `ProWstringLengthGet()` is used to find the length of a widestring.

The function `ProWstringCopy()` copies a widestring into another buffer. You should allocate enough memory in the target setting to perform the copy operation. The number of characters to be copied is provided as input through `num_chars`. Use `PRO_VALUE_UNUSED` to copy the entire string.

The function `ProWstringCompare()` compares two widedstrings for equality. The two widedstrings to be compared are given as inputs. The argument `num_chars` allows comparison of portions of the string, pass `PRO_VALUE_UNUSED` to compare the entire strings.

---

The function `ProWstringConcatenate()` concatenates two wide strings. You should allocate enough memory in the target string for the copy operation. The number of characters to concatenate is given as input through `num_chars`. Use `PRO_VALUE_UNUSED` to add the entire source string to the target string.

The source code for other useful utilities is located in the file `<TK_LOADPOINT>protk_appls\pt_examples\pt_utils\UtilString.c`

### Example 4: String Conversion

The sample code in `UgFundStringConv.c` located at `<creo_toolkit_loadpoint>\protk_appls\pt_userguide\ptu_fundament` uses the function `UsrModelFilenameGet()` to convert wide strings to character strings.

## Support for IPv6

Creo 6.0.0.0 and later releases have complete support for Internet Protocol version 6 (IPv6). By default Creo uses IPv6 for IP addressing over the network.

Set the environment variable `PTC_IPV6_MODE` to `yes` for Creo to use the IPv6 protocol for addressing. To use IPv4 communication protocol, set the environment variable to `no`.

If you want to run applications created in Creo Parametric 5.0.0.0 and previous releases in Creo Parametric 6.0.0.0 with IPv6 enabled, you must rebuild the applications.

If the environment variable is set to `no`, that is for IPv4 protocol, these applications continue to work in Creo Parametric 6.0.0.0 without rebuilding.

## Accessing LearningConnector

Function Introduced:

- **ProLearningconnectorNotify()**

LearningConnector (LC) is a feature in Creo that allows users to access the Creo training directly from a Creo application. An event triggered in the Creo user interface notifies the LearningConnector, which displays the relevant training topics for the current activity.

The function `ProLearningconnectorNotify()` notifies the LearningConnector that an event has been triggered from a Creo TOOLKIT application. The function also allows users to notify custom-made trainings other than the standard training provided by PTC for the specified module. The

---

LearningConnector displays the relevant training topics for the specified input arguments. You must read the LearningConnector documentation before using this function. The input arguments are:

- *module*—This is a mandatory argument. Specifies the name of the Creo module that triggers the event.
- *module\_info*—This is an optional argument. Specifies additional information about the Creo module that triggers the event. This additional information is used by the event-handling function of LearningConnector.

You can use the function on customized Creo TOOLKIT widgets also.

## Core : Models and Model Items

### Core: Models and Model Items

This section describes Creo TOOLKIT modes, models, and model items.

#### Modes

Functions Introduced:

- **ProModeCurrentGet()**
- **ProSectionIsActive()**

The term “mode” in Creo Parametric refers to the type of model currently being edited by the user. The possible modes are given by the options listed under the command **File ► New**.

The `ProMode` object in Creo TOOLKIT is an enumerated type, declared in the file `ProMode.h`, as are the prototypes for the mode functions.

Find the name of the mode using the function `ProModeCurrentGet()`. The function `ProModeCurrentGet()` outputs the mode in which Creo Parametric is being used, in the form of the `ProMode` enumerated type. If there is no current model—for example, because no model has been retrieved, or because the user has selected **File ► Close**—the function returns an error status (`PRO_TK_BAD_CONTEXT`).

The function `ProSectionIsActive()` checks if the sketcher is currently active even if the current mode is part or assembly.

#### Models

This section describes Creo TOOLKIT models. The topics are as follows:

- [The ProMdl Object on page 83](#)
- [Creating Models on page 74](#)

- 
- [Identifying Models on page 75](#)
  - [Models in Session on page 80](#)
  - [File Management Operations on page 83](#)

## The ProMdl Object

A model is a top-level object in a Creo Parametric mode. For example, in Part mode, the model is a part; in Assembly mode, the model is an assembly.

The object `ProMdl` is therefore used for all those functions whose action applies to models of any type, such as file management operations and version stamps.

The declaration of `ProMdl` is as follows:

```
typedef void* ProMdl;
```

Instances of the `ProMdl` object are objects for the more specific Creo Parametric modes. For example, `ProSolid` is an instance of `ProMdl`, and `ProAssembly` and `ProPart` are instances of `ProSolid`. All these object types are represented in Creo TOOLKIT by opaque handles, and you can make conversions between the types by casting.

## Creating Models

Functions Introduced

- **`ProSolidMdlnameCreate()`**
- **`ProMfgMdlCreate()`**
- **`ProSection2DAlloc()`**
- **`ProDrawingFromTpltCreate()`**
- **`ProDrawingFromTemplateCreate()`**
- **`ProMdlStartAction()`**

Creo TOOLKIT supports creation of models for Solids, Manufacturing, Section (two-dimensional only), and Drawing.

See [Creating a Solid on page 95](#) for a complete description of `ProSolidMdlnameCreate()`.

For more information on `ProMfgMdlCreate()` see [Creating a Manufacturing Model on page 1434](#).

[Allocating a Two-Dimensional Section on page 988](#) gives more details on `ProSection2DAlloc()`.

[Creating Drawings from Templates on page 1206](#) has more information on the function `ProDrawingFromTemplateCreate()`.

---

## Note

The function `ProDrawingFromTpltCreate()` will be deprecated in a future release. Use the function `ProDrawingFromTemplateCreate()` instead.

---

The notification function `ProMdlStartAction()` is a type for a callback function for `PRO_MDL_START`. This function changes the way users can create models by replacing the Creo Parametric model template dialog box with a user-specified action.

The user-specified action contains user-programmed activities that allow customization of new models by applying templates with more inputs than model creation “on-the-fly” or the standard Creo Parametric template.

The callback function is activated after the user selects **OK** from the **File ► New** dialog box, but only if the **Use Default Template** checkbox is not selected. The user’s application must create a new model of the same type and subtype specified by the callback function.

Setting the configuration option `force_new_file_options_dialog` to `yes` forces the **Use Default Template** button to be hidden, and calls the callback for all models created through the **File ► New** dialog.

This function supports all model types.

See [Event-driven Programming: Notifications on page 1974](#) for more data on using callback functions.

## Identifying Models

Functions Introduced:

- `ProMdlMdlnameGet()`
- `ProMdlOriginGet()`
- `ProMdlExtensionGet()`
- `ProMdlDirectoryPathGet()`
- `ProMdlTypeGet()`
- `ProMdlDisplaynameGet()`
- `ProMdlCommonnameGet()`
- `ProMdlCommonnameSet()`
- `ProMdlObjectdefaultnameGet()`
- `ProMdlnameInit()`

- 
- **ProMdlIdGet()**
  - **ProMdlActiveGet()**
  - **ProMdlSubtypeGet()**
  - **ProMdlFiletypeGet()**
  - **ProFileSubtypeGet()**
  - **ProMdlToModelitem()**

The object `ProMdl` is an opaque handle, and is therefore volatile. It cannot be used to refer to models that are not in memory in Creo Parametric, for example. To reference a model in a way that is valid for models not in memory, and also persistent across sessions of Creo Parametric, use the model name and type.

The functions `ProMdlMdlnameGet()` and `ProMdlTypeGet()` provide the name and type of a model, given its `ProMdl` handle. The type of a model is expressed in terms of the enumerated type `ProMdlType`. From Creo Parametric 3.0 onward, this enumerated data type contains an additional value `PRO_MDL_CE_SOLID` that represents a Layout model. Creo TOOLKIT functions will only be able to read models of type Layout, but will not be able to pass Layout models as input to other functions. PTC recommends that you review all Creo TOOLKIT applications that use the enumerated type `ProMdlType` and modify the code as appropriate to ensure that the applications work correctly.

The function `ProMdlOriginGet()` retrieves the full source path of the model, that is, the path from where the specified model has been opened. It returns `NULL` if the specified model is new in the session, and has not been saved. For instances, it returns the full path of the file that created the instance. For example, the accelerator file if applicable or otherwise the generic.

The function `ProMdlExtensionGet()` retrieves the file extension for the specified model.

The function `ProMdlDirectoryPathGet()` returns the file path where the specified model would be saved. It specifies the target home directory for the model.

The function `ProMdlDisplaynameGet()` returns the name of the model, which is displayed in the Creo Parametric user interface. The name is displayed in the graphics area, such as, the model tree, window title, and so on. If the model is an instance of native Creo model, the display name is the instance name. For configurations or instances of non-native models, the display name consists of the model name along with the configuration name or instance name. If you specify the input argument *include\_ext* as `PRO_B_TRUE`, then the display name returned by the function also includes the file extension of the model.

The functions `ProMdlCommonnameGet()` and `ProMdlCommonnameSet()` obtain and assign the common name of a model, respectively. This name is used to identify the model in a Product Database Management system such as Windchill PDMLink.

---

 **Note**

`ProMdlCommonnameSet()` can modify the name only for models that are not yet owned by Windchill PDMLink, or in certain situations if the configuration option `let_proe_rename_pdm_objects` is set to yes.

The function `ProMdlObjectdefaultnameGet()` returns the next available default name for a given model type. The type of the model is specified by the enumerated type `ProType` and has one of the following values:

- `PRO_PART`
- `PRO_ASSEMBLY`
- `PRO_CABLE`
- `PRO_DRAWING`
- `PRO_REPORT`
- `PRO_2DSECTION`
- `PRO_3DSECTION`
- `PRO_LAYOUT`
- `PRO_DWGFORM`
- `PRO_MARKUP`

---

 **Note**

For each of the above types, `ProMdlObjectdefaultnameGet()` returns the next available default name, for example `PRT00#` for `PRO_PART` or `DRW00#` for `PRO_DRAWING`, where # specifies the part or drawing number. This number depends on the following factors:

- Models present in the active Creo Parametric session
- Files in the current working directory
- Connection to an active server with the autonumber option enabled

Thus, if no object with the specified name is actually created, the next time the same name is returned; otherwise the next available name is returned.

The function `ProMdlnameInit()` does the opposite, and provides a valid `ProMdl` handle for a given name and type. The function fails if the specified model is not in memory in the Creo Parametric session.

---

A third way to identify a model is by an integer identifier. Unlike the integer identifiers of objects within a model, such as surfaces and edges, the identifier of a model is not persistent between Creo Parametric sessions. The function `ProMdlIdGet()` provides the identifier of a model, given its `ProMdl` handle.

The function `ProMdlActiveGet()` retrieves the model handle `ProMdl` for an active Creo Parametric object.

The function `ProMdlSubtypeGet()` provides the subtype (such as sheet metal) of a specified model. Valid model subtypes are Part, Assembly, or Manufacturing. This is like finding subtypes at the Creo Parametric **File ► New ► Model Type** menu.

The function `ProMdlFiletypeGet()` retrieves the file type of the specified model using the enumerated data type `ProMdlfileType`.

The function `ProFileSubtypeGet()` retrieves the following information when you specify the path to a file as the input argument. The output arguments are:

- *file\_type*—Specifies the file type using the enumerated data type `ProMdlfileType`. For native Creo models, the file type and model type are the same.
- *type*—Specifies the model type using the enumerated data type `ProMdlType`.
- *subtype*—Specifies the subtype of the model using the enumerated data type `ProMdlsubtype`. For model types that do not have subtypes, the argument returns `PROMDLSTYPE_NONE`.

The function `ProMdlToModelitem()` is used only when you need to represent the model as a `ProModelitem` object—the first step in building a `ProSelection` object that describes the role of a model in a parent assembly. Model item objects are described later in this section. See the section [Fundamentals on page 30](#) for information on the `ProSelection` object.

## Example 1: Finding the Handle to a Model

The following example shows how to find a model handle, given its name and type.

```
ProName name;
ProType type;
ProMdl part;
ProError status;
ProStringToWstring (name, "PRT0001");
type = PRO_PART;
status = ProMdlnameInit (name, type, &);
```

## Surface Properties of Models

Functions Introduced:

- **ProMdlVisibleSideAppearancepropsGet()**
- **ProMdlVisibleSideAppearancepropsSet()**
- **ProMdlVisibleSideTexturepropsGet()**
- **ProMdlVisibleSideTexturepropsSet()**
- **ProMdlLockGet()**
- **ProMdlLockSet()**
- **ProMdlVisibleSideTexturereplacementpropsGet()**
- **ProMdlVisibleSideTexturereplacementpropsSet()**

From Creo Parametric 5.0.0.0 onwards, the following functions have been deprecated:

- `ProMdlVisibleAppearancepropsGet()`
- `ProMdlVisibleAppearancepropsSet()`
- `ProMdlVisibleTexturepropsGet()`
- `ProMdlVisibleTexturepropsSet()`
- `ProMdlVisibleTexturereplacementpropsGet()`
- `ProMdlVisibleTexturereplacementpropsSet()`

The functions described in this section enable you to retrieve and set the surface and texture properties of models. You can retrieve and set these properties for any level in the model hierarchy. For assemblies, set the owner of `ProModelitem` as the top-level assembly. These properties may or may not be visible in the user interface depending on the properties set by the higher level assembly.

Use the function `ProMdlVisibleSideAppearancepropsGet()` to retrieve the surface properties for a specified part, assembly component, subassembly, specified side of a quilt or surface using the `ProSurfaceAppearanceProps` data structure. Refer to the section [Surface Properties on page 514](#), for more information on

`ProSurfaceAppearanceProps` data structure. The input arguments are:

- *item*—Specifies a `ProAsmitem` object that represents the part, assembly component, subassembly, quilt, or surface.
- *surface\_side*—Specifies the direction of the side for the surface or quilt. Pass the value as 0 to specify the side which is along the surface normal. Pass 1 to specify the side opposite to surface normal.

Use the function `ProMdlVisibleSideAppearancepropsSet()` to set the surface properties for a specified element. To see the changes in the Creo Parametric user interface, call the function `ProWindowRepaint()` after `ProMdlVisibleSideAppearancepropsSet()`. To set the default surface appearance properties, pass the value of the input argument `appearance_properties` as `NULL`.

---

Use the functions `ProMdlVisibleSideTexturepropsGet()` and `ProMdlVisibleSideTexturepropsSet()` to apply textures to the surface. These functions use the `ProSurfaceTextureProps` data structure to retrieve and set the texture properties of the surface for a specified element. Refer to the section [Surface Properties on page 514](#), for more information on `ProSurfaceTextureProps` data structure.

Use the functions `ProMdlVisibleSideTexturereplacementpropsGet()` and `ProMdlVisibleSideTexturereplacementpropsSet()` to retrieve and set the properties related to the placing of surface texture for the specified element. These functions use the `ProSurfaceTexturePlacementProps` data structure to define the placement properties.

Refer to the section [Surface Properties on page 514](#), for more information on `ProSurfaceTexturePlacementProps` data structure.

The functions `ProMdlLockGet()` and `ProMdlLockSet()` get and set the lock/unlock state of the model. The function `ProMdlLockGet()` returns `PRO_B_TRUE` if the model is locked and `PRO_B_FALSE` if it is unlocked.

The input arguments to the function `ProMdlLockSet()` follow:

- *model*—The model to be locked or unlocked.
- *lock*—Pass the value as `PRO_B_TRUE` to lock the model and `PRO_B_FALSE` to unlock it.

## Models in Session

Functions Introduced:

- **ProSessionMdlList()**
- **ProMdlCurrentGet()**
- **ProMdlDependenciesDataList()**
- **ProMdlDependenciesCleanup()**
- **ProMdlDeclaredDataList()**
- **ProMdlModificationVerify()**
- **ProMdlVisibleModificationVerify()**
- **ProMdlIsModifiable()**
- **ProMdlHasNoConflict()**
- **ProMdlAreModifiable()**
- **ProMdlHaveNoConflict()**
- **ProMdlIsEmbeddedName()**
- **ProMdlVisibleGet()**

---

The function `ProSessionMdlList()` provides an array of `ProMdl` handles to models of a specified type currently in memory.

The function `ProMdlCurrentGet()` provides the `ProMdl` handle to the model currently being edited by the user.

The function `ProMdlDependenciesDataList()` provides an array of `ProMdl` handles to the models in memory upon which a specified model depends. One model depends on another if its contents reference that model in some way. For example, an assembly depends on the models that form its components, and a drawing model depends on the solid models contained in it. Sometimes, two models can be mutually dependent, such as when a model feature references a geometry item in a parent assembly. Clean the dependencies in the database using the function `ProMdlDependenciesCleanup()` to get an accurate list of dependencies for an object in the Creo Parametric workspace.

Use the function `ProMdlDependenciesCleanup()` to clean the dependencies for an object in the Creo Parametric workspace.

---

 **Note**

Do not call the function `ProMdlDependenciesCleanup()` during operations that alter the dependencies, such as, restructuring components and creating or redefining features.

---

The function `ProMdlDeclaredDataList()` provides an array of `ProMdl` handles to first-level notebook models that have been declared to a specified solid model.

The function `ProMdlModificationVerify()` tells you whether a specified model in memory has been modified since it was last saved or retrieved. See the section [Version Stamps on page 87](#) for a more flexible way of keeping track of changes to a model.

The function `ProMdlVisibleModificationVerify()` checks if the visible model of the specified model has been modified since the last save. The input argument *handle* is used to verify the `ProMdl` object.

The output argument *p\_modified* returns `PRO_B_TRUE` if the model was modified and returns `PRO_B_FALSE` if the model was not modified.

The function `ProMdlIsModifiable()` checks if the specified model is modifiable. The input arguments are as follows:

- *pp\_models*—`ProArray` of models to check.

- 
- *show\_ui*—Pass a Proboolean value `PRO_B_TRUE`, if you want the **Conflicts** dialog box to be displayed to resolve detected conflicts. If you pass `PRO_B_FALSE`, the dialog box is not displayed.

---

 **Note**

In case of multiple models, you need to use the function `ProMdlAreModifiable()`.

---

The function `ProMdlHasNoConflict()` checks if the specified model does not have a storage conflict at the time of saving the modifications. The input arguments are as follows:

- *model to check*—The model to be checked.
- *resolve*—Pass a Proboolean with the value `PRO_B_TRUE`, to apply the default resolutions to the detected conflicts. The default conflict resolution in Windchill workspace for checked-in objects is controlled by the configuration option `dm_checkout_on_the_fly`. The valid values are:
  - Checkout
  - Continue

The function `ProMdlAreModifiable()` checks if the specified models are modifiable. The input arguments are as follows:

- *pp\_models*—ProArray of models to check.
- *show\_ui*—Pass a Proboolean value `PRO_B_TRUE`, if you want the **Conflicts** dialog box to be displayed to resolve detected conflicts.

The function `ProMdlHaveNoConflict()` checks if the specified models do not have a storage conflict at the time of saving the modifications. The input arguments are as follows:

- *pp\_models*—ProArray of models to check.
- *resolve*—Pass a Proboolean value `PRO_B_TRUE`, to apply the default resolutions to the detected conflicts.

The output argument `no_conflict` is a boolean `PRO_B_TRUE` which indicates that no conflict are found

The function `ProMdlIsEmbeddedName()` checks if the specified model name or full path that includes the model name is an embedded model name. The output argument `is_embedded_name` returns `PRO_B_TRUE` if the model name is an embedded name, `PRO_B_FALSE` if not.

In intersected embedded components, the name of the embedded model cannot be used for file operations. If you are using the embedded name while creating a new application, the file operation might fail. In such case, you must use the generic or visible model name.

---

The function `ProMdlVisibleGet()` returns the handle to the generic or visible model for the specified model. The function returns an error `PRO_TK_E_NOT_FOUND`, when the generic or visible model does not exist or is not found in the Creo Parametric session.

When an embedded component is extracted, a copy of the embedded solid is created and the embedded component model is replaced by the new non-embedded copy. In this extract operation, the original embedded model is erased and the name of the model is changed.

For embed operations, if a model has embedded components, a copy of the existing embedded models is created under the currently embedded model.

## File Management Operations

Functions Introduced:

- **ProMdlnameCopy()**
- **ProMdlfileMdlnameCopy()**
- **ProMdlnameRetrieve()**
- **ProMdlMultipleRetrieve()**
- **ProSolidRetrievalErrorsGet()**
- **ProMdlSave()**
- **ProMdlIsSaveAllowed()**
- **ProMdlErase()**
- **ProMdlEraseNotDisplayed()**
- **ProMdlEraseAll()**
- **ProMdlnameRename()**
- **ProMdlnameBackup()**
- **ProMdlDelete()**
- **ProMdlLocationIsStandard()**

These functions perform the same actions as the corresponding Creo Parametric file management commands, with the following exceptions:

- `ProMdlnameCopy()` and `ProMdlfileMdlnameCopy()` are equivalent to the **Save As** command in the **File** pull-down menu of the Creo Parametric menu bar. `ProMdlnameCopy()` takes the model handle as input, whereas `ProMdlfileMdlnameCopy()` takes the type and name of the model to copy.
- `ProMdlnameRetrieve()` retrieves the model into memory, but does not display it or make it the current model.

- 
- `ProMdlMultipleRetrieve()` retrieves multiple models into memory. Use the *ui\_flag* parameter to set model display to on or off.
  - `ProSolidRetrievalErrorsGet()` returns the data structure containing errors that occur during model retrieval. While retrieving a complex assembly, Creo Parametric sometimes encounters errors in retrieving particular components and assembling them appropriately in the assembly. In the user interface, you are informed of errors as they occur, through a dialog box. In Creo TOOLKIT, the retrieval functions automatically suppress or freeze problem components and return `PRO_TK_NO_ERROR`. To know whether errors have occurred during retrieval, use the function `ProSolidRetrievalErrorsGet()`. The errors are returned as the elements of the `ProSolidretrievalerrs` array. The retrieval error information must be obtained immediately after a call to the `ProMdlNameRetrieve()` or equivalent retrieval function.
  - `ProMdlSave()` saves the specified model to disk. For drawings, sketches and other 2D model types, to save the graphics data, you must display it. Call the function `ProMdlDisplay()` before `ProMdlSave()`, so that the graphics data is saved along with the geometry for the model.
  - `ProMdlIsSaveAllowed()` checks whether a given model can be saved.
  - `ProMdlEraseNotDisplayed()` erases all the models that are not referenced in a window from the current session.
  - `ProMdlErase()` erases the specified model from memory.
  - `ProMdlEraseAll()` erases a model and all the models that it uses, except those that have cyclic dependencies (that is, models used by other models in the session). For example, `ProMdlEraseAll()` recursively erases all subassemblies of an assembly and all solids referenced from a drawing. This function also works in cases where some models to be erased have mutual dependencies, but only if the erased models are not used by other models.

However, while erasing an active model, `ProMdlErase()` and `ProMdlEraseAll()` only clear the graphic display immediately, they do not clear the data in the memory until the control returns to Creo Parametric from the Creo TOOLKIT application. Therefore, after calling them the control must be returned to Creo Parametric before calling any other function, otherwise the behavior of Creo Parametric may be unpredictable.

The function `ProMdlLocationIsStandard()` checks if the specified model was opened from a standard location. A standard file location can be the local disk or a mapped drive on a remote computer. The Universal Naming Convention (UNC) path for network drives is also considered as a standard path if the value

---

for **DisableUNCCheck** is set to True for the key HKEY\_CURRENT\_USER\Software\Microsoft\Command Processor, in the registry file. The function returns:

- PRO\_B\_TRUE when the file is loaded from a standard file location.
- PRO\_B\_FALSE when the file is loaded from a nonstandard file location, such as, http, ftp, Design Exploration mode, and so on.

## Model Items

A “model item” is a generic object used to represent any item contained in any type of model, for the purpose of functions whose actions are applicable to all these types of item. (Some items, such as “version stamp,” retain their own object types.)

The object type ProModelitem is a DHandle (data handle), a structure that contains the item type, the persistent integer identifier of the item, and the handle to the owning object.

The object ProGeomitem, a generic geometrical object described later in this guide, is an instance of ProModelitem, and is a DHandle that shares the same type declaration. Therefore, the functions in this section are also directly applicable to ProGeomitem objects.

The typedef for the ProModelitem data handle is as follows:

```
typedef struct pro_model_item
{
 ProType type;
 int id;
 ProMdl owner;
} ProModelitem
```

Functions Introduced:

- **ProModelitemByNameInit()**
- **ProModelitemInit()**
- **ProModelitemMdlGet()**
- **ProModelitemDefaultnameGet()**
- **ProModelitemNameGet()**
- **ProModelitemNameSet()**
- **ProModelitemNameCanChange()**
- **ProModelitemUsernameDelete()**
- **ProModelitemHide()**
- **ProModelitemUnhide()**
- **ProModelitemIsHidden()**

---

The function `ProModelitemByNameInit()` returns a pointer to an item (structure), given the name and the type of the item. The valid item types are:

- Edge
- Surface
- Feature
- Co-ordinate System
- Axis
- Point
- Quilt
- Curve
- Layer
- Note
- Combined State

The function `ProModelitemInit()` is used to generate a `ProModelitem` object from the information contained in the structure. You can create such a structure directly, but using this function you can also confirm the existence of the item in the model database.

The function `ProModelitemMdlGet()` extracts the `ProMdl` handle from the structure.

The function `ProModelitemDefaultnameGet()` gets the default name for a new model item of a particular type if it was created taking the model handle as input.

The two functions `ProModelitemNameGet()` and `ProModelitemNameSet()` read and set the name of the Creo Parametric database object referred to by the model item. These functions are therefore applicable to all the instances of `ProModelitem`, such as `ProGeomitem` and all its instances, including `ProSurface`, `ProEdge`, `ProCsys`, `ProAxis`, and `ProCombinedState`.

---

## Note

In addition to notes of the type `PRO_NOTE`, the functions `ProModelitemNameGet()` and `ProModelitemNameSet()` can be used to read and set the name of the following annotation types:

- Driving or driven dimension of the type `PRO_DIMENSION`
- Reference dimension of the type `PRO_REF_DIMENSION`
- Symbol instance of the type `PRO_SYMBOL_INSTANCE`
- Surface finish of the type `PRO_SURF_FIN`
- Geometric tolerance of the type `PRO_GTOL`
- Set datum tag of the type `PRO_SET_DATUM_TAG` (applicable only for `ProModelitemNameGet()`)

---

The function `ProModelitemNameCanChange()` identifies whether the name of the model item can be modified by the user or by Creo TOOLKIT.

The function `ProModelitemUsernameDelete()` deletes the user-defined name of the model item from the Creo Parametric database.

The functions `ProModelitemHide()` and `ProModelitemUnhide()` are equivalent to the **View ► Hide** and **View ► Unhide** commands in the Creo Parametric menu, respectively. `ProModelitemHide()` hides the specified model item, whereas `ProModelitemUnhide()` unhides the model item.

The function `ProModelitemIsHidden()` identifies if the specified model item is hidden.

## Example 2: Renaming a Selected Surface

The sample code in `UgGeomSurfRename.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_geometry` shows how to use the functions `ProModelitemNameGet()` and `ProModelitemNameSet()`. See the [Core: 3D Geometry on page 177](#) section for an explanation of `ProSurface` and its functions.

## Version Stamps

The version stamp object provides a way of keeping track of changes in a Creo Parametric model to which your Creo TOOLKIT application may need to respond. Creo Parametric models and features contain an internal version stamp incremented each time some design change is made to that model or feature. The functions in this section enable you to read version stamps in order to look for design changes.

---

The version stamp object is called `ProWVerstamp` because it is a `WHandle`, or workspace handle. It is a workspace handle because the data structure it references is not the one in the Creo Parametric database, but a copy taken from it, which is private to the Creo TOOLKIT application.

Functions Introduced:

- **`ProMdlVerstampGet()`**
- **`ProFeatureVerstampGet()`**
- **`ProVerstampAlloc()`**
- **`ProVerstampFree()`**
- **`ProVerstampStringGet()`**
- **`ProVerstampStringFree()`**
- **`ProStringVerstampGet()`**
- **`ProVerstampEqual()`**

The functions `ProMdlVerstampGet()` and `ProFeatureVerstampGet()` enable you to make a workspace copy of the version stamp on a particular model or feature. The function `ProMdlVerstampGet()` is currently applicable to solids only (parts or assemblies). Both of these functions allocate the space for the workspace object internally. After using the contents of the version stamp object, you can free the workspace memory using `ProVerstampFree()`.

If you want to store a copy of a version stamp to compare to a newly read version later, you should use the nonvolatile representation, which is a C string. The function `ProVerstampStringGet()` allocates and fills a string that represents the contents of the specified `ProWVerstamp` object. The `ProStringVerstampGet()` function performs the reverse translation: it allocates a new `ProWVerstamp` object and fills it by copying the specified C string.

The function `ProVerstampEqual()` compares two `ProWVerstamp` objects to tell you whether the version stamps they represent are equal.

---

#### **Note**

The version stamp on a feature can change not only when the feature definition changes, but also when the feature geometry changes as a result of a change to a parent feature.

---

## Layers

Creo TOOLKIT implements two data types that enable access to layer information in Creo Parametric:

- 
- **ProLayer**—A DHandle that identifies a layer. The ProLayer object is an instance of ProModelItem.
  - **ProLayerItem**—A DHandle that identifies a layer item. The valid types of layer item are contained in the enumerated type ProLayerType.

Functions Introduced:

- **ProMdlLayerGet()**
- **ProMdlLayerVisit()**
- **ProMdlLayersVisit()**
- **ProMdlLayersCollect()**
- **ProLayerCreate()**
- **ProLayerDelete()**
- **ProLayerItemsGet()**
- **ProLayerItemsPopulate()**
- **ProLayerItemarrayFree()**
- **ProLayerItemInit()**
- **ProDwgLayerItemInit()**
- **ProLayerSavedstatusGet()**
- **ProLayerItemAdd()**
- **ProLayerItemAddNoUpdate()**
- **ProLayerItemRemove()**
- **ProLayerItemRemoveNoUpdate()**
- **ProLayeritemLayersGet()**
- **ProLayerDisplaystatusGet()**
- **ProLayerDisplaystatusSet()**
- **ProLayerDisplaystatusNoUpdateSet()**
- **ProLayerDisplaystatusUpdate()**
- **ProDwgLayerDisplaystatusGet()**
- **ProDwgLayerDisplaystatusSet()**
- **ProDwgLayerSavedstatusGet**
- **ProLayerDisplaystatusSave()**
- **ProLayerDefLayerSet()**
- **ProLayerDefLayerGet()**
- **ProLayerViewDependencySet()**

- 
- **ProLayerViewDependencyGet()**
  - **ProLayerRuleExecute()**
  - **ProLayerRuleCopy()**
  - **ProLayerRuleMatch()**
  - **ProLayerItemLayerStatusGet()**

To get the `ProLayer` object for a layer with the specified name and owner, call the function `ProMdlLayerGet()`. You must pass the name of the layer as a wide string.

To visit the layers in a model, use the function `ProMdlLayerVisit()`. As with other Creo TOOLKIT visit functions, you supply the visit action and visit filter functions.

The function `ProMdlLayerVisit()` will be deprecated in future release of Creo Parametric. The function `ProMdlLayersVisit()` calls the specified filter and action functions for each layer in the model. The input arguments are:

- *model*—Specifies the model using the `ProMdl` object.
- *visit\_action*—Specifies the action to perform on each layer. If it returns anything other than `PRO_TK_NO_ERROR`, the traversal stops, using the `ProLayerAction` object.
- *filter\_action*—Specifies the filter function. If `NULL`, the action function is applied to all layers using the `ProLayerFilter` object.
- *app\_data*—The application data is passed to the visiting and filter functions using the `ProAppData` object.

The function `ProMdlLayersCollect()` collects a `ProArray` of layers in the model.

The function `ProLayerCreate()` creates a new layer with a specified name. It requires as input the `ProMdl` handle for the model that will own the layer. The function `ProLayerDelete()` deletes the layer identified by the specified `ProLayer` object.

The function `ProLayerItemsGet()` allocates and fills an array of `ProLayerItem` objects that contains the items assigned to the specified layer.

---

#### **Note**

The function `ProLayerItemsGet()` is deprecated. For a large number of layer items, the function `ProLayerItemsGet()` may return an error `PRO_TK_OUT_OF_MEMORY` to indicate that the function was unable to allocate a `ProArray` to hold all of the layer items. To address this issue, use the new function `ProLayerItemsPopulate()`.

---

---

The function `ProLayerItemsPopulate()` allocates and fills an array of `ProLayerItem` objects that contain the type and identifier of the items assigned to the specified layer. This function can retrieve a large number of items specified on the layer. Use the function `ProLayeritemarrayFree()` to free the allocated memory.

To initialize a `ProLayerItem`, call the function `ProLayerItemInit()`. This function should be used in all cases, except when all of the following are true:

- The layer owner is a drawing.
- The layer item owner is an assembly.
- The layer item is a component.
- You want to control the display status of this component only in a subassembly with a given path.

When all of the above conditions are true, use the function `ProDwgLayerItemInit()` to initialize the `ProLayerItem`.

The function `ProLayerSavedstatusGet()` retrieves the saved status for the specified layer. The output argument `saved_status` is defined by the enumerated data type `ProLayerDisplay`.

To add items to a layer, call the function `ProLayerItemAdd()`, and pass as input a `ProLayer` object and the `ProLayeritem` object for the new layer item. To remove an item from a layer, use the function `ProLayerItemRemove()` and specify the `ProLayeritem` object for the item to remove.

The function `ProLayerItemAddNoUpdate()` adds the specified item to a layer without updating the model tree.

The function `ProLayerItemRemoveNoUpdate()` removes the specified item from the layer without updating the model tree.

To find all the layers containing a given layer item, use the function `ProLayeritemLayersGet()`. This function supports layers in solid models and in drawings.

As in an interactive session of Creo Parametric, one of the principal reasons to create a layer is to display or blank its member items selectively. The function `ProLayerDisplaystatusGet()` obtains the display status of the specified layer, in the form of the `ProLayerDisplay` enumerated type. The display status can be of following types:

- `PRO_LAYER_TYPE_NONE`—The selected layer is displayed. This is the default display status.
- `PRO_LAYER_TYPE_NORMAL`—The layer selected by the user is displayed.
- `PRO_LAYER_TYPE_DISPLAY`—The selected layer is isolated.

- 
- `PRO_LAYER_TYPE_BLANK`—The selected layer is blanked.
  - `PRO_LAYER_TYPE_HIDDEN`—The components in the hidden layers are blanked. This status is applicable only in the assembly mode.

To modify the display status of a layer, call the function `ProLayerDisplaystatusSet()`.

---

 **Note**

`ProLayerDisplaystatusSet()` does not repaint the model after it modifies the display status. This is a temporary setting. It will be lost after you save or retrieve the model. To permanently change the display status, call the function `ProLayerDisplaystatusSave()`. However, the function `ProLayerDisplaystatusSet()` updates the model tree for the change in display status of the layer.

---

The function `ProLayerDisplaystatusNoUpdateSet()` sets the display status of a layer, without updating the model tree. It returns a boolean value `PRO_B_TRUE` for the output argument *is\_update\_tree\_needed*, if the model tree requires an update for change in the display status of a layer. Use the function `ProLayerDisplaystatusUpdate()` to update the model tree for all the changes in the display statuses of all the layers in the specified model.

Unique functions are required to retrieve and set the status of layers in drawings. `ProDwgLayerDisplaystatusGet()` takes as input the layer handle and drawing view. The function `ProDwgLayerDisplaystatusSet()` takes an additional argument as input—the desired display status.

Use the function `ProDwgLayerSavedstatusGet()` to retrieve the saved status for the specified layer and view.

- *layer* —The layer for which you want to retrieve the status .
- *view* —The view of drawing for which you want to retrieve the status.

The function `ProLayerDisplaystatusSave()` saves the changes to the display status of all the layers in the specified owner. In addition, the display statuses are saved in the owner's submodels and drawing views.

To set up a default layer with a specified name, call the function `ProLayerDefLayerSet()`. This function requires the default layer type, which is defined in the enumerated type `ProDefLayerType`. To get the name of the default layer with the specified type, call the function `ProLayerDefLayerGet()`.

The function `ProLayerViewDependencySet()` sets the display of layers of the specified view to depend on the display of layers in the drawing. The syntax of this function is as follows:

---

```
ProLayerViewDependencySet (
```

```
 ProView view,
 ProBoolean depend);
```

If *depend* is set to `PRO_B_TRUE`, the layers in the view will be displayed when the layers in the drawing are displayed. If *depend* is set to `PRO_B_FALSE`, the layer display in the view will be independent of the display in the drawing. To determine whether the layer display in the view is dependent on the display in the drawing, call the function `ProLayerViewDependencyGet()`.

You can define rules in layers. Use the function `ProLayerRuleExecute()` to execute the layer rules on the specified model. The rules must be enabled in the layers to be executed.

The function `ProLayerRuleCopy()` copies the rules from the reference model to the current model for the specified layer. The input arguments are:

- **CurrentModel**—Specifies the current model to which the layer rules must be copied.
- **LayerName**—Specifies the name of an existing layer in both the models. To copy the layer rules, the name of the layer *LayerName* in both the models must be the same.
- **ReferenceModel**—Specifies the reference model from which the layer rules must be copied.

Use the function `ProLayerRuleMatch()` to compare the rules between the current and reference model for the specified layer. The name of the layer *LayerName* in both the models must be the same, for comparing the layer rules.

The function `ProLayerItemLayerStatusGet()` returns the status of an item for the specified layer. The input arguments are:

- *pro\_drawing*—Specifies the drawing which is the owner of the layer that contains the specified item.
- *pro\_layer\_item*—Specifies the layer item. If the owner type of the layer item is `PRO_LAYITEM_FROM_PATH`, it is mandatory to specify the *pro\_drawing* input argument.
- *pro\_layer*—Specifies the layer that contains the item.

The output argument returns the status of the item using the enumerated data type `ProLayerItemStatus`. The valid values are:

- `PRO_LAY_ITEM_STATUS_INCLUDE`—Specifies that the status of the layer item is **Include**. The item is included in the specified layer.
- `PRO_LAY_ITEM_STATUS_EXCLUDE`—Specifies that the status of the layer item is **Exclude**. The item is excluded in the specified layer.
- `PRO_LAY_ITEM_STATUS_ADDED_BY_RULE`—Specifies that the status of the layer item is defined by rules.

---

The enumerated data type `ProLayerItemStatus` must have one of the following values:

- `PRO_LAY_ITEM_STATUS_INCLUDE`
- `PRO_LAY_ITEM_STATUS_EXCLUDE`
- `PRO_LAY_ITEM_STATUS_INCLUDE` and `PRO_LAY_ITEM_STATUS_ADDED_BY_RULE`
- `PRO_LAY_ITEM_STATUS_EXCLUDE` and `PRO_LAY_ITEM_STATUS_ADDED_BY_RULE`

### Example 3: Creating a Layer

The sample code in `UgModelLayerCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_model` shows how to create a layer and add items to it.

This example streamlines the layer creation process (compared to interactive Creo Parametric) because the application creates the layer and adds items to it in only one step. Note that this example does not allow users to add a subassembly to the new layer.

## Notebook

The functions described in this section work with notebook (`.lay`) files.

Functions Introduced:

- **`ProLayoutDeclare()`**
- **`ProLayoutUndeclare()`**
- **`ProLayoutRegenerate()`**

The function `ProLayoutDeclare()` declares a notebook name to the specified Creo Parametric model or notebook. You can resolve conflicts using the enumerated type `ProDeclareOptions`. It has the following values:

- `PRO_DECLARE_INTERACTIVE`—Resolves the conflict in interactive mode.
- `PRO_DECLARE_OBJECT_SYMBOLS`—Keep the symbols in the specified Creo Parametric model or notebook object.
- `PRO_DECLARE_LAYOUT_SYMBOLS`—Keep the symbols specified in the notebook.
- `PRO_DECLARE_ABORT`—Abort the notebook declaration process and return an error.

---

Use the function `ProLayoutUndeclare()` to undeclare the notebook name to the specified Creo Parametric model or notebook. You can resolve conflicts using the enumerated type `ProUndeclareOptions`. It has the following values:

- `PRO_UNDECLARE_FORCE`—Continues to undeclare the notebook even if references exist.
- `PRO_UNDECLARE_CANCEL`—Does not undeclare the notebook if references exist.

The method `ProLayoutRegenerate()` regenerates the specified notebook.

## Visiting Displayed Entities

Functions Introduced:

- **`ProSolidDispCompVisit()`**
- **`ProAsmcomppathDispPointVisit()`**
- **`ProAsmcomppathDispCurveVisit()`**
- **`ProAsmcomppathDispCsysVisit()`**
- **`ProAsmcomppathDispQuiltVisit()`**

The functions in this section enable you to find quickly all the entities (points, datum curves, coordinate systems, and quilts) currently displayed in an assembly. It is possible to do this using the regular Creo TOOLKIT functions for visiting assembly components and entities, together with the `ProLayer` functions explained earlier in this section; but the functions described here are much more efficient because they make use of Creo Parametric's internal knowledge of the display structures.

The function `ProSolidDispCompVisit()` traverses the components at all levels in an assembly which are not blanked by a layer. The visit action function is called on both the downward traversal and the upward one, and is given a boolean input to distinguish them. It is also given the assembly path and the solid handle to the current subassembly. The subassembly could be found from the path using `ProAsmcomppathMdlGet()`, of course, but Creo Parametric passes this to the action function to allow greater efficiency.

The functions `ProAsmcomppathDisp*Visit()` visit the entities in a subassembly that are not blanked by a layer at any level in the root assembly.

## Core: Solids, Parts, and Materials

### Solid Objects

This section describes how to access solids, parts, and their contents.

---

The Creo Parametric term “solid” denotes a part or an assembly. The object is called `ProSolid` and is declared as an opaque handle. It is an instance of `ProMdl` and can be cast to that type to use functions that have the prefix “`ProMdl`”.

## Creating a Solid

Function Introduced:

- **`ProSolidMdlnameCreate()`**

The function `ProSolidMdlnameCreate()` creates an empty part or assembly with the specified name, and provides a handle to the new object. It does not make the new solid current, nor does it display the solid. In Creo Parametric 7.0.0.0 and later, an empty part is created with absolute accuracy, by default. Refer to the Creo Parametric help for more information on Model Accuracy.

## Contents of a Solid

Functions Introduced:

- **`ProSolidFeatVisit()`**
- **`ProSolidQuiltVisit()`**
- **`ProSolidAxisVisit()`**
- **`ProSolidCsysVisit()`**
- **`ProSolidFeatstatusGet()`**
- **`ProSolidFeatstatusSet()`**
- **`ProSolidFeatstatusWithoptionsSet()`**
- **`ProSolidFeatstatusflagsGet()`**
- **`ProSolidFailedFeatsList()`**
- **`ProSolidFailedfeaturesList()`**
- **`ProSldsurfaceShellsAndVoidsFind()`**
- **`ProSolidToleranceStandardGet()`**
- **`ProSolidToleranceStandardSet()`**
- **`ProSolidToleranceStandardVersionSet()`**
- **`ProSolidToleranceStandardVersionGet()`**
- **`ProSolidToleranceStandardUpdate()`**

The following visit functions enable you to access the various types of objects inside a part or assembly:

- `ProSolidFeatVisit()` —Visits all the features, including those used internally (which are not visible to the Creo Parametric user). You can also use this function to visit the components of an assembly.
- `ProSolidSurfaceVisit()` — Visits the surfaces of the model only if the model has a single body else returns the error `PRO_TK_MULTIBODY_UNSUPPORTED`. This includes all surfaces created by solid features, but not datum surfaces.
- `ProSolidQuiltVisit()` —Visits all the quilts in a part or an assembly.
- `ProSolidAxisVisit()` —Visits all the axes in a part or an assembly.
- `ProSolidCsysVisit()` —Visits all the coordinate system datums in a part or an assembly.

The function `ProSolidFeatstatusGet()` retrieves a list of the integer identifiers and statuses of all the features in a specified solid in the order in which they are regenerated. The integer identifier of a feature is the value of the `id` field in the `ProFeature` object and also the INTERNAL ID seen in Creo Parametric.

The function `ProSolidFeatstatusSet()` enables you to set the regeneration order and statuses of the features in the solid.

The function `ProSolidFeatstatusWithoptionsSet()` assigns the regeneration order and status bit flags for the specified features in a solid based on the bitmask containing one or more regeneration control bit flags of the type `PRO_REGEN_*` defined in `ProSolid.h`. Refer to the [Regenerating a Solid on page 99](#) section for more information on the bit flags.

The function `ProSolidFeatstatusflagsGet()` retrieves the array of integer identifiers of the features in a specified solid and the corresponding array of bitmasks representing one or more feature status bit flags of the type `PRO_FEAT_STAT_*` defined in `ProFeature.h`. Refer to the [Core: Features on page 137](#) section for more information on the feature status bit flags.

The function `ProSolidFailedFeatsList()` retrieves the list of identifiers of failed features in a specified solid.

### Note

From Pro/ENGINEER Wildfire 5.0 onward, the function `ProSolidFailedFeatsList()` has been deprecated. Use the function `ProSolidFailedfeaturesList()` instead. Pass `NULL` for the input arguments `co_failed_ids` and `co_x_failed_ids` while using `ProSolidFailedfeaturesList()` in the Resolve mode.

---

---

The function `ProSolidFailedfeaturesList()` retrieves the list of identifiers of all or any of the failed features, children of failed features, children of external failed features, or both the features and their children.

The function `ProSldsurfaceShellsAndVoidsFind()` returns an ordered list of surface-contour pairs for each shell and void in a solid.

The surface-contour pairs describe the shell faces and are specified by the `ProSldsurfaceShellface` objects. If the `contour` field in the `ProSldsurfaceShellface` object is `NULL`, it means all the contours in the geometry belong to the same surface and the `shell_faces` array contains only one surface ID. However, if the contours belong to different shells, the `shell_faces` array contains items equal to the number of contours.

The ordered list of surface-contour pairs is specified by the `ProSldsurfaceShellorder` objects; each of this object contains the following fields:

- `orientation`—Specifies the shell orientation. If this field is 1, the shell is oriented outward, if it is -1, the shell is inward oriented meaning it is a void.
- `first_face`—Specifies the index in the array of `ProSldsurfaceShellface` objects.
- `number_of_faces`—Specifies the total number of shell faces.
- `ambient_shell`—Specifies the index in the array of `ProSldsurfaceShellorder` objects.

The function `ProSolidToleranceStandardGet()` returns the tolerance standard assigned to a solid. Use the method `ProSolidToleranceStandardSet()` to set the tolerance standard for a solid. After you set the tolerance standard for a solid, you must regenerate the solid, if required. The function does not regenerate the solid.

The function `ProSolidToleranceStandardVersionSet()` sets the version for assigned tolerance standard of a specified solid.

---

 **Note**

In the Creo Parametric user interface, this operation asks to regenerate the solid. The function `ProSolidToleranceStandardVersionSet()` does not perform regeneration itself.

---

Use the function `ProSolidToleranceStandardVersionGet()` to get the version for assigned tolerance standard of a specified solid.

Use the function `ProSolidToleranceStandardUpdate()` to update the solid to the most current version of its tolerance standard. The function does not regenerate the solid.

---

## Displaying a Solid

Function Introduced:

- **ProSolidDisplay()**

The function `ProSolidDisplay()` displays a solid in the current Creo Parametric window. This does not make the object current from the point of Creo Parametric.

### Example 1: Loading and Displaying a Solid

The example in the file `UgSolidLoadDisp.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_solid`, shows how to use the functions `ProObjectwindowMdlnameCreate()` and `ProSolidDisplay()`.

## Regenerating a Solid

Function Introduced:

- **ProSolidRegenerate()**
- **ProSolidRegenerationIsNoresolvemode()**
- **ProSolidRegenerationstatusGet()**

The function `ProSolidRegenerate()` regenerates the specified solid. One of the inputs to the function is a bitmask that specifies how the regeneration must be performed. The bitmask may contain the following flags:

- `PRO_REGEN_NO_FLAGS`—Equivalent to passing no flags.
- `PRO_REGEN_CAN_FIX`—Allows the user to interactively fix the model using the user interface, if regeneration fails. This bit flag needs to be set only in case of interactive applications. If this option is not included, the user interface does not update even if regeneration is successful. Use `ProWindowRepaint()` and `ProTreetoolRefresh()` to perform the update if needed. Also, this bit flag must be set only in the Resolve mode. Otherwise, `ProSolidRegenerate()` returns `PRO_TK_BAD_CONTEXT`.
- `PRO_REGEN_ALLOW_CONFIRM`—This flag has been deprecated from Creo Parametric 4.0 M030. Allows the user to interactively select the option of retaining failed features and children of failed features via a pop-up dialog box, if regeneration fails. This bit flag must be set only in the No-Resolve mode. Otherwise, `ProSolidRegenerate()` returns `PRO_TK_BAD_CONTEXT`.

---

### Note

The interactive dialog box which provided an option to retain failed features and children of failed features, if regeneration fails is no longer supported. Creo Parametric displays a warning message which gives details of failed features.

---

- `PRO_REGEN_UNDO_IF_FAIL`—Allows the user to undo the failed regeneration and restore the previous status. This flag needs to be set only in the No-Resolve mode. Otherwise, `ProSolidRegenerate()` returns `PRO_TK_BAD_CONTEXT`. The result obtained may be different from the one attained by using the **Restore** option in the Resolve mode. **Restore** in the Resolve mode can be used immediately after the first failure. But undo in the No-Resolve mode due to this bit flag happens only after all the features are regenerated or failed. In some cases, the undo may not happen at all.

---

### Note

The bit flags `PRO_REGEN_ALLOW_CONFIRM` and `PRO_REGEN_UNDO_IF_FAIL` are not compatible with each other. Setting both of them together will result in `PRO_TK_BAD_CONTEXT`.

---

- `PRO_REGEN_SKIP_DISALLOW_SYS_RECOVER`—Skips the preparation for failure recovery. If this option is used, Undo Changes is possible if a failure occurs. This option is used only in conjunction with `PRO_REGEN_CAN_FIX`.
- `PRO_REGEN_UPDATE_INSTS`—Updates instances of the solid in memory. This may slow down the regeneration process.
- `PRO_REGEN_RGN_BCK_USING_DISK`—Stores the backup model on the disk. This is useful only if `PRO_REGEN_CAN_FIX` is set.
- `PRO_REGEN_FORCE_REGEN`—Forces the solid to fully regenerate. This will regenerate every feature in the solid. If not set, Creo Parametric uses its internal algorithm to determine which features to regenerate.
- `PRO_REGEN_TOP_ASM_ONLY`—Forces only top level assembly to regenerate. This flag forces the regeneration of all the features and components that are defined in the specified top level assembly, even when they are considered up-to-date. The features and components from the low level assembly that are essential for the correct assembly regeneration results,

---

might also be regenerated during the regeneration process. However, they are not excluded from the regeneration process.

---

 **Note**

This flag cannot be used with `PRO_REGEN_FORCE_REGEN`.

---

- `PRO_REGEN_UPDATE_ASSEMBLY_ONLY`—Updates assembly and sub-assembly placements and regenerates assembly features and intersected parts. If the affected assembly is retrieved as a simplified representation, this flag will update the locations of the components. If the flag is not set, the component locations are not updated by default when the simplified representation is retrieved.

---

 **Note**

This flag cannot be used with `PRO_REGEN_FORCE_REGEN`.

---

- `PRO_REGEN_RESUME_EXCL_COMPS`—Enables Creo Parametric to resume available excluded components of the simplified representation during regeneration. This can result in a more accurate update of the simplified representation.

---

 **Note**

Component models which are not in session at the time of the call to `ProSolidRegenerate()` will not be retrieved due to this option.

---

- `PRO_REGEN_NO_RESOLVE_MODE` — Specifies the No-Resolve mode introduced in Pro/ENGINEER Wildfire 5.0. This is the default mode in Creo Parametric. In this mode, if a model and feature regeneration fails, failed features and children of failed features are created and regeneration of other features continues.
- `PRO_REGEN_RESOLVE_MODE` — Specifies the Resolve mode. In this mode, you can continue with the Pro/ENGINEER Wildfire 4.0 behavior, wherein if a model and feature regeneration fails, the failure needs to be resolved before regeneration can be resumed. You can also switch to the Resolve mode by setting the configuration option `regen_failure_handling` to `resolve_mode` in the Creo Parametric session.

---

In Creo Parametric 7.0.1.0 and later, the configuration option `regen_failure_handling` has been deprecated. If a model and feature regeneration fails and if you want to use Resolve mode, you need to contact PTC Customer Support. For more information, refer to the section *Contacting PTC Technical Support* in the *Getting Started with Creo TOOLKIT* guide.

---

 **Note**

Setting the configuration option to switch to Resolve mode ensures the old behavior as long as you do not retrieve the models saved under the No-Resolve mode. To consistently preserve the old behavior, use Resolve mode from the beginning and throughout your Creo Parametric session. Temporarily setting the bit flag `PRO_REGEN_RESOLVE_MODE` in the relevant functions does not ensure the old behavior.

---

- `PRO_REGEN_INTERACTIVE_UI`—Supports an interactive user interface in Creo Parametric. For example, if an error occurs while reading or executing an imported `PRO_PROGRAM_FILE` file, a dialog box opens in Creo Parametric asking you if you want to continue with the operation.

The function `ProSolidRegenerationIsNoresolveMode()` identifies if the regeneration mode in the active Creo Parametric session is the No-Resolve mode. Set the `ProBoolean` argument *is\_no\_resolve* to `PRO_B_TRUE` to set the No-Resolve mode.

The function `ProSolidRegenerationStatusGet()` returns the regeneration status of the solid model. This status is similar to the regeneration status indicator (Green/Yellow/Red) in the Creo Parametric User Interface.

The regeneration status can take one of the following values:

- `PRO_SOLID_REGENERATED`—Specifies that the model is up-to-date and requires no regeneration.
- `PRO_SOLID_NEEDS_REGENERATION`—Specifies that the model has changed and requires regeneration.
- `PRO_SOLID_FAILED_REGENERATION`—Specifies that the regeneration has failed or has warnings.

---

### **Note**

Models with certain contents, such as circular references or assembly analysis features, will never return a fully “regenerated” status. Thus, this status should not provide an absolute restriction. If the flag remains in the “PRO\_SOLID\_NEEDS\_REGENERATION” status through two successful regenerations, the model could be considered up-to-date.

---

- **PRO\_SOLID\_CONNECT\_FAILED**—Specifies that the model has successfully regenerated, however, the connect operation for mechanisms in the solid model has failed. This status is applicable only for assemblies which have moving components.

### **Example 2: Combining Regeneration Flags**

The sample code in `UgSolidRegen.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_solid` shows how to use the function `ProSolidRegenerate()`.

### **Combined States of a Solid**

With a combined state, you can combine and apply multiple display states to a Creo Parametric model. Combined states are composed of the following two or more display states:

- Saved Views
- Layer state
- Annotations
- Cross section
- Exploded view
- Simplified representation
- Model style

The object `ProCombstate` for a combined state has the same declaration as the `ProModelitem` object, only with the type set to `PRO_COMBINED_STATE`.

The declaration is as follows:

```
typedef struct pro_model_item
{
 ProType type;
 int id;
 ProMdl owner;
}ProCombstate;
```

**Functions Introduced:**

- **ProMdlCombstatesGet()**
- **ProCombstateActiveGet()**
- **ProCombstateDataGet()**
- **ProCombstateActivate()**
- **ProMdlCombStateCreate()**
- **ProCombstateRedefine()**
- **ProCombstateAnnotationsGet()**
- **ProCombstateAnnotationsAdd()**
- **ProCombstateAnnotationsRemove()**
- **ProCombstateDelete()**
- **ProCombstateAnnotationsStateGet()**
- **ProCombstateSupplGeomStateGet()**
- **ProCombstateAnnotationsAndSupplGeomStateSet()**
- **ProCombstateIsPublished()**
- **ProCombstateIsDefault()**

The function `ProMdlCombstatesGet()` returns an array of combined states of a specified solid.

The function `ProCombstateActiveGet()` retrieves the active combined state in a specified solid model. The active combined state is the default state when the model is opened.

The function `ProCombstateDataGet()` returns information for a specified combined state. The output arguments of this function are:

- *cs\_name*—The name of the combined state.
- *cs\_ref\_arr*—An array of reference states of the type `ProModelitem`. This array can contain states of the following types:
  - `PRO_VIEW`
  - `PRO_LAYER_STATE`
  - `PRO_SIMP_REP`
  - `PRO_EXPLD_STATE`
  - `PRO_XSEC`
  - `PRO_STYLE_STATE`
- *p\_clip\_opt*—A pointer to the value of the cross section clip. This is applicable only in case of a valid reference of the type `PRO_XSEC`. The `PRO_XSEC` item represents a `ProXsec` object or a zone feature.

---

The values for the cross section clip are specified by the enumerated type `ProCrossecClipOpt`. The possible values are as follows:

- `PRO_VIS_OPT_NONE`—Specifies that the cross section or zone feature is not clipped.
- `PRO_VIS_OPT_FRONT`—Specifies that the cross section or zone feature is clipped by removing the material on the front side. The front side is where the positive normals of the planes of the cross section or zone feature are directed.
- `PRO_VIS_OPT_BACK`—Specifies that the cross section or zone feature is clipped by removing the material on the back side.
- *p\_is\_expld*—A `ProBoolean` value that specifies whether the combined state is exploded. This value is available only if when a valid `PRO_EXPLD_STATE` reference state is retrieved. It is not available for Creo Parametric parts since an exploded state does not exist in the part mode.

Use the function `ProCombstateActivate()` to activate a specified combined state.

The function `ProMdlCombStateCreate()` creates a new combined state based on specified references. The input arguments of this function are as follows:

- *p\_solid*—Specify the solid model in which you want to create a new combined state.
- *new\_name*—Specify the name of the new combined state.
- *ref\_arr*—Specify the array of reference states. Refer to the description of the argument *cs\_ref\_arr* on page of the function `ProCombstateDataGet()` for the valid reference states.
- *clip\_opt*—Specify the value of the cross section clip. Refer to the description of the argument *p\_clip\_opt* on page of the function `ProCombstateDataGet()` for more information.
- *is\_expld*—Specify `PRO_B_TRUE` if the combined state is exploded, else specify `PRO_B_FALSE`. This argument needs to be set only in case of a valid `PRO_EXPLD_STATE` reference state. It is not applicable for Creo Parametric parts since an exploded state does not exist in the part mode.

Use the function `ProCombstateRedefine()` to redefine a created combined state. The values specified by the input arguments *ref\_arr*, *clip\_opt*, and *is\_expld* of the function `ProMdlCombStateCreate()` are redefined.

In case you do not want to redefine a reference state, pass the reference state with the same value. While redefining, you must specify reference states. If you do not pass reference states, the combined state is redefined to a `NO_STATE` state. `NO_STATE` state means the display of the reference state is not changed on activation of combined state.

---

In case you want to refine or create a combined state that uses the most recently used instance of a reference state, use the `PRO_COMBSTATE_REF_MRU` option as the `id` field of that type of reference state in the `ProModelItem` object.

The function `ProCombstateAnnotationsGet()` retrieves an array of annotations and their status flags from a specified combined state item. If the display of supplementary geometry is controlled by the object `ProCombState`, the function returns non-annotations model items as well.

The function `ProCombstateAnnotationsAdd()` adds an array of annotations to a specified combined state item. The input argument *status\_flags* specifies if an annotation must be displayed in the combined state. If you specify the value 0 for this argument, then the annotation is displayed in the combined state. If you specify the value 1, then the annotation is not displayed.

Use the function `ProCombstateAnnotationsRemove()` to remove the annotations from a specified combined state item.

Use the function `ProCombstateDelete()` to delete a specified combined state. The function fails if the specified combined state is the default or active combined state.

Annotations and annotation elements can be assigned to a combined state. When the combined state is active, the annotations are displayed in the graphics window. Similarly, annotations and annotation elements can be assigned to layers. Supplementary geometry such as datum planes, points, coordinate systems, axes, curves, and surfaces can also be assigned to combined state or layers. The display of annotations and supplementary geometry in a model is controlled either by the combined state or layers. The configuration option `combined_state_type` is used to define how the visibility of annotations and supplementary geometry is controlled in a new combined state.

Refer to Creo Parametric Help for more information.

The function `ProCombstateAnnotationsStateGet()` checks if the display of annotations is controlled by the specified combined state or layers. The function returns `PRO_B_TRUE` when the display is controlled by combined state. Use the function `ProCombstateSupplGeomStateGet()` to check if the display of supplementary geometry is controlled by the specified combined state or layers. The function returns `PRO_B_TRUE` when the display is controlled by combined state.

The function `ProCombstateAnnotationsAndSupplGeomStateSet()` allows you to change the display of annotations and supplementary geometry by the combined state or layers. The input arguments follow:

- *cs\_item*—Specifies a pointer to the combined state item from which the state needs to be retrieved.

- *annotation\_state*—Flag to set the specified combined state to annotation state. Pass the value of *annotation\_state* as `PRO_B_TRUE` if display of annotations should be controlled by combined state. Pass it as `PRO_B_FALSE` if display of annotations should be controlled by layers.
- *supplgeom\_state*—Flag to set the specified combined state to supplementary geometry state. Pass the value of *supplgeom\_state* as `PRO_B_TRUE` if display of supplementary geometry should be controlled by combined state. Pass it as `PRO_B_FALSE` if display of supplementary geometry should be controlled by layers.

---

### Note

If value of the input argument *supplgeom\_state* is set to `PRO_B_TRUE`, the value of *annotation\_state* also, must be set to `PRO_B_TRUE`.

---

The function returns `PRO_TK_NO_CHANGE` if the current states of annotations and supplementary geometry in the combined state are same as the requested states.

The function `ProCombstateIsPublished()` checks if the specified combined state has been published to Creo View.

Use the function `ProCombstateIsDefault()` checks if the specified combined state is set as the default combined state for the model.

## Layer State

A layer state stores the display state of existing layers and all the hidden layers of the top-level assembly. You can create and save one or more layer states and switch between them to change the assembly display.

The object `ProLayerstate` represents the layer state. It has the same declaration as the `ProModelitem` object, only with the type set to `PRO_LAYER_STATE`. The declaration is as follows:

```
typedef struct pro_model_item
{
 ProType type;
 int id;
 ProMdl owner;
}ProLayerstate;
```

Functions Introduced:

- **ProLayerstatesGet()**
- **ProLayerstateActiveGet()**
- **ProLayerstateNameGet()**

- 
- **ProLayerstateActivate()**
  - **ProLayerstateCreate()**
  - **ProLayerstateLayersGet()**
  - **ProLayerstateLayerAdd()**
  - **ProLayerstateLayerRemove()**
  - **ProLayerstateActivestateUpdate()**
  - **ProLayerstateModelitemHide()**
  - **ProLayerstateModelitemUnhide()**
  - **ProLayerstateModelitemIsHidden()**
  - **ProLayerstateDelete()**
  - **ProLayerstateDefaultPropagateSet()**

The function `ProLayerstatesGet()` returns an array of layer states for a specified solid.

The function `ProLayerstateActiveGet()` retrieves the active layer state in a specified solid model.

The function `ProLayerstateNameGet()` retrieves the name of a specified layer state.

Use the function `ProLayerstateActivate()` to activate a specified layer state.

The function `ProLayerstateCreate()` creates a new layer state based on specified references. The input arguments of this function are as follows:

- *p\_solid*—Specify the solid model in which you want to create a new layer state.
- *state\_name*—Specify the name of the new layer state. The name can only consist of alphanumeric, underscore, and hyphen characters.
- *layers*—Specify an array of reference layers.
- *disp\_arr*—Specify an array of display statuses. The number of display statuses is equal to the number of reference layers.
- *hidden\_items*—Specify an array of hidden items.

---

#### **Note**

`ProLayerItem` of type `PRO_LAYER_LAYER` is not supported in the function `ProLayerstateCreate()`, when you create a new layer state.

---

---

The function `ProLayerstateLayersGet()` retrieves the reference data for a specified layer state.

The function `ProLayerstateLayerAdd()` adds a new layer to an existing layer state. Specify the new layer, its display state, and the name of the existing layer state as input arguments to this function.

The function `ProLayerstateLayerRemove()` removes a specific layer from a specified layer state.

The function `ProLayerstateActivestateUpdate()` updates the layer state, which is active in the specified model. If the display statuses of layers have changed, then calling this function ensures that the active layer state in the model is updated with the new display statuses of the layers.

Use the function `ProLayerstateModelitemHide()` to hide the display of a specific item on the specified layer state.

Use the function `ProLayerstateModelitemUnhide()` to remove a specific item from the list of hidden items on a layer state.

Use the function `ProLayerstateModelitemIsHidden()` to identify if an item is hidden on a layer state.

Use the function `ProLayerstateDelete()` to delete a specified layer state.

Use the function `ProLayerstateDefaultPropagateSet()` to control whether layer statuses propagate from the top model to sub-models by default.

The input arguments are:

- *p\_state*—Specifies the layer state using the `ProLayerstate` object.
- *set*—Sets the value of the layer status propagation as `PRO_B_TRUE` or `PRO_B_FALSE`.

### Note

Statuses are only propagated from top model layers to sub models layers having the same name.

---

## Evaluating Mathematical Expressions for a Solid

Functions Introduced:

- **ProMathExpressionEvaluate()**

The function `ProMathExpressionEvaluate()` evaluates the given mathematical expression in the context of a given solid. The expression may include parameters, dimensions, embedded functions, or predefined constants. This function returns a pointer to the calculated result and a pointer to the unit of the calculated result.

---

## Solid Outline

Functions Introduced:

- **ProSolidOutlineGet()**
- **ProSolidOutlineCompute()**
- **ProSolidOutlineWithOptionsCompute()**

The function `ProSolidOutlineGet()` provides you with the maximum and minimum values of X, Y, and Z occupied by the contents of the solid, with respect to the default, solid coordinate system.

The function `ProSolidOutlineCompute()` calculates the outline of the solid with respect to any orientation, defined by a transformation matrix. (For more information, see the [Core: Coordinate Systems and Transformations on page 228](#) section.) The function enables you to exclude from the calculation items of any or all of the following types:

- Datum plane
- Datum point
- Datum axes
- Datum coordinate system
- Facets

This function `ProSolidOutlineWithOptionsCompute()` calculates the outline of a solid using the specified filter. This filter is defined by the filter function `ProFeatureFilterAction()`, and excludes features based on user-defined logic. This filter works in addition to the excluded types, that is, if either check excludes a feature, it will be excluded. The input arguments are:

- *p\_solid*—The solid whose outline is to be calculated.
- *matrix*—The orientation matrix (with respect to the base coordinate system) that will be used to calculate the outline.
- *excludes*—An array of types that are excluded from the outline calculations such as nongeometric features and is defined by the enumerated data type `ProSolidOutlExclTypes`. If you set this to `PRO_OUTL_EXC_NOT_USED`, nothing is excluded.
- *num\_excludes*—Specifies the number of exclusions in the array.
- *filter\_action*—The filter defined by the callback function `ProFeatureFilterAction()`. If this is null, all features are considered while computing the outline.
- *app\_data*—The application data that is passed to the filter functions.

The output argument *r\_outline\_points* are the two points that define the boundary box of the solid in the specified orientation.

---

### Example 3: Computing the Outline of a Solid

The sample code in `UgSolidOutlineComp.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_solid` computes the outline of a solid with respect to a selected coordinate system, and converts the result back to solid coordinates.

### Calculated Text Height

The detail option **text\_height** sets the default text height for newly created annotations. The default value is calculated.

Functions Introduced:

- **ProSolidCalcTextHeightGet()**
- **ProAnnotationOffsetSymbolsGet()**

Use the function `ProSolidCalcTextHeightGet()` to get the calculated text height of a model, which is derived from the model's size. This text height is used when an annotation is created, when the detail option **text\_height** is set to calculated.

Use the function `ProAnnotationOffsetSymbolsGet()` to get all offset symbol instances for the annotation. This function has a valid annotation and the top drawing as the input argument. The output argument of this function is *syminsts* that specifies the `ProArray` of the associated syminsts.

### Solid Accuracy

Functions Introduced:

- **ProSolidAccuracyGet()**
- **ProSolidAccuracySet()**
- **ProSolidMaxsizeGet()**

Use the functions `ProSolidAccuracyGet()` and `ProSolidAccuracySet()` to retrieve and set the accuracy of a specified part or assembly, respectively.

---

#### Note

To set or retrieve the accuracy for an assembly you must traverse through all its parts in the assembly with these functions.

---

The input arguments for the function `ProSolidAccuracySet()` are as follows:

- *solid*—The part or assembly whose accuracy you want to set.

- *type*—The type of the accuracy. The valid values are:
  - `PRO_ACCURACY_RELATIVE`—Specifies the relative accuracy
  - `PRO_ACCURACY_ABSOLUTE`—Specifies the absolute accuracy
- *accuracy*—The value of the accuracy that you want to set. The unit used for the absolute accuracy of the dimension is based on the unit of the part or assembly.

---

 **Note**

Regenerate the model using the function `ProSolidRegenerate()` after setting the accuracy using `ProSolidAccuracySet()`.

---

The function `ProSolidAccuracyGet()` returns the type and value of the accuracy. The accuracy may be relative or absolute.

Using these functions to set and retrieve part accuracy is similar to performing these functions in Creo Parametric using **File ► Prepare ► Model Properties**.

Derive the geometry epsilon for the required relative accuracy as follows:

`geometry_epsilon = max_model_size x relative_accuracy x 0.08333`

where, `max_model_size` is the output returned by the function `ProSolidMaxsizeGet()` and `0.08333` is the scaling factor.

Use the function `ProSolidMaxsizeGet()` to get the maximum model size of the specified solid. The maximum model size does not decrease even when material is removed from the solid.

## Introduction to Unit of Measurement and System of Units

Each model has a basic system of unit to ensure that all material properties of that model are consistently measured and defined. All models are defined on the basis of system of units. A part can have only one system of unit.

Following are the types of quantities which govern the definition of unit of measurement:

- **Basic Quantities**—The basic units and dimensions of the system of units. For example, consider the Centimeter Gram Second (CGS) system of unit. The basic quantity for this system of unit is:
  - Length—cm
  - Mass—g
  - Force—dyne
  - Time—sec

- Temperature—K
- Derived Quantities—The derived units are those that are derived from the basic quantities. For example, consider the Centimeter Gram Second (CGS) system of unit. The derived quantities for this system of unit are as follows:
  - Area—cm<sup>2</sup>
  - Volume—cm<sup>3</sup>
  - Velocity—cm/sec

## Types of Systems of Units

Following are the types of system of units:

- Pre-defined system of unit—This system of unit is provided by default.
- Custom-defined system of unit—This system of unit is defined by the user only if the model does not contain standard metric or nonmetric units or if the material file contains units that cannot be derived from the predefined system of units or both.

In Creo Parametric, the system of units are categorized as follows:

- Mass Length Time (MLT)
  - The following systems of units belong to this category:
  - CGS —Centimeter Gram Second
  - MKS—Meter Kilogram Second
  - mmKS—millimeter Kilogram Second
- Force Length Time (FLT)
  - The following systems of units belong to this category:
  - Creo Parametric Default—Inch lbm Second. This is the default system followed by Creo Parametric.
  - FPS—Foot Pound Second
  - IPS—Inch Pound Second
  - mmNS—Millimeter Newton Second

## Definitions

For Creo TOOLKIT, a system of units is represented by the structure ProUnitsystem. This structure is defined as:

```
typedef struct {
 ProMdl owner;
 ProName name;
}ProUnitsystem;
```

---

where the name is the user-visible name used in the Unit Manager dialog.

An individual unit is represented by the structure `ProUnititem`. This structure is defined as:

```
typedef struct {
 ProMdl owner;
 ProName name;
}ProUnititem;
```

where the name is the user-visible abbreviation used in the Unit Manager dialog.

---

#### **Note**

The functions described in the following sections supersede the functions `prodb_get_model_units()` and `prodb_set_model_units()`.

---

## Retrieving Systems of Units

Functions Introduced:

- **ProMdlUnitsystemsCollect()**
- **ProMdlPrincipalunitsystemGet()**

Use the function `ProMdlUnitsystemsCollect()` to retrieve the set of systems of units which are accessible to the model in the form of an array. The input arguments of the function are as follows:

- *mdl*—Specifies a handle to the model.

The function outputs a `ProArray` containing the set of systems of units for the specified model.

---

#### **Note**

The function retrieves both the pre-defined as well as the custom-defined system of unit.

---

Use the function `ProMdlPrincipalunitsystemGet()` to retrieve the principal system of units for the specified model.

## Modifying Systems of Units

Functions Introduced:

- **ProUnitssystemRename()**
- **ProUnitssystemDelete()**

---

Use the function `ProUnitssystemRename()` to rename a custom- defined system of unit. The input parameters for this function are as follows:

- *system*—Specifies a handle to the system of unit.
- *new\_name*—Specifies the new name for the system.

Use the function `ProUnitssystemDelete()` to delete a custom- defined system of unit. Specify a handle to the system of units to be deleted as the input parameter for this function.

### Note

You can only delete a custom-defined system of units. You cannot delete a pre-defined system of units.

---

## Accessing Systems of Units

Functions Introduced:

- **ProUnitssystemIsStandard()**
- **ProUnitssystemTypeGet()**
- **ProUnitssystemUnitGet()**

Use the function `ProUnitssystemIsStandard()` to check whether the system of unit is a Creo Parametric standard system. Specify the name of the system of unit as the input parameter.

Use the function `ProUnitssystemTypeGet()` to retrieve the type of system of unit. Specify the name of the system of unit as the input argument. The output argument of this function is as follows:

- *type*—The type of system of unit. It can have the following values:
  - `PRO_UNITSYSTEM_MLT`—Mass Length Time
  - `PRO_UNITSYSTEM_FLT`—Force Length Time

For more information on the same refer to the section on [Types of Systems of Units on page 113](#) above.

Use the function `ProUnitssystemUnitGet()` to retrieve the unit of particular type for a specified system of derived unit.

## Creating a New System of Units

Function Introduced:

- **ProMdlUnitssystemCreate()**

---

Use the function `ProMdlUnitsystemCreate()` to create a new system of unit or to create a copy of an existing system of unit. The function expects the following input parameters:

- *mdl*—Specifies a handle to the model.
- *type*—Specifies the new type of system of unit.
- *name*—Specifies the name of the new system of unit.
- *units*—Specifies the set of units for the new system of unit created.

It outputs the newly created system of unit.

## Accessing Individual Units

Functions Introduced:

- **ProMdlUnitsCollect()**
- **ProUnitInit()**
- **ProUnitTypeGet()**
- **ProUnitNameGet()**
- **ProUnitConversionGet()**
- **ProUnitConversionCalculate()**
- **ProUnitIsStandard()**
- **ProUnitExpressionGet()**
- **ProUnitInitByExpression()**
- **ProUnitCreateByExpression()**
- **ProUnitModifyByExpression()**
- **ProUnitCreateByExpressionAndType()**
- **ProUnitModifyByExpressionAndType()**
- **ProUnitInitByExpressionAndType()**

Use the function `ProMdlUnitsCollect()` to retrieve a set of derived units of a particular type that are available to the specified model.

The function `ProUnitInit()` retrieves the unit of a particular name for a specified model.

---

### Note

The function is applicable only for basic units and not for derived ones.

---

---

The function `ProUnitNameGet()` returns the name of the unit. For system generated unit, that has no user-friendly name, it returns the error `PRO_TK_NOT_DISPLAYED`.

Use the function `ProUnitTypeGet()` to retrieve the unit type of a particular unit.

Unit types can have any of the following values for basic units:

- `PRO_UNITTYPE_LENGTH`
- `PRO_UNITTYPE_MASS`
- `PRO_UNITTYPE_FORCE`
- `PRO_UNITTYPE_TIME`
- `PRO_UNITTYPE_TEMPERATURE`
- `PRO_UNITTYPE_ANGLE`

Unit types can have any of the following values for derived units:

- `PRO_UNITTYPE_AREA`
- `PRO_UNITTYPE_VOLUME`
- `PRO_UNITTYPE_VELOCITY`
- `PRO_UNITTYPE_ACCELERATION`
- `PRO_UNITTYPE_ROTATIONAL_VELOCITY`
- `PRO_UNITTYPE_ROTATIONAL_ACCELERATION`
- `PRO_UNITTYPE_FREQUENCY`
- `PRO_UNITTYPE_DENSITY`
- `PRO_UNITTYPE_TORQUE_MOMENT`
- `PRO_UNITTYPE_FORCE_ALONG_CURVE`
- `PRO_UNITTYPE_FORCE_PER_LENGTH`
- `PRO_UNITTYPE_MOMENT_ALONG_CURVE`
- `PRO_UNITTYPE_MOMENT_PER_LENGTH`
- `PRO_UNITTYPE_FORCE_OVER_SURFACE`
- `PRO_UNITTYPE_FORCE_PER_AREA`
- `PRO_UNITTYPE_MOMENT_PER_VOLUME`
- `PRO_UNITTYPE_PRESSURE`
- `PRO_UNITTYPE_STRESS`
- `PRO_UNITTYPE_YOUNG_MODULUS`
- `PRO_UNITTYPE_MOMENT_OVER_SURFACE`
- `PRO_UNITTYPE_MOMENT_PER_AREA`

- 
- PRO\_UNITTYPE\_TRANSLATIONAL\_STIFFNESS
  - PRO\_UNITTYPE\_ROTATIONAL\_STIFFNESS
  - PRO\_UNITTYPE\_THERMAL\_EXPANSION\_COEFF
  - PRO\_UNITTYPE\_MOMENT\_OF\_INERTIA\_SECTION
  - PRO\_UNITTYPE\_MOMENT\_OF\_INERTIA\_SECTION
  - PRO\_UNITTYPE\_MASS\_MOMENT\_OF\_INERTIA
  - PRO\_UNITTYPE\_ENERGY
  - PRO\_UNITTYPE\_WORK
  - PRO\_UNITTYPE\_HEAT
  - PRO\_UNITTYPE\_POWER
  - PRO\_UNITTYPE\_HEAT\_TRANSFER\_RATE
  - PRO\_UNITTYPE\_TEMPERATURE\_GRADIENT
  - PRO\_UNITTYPE\_HEAT\_FLUX
  - PRO\_UNITTYPE\_HEAT\_FLUX\_PER\_LENGTH
  - PRO\_UNITTYPE\_THERMAL\_CONDUCTIVITY
  - PRO\_UNITTYPE\_CONVECTION\_COEFF
  - PRO\_UNITTYPE\_CONVECTION\_COEFF\_PER\_AREA
  - PRO\_UNITTYPE\_SPECIFIC\_HEAT
  - PRO\_UNITTYPE\_THERM\_RES\_FORCE
  - PRO\_UNITTYPE\_THERM\_RES\_MOMENT
  - PRO\_UNITTYPE\_WARPING\_COEFFICIENT
  - PRO\_UNITTYPE\_MASS\_PER\_LENGTH
  - PRO\_UNITTYPE\_MASS\_INERTIA\_PER\_LENGTH
  - PRO\_UNITTYPE\_DAMPING\_COEFFICIENT
  - PRO\_UNITTYPE\_HEAT\_RATE\_PER\_LENGTH
  - PRO\_UNITTYPE\_DIMENSIONLESS
  - PRO\_UNITTYPE\_MASS\_PER\_AREA
  - PRO\_UNITTYPE\_ROT\_DAMPING\_COEFF
  - PRO\_UNITTYPE\_VOLUME\_HEAT\_GEN
  - PRO\_UNITTYPE\_TRANS\_STIFF\_PER\_AREA
  - PRO\_UNITTYPE\_FORCE\_PER\_VOLUME
  - PRO\_UNITTYPE\_CURVATURE
  - PRO\_UNITTYPE\_CURVATURE\_SQ

- 
- PRO\_UNITTYPE\_LINEAR\_MOMENTUM
  - PRO\_UNITTYPE\_ANGULAR\_MOMENTUM
  - PRO\_UNITTYPE\_INV\_STRESS
  - PRO\_UNITTYPE\_TRANS\_STIFF\_PER\_LENGTH
  - PRO\_UNITTYPE\_ROT\_STIFF\_PER\_LENGTH
  - PRO\_UNITTYPE\_DAMPING\_COEFF\_PER\_LENGTH
  - PRO\_UNITTYPE\_INV\_VELOCITY
  - PRO\_UNITTYPE\_CONVECTION\_COEFF\_PER\_VOLUME
  - PRO\_UNITTYPE\_CONVECTION\_COEFF\_PER\_LENGTH
  - PRO\_UNITTYPE\_CONVECTION\_COEFF\_PER\_POINT
  - PRO\_UNITTYPE\_RADIATION\_COEFF\_PER\_VOLUME
  - PRO\_UNITTYPE\_RADIATION\_COEFF\_PER\_AREA
  - PRO\_UNITTYPE\_RADIATION\_COEFF\_PER\_LENGTH
  - PRO\_UNITTYPE\_RADIATION\_COEFF\_PER\_POINT
  - PRO\_UNITTYPE\_ENERGY\_PER\_VOLUME
  - PRO\_UNITTYPE\_ENERGY\_PER\_AREA
  - PRO\_UNITTYPE\_ENERGY\_PER\_LENGTH
  - PRO\_UNITTYPE\_LENGTH\_SPECTDENS
  - PRO\_UNITTYPE\_VELOCITY\_SPECTDENS
  - PRO\_UNITTYPE\_ACCELERATION\_SPECTDENS
  - PRO\_UNITTYPE\_STRESS\_SPECTDENS
  - PRO\_UNITTYPE\_STRAIN\_SPECTDENS
  - PRO\_UNITTYPE\_ROTATIONAL\_VELOCITY\_SPECTDENS
  - PRO\_UNITTYPE\_ROTATIONAL\_ACCELERATION\_SPECTDENS
  - PRO\_UNITTYPE\_FORCE\_SPECTDENS
  - PRO\_UNITTYPE\_MOMENT\_SPECTDENS
  - PRO\_UNITTYPE\_ROTATIONAL\_LENGTH\_SPECTDENS
  - PRO\_UNITTYPE\_MASS\_FLOW\_RATE
  - PRO\_UNITTYPE\_VISCOSITY
  - PRO\_UNITTYPE\_VOLUME\_FLOW

The following units have been added to the volume flow:

- m<sup>3</sup>/sec
- cm<sup>3</sup>/sec

- 
- mm<sup>3</sup>/sec
  - ft<sup>3</sup>/sec
  - in<sup>3</sup>/sec
  - L/sec
  - gal/sec
  - mL/sec

Use the function `ProUnitConversionGet()` to retrieve the conversion factor for a particular unit. The output arguments of this function are:

- *conversion*—Specifies the conversion factor for a unit in terms of scale of the unit and an offset value.

Example - Consider the formula to convert temperature from Centigrade to Fahrenheit

$$F = a + (C * b)$$

where

F is the temperature in Fahrenheit

C is the temperature in Centigrade

a = 32 (constant signifying the offset value)

b = 9/5 (ratio signifying the scale of the unit)

---

 **Note**

Creo Parametric scales the length dimensions of the model using the factor specified. If the scale is modified, the model is regenerated. When you scale the model, the model units are not changed. Imported geometry cannot be scaled.

---

- *ref\_unit*— Specifies the reference unit for the conversion.

Use the function `ProUnitConversionCalculate()` to calculate the conversion factor between two units. These units can belong to the same model or two different models.

Use the function `ProUnitIsStandard()` to determine whether the unit is a standard unit as defined in Creo Parametric.

Creo Parametric uses named quantities to represent units other than the basic units (e.g. "Ilbs\_stress\_unit", which represents a quantity of stress in the default Creo Parametric unit systems). Parameters and material properties which are assigned derived units will return the name in the `ProUnitItem` structure, rather than the actual unit-based expression for the quantity.

Use the function `ProUnitExpressionGet()` to retrieve the unit-based expression for a given Creo Parametric unit name.

---

Use the function `ProUnitInitByExpression()` to retrieve the `ProUnitItem` given a unit-based expression.

The function `ProUnitCreateByExpression()` creates a derived or basic unit, based on expression. Use the function `ProUnitModifyByExpression()` to modify a derived unit.

The function `ProUnitCreateByExpressionAndType()` creates a derived unit for the specified unit-based expression and type.

Use the function `ProUnitModifyByExpressionAndType()` to modify a derived unit based on the specified unit-based expression and type. The input arguments are as follows:

- *unit*—Unit to be modified.
- *type*—Type of unit specified by the enumerated data type `ProUnitType`.
- *expression*—Expression of the unit specified by the character string using the `ProPath` object.

The function `ProUnitInitByExpressionAndType()` returns a `ProUnitItem` structure for the specified unit-based expression. The input arguments are as follows:

- *mdl*—The model that owns the units.
- *type*—Type of unit specified by the enumerated data type `ProUnitType`.
- *expression*—Expression of the unit specified by the character string using the `ProPath` object.

## Modifying Units

Functions Introduced:

- **ProUnitModify()**
- **ProUnitDelete()**
- **ProUnitRename()**

Use the function `ProUnitModify()` to modify a pre-defined unit. Modifying the units can invalidate your relations, as they are not scaled along with the model. The input parameters are:

- *unit*—Specifies the unit to be modified.
- *conversion*—Specifies the conversion factor for the unit.
- *ref\_unit*—Specifies the reference unit.

Use the function `ProUnitDelete()` to delete a previously created unit.

## Note

You cannot delete a pre-defined unit. If you delete a unit, you cannot undo the deletion.

Use the function `ProUnitRename()` to rename an existing unit.

## Creation of a new Unit

- **ProUnitCreate()**

Use the function `ProUnitCreate()` to create a new basic unit given a reference unit and the required conversion factor.

## Conversion of Models to a New Unit System

Function Introduced:

- **ProMdlPrincipalunitsystemSet()**

Use the function `ProMdlPrincipalunitsystemSet()` to change the principal system of units assigned to the solid model. The options available for the conversion are:

- `PRO_UNITCONVERT_SAME_DIMS`—Specifies the option to keep the dimension values despite the change in units.
- `PRO_UNITCONVERT_SAME_SIZE`—Specifies the option to scale the dimension values to keep the same size for the model.

Conversion of a system of units may result in regeneration failures due to the modification of dimensions, parameters, and relations.

`ProMdlPrincipalunitsystemSet()` does not support a flag to undo the changes made by the unit system conversion, and will always bring the **Fix Model** interface to fix any regeneration failure. Therefore use this function only in interactive mode applications. While updating the principal system of units in an assembly environment, update the system of units in the following order:

1. Update the system of unit for all the parts separately. Update the parts using the following procedure:
  - a. Retrieve the parts.
  - b. Update the units.
  - c. Save the part and erase it from the current session.
2. Update all the sub-assemblies, that either need to be changed, or contain already processed components.
3. Update the topmost level assembly.

---

 **Note**

The initial units for an assembly are those of its base component. If, however, the units of the base component have been changed, the assembly units do not automatically change. You must also modify the units of the assembly. You cannot change the units of an assembly containing assembly features that intersect a part.

---

## Mass Properties

Function Introduced:

- **ProSolidMassPropertyGet()**
- **ProSolidMassPropertyWrite()**
- **ProSolidBodyMassPropertyGet()**
- **ProSolidBodyDensityGet()**
- **ProSolidMassPropertyWithDensityGet()**
- **ProAssemblySolidMassPropertyGet()**

In Creo Parametric 7.0.0.0 and later, the density parameter for any material is `PTC_MASS_DENSITY`. When you edit the density of a material, the value of this parameter is updated. The alternate mass property parameter for an assembly, part, or body is `PRO_MP_ALT_DENSITY`. The reported density parameter for an assembly, part, or body is `PRO_MP_DENSITY`. In the case of an assembly or a part with different materials, the value of this parameter is the average density.

The function `ProSolidMassPropertyGet()` provides information about the distribution of mass in the part or assembly.

The function `ProSolidMassPropertyWrite()` writes the mass properties of the specified solid or body referenced by the coordinate system selection in the specified format. The input arguments are as follows:

- *solid\_or\_body*—`ProSelection` handle to the solid or body.
- *csys\_sel*—`ProSelection` handle for the coordinate system. If this value is `NULL`, the function uses the default coordinate system of the input solid.

---

 **Note**

You can select the coordinate system using the component path of component or subassembly whose mass properties are required.

---

- 
- *format*—Format of the mass property file. This is specified using the enumerated data type `ProMassPropertyFormat` and the valid values are:
    - `PRO_MP_TXT`—Text format. The default value is 0.
    - `PRO_MP_CSV`—CSV format. The default value is 1.
    - `PRO_MP_XML`—XML format. The default value is 2.

The function `ProSolidBodyMassPropertyGet()` calculates the mass properties of a body in the specified coordinate system. The input parameter *body* is the handle to a part or an assembly.

Both the functions provide the mass distribution information relative to the specified coordinate system datum *csys\_name*. If the value of the parameter *csys\_name* is `NULL`, the default coordinate system is used.

The functions `ProSolidMassPropertyGet()` and `ProSolidBodyMassPropertyGet()` return the information in the structure `ProMassProperty`, declared in the header file `ProSolid.h`.

The `ProMassProperty` structure contains the following fields (all doubles):

- *volume*—The volume.
- *surface\_area*—The surface area.
- *density*—The density is not defined until a material with well-defined density is assigned.
- *mass*—The mass.
- *center\_of\_gravity*[3]—The center of gravity (COG).
- *coord\_sys\_inertia*[3][3]—The inertia matrix.
- *coord\_sys\_inertia\_tensor*[3][3]—The inertia tensor.
- *cg\_inertia\_tensor*[3][3]—The inertia about the COG.
- *principal\_moments*[3]—The principal moments of inertia (the eigenvalues of the COG inertia).
- *principal\_axes*[3][3]—The principal axes (the eigenvectors of the COG inertia).

The function `ProSolidBodyDensityGet()` determines the density of the material assigned to a body. The input parameters *body* is the handle to the body.

---

#### **Note**

If a material is already assigned to the part, the output of the function is the density of the material that is assigned to the body. The density is measured in the units of the model. The density of the body is always the density of the material assigned to the body.

---

---

The function `ProSolidMassPropertyWithDensityGet()` calculates the mass properties of a part or an assembly in the specified coordinate system. This function does not impact the mass properties of a solid. The input arguments are as follows:

- *solid*—Handle to the part or assembly specified by the `ProSolid` object.
- *csys\_name*—Name of the coordinate system. If this is `Null`, the function uses the default coordinate system.
- *dens\_use\_flag*—Value of the density flag specified using the enumerated data type `ProMPDensUse` and the valid values are as follows:
  - `PRO_MP_DENS_DEFAULT`—Calculate the mass properties using the material density.
  - `PRO_MP_DENS_USE_ALWAYS`—Calculate the mass properties using the specified density, even if material has a defined density.
  - `PRO_MP_DENS_USE_IF_MISSING`—Calculate mass properties using specified density, even if material does not have a defined density.
- *density*—Density used while calculating mass properties depending on the value specified for the input argument *dens\_use\_flag*.

The function `ProAssemblySolidMassPropertyGet()` calculates the mass properties of a solid that is referenced by the specified coordinate system selection. The input arguments follow:

- *solid* —The handle to top assembly or component/sub-assembly.
- *csys\_sel*—Selection of coordinate system specified using the array of `ProSelection` object. If this is `NULL`, the function uses the default coordinate system of the specified solid.

## Solid Postfix Identifiers

Functions Introduced:

- **ProSolidToPostfixId()**
- **ProPostfixIdToSolid()**

The postfix identifier of a solid is the integer run-time identifier used in relations to make the names of its dimensions unique in the context of a parent assembly. Creo Parametric automatically updates these values when they are used in relations. The function `ProSolidToPostfixId()` gives you the identifier for the solid in session. The `ProPostfixIdToSolid()` function provides the solid handle, given the identifier.

---

## Part Objects

The object `ProPart` is an instance of `ProSolid`. It is an opaque handle that can be cast to a `ProSolid` or `ProMdl` so you can use any of the functions for those objects.

### Density

Functions Introduced:

- **`ProPartDensityGet()`**

Superseded Functions:

- **`ProPartDensitySet()`**

The density of a part is used in many calculations inside of Creo Parametric, including mass properties calculations and shrinkwrap export. The function `ProPartDensityGet()` returns the calculated or reported density that is defined by the parameter `PRO_MP_DENSITY`.

In Creo Parametric 7.0.0.0 and later, the function `ProPartDensitySet()` is deprecated. Use the functions `ProMaterialCurrentSet()` and `ProMaterialPropertySet()` instead.

For more information about materials, refer to [Accessing Material Data on page 127](#).

## Example 4: Writing the Mass of a Given Part to the Model Tree

The sample code in `UgSolidInfoMass.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_solid` demonstrates the use of `ProPartDensityGet()`, `ProSolidMassPropertyGet()` and several units related functions. It writes the mass of the given part to the model tree, along with the appropriate units for the mass value.

## Material Objects

Creo TOOLKIT enables you to programmatically access the material properties of parts. Using the Creo TOOLKIT functions, you can do the following actions:

- Create or delete materials.
- Set the current material.
- Retrieve and set the material types and properties.
- Read and write to material files.

To enable access to materials, Creo TOOLKIT uses the following objects:

- 
- **ProMaterial**—A structure that contains a material name and the part (ProSolid object) to which it is assigned. This handle is used in older material functions.
  - **ProMaterialItem**—Another name for a ProModelitem, it contains the material owner, ID, and type (PRO\_RP\_MATERIAL).

To convert between ProMaterial and ProMaterialItem, use ProModelitemByNameInit() to obtain the item from the material owner and name. To obtain a ProMaterial from a ProMaterialItem, use ProModelitemNameGet() to get the material name.

## Accessing Material Data

Functions Introduced:

- **ProMaterialCreate()**
- **ProPartMaterialsGet()**
- **ProMaterialDelete()**
- **ProMaterialCurrentGet()**
- **ProMaterialCurrentSet()**

The function ProMaterialCreate() creates a new material with the name you specify, and sets the default values within an associated ProMaterialdata object. Your application must set the correct material properties in the fields of the ProMaterialdata structure.

The input arguments of this function are as follows:

- *part* — Specifies the part.
- *matl\_name* — Specifies the material name.
- *p\_matl\_data* — This argument has been deprecated. Pass NULL to create an empty material item whose properties can be set by ProMaterialPropertySet().

The function ProPartMaterialsGet() obtains an array containing material names that exist in a part database. Note that you must use ProArrayAlloc() to allocate memory for this array. To remove a specified material from the part's database, call the function ProMaterialDelete().

The current material of a part determines the material properties that will be used in some computational analyses of that part. Although multiple materials can be stored in a part database, only one material can be current. The function ProMaterialCurrentGet() gets the handle for the master material of the specified part. To set the master material, call the function ProMaterialCurrentSet().

---

## Note

- When the master material on a part with a single body is changed, the appearance, density, and sheet metal properties of the body are updated. When you create a new body, it is automatically assigned the material assigned to the part. You can also explicitly assign a material to a body. In this case, even when the master material on the model is changed, the appearance, density, and sheet metal properties of the body are not changed.
- By default, when assigning a material to a sheet metal part, the function `ProMaterialCurrentSet()` might modify the values of the sheet metal properties such as Y factor and bend table according to the material file definition. This triggers a modification of the developed length parameters of the sheet metal part. To prevent this modification, set the value of the configuration option `material_update_smt_bend_table` to `never_replace`. To trigger a modification of the developed length parameters of the sheet metal part, set the configuration option `material_update_smt_bend_table` to `always_replace`. The default value is `always_replace`. Call `ProSolidRegenerate()` to trigger the regeneration and recalculate the developed length dimension of the part.

See the Creo Parametric Sheetmetal online help for more information on Bend Allowance.

- The function `ProMaterialCurrentSet()` may change the model display, if the new material has a default appearance assigned to it.
- The function may also change the family table, if the parameter `PTC_MASTER_MATERIAL` is a part of the family table.
- You can still use the legacy parameter `PTC_MASTER_MATERIAL`, however, these legacy parameters do not appear correctly in calculations and reports when you are working with a part that uses multiple materials.

---

## Material Types and Properties

The enumerated type `ProMaterialPropertyType` contains the material types and material property types.

The material type is given by `PRO_MATPROP_TYPE` that takes the following values:

- 
- `PRO_MATERIAL_TYPE_STRUCTURAL_ISOTROPIC`—Specifies a material with an infinite number of planes of material symmetry, making the structural material properties equal in all directions.
  - `PRO_MATERIAL_TYPE_STRUCTURAL_ORTHOTROPIC`—Specifies a material with symmetry relative to three mutually perpendicular planes for structural material properties.
  - `PRO_MATERIAL_TYPE_STRUCTURAL_TRANS_ISOTROPIC`—Specifies a material with rotational symmetry about an axis for structural material properties. These properties are equal for all directions in the plane of isotropy.
  - `PRO_MATERIAL_TYPE_THERMAL_ISOTROPIC`—Specifies a material with an infinite number of planes of material symmetry, making the thermal material properties equal in all directions.
  - `PRO_MATERIAL_TYPE_THERMAL_ORTHOTROPIC`—Specifies a material with symmetry relative to three mutually perpendicular planes for thermal material properties.
  - `PRO_MATERIAL_TYPE_THERMAL_TRANS_ISOTROPIC` — Specifies a material with rotational symmetry about an axis for thermal material properties. These properties are equal for all directions in the plane of isotropy.
  - `PRO_MATERIAL_TYPE_FLUID`—Specifies a material with fluid properties.

The material subtype is given by `PRO_MATPROP_SUB_TYPE` that takes the following values:

- `PRO_MATERIAL_SUB_TYPE_LINEAR`—Specifies the linear elastic material type. This is the default value.
- `PRO_MATERIAL_SUB_TYPE_HYPERELASTIC`—Specifies the hyperelastic (non-linear) material types, such as rubber, that exhibit instantaneous elastic response to large strains.
- `PRO_MATERIAL_SUB_TYPE_ELASTOPLASTIC`—Specifies the elastoplastic (non-linear) material types, such as metals, with the following isotropic hardening laws:
  - `Perfect Plasticity`—Given by the value `PRO_MATERIAL_HARDENING_PERFECT_PLASTICITY`
  - `Linear Hardening`—Given by the value `PRO_MATERIAL_HARDENING_LINEAR_HARDENING`
  - `Power Law`—Given by the value `PRO_MATERIAL_HARDENING_POWER_LAW`
  - `Exponential Law`—Given by the value `PRO_MATERIAL_HARDENING_EXPONENTIAL_LAW`

---

The above three subtypes are available only for `PRO_MATERIAL_TYPE_STRUCTURAL_ISOTROPIC` and `PRO_MATERIAL_TYPE_THERMAL_ISOTROPIC` material types.

From Creo Parametric 3.0 onward, two additional material types `PRO_MATERIAL_FATIGUE_MAT_TYPE_FERROUS` and `PRO_MATERIAL_FATIGUE_MAT_TYPE_OTHER` have been added for fatigue analysis. The material types `PRO_MATERIAL_FATIGUE_MAT_TYPE_UNALLOYED_STEELS` and `PRO_MATERIAL_FATIGUE_MAT_TYPE_LOW_ALLOY_STEELS` are obsolete. Use the material type `PRO_MATERIAL_FATIGUE_MAT_TYPE_FERROUS` instead. The following surface finish types for fatigue analysis are also obsolete:

- `PRO_MATERIAL_FATIGUE_FINISH_FORGED`
- `PRO_MATERIAL_FATIGUE_FINISH_WATER_CORRODED`
- `PRO_MATERIAL_FATIGUE_FINISH_SEA_WATER_CORRODED`
- `PRO_MATERIAL_FATIGUE_FINISH_NITRIDED`
- `PRO_MATERIAL_FATIGUE_FINISH_SHOT_PEENED`

PTC recommends that you review your existing Creo TOOLKIT applications and modify the code as appropriate to ensure that the applications work correctly for the fatigue materials and material finish types.

Functions Introduced:

- **`ProMaterialPropertyGet()`**
- **`ProSolidBodyMaterialGet()`**
- **`ProSolidBodyMaterialSet()`**
- **`ProUnitExpressionGet()`**
- **`ProMaterialPropertySet()`**
- **`ProUnitInitByExpression()`**
- **`ProMaterialDescriptionGet()`**
- **`ProMaterialDescriptionSet()`**
- **`ProMaterialPropertyDelete()`**
- **`ProMaterialUsageParametersCollect()`**

The functions `ProMaterialDataGet()` and `ProMaterialDataSet()` have been deprecated, and do not support all of the available material properties. PTC recommends that for accessing material properties, you convert the `ProMaterial` type to a model item using `ProModelItemByNameInit()`, and use `ProMaterialPropertyGet()` and `ProMaterialPropertySet()` the properties of that item, respectively.

---

A part created in Creo Parametric 7.0.0.0 and later, can contain multiple solid bodies where each body can have its own material assignment. A part created in an earlier release of Creo Parametric contains one body and one material is assigned to the part.

The function `ProSolidBodyMaterialSet()` assigns a material to the specified body. You can set the default material by specifying the value of the system parameter `PTC_MASTER_MATERIAL` as `PTC_SYSTEM_MTRL_PROPS`. In legacy parts, the value of `PTC_MASTER_MATERIAL` is the material assigned to the part. The input arguments follow:

- `body`—Body for which the material needs to be assigned.
- `mtl`—Name of the material that needs to be assigned to the body.

Use the function `ProSolidBodyMaterialGet()` to retrieve the information of the material assigned to the body.

---

 **Note**

Refer to the Creo Parametric online help for more information about Materials.

---

If you do not assign a material to a body, Creo Parametric assigns `PTC_GENERIC_MATERIAL` material to the body. The density of this material as well as other properties are empty.

The function `ProMaterialPropertyGet()` returns the value and the units for a material property.

---

 **Note**

The name of the units returned can be the name of a Creo Parametric unit, which may not be obviously understood by a user. Use `ProUnitExpressionGet()` to change this name to familiar units.

---

Use the function `ProMaterialPropertySet()` to create or modify a material property. It has the following input parameters:

- `p_material`—Specifies the material as defined by `ProMaterialItem`.
- `prop_type`—Specifies the material property type as defined by `ProMaterialPropertyType`.
- `p_value`—Specifies the material property value.
- `p_units`—Specifies the material property units.

---

 **Note**

This function expects the Creo Parametric unit name for some unit properties. To obtain this name, pass the user-visible units through `ProUnitByExpressionInit()`.

---

The following table displays the possible combinations of arguments for *p\_value* and *p\_units*:

| <b>p_value</b>    | <b>p_units</b>                                                            | <b>Is the property already created in the material?</b> | <b>Result</b>                                                                                                |
|-------------------|---------------------------------------------------------------------------|---------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| Any value         | Appropriate units for this property, or NULL, if the property is unitless | NO                                                      | Property is created with the given units and value.                                                          |
| Any value         | NULL                                                                      | NO                                                      | Property is created with the given value using the appropriate units from the owner model.                   |
| Any value         | Current units for this property, or NULL, if the property is unitless     | YES                                                     | Property value is changed to the new value.                                                                  |
| Any value         | NULL                                                                      | YES                                                     | Property value is changed to the new value (which is interpreted as being in the units from the owner model) |
| The current value | New appropriate units                                                     | YES                                                     | Property units are changed but the value is interpreted as being for the new units.                          |
| NULL              | New appropriate units                                                     | YES                                                     | Property units are changed and the current value is converted to the new units.                              |

---

 **Note**

When using `ProMaterialPropertySet()` to change the sheet metal Y-factor or bend table assigned to the current material, pass the current material to `ProMaterialCurrentSet()` again to force Creo Parametric to update the bend allowance preferences of the sheet metal part.

---

Use the function `ProMaterialDescriptionGet()` to get the material description. This property is also accessible as the material property `PRO_MATPROP_MATERIAL_DESCRIPTION`.

---

Use the function `ProMaterialDescriptionSet()` to set the material description.

Use the function `ProMaterialPropertyDelete()` to remove a property from the material definition.

The function `ProMaterialUsageParametersCollect()` collects all usage parameters for the specified material. The output argument `usageParams` is a list of usage parameters of the material. Use the method `ProArrayFree()` to free the memory allocated for the list of usage parameters.

## Material Input and Output

Functions Introduced:

- **ProMaterialfileWrite()**
- **ProMaterialfileRead()**

Material properties are frequently stored in text files accessible for repeated assignment to parts. Creo TOOLKIT includes functions that write to and read these files.

The function `ProMaterialfileWrite()` writes the information contained in a `ProMaterial` object to a file with the specified name.

The format of this file is the new material file format which is consistent with the Creo Parametric materials library.

The function `ProMaterialfileRead()` reads from a material file, the properties of the material with the specified name. The name of the file read can be either:

- `<name>.mtl`—Specifies a new material file format.
- `<name>.mat`—Specifies an old material file format (pre-Wildfire 3.0).

If the material is not already in the part database, `ProMaterialfileRead()` adds the material to the database after reading the material file. If the material is already in the database, the function replaces the material properties in the database with those contained in the material file.

### Example 5: Working with Materials and Material Properties

The sample code in `UgMaterial.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_param` shows how to work with materials and material properties.

### Example 6: Creating a Non-linear Material

The sample code in `UgSolidMaterial.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_solid` shows how to create a non-linear material and assign it to a solid.

---

# Core: Solid Body

## Introduction to Solid Body

This section describes how to access, create, or delete bodies in a model.

In Creo Parametric 7.0.0.0 and later, the term “solid body” denotes a container object for solid geometry.

In earlier versions of Creo Parametric all solid geometry in a part is considered as one piece of a single material, even when the geometry has disjoint volumes. Starting in Creo Parametric 7.0.0.0, you can create parts that contain one or more geometric bodies. Each body can be handled individually, and can have different characteristics. For example, you can assign a different material to each body.

Bodies contain only solid geometry. Nonsolid entities, like datums, curves, and quilts, are not contained in any body.

When you create a new part, it has an empty body in it. This body will contain the solid geometry created by the features. If no solid geometry is created, or as long as the part contains only nonsolid geometry, this body remains empty. A part must always have at least one body in it.

When you retrieve a part that was created using a version earlier of Creo Parametric, it shows a single body in it. This body contains all the solid geometry in the part, if any exists.

Using Creo Parametric solid body feature, you can create parts with one or more geometric bodies. A body consists of solid geometry of the same material. You can assign a different material to each body and a single part can have more than one material.

## Solid Body Objects

The structure `ProSolidBody` describes the contents of the solid body object. This object uses the same declaration as the `ProModelItem` object, which is as follows:

```
typedef struct pro_model_item
{
 ProType type;
 int id;
 ProMdl owner;
} ProSolidBody;
```

---

## States of bodies

When a body has geometry, it does not have a special state. A body can have a state derived from features and geometry.

- **No Contributing Features**—No feature contributes geometry to the body.
- **No Geometry**—Features which contribute to the body, however other features cut the entire geometry of this body. Or all the contributing features are suppressed.
- **Construction**—Does not participate in mass properties calculations and is not considered in global or volume interference analysis or in collision detection. The construction state does not change the other properties of the body. Setting a body to construction state is reversible.

## Creating a Body

A new part is created with a default body. This body is in the **No Contributing Features** state. When you add solid geometry to this part, you can add to this body, or create a new body. You can delete bodies that are in the **No Contributing Features** state. When you delete a body, it is removed from the part and the **Bodies** folder in the model tree. The parameters and relations for the body are deleted.

Functions introduced:

- **ProSolidBodyCreate()**
- **ProSolidBodiesCollect()**
- **ProSolidDefaultBodyGet()**
- **ProSolidDefaultBodySet()**
- **ProSolidBodySurfaceVisit()**
- **ProSolidBodyDelete()**
- **ProSolidBodyStateGet()**
- **ProSolidBodyIsConstruction()**
- **ProSolidBodyConstructionSet()**
- **ProSolidBodyOutlineGet()**
- **ProSolidBodyIsSheetmetal()**

The function `ProSolidBodyCreate()` creates a new body. The input argument *sld* is the solid owner on which the body needs to be created. The output argument *body* is the body that is created.

Refer to the Creo Parametric online help for more information about body creation.

---

The function `ProSolidBodiesCollect()` collects all the bodies in the specified solid.

The function `ProSolidDefaultBodyGet()` returns the default body in the specified solid.

The function `ProSolidDefaultBodySet()` sets the specified body as default body in the specified solid. The input argument `default_body` is the body to be set as the default body.

Use the function `ProSolidBodySurfaceVisit()` to visit the surfaces that are included in the specified body.

The function `ProSolidBodyDelete()` deletes the body in the specified solid. When you delete a body, it is removed from the part and the **Bodies** folder in the model tree.

The function `ProSolidBodyStateGet()` returns the state of the body and is defined by the enumerated data type `ProSolidBodyState` and the valid values are:

- `PRO_BODY_STATE_MISSING`
- `PRO_BODY_STATE_CONSUMED`
- `PRO_BODY_STATE_NO_CONTR_FEAT`
- `PRO_BODY_STATE_NO_GEOMETRY`
- `PRO_BODY_STATE_ACTIVE`

Use the function `ProSolidBodyIsConstruction()` to check if the specified body is a construction body.

Use the function `ProSolidBodyConstructionSet()` to set the specified body as a construction body. The function returns the error `PRO_TK_NO_CHANGE` if the body is already a construction body.

Use the function `ProSolidBodyOutlineGet()` to retrieve the regeneration outline of a solid body, with respect to the base coordinate system orientation. This outline defines the boundary box of the body. The function returns `PRO_TK_E_NOT_FOUND` if the solid body is empty.

The function `ProSolidBodyIsSheetmetal()` checks if the specified body is an active sheetmetal body.

In Creo Parametric 7.0, a sheetmetal part can have a single sheetmetal body and any number of solid bodies.

## Listing Features

Functions Introduced:

- **ProSolidBodyFeaturesGet()**

---

The function `ProSolidBodyFeaturesGet()` lists all the features that are associated with the specified body. The output argument `features` is a `ProArray` of features.

The function returns the error `PRO_TK_E_NOT_FOUND` if there are no contributing features associated with the body.

## Multibody Operations

Each body has its own geometry. You can perform geometric operations such as splitting a body or merging with other bodies. Bodies contribute to the mass properties of the model. You can select bodies as references for features. You can split a body into two bodies and also perform move or copy operations on bodies. The geometry of the original body is divided between the original body and the new body. For more information on body options and body operations, refer to the [Element Trees: Solid Body on page 1050](#) topic.

You can use the Boolean Operations feature to perform geometric operations such as:

- **Merge**—Combines the geometry of two or more bodies into one body.
- **Intersect**—Keeps the geometry that is shared by two or more bodies.
- **Subtract**—Removes the geometry of one body from one or more bodies.

## Core: Features

### Core: Features

This section describes the Creo TOOLKIT functions that deal with features as a whole and the way they relate to each other.

Access to the geometry objects created by features is described in the [Core: 3D Geometry on page 177](#) section.

Access to the internal structure of a feature is described in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Feature Objects

Function Introduced:

- **ProFeatureInit()**

Features are represented by the object `ProFeature`, which is declared as a `DHandle`, or data handle. It shares the same declaration as `ProModelitem` and `ProGeomitem`, and therefore contains the type and integer identifier as fields in the structure.

---

Like `ProGeomitem`, `ProFeature` is an instance of `ProModelitem`. `ProFeature` objects are contained in `ProSolid` objects, and contain `ProGeomitem` objects.

You can create a new `ProFeature` handle using the function `ProFeatureInit()`.

## Visiting Features

Function Introduced:

- **`ProSolidFeatVisit()`**

The function `ProSolidFeatVisit()` enables you to visit all the features in a part or assembly. It visits not only those features visible to the user, but also features used internally for construction purposes. To skip over such internal, “invisible” functions, call `ProFeatureVisibilityGet()`.

Note that the function `ProSolidFeatstatusGet()` (described in detail in the [Core: Solids, Parts, and Materials on page 95](#) section) provides an array of integer identifiers for all the features in a solid, thereby offering an alternate way of finding all the features.

## Feature Inquiry

Functions Introduced:

- **`ProFeatureTypeGet()`**
- **`ProFeatureSubtypeGet()`**
- **`ProFeatureTypenameGet()`**
- **`ProFeatureStatusGet()`**
- **`ProFeatureStatusflagsGet()`**
- **`ProFeatureIsIncomplete()`**
- **`ProFeatureIsNcseq()`**
- **`ProFeatureSolidGet()`**
- **`ProFeatureChildrenGet()`**
- **`ProFeatureParentsGet()`**
- **`ProFeatureSelectionGet()`**
- **`ProFeatureHasGeomchks()`**
- **`ProFeatureIsReadonly()`**
- **`ProFeatureIsEmbedded()`**
- **`ProInsertModelIsActive()`**

- **ProFeatureCopyinfoGet()**
- **ProFeatureZoneGet()**
- **ProFeatureZonesectionCreate()**
- **ProFeatureZonesectionGet()**
- **ProZoneReferenceFree()**
- **ProZoneReferenceArrayFree()**
- **ProFeatureZonesectionWithflipCreate()**
- **ProFeatureZoneXsecgeomGet()**
- **ProFeatureZoneXsecGeomArrayFree()**
- **ProModelitemIsZone()**
- **ProFeatureIsInFooter()**
- **ProFeatureToFooterMove()**
- **ProFeatureFromFooterMove()**
- **ProFeatureIsComponentLike()**

As described earlier, the function `ProSolidFeatVisit()` finds all the features belonging to a part or an assembly. The feature inquiry functions provide more information about a particular feature.

The function `ProFeatureTypeGet()` provides the type of the feature. This feature type uses the data type `ProFeattype`, which is really an integer that takes defined values such as the following:

- `PRO_FEAT_FIRST_FEAT`
- `PRO_FEAT_HOLE`
- `PRO_FEAT_SHAFT`
- `PRO_FEAT_ROUND`

See the include file `ProFeatType.h` for the list of defined values.

The function `ProFeatureTypeNameGet()` returns the name of the feature type. Given a `ProFeature` pointer to a specific feature, this function returns the name of the feature type, for example, `CHAMFER`, `DATUM`, `COORDINATE SYSTEM`, and so on. Arguments to this function must not be `NULL`.

The function `ProFeatureSubtypeGet()` provides the subtype (such as sheet metal) of a specified feature. Note that not all features support subtypes. This is like viewing valid model subtypes by opening the **Model Tree** settings command in Creo Parametric. Click **Settings ► Tree Columns** menu and then select **Feat Subtype** in the **Model Tree Columns** dialog box, as an additional display column.

The function `ProFeatureStatusGet()` classifies the feature according to the following status values:

- `PRO_FEAT_ACTIVE`—An ordinary feature.
- `PRO_FEAT_SUPPRESSED`—A suppressed feature.
- `PRO_FEAT_FAMTAB_SUPPRESSED`—A feature suppressed due to the family table settings.
- `PRO_FEAT_SIMP_REP_SUPPRESSED`—A feature suppressed due to the simplified representation.
- `PRO_FEAT_PROG_SUPPRESSED`—A feature suppressed due to Pro/PROGRAM.
- `PRO_FEAT_INACTIVE`—A feature that is not suppressed, but is not currently in use for reasons other than the ones identified above.
- `PRO_FEAT_UNREGENERATED`—A feature that has not yet been regenerated. This is due to a regeneration failure or if the status is obtained during the regeneration process.
- `PRO_FEAT_INVALID`—The feature status could not be retrieved.

The function `ProFeatureStatusflagsGet()` retrieves the bitmask containing one or more of the following feature status bit flags for a specified feature:

- `PRO_FEAT_STAT_INVALID`—Specifies an invalid feature.
- `PRO_FEAT_STAT_INACTIVE`—Specifies an inactive feature. If the bit flag is set to 0, then it means an active feature.
- `PRO_FEAT_STAT_ACTIVE`—Specifies an active feature.
- `PRO_FEAT_STAT_FAMTAB_SUPPRESSED`—Specifies a feature suppressed due to the family table settings.
- `PRO_FEAT_STAT_SIMP_REP_SUPPRESSED`—Specifies a feature suppressed due to the simplified representation.
- `PRO_FEAT_STAT_PROG_SUPPRESSED`—Specifies a feature suppressed due to Pro/PROGRAM.
- `PRO_FEAT_STAT_SUPPRESSED`—Specifies a suppressed feature.
- `PRO_FEAT_STAT_UNREGENERATED`—Specifies an active feature that has not yet been regenerated. This is due to a regeneration failure or if the status is obtained during the regeneration process.
- `PRO_FEAT_STAT_FAILED`—Specifies a failed feature.
- `PRO_FEAT_STAT_CHILD_OF_FAILED`—Specifies a child of a failed feature.
- `PRO_FEAT_STAT_CHILD_OF_EXT_FAILED`—Specifies a child of an external failed feature.

---

The function `ProFeatureIsIncomplete()` tells you whether a specified feature is incomplete. An incomplete feature is one that has been created by using `ProFeatureCreate()` from a Creo TOOLKIT application, but which does not yet contain all the necessary feature elements to allow regeneration.

The function `ProFeatureIsNcseq()` determines whether a feature is a Creo NC sequence.

The `ProFeatureSolidGet()` function provides the identifier of the solid that owns the specified feature.

The `ProFeatureChildrenGet()` and `ProFeatureParentsGet()` functions get the children and parents of the specified feature. For these functions, the parent of a feature means a feature it directly depends on, and a child is a feature that directly depends on it. This differs from the Creo Parametric command **Info ► Feature**, which also shows indirect dependencies.

The function `ProFeatureSelectionGet()` is used for features that were created in a part as a result of a feature in a parent assembly. For example, if you create a hole in Assembly mode, then select a part to be intersected by that hole, the geometry of the hole is visible to Creo TOOLKIT as belonging to the part, even if the original feature is specified as being visible at the assembly level. This geometry—a list of the surfaces forming the hole—belongs to a feature in the part whose type is `PRO_FEAT_ASSEM_CUT`. The function `ProFeatureSelectionGet()`, when applied to that part feature, identifies the assembly, and the path down through it to the part in question, which contains the original feature.

During regeneration, Creo Parametric performs geometry checking to prevent regeneration errors. The geometry check process identifies features that could cause problems if the part or assembly is modified, but which do not cause regeneration failure in the model in its present state. The `ProFeatureHasGeomchks()` function outputs a variable of type `ProBoolean` that indicates whether a particular feature, identified as an input argument to the function, has geometry checks.

The function `ProFeatureIsReadonly()` provides information about the read status of the specified feature. Its first argument is a pointer to the feature's (`ProFeature`) handle. If the feature is read only, the function outputs a `ProBoolean` with the value `PRO_B_TRUE`; otherwise, the value is `PRO_B_FALSE`.

The function `ProFeatureIsEmbedded()` identifies whether the feature is an embedded datum. Embedded features are visible in the model tree, but cannot be used as reference parents for features other than the feature into which they are embedded.

To determine whether insert mode is active in a specified solid, use the function `ProInsertModeIsActive()`. If activated, features are inserted into the feature list after the feature specified when `ProFeatureInsertModeActivate()` was called. New features continue to

---

be inserted until you call the function `ProInsertModeCancel()`. See the section [Manipulating Features on page 144](#) for more information about insert mode.

The function `ProFeatureCopyinfoGet()` returns information about a copied feature. The information includes the type of copy operation, dependency, source feature, and additional features copied in the same operation. This function supersedes the `Pro_copy_info` structure returned by the Pro/Develop function `prodb_feature_info()`.

The function `ProFeatureZoneGet()` returns the following parameters related to a feature zone:

- *p\_planes*—ProArray of planes.
- *p\_oper\_arr*—ProArray of operations; where 0 specifies intersection of half spaces and 1 specifies union of half spaces. Creo Parametric retains the material that belongs to the intersection or union of the half spaces of the planes.

The function `ProFeatureZonesectionCreate()` creates a zone feature handle using reference planes and operations. The input arguments are as follows:

- *p\_solid*—A handle to the model.
- *zone\_refs*—An array of zone reference planes of type `ProZoneReference`. The structure `ProZoneReference` contains the geometric ID of the reference zone plane, the value for the operation, that is, 0 or 1 and the member ID of the part to which the reference plane belongs to. Pass `NULL` to *memb\_id\_tab* if the feature is owned by the part on which the zone is being created.

Creo Parametric retains the material that belongs to the intersection or union of the half spaces of the reference planes.

- *zone\_name*—The name of the zone feature handle. `Feature_InquiryIf` a zone with the specified name exists, then the function returns the error `PRO_TK_E_FOUND` and the zone is not created.

The function `ProFeatureZonesectionGet()` returns the zone references for the specified feature. The output argument *p\_zone\_refs* contains an array of planes of type `ProZoneReferenceWithflip`. The structure `ProZoneReferenceWithflip` contains:

- The geometric ID of the reference zone plane.
- The value for the operation, where 0 specifies intersection of half spaces that is, the AND operator and 1 specifies union of half spaces that is, the OR operator.
- The member ID of the part to which the reference plane belongs.
- The side of the plane where the model is kept. 1 indicates positive normal of the plane and -1 indicates the opposite side.

---

Use the function `ProZoneReferenceFree()` to free the memory allocated to the zone reference data.

Use the function `ProZoneReferenceArrayFree()` to free the `ProArray` of zone reference data.

The function `ProFeatureZonesectionWithflipCreate()` creates a zone feature using reference planes and operations. This function allows you to flip the direction of zone planes while creating the zone feature.

The function `ProFeatureZoneXsecgeomGet()` creates an array of cross section geometry of type `ProXsecGeometry` for each zone plane. It returns an array of these arrays in the specified zone feature. Use the function `ProFeatureZoneXsecGeomArrayFree()` to free the memory allocated for the `ProArray` of `ProArrays` of type `ProXsecGeometry`.

The function `ProModelitemIsZone()` checks if the specified model item is a zone feature. Specify the handle to the model item as the input argument of this function.

Use the function `ProFeatureIsInFooter()` to check if the specified feature is currently located in the model tree footer. The footer is a section of the model tree that lists certain types of features such as, component interfaces, annotation features, zones, reference features, publish geometry, and analysis feature. The features in the footer are always regenerated at the end of the feature list. You can move features, such as, reference features, annotation features, and so on, to the footer. Some features, such as, component interfaces, zones, and so on, are automatically placed in the footer. Refer to the Creo Parametric online Help for more information on footer. Refer to the Creo Parametric online Help for more information on footer.

Use the function `ProFeatureToFooterMove()` to move the specified feature into the model tree footer.

Use the function `ProFeatureFromFooterMove()` to move the specified feature out of the model tree footer.

Some features behave like components because they have some properties that are similar to those of components. These features have some association with a solid model and are interpreted as placed components. When a component is placed it means it has been explicitly positioned at some location in the assembly.

Examples of such features are solid welds, physical sensors, and so on. Solid welds organize their geometry as a special internal solid model, which gives them component-like characteristics. Similarly, physical sensors represent actual hardware that is placed on the model to measure parameters. Use the function `ProFeatureIsComponentLike()` to identify components and other features that behave like components. Refer to the section [Assembly: Basic Assembly Access on page 1115](#) for more information on placed components.

---

## Feature Geometry

Functions Introduced:

- **ProFeatureGeomitemVisit()**
- **ProGeomitemFeatureGet()**

For information about feature geometry, see section [Core: 3D Geometry](#) on page 177.

## Manipulating Features

Functions Introduced:

- **ProFeatureDelete()**
- **ProFeatureSuppress()**
- **ProFeatureResume()**
- **ProFeatureRedefine()**
- **ProFeatureInsertModeActivate()**
- **ProInsertModeCancel()**
- **ProFeatureReadonlySet()**
- **ProFeatureReadonlyUnset()**
- **ProFeatureReorder()**
- **ProFeatureNumberGet()**

The functions `ProFeatureDelete()` and `ProFeatureSuppress()` act like the right-mouse button Creo Parametric commands **Delete** and **Suppress**, except they do not repaint the window. You can process many features in a single call using an input of type `ProFeatlist`. Each of these functions takes an array of options as the input that indicates whether to also delete or suppress features dependent on those being acted on directly. The options used while deleting or suppressing features are as follows:

- `PRO_FEAT_DELETE_NO_OPTS`—Delete or suppress the features without deleting or suppressing their dependent children features. This may result in regeneration failures. Use the option `PRO_FEAT_DELETE_FIX`, or one of the `CLIP` options to fix these failures.
- `PRO_FEAT_DELETE_CLIP`—Delete or suppress the features along with their dependent children features.
- `PRO_FEAT_DELETE_FIX`—Delete or suppress the features without deleting or suppressing their dependent children features. The fix model user interface will be prompted in case of a regeneration failure. This option must be used

---

only in the Resolve mode. Otherwise, the function returns `PRO_TK_BAD_CONTEXT`.

- `PRO_FEAT_DELETE_RELATION_DELETE`—Delete relations with obsolete dimensions.
- `PRO_FEAT_DELETE_RELATION_COMMENT`—Change relations with obsolete dimensions into comments.
- `PRO_FEAT_DELETE_CLIP_ALL`—Delete or suppress the features along with all the following features.
- `PRO_FEAT_DELETE_INDIV_GP_MEMBERS`—Individually delete or suppress the features out of the groups to which they belong. If this option is not included, the entire group of features is deleted or suppressed. This option can be included only if the option `PRO_FEAT_DELETE_CLIP` is also included.
- `PRO_FEAT_DELETE_CLIP_INDIV_GP_MEMBERS`—Individually delete or suppress the children of features out of the group to which they belong. If this option is not included, the entire group containing the features and their children is deleted or suppressed. This option can be included only if the options `PRO_FEAT_DELETE_CLIP` and `PRO_FEAT_DELETE_INDIV_GP_MEMBERS` are also included.
- `PRO_FEAT_DELETE_KEEP_EMBED_DATUMS`—Retain the embedded datums stored in a feature while deleting the feature using `ProFeatureDelete()`. If this option is not included, the embedded datums will be deleted along with the parent feature.

The function `ProFeatureRedefine()` is equivalent to the Creo Parametric command **Feature>Redefine**. Additionally, it can redefine an existing feature with the new element tree. The data passed in through the new element tree replaces the existing data in the feature.

Creo TOOLKIT provides access to the Creo Parametric feature insert mode functionality with the `ProFeatureInsertModeActivate()` and `ProInsertModeCancel()` functions. The function `ProFeatureInsertModeActivate()` takes a single argument—the handle to the feature after which new features are to be inserted. This feature becomes the last feature in the feature regeneration list. All features that had appeared after that feature are temporarily suppressed. New features are added after the (new) last feature. Feature insertion continues until insert mode is terminated with a call to `ProInsertModeCancel()`. Its first argument is a handle to the solid, and the second is a `ProBoolean` that enables you to specify whether suppressed features are to be resumed.

The function `ProFeatureReadOnlySet()` assigns a read-only status to model features. Its only argument is a `ProFeature` handle that specifies the last feature in the feature list to be designated as read only. All preceding features are

---

read only; all features following this feature have standard access. From Creo Parametric 3.0 onward, the features that are made read-only appear under a separate container node at the top of the model tree. The node has its label as **Read Only Features** and also has a padlock glyph associated with it.

The function `ProFeatureReadonlyUnset()` removes the read-only status from all features in the specified solid. From Creo Parametric 3.0 onward, the container node **Read Only Features** is dismissed from the model tree when the read-only status is removed.

The function `ProFeatureReorder()` enables you to change the position of one or more features in the feature regeneration sequence. Its input arguments are as follows:

- `ProSolid solid`—The handle to the solid owner of the features.
- `int *feat_ids`—An array of feature identifiers that specifies the features to be reordered. The array should contain features that formed a contiguous sublist within the original feature regeneration list. If reordering a group, all the features in the group including the Group Header feature must be included in this array.
- `int n_feats`—The number of features to reorder.
- `int new_feat_num`—An integer that indicates the intended location of the first feature in the specified set after reorder. This integer is not the feature identifier, but rather the regeneration sequence number of the feature. You obtain this number by calling the function `ProFeatureNumberGet()`.

Use the function `ProSolidFeatstatusGet()` to get the current sequence and statuses. You must use care when you change the sequence of features. Unless you have advance knowledge of the relationship between the features you are reordering, you should use the functions `ProFeatureParentsGet()` and `ProFeatureChildrenGet()` before changing the feature order to ensure that no feature is reordered to be before its parent features.

## Manipulating Features based on Regeneration Flags

Functions Introduced:

- **`ProFeatureWithoptionsCreate()`**
- **`ProFeatureWithoptionsDelete()`**
- **`ProFeatureWithoptionsSuppress()`**
- **`ProFeatureWithoptionsResume()`**
- **`ProFeatureWithoptionsRedefine()`**
- **`ProFeatureWithoptionsReorder()`**
- **`ProFeatureInsertmodeWithoptionsActivate()`**

- **ProFeatureInsertmodeWithoptionsUpdate()**
- **ProInsertmodeWithoptionsCancel()**

The functions in this section enable you to create, delete, or manipulate the specified features in a solid, based on the bitmask specified by the input argument *flags*. The bitmask must contain one or more regeneration control bit flags of the type `PRO_REGEN_*` defined in `ProSolid.h`. Refer to the [Regenerating a Solid on page 99](#) topic in the [Core: Solids, Parts, and Materials on page 95](#) section for more information on the bit flags.

From Pro/ENGINEER Wildfire 5.0 onwards, the functions listed above supersede the following functions described in the [Manipulating Features on page 144](#) section.

- `ProFeatureCreate()`
- `ProFeatureDelete()`
- `ProFeatureSuppress()`
- `ProFeatureResume()`
- `ProFeatureRedefine()`
- `ProFeatureReorder()`
- `ProFeatureInsertModeActivate()`
- `ProInsertModeCancel()`

Use the superseding functions with the input argument *flags* set to `PRO_REGEN_NO_FLAGS` for the behavior that is similar to the one provided by the above deprecated functions.

The function `ProFeatureInsertmodeWithoptionsUpdate()` updates insert mode such that the specified feature becomes the last feature. The input arguments follow:

- *p\_last\_feat*—the last feature. All the features after this feature are detached. Feature creation will resume after the update of the insert mode and are created after this specified last feature. If you cancel the insert mode, the detached features are added at the end.
- *flags*—the regeneration control flags. Pass as bitmask containing one or more of the bit flags `PRO_REGEN*` defined in `ProSolid.h`.

## Feature References

Functions Introduced:

- **ProFeatureReferenceEdit()**
- **ProMdlFeatBackupOwnerNamesGet()**
- **ProMdlFeatBackupRefMdlNamesGet()**

- **ProFeatureReferenceEditRefsGet()**
- **ProFeatureMdltreeDisplaynameGet()**

The function `ProFeatureReferenceEdit()` replaces the old references of a feature with new references based on the bitmask specified for its input argument *flags*. The bitmask must contain one or more regeneration control bit flags of the type `PRO_REGEN_*` defined in `ProSolid.h`. Refer to the [Regenerating a Solid on page 99](#) topic in the [Core: Solids, Parts, and Materials on page](#) section for more information on the bit flags.

The function `ProMdlFeatBackupOwnerNamesGet()` returns the names of the models, along the model path, from the top model to the owner model for the specified feature. The input arguments are:

- *model*—Specifies the model, which contains the specified feature.
- *feature*—Specifies a feature whose references are to be retrieved.

The function `ProMdlFeatBackupRefMdlNamesGet()` returns the names of the models, along the model path, from the top model to the external reference model for the specified feature. Feature references can be from a local or external model. The system creates a geometry backup of the local and external references, which is used for information and display purposes. This function retrieves the model names from the backup information. The input arguments are:

- *model*—Specifies the model, which contains the specified feature.
- *feature*—Specifies a feature whose references are to be retrieved.
- *path*—Specifies the path as a `ProArray` of IDs of a subassembly or component from the top model to the reference model. Specify `NULL` for local reference.

To give an example on how to specify the path, consider an assembly A, which has a component C1 with ID 9 and a subassembly S with ID 7. The subassembly S has a component C2 with ID 11. If a feature under C1 references an object in the model of C2, the reference ID path must contain two IDs 7 and 11.

- *ref\_id*—Specifies the ID of the external reference, which is referenced in the specified feature.

Refer to the Creo Parametric Assembly Design online help for more information on references and backup data.

The function `ProFeatureReferenceEditRefsGet()` returns an array of the original references of a feature that are used to perform the edit reference operation. The input arguments follow:

- *solid*—The part or assembly to which the features belong.
- *p\_feat\_handle*—The feature handle.

- 
- *flags*—Indicates the type of references to collect. To collect all types of references, set the value to `PRO_EDITREF_REF_TYPE_ALL`.

The function returns the output argument `r_orig_ref_arr` as a `ProArray` of all the original references.

Use the function `ProReferencearrayFree()` to free the memory.

Use the function `ProFeatureMdltreeDisplaynameGet()` to retrieve the name of the node displayed in the model tree.

## Feature Dimensions

Function Introduced:

- **ProFeatureDimensionVisit()**

The function `ProFeatureDimensionVisit()` visits all the dimensions which belong to the feature.

### Note

Some feature dimensions are dependent on dimensions of other features. For example, sketch-based features with shared, patterned or external sections, dependent copied or mirrored features, and so on. In case of such dependent dimensions, use the function `ProDimensionParentGet()` to get the value of the parent dimension .

---

For more information about dimensions, refer to [Dimensions on page 579](#) from the section [Annotations: Annotation Features and Annotations on page 555](#).

## Manipulating\_Patterns

### Patterns as Features

From the Pro/ENGINEER Wildfire release, the following changes are implemented in patterns.

Patterns are treated as features in Creo Parametric. Patterns are assigned a header feature of the type `PRO_E_PATTERN_HEAD`.

The Pattern feature in Pro/ENGINEER Wildfire effects the previous releases of Pro/ENGINEER as follows:

- Models containing patterns automatically get one extra feature of type `PRO_FEAT_PATTERN_HEAD` in the regeneration list. This changes the feature numbers of all the subsequent features, including those in the pattern.

- The pattern access functions such as `ProFeaturePatternGet()`, `ProPatternMembersGet()` and `ProPatternLeaderGet()` are unaffected by the addition of the pattern header feature. The pattern leader is still the first geometric feature contained in the pattern.

The new function `ProPatternHeaderGet()` returns the header feature.

## Fill Patterns

Creo Parametric uses the Fill type of pattern.

Functions Introduced:

- **`ProFeaturePatternStatusGet()`**
- **`ProFeatureGrppatternStatusGet()`**
- **`ProFeaturePatternleaderGet()`**
- **`ProFeaturePatternGet()`**
- **`ProPatternDelete()`**
- **`ProPatternLeaderGet()`**
- **`ProPatternHeaderGet()`**

The function `ProFeaturePatternStatusGet()` classifies the feature according to its possible role in a feature pattern. The possible values are as follows:

- `PRO_PATTERN_NONE`—The feature is not in a pattern.
- `PRO_PATTERN_LEADER`—The feature is the leader of a pattern.
- `PRO_PATTERN_MEMBER`—The feature is a member of a pattern.
- `PRO_PATTERN_HEADER`—The feature is the header of a pattern.

The function `ProFeatureGrppatternStatusGet()` does the equivalent for group patterns. The possible values are as follows:

- `PRO_GRP_PATTERN_NONE`—The feature is not in a group pattern.
- `PRO_GRP_PATTERN_LEADER`—The feature is the leader of a group pattern.
- `PRO_GRP_PATTERN_MEMBER`—The feature is a member of a group pattern.
- `PRO_GRP_PATTERN_HEADER`—The feature is the header of a group pattern.

The function `ProFeaturePatternleaderGet()` returns the pattern leader feature for the specified pattern member feature.

The function `ProFeaturePatternGet()` obtains the `ProPattern` handle for the pattern containing the specified feature. (The `ProPattern` handle is described in detail in the section [Element Trees: Patterns on page 964](#).)

---

To delete a pattern, pass the corresponding `ProPattern` handle to the function `ProPatternDelete()`.

To obtain the leader feature for a given pattern, pass a `ProPattern` object to the function `ProPatternLeaderGet()`.

To obtain the header feature for a given pattern, pass a `ProPattern` object to the function `ProPatternHeaderGet()`.

To access pattern information use the pattern element tree described in section [Element Trees: Patterns on page 964](#). You can access element tree information using the functions `ProElement*`, described in the section [Element Trees: Principles of Feature Creation on page 771](#).

## Table-Driven Patterns

The Table-Driven Pattern functions have been deprecated. Use the Table Pattern feature element tree to read and manipulate table patterns. See the topic [Table Patterns on page 970](#) for more details.

## Creating Local Groups

Function Introduced:

- **ProLocalGroupCreate()**

Local groups offer a way to collect several features together as if they were one feature. This functionality is particularly useful when you are creating patterns.

The function `ProLocalGroupCreate()` groups together features specified by an array of feature identifiers. The output of `ProLocalGroupCreate()` is the object `ProGroup`, which is a typedef of a structure similar to `ProFeature`.

The feature identifiers passed to `ProLocalGroupCreate()` must correspond to features that possess consecutive regeneration numbers. That is, the feature identifiers can have any values, but the corresponding features must occupy a contiguous portion of the regeneration list. (To see the regeneration number of a feature, add the column `Feat #` to the model tree.)

If there are features whose regeneration numbers lie between those belonging to the features to be grouped, Creo Parametric asks the user whether these unspecified features are to be included in the group. If the user responds with `No`, the group is not created.

After you create a local group, you may want to refresh the model tree to see the changes. To refresh the model tree, call `ProTreetoolRefresh()`.

---

## Read Access to Groups

Groups in Creo Parametric represent sets of contiguous features that act as a single feature for purposes of some operations. While the individual features can be affected by most operations individually, certain operations apply to the entire group:

- Suppress
- Delete
- Layer operations
- Patterning operations

For more information about local groups, see the *Part Modeling User's Guide*.

User-Defined Features (UDFs) are groups of features that can be stored in a file. When a UDF is placed in a new model, the features created are automatically assigned to a group.

A local group is a set of features that have been explicitly assigned to a group, for purposes of ease of modification or patterning.

---

### Note

All the functions in this section work for both UDFs and local groups.

---

Each instance of a group is identified in Creo TOOLKIT as a `ProGroup` structure. This structure is the same as a `ProFeature` data handle:

```
typedef struct pro_model_item {
 ProMdl owner;
 int id;
 ProType type;
} ProGroup;
```

The integer `id` in this case is the id of the group header feature, which is the first feature in the group. All groups, including those in models created before release 200i2, are assigned with a group header feature upon retrieval.

The consequences of the group header feature for users of previous versions of Pro/TOOLKIT is as follows:

- Models that contain groups automatically get one extra feature in the regeneration list, of type `PRO_FEAT_GROUP_HEAD`. This changes the feature numbers of all subsequent features, including those in the group.
- Each group automatically contains one new feature in the arrays returned by Pro/TOOLKIT.

- 
- Each group automatically gets a different leader feature (the group head feature is the leader). The leader is the first feature in the arrays returned by Pro/TOOLKIT.
  - Each group pattern contains, of course, a series of groups, and each group in the pattern is similarly altered.

## Finding Groups

Functions Introduced:

- **ProSolidGroupVisit()**
- **ProSolidGroupsCollect()**
- **ProFeatureGroupStatusGet()**
- **ProFeatureGroupGet()**

The function `ProSolidGroupVisit()` allows you to visit the groups in the solid model. The function `ProSolidGroupsCollect()` returns an array of the group structures.

The function `ProFeatureGroupStatusGet()` tells you if the specified feature is in a group.

The function `ProFeatureGroupGet()` returns the `ProGroup` that includes the feature.

## Group Information

Functions Introduced

- **ProUdfNameGet()**
- **ProGroupIsTableDriven()**
- **ProGroupFeatureVisit()**
- **ProGroupFeaturesCollect()**
- **ProUdfDimensionVisit()**
- **ProUdfDimensionsCollect()**
- **ProUdfDimensionNameGet()**

The function `ProUdfNameGet()` returns the name of the group. For a local group, this is the name assigned upon creation. For a UDF-created group, this is the name of the UDF file. If the UDF is an instance in a UDF family table, the function also returns the instance name.

The function `ProGroupFeatureVisit()` traverses the members of the feature group. The function `ProGroupFeaturesCollect()` returns an array containing the feature handles.

---

The function `ProUdfDimensionVisit()` traverses the variable dimensions used in the creation of the UDF (this is only applicable to UDF-created groups). The function `ProUdfDimensionsCollect()` returns an array of the variable dimensions. The variable dimensions are the dimensions that Creo Parametric prompts for when you create the UDF.

The function `ProUdfDimensionNameGet()` returns the original dimension symbol for the variable dimension in the UDF. This symbol is different from the symbol assigned to the dimension in the group.

---

 **Note**

In Creo Parametric 6.0.0.0 and later, for the function `ProUdfDimensionNameGet()`, it is mandatory to pass the input argument *udf* as `ProGroup` object type. If you pass any other object type, the function returns the `PRO_TK_BAD_CONTEXT` error.

---

## Creating Groups

Functions Introduced:

- **ProLocalGroupCreate()**

The function `ProLocalGroupCreate()` creates a group out of a set of specified features. The features must represent a contiguous set of features in the solid model. (Refer also to [Creating Local Groups on page 151](#)).

## Deleting Groups

Functions Introduced:

- **ProGroupUngroup()**
- **ProGroupUngroupPreAction()**
- **ProGroupUngroupPostAction()**

The function `ProGroupUngroup()` removes the indicated group and deletes the group header feature.

The function prototype `ProGroupUngroupPreAction()` should be used for a notification corresponding to the `ProNotifyType` `PRO_GROUP_UNGROUP_PRE`. This callback will be called just before the user ungroups an existing local group or UDF group in the user interface. If the application returns an error from this callback, ungroup activity will be prevented (thus providing a means by which UDFs or other groups may be effectively locked). If ungroup is being cancelled by the application, the application is required to provide an informational message to the user explaining this action.

---

The function prototype `ProGroupUngroupPostAction()` should be used for a notification corresponding to the `ProNotifyType` `PRO_GROUP_UNGROUP_POST`. This prototype provides information about the group that was just ungrouped:

- *solid*—The solid model that owns the group.
- *group\_id*—The former group feature id.
- *udf\_name*—The name of the UDF the group was created from.
- *feature\_list*—The feature ids that were members of the group.

## Updating or Replacing UDFs

This section lists operations, which you can perform on UDFs.

Functions Introduced:

- **ProUdfUpdate()**
- **ProUdfReplace()**
- **ProUdfFileIsPreCreo7()**

The function `ProUdfUpdate()` updates a dependent UDF to the latest version of the `.gph` file. The function should be able to locate the `.gph` file from within the session or by the search path. Only dependent UDFs are updated from their original definitions.

Use the function `ProUdfReplace()` to replace a UDF placement with a similar UDF provided that the two UDF's must use the same reference types. The input to the function can include data that would be used to respond to prompts shown during an interactive replacement (for items like scale, dimension display and orientation prompts).

The function `ProUdfFileIsPreCreo7()` identifies if the `.gph` file is created or modified in a release earlier than Creo Parametric 7.0.0.0. The input argument *gph\_path* is the path to the `.gph` file.

If the `.gph` file is created or modified in a release earlier than Creo Parametric 7.0.0.0, the function outputs a `ProBoolean` with the value `PRO_B_TRUE`; otherwise, the value is `PRO_B_FALSE`.

## Placing UDFs

Function Introduced:

- **ProUdfCreate()**

The function `ProUdfCreate()` is used to create a new group by retrieving and applying the contents of an existing UDF file. It is equivalent to the Creo Parametric command **Model ► User-Defined Feature**.

---

To understand this function explanation, you must have a good knowledge and understanding of the use of UDFs in Creo Parametric. PTC recommends that you read about UDFs in the *Part Modeling User's Guide*, and practice defining and using UDFs in Creo Parametric before you attempt to use this function.

When you create a UDF interactively, Creo Parametric prompts you for the information it needs to fix the properties of the resulting features. When you create a UDF from Creo TOOLKIT, you can provide some or all of this information programmatically by assembling the data structure that is the input to the function `ProUdfCreate()`.

During the call to `ProUdfCreate()`, Creo Parametric prompts you for the following:

- Any information the UDF needs that you did not provide in the input data structure
- Correct information to replace erroneous information

Such prompts are a useful way of diagnosing errors when you develop your application. This also means that, in addition to creating UDFs fully programmatically to provide automatic synthesis of model geometry, you can also use `ProUdfCreate()` to create UDFs semi-interactively. This can simplify the interactions needed to place a complex UDF, making it easier for the user and less prone to error.

Creating a UDF may require the following types of information:

- Name—The name of the UDF library to create, and the instance name, if applicable.
- Name or path—the name (or full path) of the UDF to create, and the instance name, if applicable.
- Dependency—Whether the UDF is independent of the UDF definition, or is modified by changes made to it.
- Scale—How to scale the UDF relative to the placement model.
- Variable parameters—The new values of the variable parameters allowed to be changed during UDF placement.
- Variable annotations—The new values of the variable gtol values, surface finish values and dimension tolerances allowed to be changed during UDF placement.
- Variable dimensions—The new values of the variable dimensions and pattern parameters; those whose values can be modified each time the UDF is created.
- Dimension display—Whether to show or blank non-variable dimensions created within the UDF group.
- References—The geometrical elements (surfaces, edges, datum planes, and so on) that the UDF needs to relate the features it contains to the existing model

---

features. The elements correspond to the picks that Creo Parametric prompts you for when you create the UDF interactively (using the prompts defined when the UDF was set up). You cannot select an embedded datum as the UDF reference.

- **Part intersections**—If the UDF is being created in an assembly and contains features that modify existing solid geometry, you need to define which parts in the assembly are to be affected (or "intersected"), and at which level in the assembly each such intersection is to be visible.
- **Orientations**—If a UDF contains a feature whose direction is defined with respect to a datum plane (for example, a hole feature that uses a datum plane at its placement plane), Creo Parametric needs to know in which direction the new feature is to point (that is, on which side of the datum plane it should lie). When you create such a UDF interactively, Creo Parametric prompts you for this orientation with a flip arrow.
- **Quadrants**—If a UDF contains a linearly placed feature that references two datum planes to define its location (in the new model), Creo Parametric prompts you to pick the location of the new feature. This decides on which side of each datum plane the feature must lie. This choice is referred to as the "quadrant," because there are four combinations of possibilities for each linearly placed feature.
- **External symbols**—The parameter or dimension to use in place of a missing external symbol from a note callout or relation.
- **Copied model names**—If a UDF creates components in an assembly, this argument specifies the names of the new copied components that the placement creates.

The function `ProUdfCreate()` takes the following arguments:

- *solid*—The solid model (part or assembly) on which to place the UDF.
- *data*—The UDF creation data, described below.
- *asm\_reference*—An external reference assembly for calculating intersections and external references.
- *options*—An array of option flags.
- *n\_options*—The size of the options array.

## The UDF Input Data Structure `ProUdfdata`

Most of the input needed by the function `ProUdfCreate()` is contained in the single `ProUdfdata` structure. This structure can be assembled using the `ProUdfdata` functions.

---

The options in the data structure correspond closely to the prompts Creo Parametric gives you when you create a UDF interactively. PTC strongly recommends that before you write the Creo TOOLKIT code to fill the structure, you experiment with creating the UDF interactively using Creo Parametric, noting what prompts it gives you, and use this as a guide to the information you need to provide.

Functions Introduced:

- **ProUdfdataAlloc()**
- **ProUdfdataFree()**
- **ProUdfdataNameSet()**
- **ProUdfdataPathSet()**
- **ProUdfdataInstancenameSet()**
- **ProUdfdataDependencySet()**
- **ProUdfdataScaleSet()**
- **ProUdfdataDimdisplaySet()**
- **ProUdfdataOrientationAdd()**
- **ProUdfdataQuadrantAdd()**

The function `ProUdfdataAlloc()` allocates memory for the `ProUdfdata` structure. The function `ProUdfdataFree()` frees the data structure memory.

The function `ProUdfdataNameSet()` allows you to set the name of the UDF (the root of the file name) to create and, optionally, the instance in the UDF family table to use.

Use the function `ProUdfdataPathSet()` to set the path of the UDF file. `ProUdfCreate()` will use the input from this path, if set, otherwise the data from `ProUdfdataNameSet()` is used.

Use function `ProUdfdataInstancenameSet()` to assign the instance to be used when placing this UDF.

The function `ProUdfdataDependencySet()` specified the dependency of the UDF. The choices correspond to the choices available when you create the UDF interactively. The default for this option, if not explicitly specified, is to create the group independent of the UDF definition.

The function `ProUdfdataScaleSet()` specifies how to modify the dimensions of the UDF with respect to the placement model. The choices correspond to the options presented when you create the UDF interactively. A value for a user-defined scale can also be specified by this function. The default for this option, if not explicitly specified, is to use the same size for the UDF, regardless of the units of the placement model.

---

The function `ProUdfdataDimdisplaySet()` specifies how to present the non-variable dimensions in the created group. These values correspond to the options presented in Creo Parametric when placing the UDF interactively. The default for this option, if not explicitly specified, is to display the dimensions normally (allowing modification).

The function `ProUdfdataOrientationAdd()` adds to an array of orientation choices. These orientation options answer the Creo Parametric prompts that propose a flip arrow (presented, for example, when using datum planes as a reference). There should be one orientation answer presented for each prompt in Creo Parametric, and the order of the options should correspond to the order as presented in Creo Parametric. If an orientation option is not provided, the value “no flip” is applied.

The function `ProUdfdataQuadrantAdd()` adds to an array of 3-dimensional points that correspond to the picks answering the Creo Parametric prompts for the feature positions. The quadrant is requested when placing a hole or a shaft with respect to two datum planes if the UDF references were also datum planes. The order of quadrants specified should correspond to the order in which Creo Parametric prompts for them when the UDF is created interactively.

## Variable Parameters and Annotations

The data structure for both variable parameters and annotations is `ProUdfvarparam`.

Functions Introduced:

- **`ProUdfvarparamAlloc()`**
- **`ProUdfdataVarparamAdd()`**
- **`ProUdfvarparamValueSet()`**
- **`ProUdfvarparamFree()`**

The function `ProUdfvarparamAlloc()` allocates a UDF variable parameter or annotation structure which describes a variable parameter or annotation. The input arguments of this function are:

- *name*—Specifies the parameter name. If it represents a variable annotation, then this must be one of the standard annotation parameter names:
  - `PTC_GTOL_PRIMARY_TOL`—gtol value
  - `PTC_ROUGHNESS_HEIGHT`—surface finish value
  - `PTC_DIM_TOL_VALUE`—dimension symmetric tolerance value
  - `PTC_DIM_UPPER_TOL_VALUE`—upper dimension tolerance
  - `PTC_DIM_LOWER_TOL_VALUE`—lower dimension tolerance

- *item*—Specifies the owner item. This item must have type and id filled out. (The owner field is ignored by Creo Parametric). The following types are allowed here:

- PRO\_FEATURE
- PRO\_ANNOTATION\_ELEM

Use the function `ProUdfdataVarparamAdd()` to add information about a variable parameter assignment to the UDF data.

The function `ProUdfvarparamValueSet()` assigns the value to be used for a variable parameter or annotation value when the UDF is placed. Note: you still must add the variable parameter to the UDF data using `ProUdfdataVarparamAdd()`.

Use the function `ProUdfvarparamFree()` to free the UDF variant parameter handle.

## Variable Dimensions and Pattern Parameters

The data structure for variable dimensions and pattern parameters is `ProUdfvardim`.

Functions Introduced:

- **ProUdfvardimAlloc()**
- **ProUdfdataUdfvardimAdd()**
- **ProUdfvardimValueSet()**
- **ProUdfvardimFree()**

The function `ProUdfvardimAlloc()` sets the values used to determine the variant dimension value. This function requires the following inputs:

- *dim\_name*—The symbol that the dimension or pattern parameter had when the UDF was originally defined; not the prompt that the UDF uses when interactively created. To make the name easy to remember, modify the symbols of all the dimensions that you want to select to be variable before you define the UDF that you plan to create with Creo TOOLKIT.

If you do not remember the name, find it by creating the UDF interactively in a test model and then using the Creo TOOLKIT functions `ProUdfDimensionVisit()` and `ProUdfDimensionNameGet()` on the resulting UDF.

If you get the name wrong, `ProUdfCreate()` does not recognize the dimension and prompts the user for the value.

- *value*—The new value of the dimension or pattern parameter.
- *type*—This enumerated type takes one of the following values:

- 
- `PROUDFVARTYPE_DIM`—For a dimension.
  - `PROUDFVARTYPE_IPAR`—For a pattern parameter.

The function `ProUdfdataUdfvardimAdd()` adds a variant dimension data structure to the UDF creation data.

The function `ProUdfvardimValueSet()` assigns the value to be used for a variable dimension value when the UDF is placed.

---

 **Note**

The variant dimension must be added to the UDF data structure using `ProUdfdatavardimAdd()` in order for it to be used during placement.

---

Use the function `ProUdfvardimFree()` to free the UDF variant dimension handle.

## UDF References

Functions Introduced:

- **`ProUdfreferenceAlloc()`**
- **`ProUdfdataReferenceAdd()`**
- **`ProUdfreferenceFree()`**

The function `ProUdfreferenceAlloc()` creates a new reference data structure. The data that must be provided to allocate the structure is:

- *prompt*—The prompt defined for this reference when the UDF was originally set up. It indicates which reference this structure is providing.
- *ref\_item*—A `ProSelection` object representing the geometry to use as the reference. You can allocate an embedded datum as the UDF reference. If the reference is external, the selection component path should represent the path to the owning model relative to the external reference assembly specified in the call to `ProUdfCreate()`. If this reference item refers to an annotation reference, you can pass `NULL` to make the placed annotation incomplete.
- *external*—`PRO_B_TRUE` if the reference is external, and `PRO_B_FALSE` if it is internal.
  - Internal—The referenced element belongs directly to the model that contains the UDF. For an assembly, this means that the element belongs to the top-level assembly.
  - External—The referenced element belongs to an assembly member other than the placement member.

---

The function `ProUdfdataReferenceAdd()` adds the reference structure to the `ProUdfdata` structure.

Use the function `ProUdfreferenceFree()` to free the UDF reference handle.

## Assembly Intersections

The data structure used for assembly intersections is `ProUdfintersection`.

Functions Introduced:

- **`ProUdfintersectionAlloc()`**
- **`ProUdfdataIntersectionAdd()`**
- **`ProUdfintersectionFree()`**

The function `ProUdfintersectionAlloc()` sets the values used to determine how a UDF placed in the context of an assembly intersects the members of the assembly. This function requires the following inputs:

- *intersect\_part*—The component path from either the placement assembly or the external reference assembly down to the intersected component. The external reference assembly is provided by the *asm\_reference* argument to `ProUdfCreate()`.
- *visibility*—The depth of the component path into the assembly where the intersected UDF is visible. If visibility is equal to the length of the component path, the feature is visible in the part that it intersects and all assemblies and subassemblies. If visibility is 0, the feature is only visible in the top-level assembly.
- *instance\_names*—An array of names for the new instances of parts created to represent the intersection geometry.

The function `ProUdfdataIntersectionAdd()` adds the intersection structure to the `ProUdfdata` structure.

Use the function `ProUdfintersectionFree()` to free the UDF intersection handle.

## External Symbol: Parameters

The data structure for external symbol parameters is `ProUdfextparam`.

Functions Introduced:

- **`ProUdfextparamAlloc()`**
- **`ProUdfdataExtparamAdd()`**
- **`ProUdfextparamFree()`**

---

The function `ProUdfextparamAlloc()` allocates and sets a `ProUdfextparam` structure, which describes an external symbol referencing a parameter. The input arguments of this function are:

- *prompt*—The prompt for the external parameter symbol.
- *parameter*—The parameter which is used to resolve this external symbol in the placement model.

Use the function `ProUdfdataExtparamAdd()` to add information about an external symbol parameter to the UDF data. Use the function `ProUdfextparamFree()` to free the UDF external parameter handle.

## External Symbol: Dimensions

The data structure for external symbol dimensions is `ProUdfextdim`.

Functions Introduced:

- **`ProUdfextdimAlloc()`**
- **`ProUdfdataExtdimAdd()`**
- **`ProUdfextdimFree()`**

Use the function `ProUdfextdimAlloc()` to allocate and set a structure which describes an external dimension symbol required by the UDF. The input arguments of this function are:

- *prompt*—Specifies the prompt used for this external symbol.
- *dimension*—Specifies the dimension handle to be used to resolve the external symbol in the placement model.

Use the function `ProUdfdataExtdimAdd()` to add information about a required external dimension symbol to the UDF data. Use the function `ProUdfextdimFree()` to free the UDF dimension external symbol handle.

## Copied Model Names

The data structure used for specifying new component model names is `ProUdfmdlNames`.

Functions Introduced:

- **`ProUdfmdlMdlNamesAlloc()`**
- **`ProUdfmdlNamesSet()`**

The function `ProUdfmdlMdlNamesAlloc()` sets the values used to determine the names of new components created by the UDF placement. This function requires the following inputs:

- *old\_name*—The old name of the component.

- 
- *new\_name*—The new name of the component to be created.

The function `ProUdfmdlNamesSet()` adds the model names structure to the `ProUdfdata` structure.

## Reading UDF Properties

The functions in this section provide the ability to read the options for placement directly from a UDF file (a `.gph` file) in order for an application to decide at runtime the inputs it will use for placing a given UDF. The following functions operate on `ProUdfdata`. These functions are capable of reading properties from the UDF file so long as the UDF name or path has already been set by `ProUdfdataNameSet()` or `ProUdfdataPathSet()`.

Some of the data retrieved by the functions in this section uses the same data types as the corresponding `ProUdfdata` set functions used for placing the UDF (as listed in the earlier section). However, data that you read out of the `ProUdfdata` is not related to data that you are using to place the UDF. You must explicitly pass each piece of data to the `ProUdfdata` functions if you want the UDF to be placed with this information.

## Variable Dimensions

Functions Introduced:

- **`ProUdfdataVardimsGet()`**
- **`ProUdfvardimNameGet()`**
- **`ProUdfvardimPromptGet()`**
- **`ProUdfvardimDefaultvalueGet()`**

Use the function `ProUdfdataVardimsGet()` to obtain an array of available variant dimensions that may be set when placing this UDF. You can use the function `ProUdfvardimProarrayFree()` to free this `ProArray` of variant dimensions.

---

### Note

The handles obtained when the function `ProUdfdataVardimsGet()` is called are not automatically assigned to the UDF for placement. In order to place the UDF with a user-defined variant dimension value, you must use `ProUdfdataVardimAdd()`.

---

Use the function `ProUdfvardimNameGet()` to obtain the symbol of the variant dimension. This symbol of the dimension in the reference model should be used in `ProUdfvardimAlloc()`.

---

Use the function `ProUdfvardimPromptGet()` to obtain the prompt of the variant dimension.

Use the function `ProUdfvardimDefaultvalueGet()` to obtain the default value for the variant dimension.

## Variable Parameters

Functions Introduced:

- **`ProUdfdataVarparamsGet()`**
- **`ProUdfvarparamOwnerGet()`**
- **`ProUdfvarparamNameGet()`**
- **`ProUdfvarparamDefaultvalueGet()`**
- **`ProUdfvarparamProarrayFree()`**

Use the function `ProUdfdataVarparamsGet()` to obtain an array of available variant parameters and/or annotation values that can optionally be set when placing this UDF. You can use the function `ProUdfvarparamProarrayFree()` to free this `ProArray` of variant items.

### Note

The handles obtained when the function `ProUdfdataVarparamsGet()` is called are not automatically assigned to the UDF for placement. In order to place the UDF with a user-defined variant parameter or annotation value, you must use `ProUdfdataVarparamAdd()`.

---

Use the function `ProUdfvarparamOwnerGet()` to obtain the feature or annotation element that owns this variant parameter or annotation value.

Use the function `ProUdfvarparamNameGet()` to obtain the name or the symbol of the variant parameter or annotation value.

Use the function `ProUdfvarparamDefaultvalueGet()` to obtain the default value for the variant parameter or annotation value.

## UDF References

Functions Introduced:

- **`ProUdfdataRequiredreferencesGet()`**
- **`ProUdfrequiredrefPromptGet()`**
- **`ProUdfrequiredrefTypeGet()`**

- **ProUdfrequiredrefIsannotationref()**
- **ProUdfrequiredrefFree()**
- **ProUdfrequiredrefProarrayFree()**

Use the function `ProUdfdataRequiredreferencesGet()` to obtain a list of the references required to be set for UDF placement. In order to use this function, the UDF data must have its name or path set, and Creo Parametric must be able to successfully find the .gph file based on this information.

Use the function `ProUdfrequiredrefPromptGet()` to obtain the reference prompt for a UDF reference.

Use the function `ProUdfrequiredrefTypeGet()` to obtain the type of item that should be supplied for a UDF reference.

Use the function `ProUdfrequiredrefIsannotationref()` to determine if the reference is an annotation reference and is allowed to be left incomplete.

You can use the function `ProUdfrequiredrefFree()` to free a required reference handle for a UDF. Use the function `ProUdfrequiredrefProarrayFree()` to free a `ProArray` of handles to the required references of a UDF.

## External Symbols

Functions Introduced:

- **ProUdfdataExternalsymbolsGet()**
- **ProUdfextsymbolTypeGet()**
- **ProUdfextsymbolPromptGet()**
- **ProUdfextsymbolParametertypeGet()**
- **ProUdfextsymbolFree()**
- **ProUdfextsymbolProarrayFree()**

Use the function `ProUdfdataExternalsymbolsGet()` to obtain an array of external symbols required by this UDF. You can free a UDF external symbol handle using the function `ProUdfextsymbolFree()` and use the function `ProUdfextsymbolProarrayFree()` to free an array of external symbol handles.

Use the function `ProUdfextsymbolTypeGet()` to obtain the type of external symbol required (dimension or parameter).

Use the function `ProUdfextsymbolPromptGet()` to obtain the prompt for this external symbol.

Use the function `ProUdfextsymbolParametertypeGet()` used to obtain the expected parameter type for an external symbol, if the type is `PRO_UDFEXTSYMBOL_PARAM`.

---

## Instance Names

Function Introduced:

- **ProUdfdataInstancenamesGet()**

Use the function `ProUdfdataInstancenamesGet()` to obtain an array of the instance names that may be used when placing this UDF. You can free this `ProArray` of instances using the function `ProArrayFree()`.

## Notification on UDF Library Creation

Creo TOOLKIT provides the ability to be notified whenever a new UDF library is created or when one is modified. You can use this notification to store additional information about the UDF library file, for example, the names and values of parameters used in the UDF.

Functions Introduced:

- **ProUdfLibraryCompletePostAction()**

Use the function prototype `ProUdfLibraryCompletePostAction()` for a notification corresponding to the `ProNotifyType` `PRO_UDF_LIB_COMPLETE_POST`. This function provides the name of the newly created or modified UDF library file, and a list of all the features included in the UDF.

### Note

If you modify a UDF library, which is independent and contains no reference model then no features will be included in the input to the notification.

---

## Automatic Filling of the Body Reference

In Creo Parametric 7.0.0.0, when you are prompted for a body reference, the prompt will be automatically filled with the default body in the following cases:

- When placing a UDF created in an earlier release, in a single body target model.
- When placing a UDF created in an earlier release, in a multibody target model, and when the configuration option `tk_pre_creo7_udf_body_autofill` is set to yes. Use this configuration option to automatically fill the default body during UDF placement in Creo TOOLKIT.
- In UDFs created in Creo Parametric 7.0.0.0, the body references are not automatically filled.

The following table lists the changes in the UDF functions `ProUdfCreate()` and `ProUdfdataRequiredreferencesGet()`:

| Version of gph file                          | Bodies in target model | Value of the configuration option <code>tk_pre_creo7_udf_body_autofill</code> | <code>ProUdfCreate()</code>                                                                                                                                                                                  | <code>ProUdfdataRequiredreferencesGet()</code>                               |
|----------------------------------------------|------------------------|-------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------|
| Release earlier than Creo Parametric 7.0.0.0 | Single Body            | No                                                                            | Returns <code>PRO_TK_NO_ERROR</code> and automatically fills the UDF with the only available body                                                                                                            | Returns <code>PRO_TK_NO_ERROR</code> and also the body ref/prompt            |
| Release earlier than Creo Parametric 7.0.0.0 | Single Body            | Yes                                                                           |                                                                                                                                                                                                              | Returns <code>PRO_TK_NO_ERROR</code> but does not return the body ref/prompt |
| Release earlier than Creo Parametric 7.0.0.0 | Multibody              | No                                                                            | <ul style="list-style-type: none"> <li>1. If body reference is not specified, returns <code>PRO_TK_MULTIBODY_UNSUPPORTED</code> and the UDF creation fails.</li> <li>If correct body reference is</li> </ul> | Returns <code>PRO_TK_NO_ERROR</code> and also the body ref/prompt            |

| Version of<br>gph file                                | Bodies in<br>target model | Value of the<br>configura-<br>tion option<br>tk_pre_<br>creo7_udf_<br>body_<br>autofill | ProUdf<br>Create ()                                                                               | ProUdfda<br>taRequire<br>dreferen<br>cesGet ()                                    |
|-------------------------------------------------------|---------------------------|-----------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
|                                                       |                           |                                                                                         | specified,<br>returns<br>PRO_TK_<br>NO_<br>ERROR                                                  |                                                                                   |
| Release earlier<br>than Creo<br>Parametric<br>7.0.0.0 | Multibody                 | Yes                                                                                     | Returns PRO_<br>TK_NO_<br>ERROR and<br>automatically<br>fills the UDF<br>with the<br>default body | Returns PRO_<br>TK_NO_<br>ERROR but<br>does not return<br>the body ref/<br>prompt |

## Automatic Filling of the Body Reference

In Creo Parametric 7.0.0.0, when you are prompted for a body reference, the prompt will be automatically filled with the default body in the following cases:

- When placing a UDF created in an earlier release, in a single body target model.
- When placing a UDF created in an earlier release, in a multibody target model, and when the configuration option `tk_pre_creo7_udf_body_autofill` is set to yes. Use this configuration option to automatically fill the default body during UDF placement in Creo TOOLKIT.
- In UDFs created in Creo Parametric 7.0.0.0, the body references are not automatically filled.

The following table lists the changes in the UDF functions `ProUdfCreate()` and `ProUdfdataRequiredreferencesGet()`:

| Version of gph file                          | Bodies in target model | Value of the configuration option <code>tk_pre_creo7_udf_body_autofill</code> | <code>ProUdfCreate()</code>                                                                                                                                                                                  | <code>ProUdfdataRequiredreferencesGet()</code>                               |
|----------------------------------------------|------------------------|-------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------|
| Release earlier than Creo Parametric 7.0.0.0 | Single Body            | No                                                                            | Returns <code>PRO_TK_NO_ERROR</code> and automatically fills the UDF with the only available body                                                                                                            | Returns <code>PRO_TK_NO_ERROR</code> and also the body ref/prompt            |
| Release earlier than Creo Parametric 7.0.0.0 | Single Body            | Yes                                                                           |                                                                                                                                                                                                              | Returns <code>PRO_TK_NO_ERROR</code> but does not return the body ref/prompt |
| Release earlier than Creo Parametric 7.0.0.0 | Multibody              | No                                                                            | <ul style="list-style-type: none"> <li>1. If body reference is not specified, returns <code>PRO_TK_MULTIBODY_UNSUPPORTED</code> and the UDF creation fails.</li> <li>If correct body reference is</li> </ul> | Returns <code>PRO_TK_NO_ERROR</code> and also the body ref/prompt            |

## API Behavior for All Combinations of UDF Type, Creation and Placement

The following cases use an example of the Solid Extrude or Cut feature requiring 3 references for placement — Top, Right and Front datum planes.

## Subordinate UDF Created in a release earlier than Creo Parametric 7.0.0.0

| Created in a Part or Assembly | UDFs that are Retrieved and Placed                                                                                                                                                                                 |                                                                                                                                                                                                                                                        |

### Stand-alone UDF with a Reference Model, Created in a Release Earlier than Creo Parametric 7.0.0.0

You can create a stand-alone UDF with a reference model in a part but not in an assembly

| Created in a Part or Assembly | UDFs that are Retrieved and Placed                                                                                                                                         |                                                                                                                                                                                                                                        |

### Stand-alone UDF without Reference Model, Created in a Release Earlier than Creo Parametric 7.0.0.0

For a stand-alone UDF created without a reference model, there is no information where it was created and creating in an assembly is assumed. Therefore, body references are not appended.

| Created in a Part or Assembly                                                                                  | UDFs that are Retrieved and Placed                                                                                                                                                                           |                                                                                                                                                                                                                                                     |

### Stand-alone UDF without Reference Model, Created in Creo Parametric 7.0.0.0

Body references for features like Extrude or Cut created in a part in Creo Parametric 7.0.0.0 are included in the feature definition and saved in the UDF. When such UDFs are retrieved in a part, you are always prompted in the user interface for the body references, and ProUdfdataRequiredreferencesGet () always returns the actual number of references stored in the UDF.

| Created in a Part or Assembly | UDFs that are Retrieved and Placed                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                                                                                                                                                                                                                                                                                                                                    |

## Core: 3D Geometry

### Core: 3D Geometry

This section deals with the objects and actions used to extract the geometry of a Creo Parametric solid. Because the geometry objects are closely related to each other and they have a number of generic action types in common, this section is organized not by object, but by type of action needed in Creo TOOLKIT.

Some of the objects and actions in this topic section also apply to assemblies. See section [Assembly: Basic Assembly Access on page 1115](#) section [Assembly: Basic Assembly Access on page 1115](#) section for information on objects and actions specific to assemblies.

### Geometry Objects

The generic object for geometry is called `ProGeomitem`, or “geometry item”. It is a `DHandle` that shares the declaration of `ProModelitem`. Its own instances are the specific types of geometrical item familiar to users of Creo Parametric. Each of these is declared as an `OHandle`, or opaque handle.

The `ProGeomitem` types are as follows:

- `ProSurface`—Surface, datum surface, or datum plane
- `ProEdge`—Edge
- `ProCurve`—Datum curve
- `ProCompcurv`—Composite datum curve
- `ProQuilt`—Quilt
- `ProAxis`—Axis
- `ProPoint`—Datum point
- `ProCsys`—Datum coordinate system

Every `ProGeomitem` is contained in a feature, and each feature is contained in a solid, as shown in the following figure.

## ProGeomItem in Feature In Solid

Some geometrical items in a part are also contained in another hierarchy, which shows how they connect together geometrically, rather than to which features they belong. This type of hierarchy is shown in the following figure.

## Hierarchy of Geometrical Items in a Part

The Creo TOOLKIT object `ProContour` is also an `OHandle`, but has no corresponding integer identifier, and therefore is not an instance of `ProGeomItem`.

There are a number of actions applicable to many of these types, whose corresponding functions begin with “`ProGeomItem`”. These include functions such as `ProGeomItemdataGet()`, for which there are also specific functions for the subtypes (where appropriate), and some functions for generic measurement operations. These functions are described under the context of their action type.

To read and modify the name of a `ProGeomItem`, use the functions `ProModelItemNameGet()` and `ProModelItemNameSet()`, described in the section [Core: Models and Model Items on page 73](#).

---

## Visiting Geometry Objects

Visiting geometry objects means acquiring the object handles to all the geometry objects in a solid model, either in the form of a `ProGeomItem`, or in the form of the various specific opaque handles.

The term “solid” is used in Creo TOOLKIT to distinguish models that contain three-dimensional geometry—parts and assemblies—from other model types, such as drawings. However, to the Creo Parametric user, the term “solid” is used in parts and assemblies to distinguish features that represent the geometry of the design object from features used in construction only—the various types of “datum.” Within this section, therefore, the terms “solid geometry” and “datums” are used in that sense.

The most general way to visit geometrical items is through their features. The section [Visiting Feature Geometry on page 179](#) describes this in detail, and includes an illustration of the hierarchy used.

You can also traverse solid geometry items through the hierarchy of surfaces, contours, and edges in a part. This is described in the section [Visiting Solid Geometry on page 181](#).

The following sections describe the traversal of the various datums. Some of these datums have their own visit functions, whereas others are visited through the feature hierarchy.

---

### Note

Although the Creo Parametric user can create solid features in Assembly mode, the geometrical items that result from them are stored only within the component parts whose geometry is modified—not in the assembly features themselves. Therefore, although traversal of datums is applicable to assemblies exactly as to parts, no solid geometry items are found in assemblies.

---

Datum planes, datum surfaces, and solid surfaces are all represented by the `ProSurface` object because they share the same types of mathematical description.

### Visiting Feature Geometry

Functions Introduced:

- **`ProSolidFeatVisit()`**
- **`ProFeatureStatusGet()`**
- **`ProFeatureTypeGet()`**
- **`ProFeatureVisibilityGet()`**

- 
- **ProFeatureGeomitemVisit()**
  - **ProGeomitemIsInactive()**
  - **ProGeomitemdataGet()**

All geometry in Creo Parametric is created as a result of features, so each geometry object in Creo TOOLKIT belongs to a feature. Therefore, the most general way to traverse geometry of all types is to traverse the features, then traverse the geometry each one contains.

The function `ProSolidFeatVisit()` visits every feature in a solid. The function `ProFeatureTypeGet()` reports the type of a feature in terms of the enumerated type `ProFeattype` (described in the include file `ProFeattype.h`).

Note that `ProSolidFeatVisit()` is designed partly for internal use within Creo Parametric. It visits not only the features seen by the Creo Parametric users, but also the features created internally to help in the construction of geometry. These internal features are rarely of interest to Creo TOOLKIT users. To distinguish the visible features from the internal, or invisible, features, call the function `ProFeatureVisibilityGet()`. Internal features are invisible features used internally for construction purposes.

#### **Note**

The function `ProFeatureVisibilityGet()` is primarily used in the action and filter callbacks of the function `ProSolidFeatVisit()`.

---

The function `ProFeatureStatusGet()` reports whether a feature is suppressed or inactive for some reason—only active features contain active geometry.

The function `ProFeatureGeomitemVisit()` visits the geometry items within a feature. It can visit all the geometry items, or one of these specific types: `SURFACE`, `PRO_EDGE`, or `PRO_CURVE`. Like `ProSolidFeatVisit()`, this function visits not only the visible items, but also items used internally to aid in regeneration. Use the function `ProGeomitemIsInactive()` to skip over the internal, or inactive, geometry items. For features with solid geometry, `ProFeatureGeomitemVisit()` visits not only the surfaces, but also the edges. Contrast this with the visit functions specific to those items, described in the next section, that show the hierarchical relationships between surfaces, contours, and edges.

If you want the function `ProFeatureGeomitemVisit()` to visit annotation elements only, use the feature type `PRO_ANNOTATION_ELEM`.

---

Active geometry objects for datums will usually be found in features created for them, and therefore have the corresponding type. For example, a `ProGeomitem` object of type `PRO_CSYS` is usually contained in a feature of type `PRO_FEAT_CSYS`. However, this is not always true; a geomitem of type `PRO_AXIS` can exist in a feature of type `PRO_FEAT_HOLE`, for example. A feature of type `PRO_FEAT_MERGE`, which may arise from a `Mirror` operation in Part mode, or from a `Merge` in Assembly mode, contains geometry objects corresponding to all those in the referenced features, whatever their type. In general, it is best to make no assumptions about what kinds of feature in which you should look for datums.

Remember to distinguish the feature object from the geometry object it contains, even when they have a one-to-one relationship. For example, a feature of type `PRO_FEAT_DATUM_AXIS` contains a single geometry item of type `PRO_AXIS`, and each of these can be represented as a `ProModelitem` object. However, they are still distinct items with their own identifiers and types.

To extract the type and shape of each geometry item, use the function `ProGeomitemdataGet()`, described in detail in the section [Geometry Equations on page 194](#).

---

 **Note**

Some of the following sections about traversing specific geometry items introduce new functions specific to those types. PTC recommends that you use the more specific functions rather than the general method described in this section, because they are easier to use and usually have better performance.

---

All the functions in this section specific to features are described in detail in the section [Core: Features on page 137](#).

### Visiting Solid Geometry

Functions Introduced:

- **`ProSolidBodySurfaceVisit()`**
- **`ProSurfaceContourVisit()`**
- **`ProContourEdgeVisit()`**
- **`ProEdgeContourGet()`**
- **`ProContourTraversalGet()`**
- **`ProContainingContourFind()`**
- **`ProEdgeDirGet()`**
- **`ProEdgeNeighborsGet()`**
- **`ProEdgeVertexdataGet()`**

---

Superseded Functions:

- **ProSolidSurfaceVisit()**

In Creo Parametric 7.0.0.0 and later, the function `ProSolidSurfaceVisit()` has been deprecated. The function `ProSolidSurfaceVisit()` visits the surfaces of the model only if the model has a single body else returns the error `PRO_TK_MULTIBODY_UNSUPPORTED`.

The method `ProSolidBodySurfaceVisit()` visits all the surfaces in the specified body.

In a Creo Parametric solid, each surface contains a list of contours, and each contour contains a list of edges. The edges in a contour form a closed loop, and are ordered such that following the edges keeps the surface on the right. External contours go clockwise, and internal contours go counterclockwise.

The functions `ProSolidBodySurfaceVisit()`, `ProSurfaceContourVisit()`, and `ProContourEdgeVisit()` traverse all the objects in this three-level hierarchy. If you visit all the surfaces, the contours of each surface, and the edges of each contour, the resulting code visits each surface and contour one time, and each edge twice. This is true because each edge forms the intersection between two surfaces, and is therefore listed in one contour of each of the two surfaces.

The function `ProEdgeContourGet()` returns a pointer to the contour, which is associated with the specified edge. The input arguments are:

- *surface*—Specifies the surface of the contour.
- *edge*—Specifies the handle of the edge.

The function `ProContourTraversalGet()` tells you whether the specified contour is internal or external. The function `ProContainingContourFind()` finds the innermost contour that closes the specified contour. If the specified contour is internal, the returned contour will be external, and vice versa. If the specified contour is the outermost contour for the surface, `ProContainingContourFind()` outputs `NULL`.

Each contour has a natural direction in terms of the order in which `ProContourEdgeVisit()` visits its edges. Each edge also has its own direction, in terms of its parameterization—the parameter, *t*, moves from 0 to 1 along the edge. The function `ProEdgeDirGet()` tells you whether an edge is parameterized along or against the direction of the specified contour. Note that each edge belongs to two contours, and will be in the same direction as one contour, and in the opposite direction of the other.

The function `ProEdgeNeighborsGet()` returns the two surfaces that intersect at the specified edge, and which edges on each of those surfaces is the next one following the specified edge when traversing its contour.

The function `ProEdgeVertexdataGet()` returns the list of surfaces and edges that meet at the specified vertex.

---

## Note

The functions in this section visit active geometry items only, so you do not need to call the function `ProGeomitemIsInactive()`.

---

### Example 1: Finding the Surfaces Penetrated by a Hole

The sample code in `UgGeomHoleSrfDisp.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_geometry` uses the techniques of feature traversal and solid geometry traversal to find the surfaces that neighbor the surfaces of the selected hole.

### Visiting Axis Datums

Functions Introduced:

- **ProSolidAxisVisit()**
- **ProAxisIdGet()**
- **ProAxisInit()**
- **ProGeomitemFeatureGet()**
- **ProAxisSurfaceGet()**

An axis is represented by the object `ProAxis`, which is declared as an opaque handle. The function `ProSolidAxisVisit()` visits all the axes in a part or assembly. An axis created explicitly using the Creo Parametric command **Model ► Axis** will be contained in a feature of type `PRO_FEAT_DATUM_AXIS`, but axes can also exist in features of other types, such as `PRO_FEAT_HOLE`.

To find the feature that an axis belongs to, describe the axis in terms of a `ProGeomitem` object using the functions `ProAxisIdGet()` and `ProModelitemInit()`, then call `ProGeomitemFeatureGet()`.

You could also traverse axes using the functions `ProSolidFeatVisit()` and `ProFeatureGeomitemVisit()`, described in the section [Visiting Feature Geometry on page 179](#). As input to `ProFeatureGeomitemVisit()`, use the type `PRO_AXIS`. You would have to visit features of any type that could contain axes.

Always remember to use the function `ProGeomitemIsInactive()` to skip over axes used internally only.

The function `ProAxisSurfaceGet()` provides the `ProSurface` object that identifies the surface used to define the axis position.

### Visiting Coordinate System Datums

Functions Introduced:

- 
- **ProSolidCsysVisit()**
  - **ProCsysIdGet()**
  - **ProCsysInit()**

A coordinate system datum is represented by the object `ProCsys`, which is declared as an opaque handle. The function `ProSolidCsysVisit()` visits all the coordinate system datums in a part or an assembly.

You could also traverse the coordinate system datums using the `ProSolidFeatVisit()` and `ProFeatureGeomitemVisit()` functions, described in the section [Visiting Feature Geometry on page 179](#). The coordinate system datums are usually found in features of type `PRO_FEAT_CSYS`, although they can appear in others, and have the geomitem type `PRO_CSYS`.

Always remember to use the function `ProGeomitemIsInactive()` to skip over coordinate system datums used internally only.

The function `ProCsysIdGet()` provides the persistent integer identifier of the coordinate system, which is used if you need to make a `ProGeomitem` representation of the coordinate system. The function `ProCsysInit()` creates a `ProCsys` object from the integer identifier.

## Visiting Datum Planes

Functions Introduced:

- **ProSurfaceInit()**
- **ProSurfaceIdGet()**

A datum plane is represented by the object `ProSurface`, which is declared as an opaque handle and is also used to represent solid surfaces and datum surfaces.

To visit all the datum planes, use the functions `ProSolidFeatVisit()` and `ProFeatureGeomitemVisit()`, described in the section [Visiting Feature Geometry on page 179](#). The datum planes are contained in features of type `PRO_FEAT_DATUM`, each of which contains a single active `ProGeomitem` object whose `type` field is `PRO_SURFACE`.

Always remember to use the function `ProGeomitemIsInactive()` to skip over datum planes used internally only. (Active datum planes occur in features of type `PRO_FEAT_DATUM` only; datum planes created on-the-fly during creation of other features are inactive.)

To convert the `ProGeomitem` to a `ProSurface`, use the `id` field in the `ProGeomitem` as input to the function `ProSurfaceInit()`.

The function `ProSurfaceIdGet()` gives the integer identifier of a `ProSurface`, so you can convert back to a `ProGeomitem` using the function `ProModelitemInit()`.

---

 **Note**

Although a datum plane has a nominal outline used to visualize the datum in the Creo Parametric display, this is not part of the geometry because a datum plane is an infinite, unbounded plane. Therefore, if you try to use the function `ProSurfaceContourVisit()` on a datum plane, it will not find any contours.

---

## Visiting Quilts and Datum Surfaces

Functions Introduced:

- **ProSolidQuiltVisit()**
- **ProQuiltSurfaceVisit()**
- **ProQuiltIdGet()**
- **ProQuiltInit()**

A datum surface is represented by the object `ProSurface`, which is declared as an opaque handle and is also used to represent solid surfaces and datum planes.

From the viewpoint of Creo TOOLKIT, every datum surface belongs to a quilt, even if no explicit quilt feature has been made in Creo Parametric. If the user creates a single datum surface, it belongs to an internal quilt created for that purpose.

A quilt is represented by the object `ProQuilt`, which is declared as an opaque handle.

To visit datum surfaces, you must therefore first visit all the quilts, using `ProSolidQuiltVisit()`, then visit each surface in the quilt using `ProQuiltSurfaceVisit()`.

The function `ProSolidQuiltVisit()` takes the filter function `ProQuiltFilterAction()` and the visit function `ProQuiltVisitAction()` as its input arguments. The function `ProQuiltFilterAction()` is a generic action function for filtering quilts from a solid model. It returns the filter status of the quilts. This status is used as an input argument by the visit action function `ProQuiltVisitAction()`.

The function `ProQuiltSurfaceVisit()` takes the filter function `ProQuiltSurfaceFilterAction()` and the visit function `ProQuiltSurfaceVisitAction()` as its input arguments. The function `ProQuiltSurfaceFilterAction()` is a generic action function for filtering datum surfaces in a quilt. It returns the filter status of the datum surfaces. This status is used as an input argument by the visit function `ProQuiltSurfaceVisitAction()`.

---

Always remember to use the function `ProGeomitemIsInactive()` to skip over quilts and datum surfaces used internally only.

To convert a `ProQuilt` object to a `ProGeomitem`, use the functions `ProQuiltIdGet()` and `ProModelitemInit()`.

To create a `ProQuilt` object from the integer identifier, use `ProQuiltInit()`.

To find the contours and edges of a datum surface, use the visit functions `ProSurfaceContourVisit()` and `ProContourEdgeVisit()`, described in the section [Visiting Solid Geometry on page 181](#).

### Visiting Datum Curves

Functions Introduced:

- **`ProCurveIdGet()`**
- **`ProCurveInit()`**
- **`ProCurvePersistentColorGet()`**
- **`ProCurvePersistentColorSet()`**
- **`ProCurvePersistentLinestyleGet()`**
- **`ProCurvePersistentLinestyleSet()`**

A datum curve is represented by the object `ProCurve`, which is declared as an opaque handle.

To visit all the datum curves, use the functions `ProSolidFeatVisit()` and `ProFeatureGeomitemVisit()`, described in the section [Visiting Feature Geometry on page 179](#). The datum curves are contained in features of many different types, each of which contains one or more active `ProGeomitem` objects whose type field is `PRO_CURVE`.

Always remember to use the function `ProGeomitemIsInactive()` to skip over datum curves used internally only.

To convert a `ProCurve` object to a `ProGeomitem`, use the functions `ProCurveIdGet()` and `ProModelitemInit()`.

To create a `ProCurve` object from the integer identifier, use `ProCurveInit()`.

Use the functions `ProCurvePersistentColorGet()` and `ProCurvePersistentColorSet()` to obtain and set the color of a specified curve. In order to view the color changes, use the function `ProDisplstInvalidate()` on the owner model.

Use the functions `ProCurvePersistentLinestyleGet()` and `ProCurvePersistentLinestyleSet()`. In order to view the linestyle changes, use the function `ProDisplstInvalidate()` on the owner model.

---

## Visiting Composite Datum Curves

Function Introduced:

- **ProCurveCompVisit()**

A composite datum curve is also represented by the object `ProCurve`. To distinguish a composite curve from an ordinary curve when dealing with a `ProCurve` object, use the function `ProCurveTypeGet()`. This function outputs the value `PRO_ENT_CMP_CRV` for a composite curve.

To visit all the composite datum curves, use the functions `ProSolidFeatVisit()` and `ProFeatureGeomitemVisit()`, described in the section [Visiting Feature Geometry on page 179](#).

The composite curves are contained in features of many different types, each of which contains one or more active `ProGeomitem` objects whose `type` field is `PRO_CURVE`.

To visit the datum curves in a composite curve, use the function `ProCurveCompVisit()`.

Remember that each curve in a composite may be a composite itself, so you may need to make recursive calls. However, you can find all non-composite curves, including those contained in composites, using the method described in the previous section. It is therefore unnecessary to traverse all the composite curves to find all the non-composite curves.

## Visiting Datum Points

Functions Introduced:

- **ProPointIdGet()**
- **ProPointInit()**

A datum point is represented by the object `ProPoint`, which is declared as an opaque handle.

To visit all the datum points, use the functions `ProSolidFeatVisit()` and `ProFeatureGeomitemVisit()`, described in the section [Visiting Feature Geometry on page 179](#). The datum points are usually contained in features of type `PRO_FEAT_DATUM_POINT`, although they can also occur in others, such as `PRO_FEAT_MERGE`. Datum points are represented by geometry items of type `PRO_POINT`.

Always remember to use the function `ProGeomitemIsInactive()` to skip over datum points used internally only.

To convert a `ProPoint` object to a `ProGeomitem`, use the functions `ProPointIdGet()` and `ProModelitemInit()`.

To create a `ProPoint` object from the integer identifier, use `ProPointInit()`.

---

## Curve and Edge Tessellation

You can calculate tessellation for different types of Creo Parametric geometry. The tessellation is made up of small lines (for edges and curves), or triangles (for surfaces and solid models).

Functions Introduced:

- **ProEdgeTessellationGet()**
- **ProCurveTessellationGet()**

The function `ProEdgeTessellationGet()` enables you to invoke the algorithm that generates a sequence of lines from an arbitrary curved edge. This function provides the following outputs:

- An array of the XYZ coordinates of the vertices between the tessellations
- The two surfaces that neighbor the edge (as also provided by `ProEdgeNeighborsGet()`). If the edge is a single-sided edge, then the output argument returns only one surface.
- An array of uv pairs for the tessellation vertices in the first neighboring surface
- An array of uv pairs for the second neighboring surface
- The number of tessellation vertices

The function `ProCurveTessellationGet()` retrieves the curve tessellation for a datum curve. It returns the number of tessellation points and a list of them.

## Curve and Edge Tessellation

You can calculate tessellation for different types of Creo Parametric geometry. The tessellation is made up of small lines (for edges and curves), or triangles (for surfaces and solid models).

Functions Introduced:

- **ProEdgeTessellationGet()**
- **ProCurveTessellationGet()**

The function `ProEdgeTessellationGet()` enables you to invoke the algorithm that generates a sequence of lines from an arbitrary curved edge. This function provides the following outputs:

- An array of the XYZ coordinates of the vertices between the tessellations
- The two surfaces that neighbor the edge (as also provided by `ProEdgeNeighborsGet()`). If the edge is a single-sided edge, then the output argument returns only one surface.
- An array of uv pairs for the tessellation vertices in the first neighboring surface

- 
- An array of uv pairs for the second neighboring surface
  - The number of tessellation vertices

The function `ProCurveTessellationGet()` retrieves the curve tessellation for a datum curve. It returns the number of tessellation points and a list of them.

## Surface Tessellation

Functions Introduced:

- **`ProSurfaceTessellationGet()`**
- **`ProTessellationFree()`**
- **`ProTessellationVerticesGet()`**
- **`ProTessellationFacetsGet()`**
- **`ProTessellationNormalsGet()`**
- **`ProTessellationParamsGet()`**
- **`ProSurfacetessellationinputAlloc()`**
- **`ProSurfacetessellationinputFree()`**
- **`ProSurfacetessellationinputChordheightSet()`**
- **`ProSurfacetessellationinputAnglecontrolSet()`**
- **`ProSurfacetessellationinputStepsizeSet()`**
- **`ProSurfacetessellationinputUvprojectionSet()`**

The function `ProSurfaceTessellationGet()` calculates the tessellation data given by the `ProTessellation` object for a specified surface. Use the function `ProTessellationFree()` to release the memory used by this data object.

The function `ProTessellationVerticesGet()` obtains the vertices for the tessellation for a specified surface.

The function `ProTessellationFacetsGet()` obtains the indices indicating the vertices used for each facet of the tessellated item.

The function `ProTessellationNormalsGet()` obtains the normal vectors for each of the tessellation vertices.

The function `ProTessellationParamsGet()` obtains the UV parameters for each of the tessellation vertices.

The function `ProSurfacetessellationinputAlloc()` allocates the `ProSurfaceTessellationInput` data object containing the options for surface tessellation. Use the function `ProSurfacetessellationinputFree()` to release the memory allocated to this data object.

---

The function `ProSurfaceTessellationInputChordHeightSet()` assigns the chord height used for surface tessellation.

The function `ProSurfaceTessellationInputAngleControlSet()` assigns the value of the angle control used for surface tessellation.

The function `ProSurfaceTessellationInputStepsizeSet()` assigns the maximum value for the step size used for surface tessellation.

The function `ProSurfaceTessellationInputUvprojectionSet()` assigns the parameters used to calculate the UV projection for the texture mapping to the tessellation inputs. The types of UV projection are given by the enumerated type `ProSurfaceTessellationProjection`, and are as follows:

- `PRO_SRFTESS_DEFAULT_PROJECTION`—Provides the UV parameters for the tessellation points that map to a plane whose U and V extents are [0,1] each. This is the default projection.
- `PRO_SRFTESS_PLANAR_PROJECTION`—Projects the UV parameters using a planar transform, where  $u=x$ ,  $v=y$ , and  $z$  is ignored.
- `PRO_SRFTESS_CYLINDRICAL_PROJECTION`—Projects the UV parameters using a cylindrical transform, where  $x=r*\cos(\theta)$ ,  $y=r*\sin(\theta)$ ,  $u=\theta$ ,  $v=z$ , and  $r$  is ignored.
- `PRO_SRFTESS_SPHERICAL_PROJECTION`—Projects the UV parameters onto a sphere, where  $x=r*\cos(\theta)*\sin(\phi)$ ,  $y=r*\sin(\theta)*\sin(\phi)$ ,  $z=r*\cos(\phi)$ ,  $u=\theta$ ,  $v=\phi$ , and  $r$  is ignored.
- `PRO_SRFTESS_NO_PROJECTION`—Provides the unmodified UV parameters for the tessellation points. This is similar to using the function `ProSurfaceParamEval()`.
- `PRO_SRFTESS_BOX_PROJECTION`—Projects the UV parameters using the box transform. The box transformation uses planar projection to project a point from the face of the box onto the model or surface, which is opposite to the face of the box, where  $u = x$ ,  $v = y$ , and  $z$  is ignored.

---

## Note

- If the function `ProSurfaceTessellationInputUvProjectionSet()` is not used, the output tessellation will not contain any UV parameters and the function `ProTessellationParamsGet()` will not return any values.
  - Specify the unmodified UV parameters obtained using `PRO_SRFTESS_NO_PROJECTION` as the input `u` and `v` values for the functions `ProSurfaceXyzDataEval()`, `ProSurfaceUvpntVerify()`, `ProSurfaceDiameterEval()`, and `ProSurfacePrincipalCrvtEval()`.
- 

## Part and Assembly Tessellation

Functions Introduced:

- **ProPartTessellate()**
- **ProPartTessellationFree()**

The function `ProPartTessellate()` tessellates all surfaces of the specified part or assembly in one operation. On parts, `ProPartTessellate()` acts on all surfaces. On assemblies, this function acts only on surfaces that belong to the assembly, that is, it does not tessellate surfaces of the assembly components.

`ProPartTessellate()` returns an array of `ProSurfaceTessellationData` data objects. Use the function `ProPartTessellationFree()` to release the memory assigned to these data objects.

## Evaluating Geometry

The geometry of each edge or curve in Creo Parametric is described as a set of three parametric equations that represent the values of *X*, *Y*, and *Z* as functions of the independent parameter, *t*. For a surface, the three equations are functions of the two independent parameters *u* and *v*.

The Creo TOOLKIT functions described in this section provide the ability to evaluate the parametric edge and surface functions—that is, find the values and derivatives of *X*, *Y* and *Z* for the specified values of *t*, or *u* and *v*. They also provide for reverse evaluation.

## Evaluating Surfaces, Edges, and Curves

Functions Introduced:

- **ProSurfaceXYZdataEval()**
- **ProEdgeXYZdataEval()**
- **ProCurveXYZdataEval()**
- **ProEdgeUvdataEval()**
- **ProSurfaceUvpntVerify()**
- **ProContourUvpntVerify()**

The function `ProSurfaceXYZdataEval()` evaluates the parametric equations for a surface at a point specified by its *u* and *v* values. The inputs to the function are the `ProSurface` object and the *u* and *v* values. The *u* and *v* values are obtained by specifying the projection type as `PRO_SRFTESS_NO_PROJECTION` for the function `ProSurfacetessellationinputUvprojectionSet()`.

The function outputs are as follows:

- The X, Y, and Z coordinates of the point, with respect to the model coordinates
- The first partial derivatives of X, Y, and Z, with respect to *u* and *v*
- The second partial derivatives of X, Y, and Z, with respect to *u* and *v*
- A unit vector in the direction of the outward normal to the surface at that point

The function `ProEdgeXYZdataEval()` performs a similar role for an edge. Its inputs are the `ProEdge` object and the value of *t* at the required point. The function outputs are as follows:

- The X, Y, and Z coordinates of the point, with respect to the model coordinates
- The first partial derivatives of X, Y, and Z, with respect to *t*
- The second partial derivatives of X, Y, and Z, with respect to *t*
- A unit vector in the direction of the edge

You must allocate a memory location for each of the output arguments of these two functions. Pass a `NULL` pointer if you do not want to use an output argument. You cannot pass a null for both the output arguments.

The function `ProCurveXYZdataEval()` is equivalent to `ProEdgeXYZdataEval()`, but works for datum curves.

The `ProEdgeUvdataEval()` function relates the geometry of a point on an edge to the surfaces that meet at that point.

The function `ProSurfaceUvpntVerify()` verifies whether a surface point, specified by its *u* and *v* values, lies inside, outside, or very close to the boundary of the surface. The *u* and *v* values are obtained by specifying the projection type as `PRO_SRFTESS_NO_PROJECTION` for the function `ProSurfacetessellationinputUvprojectionSet()`.

---

Function `ProContourUvpntVerify()` does the same for points on a given contour.

## Inverse Evaluation and Minimum Distances

Functions Introduced:

- **ProSurfaceParamEval()**
- **ProEdgeParamEval()**
- **ProCurveParamEval()**
- **ProGeomitemBodyGet()**

These functions provide the parameters of a point on a surface, edge, or datum curve nearest to the specified XYZ coordinate point.

You can use the function `ProEdgeParamEval()` only for the points that are either on the edge or very close to the edge.

The function `ProSurfaceParamEval()` returns the closest approximation to the unmodified *u* and *v* values obtained by specifying the projection type as `PRO_SRFTESS_NO_PROJECTION` for the function `ProSurfaceTessellationInputUvprojectionSet()`.

Use the function `ProGeomitemBodyGet()` to retrieve the body that is associated with the specified geometry item.

## Geometry at Points

Functions Introduced:

- **ProGeometryAtPointFind()**
- **ProPoint3dOnsurfaceFind()**
- **ProPoint3dIntoleranceFind()**
- **ProSolidProjectPoint()**

The function `ProGeometryAtPointFind()` locates the geometry items that lie on a given point. This function supports solid geometry only.

The function `ProPoint3dOnsurfaceFind()` determines if the distance between the specified point and the specified surface is less than the Creo Parametric model accuracy as set in the current Creo Parametric session. Accuracy can also be set with function `ProSolidAccuracySet()`. This function is applicable to solid and datum surfaces.

The function `ProPoint3dIntoleranceFind()` determines if two specified points are co-incident, that is, if the distance between the two points is within the Creo Parametric tolerance set in `ProSolidToleranceGet()`.

---

The function `ProSolidProjectPoint()` projects a point along the shortest possible line normal to a surface, finds the point where that line hits the solid, and returns that point. Note that this function works on parts only.

## Geometry Equations

Functions Introduced:

- **ProGeomitemdataGet()**
- **ProGeomitemdataFree()**
- **ProLogObjectitemdataGet()**

The parametric equations that describe surfaces, edges, and datum curves in Creo Parametric are documented in the section [Geometry Representations on page 2078](#). (Datum curves are geometrically equivalent to edges, but because they play a different role in Creo Parametric, they need a parallel set of functions to access them. The word curve is used as a generic word for the shape of either an edge or a datum curve.)

To know the form of a particular geometry item, you need to know not only which type of equation is being used, but also the values of the various coefficients and constants used in that equation for that item. [Geometry Representations on page 2078](#) documents the equations using the same names for these coefficients and constants used to store them in the Creo Parametric data structures. The functions in this section enable you to get copies of the data structures containing those coefficients and constants. Therefore, you can perform your own evaluations.

The data structures for `ProSurfacedata` are defined in the include file `ProSurfacedata.h`, and those for `ProCurvedata` are defined in `ProCurvedata.h`.

The function `ProGeomitemdataGet()` allocates and fills a data structure that describes the geometry of the item. The structure `ProGeomitemdata` is declared in the file `ProGeomitemdata.h`, and looks like this:

```
typedef struct geom_item_data_struct
{
 ProType obj_type;
 union
 {
 ProCurvedata *p_curve_data;
 ProSurfacedata *p_surface_data;
 ProCsysdata *p_csys_data;
 } data;
} ProGeomitemdata;
```

The `type` field has the same value as the `type` field in the `ProGeomitem` object.

---

The three fields in the union contain data structures for the geometry of curves (including solid edges and axes), surfaces, and coordinate system datums. These three data structures are described in detail in the section [Geometry of Solid Edges on page 2078](#), and [Geometry of Coordinate System Datums on page 198](#), respectively.

The memory for the data structure is allocated by the function, but is never freed. To free the memory when you have finished with it, call `ProGeomitemdataFree()`.

Use the function `ProLogObjectitemdataGet()` to retrieve the geometric representation data for the specified log object type item. The input argument `p_item` is the handle to the `ProGeomitem` object. The function supports the `PRO_LOG_OBJECT` item type only. The output argument `p_surf_arr` is the item data specified using the `ProSurface` object.

## Geometry of Solid Edges

Functions Introduced:

- **ProEdgeTypeGet()**
- **ProEdgeDataGet()**
- **ProEdgedataMemoryFree()**
- **ProEdgedataFree()**

Function `ProEdgeTypeGet()` provides the equation used to describe the edge. Function `ProEdgeDataGet()` returns the data structure associated with the specified edge.

Use function `ProEdgedataMemoryFree()` to free the top-level memory associated with the edge data structure. Function `ProEdgedataFree()` frees the underlying memory of the data structure.

Follow these steps to get the description of an edge:

1. Get the type of equation used to describe the edge using the function `ProEdgeTypeGet()`. The possible types for a solid edge are as follows:
  - `PRO_ENT_LINE`—A straight line
  - `PRO_ENT_ARC`—An arc
  - `PRO_ENT_ELLIPSE`—An ellipse
  - `PRO_ENT_SPLINE`—A nonuniform cubic spline
  - `PRO_ENT_B_SPLINE`—A nonuniform rational B-spline (NURBS)
2. Get the data structure for the geometry using the function `ProEdgeDataGet()`. For an edge, the `type` field is set to `PRO_EDGE`, and the relevant field from the union is `p_curve_data`. The type for that field, `ProCurvedata`, is itself a union that contains a field for each type of edge

---

equation. For example, if the edge type is `PRO_ENT_ARC`, the relevant field in the `ProCurvedata` structure is the one called `arc`, of type `ProArcdata`. Each such structure contains fields for the coefficients and constants in the relevant equations (described in the [Geometry Representations on page 2078](#) appendix section), and share the same names.

3. When you have read the information you need from the `ProGeomitemdata` structure, free the memory using `ProGeomitemdataFree()`.

### Example 2: Extracting the Diameter of an Arc Edge

The sample code in `UgGeomArcDiaDisp.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_geometry` shows how to extract the geometry equation of a solid edge.

## Geometry of Surfaces

Functions Introduced:

- **`ProSurfaceTypeGet()`**
- **`ProSurfaceDataGet()`**
- **`ProSurfaceIsDatumPlane()`**
- **`ProSurfaceSameSrfsFind()`**
- **`ProSldsurfaceVolumesFind()`**
- **`ProSurfacePeriodicityGet()`**
- **`ProSurfaceNextGet()`**

The method for getting the description of surface geometry is analogous to that described in the previous section for solid edges. Function `ProSurfaceTypeGet()` provides the equation used to describe the surface. Function `ProSurfaceDataGet()` returns the data structure associated with the specified surface.

Use function `ProSurfacedataMemoryFree()` to free the top-level memory associated with the surface data structure. Function `ProSurfacedataFree()` frees the underlying memory of the data structure.

The possible types of surface are as follows:

- `PRO_SRF_PLANE`—A plane
- `PRO_SRF_CYL`—A cylinder
- `PRO_SRF_CONE`—A cone
- `PRO_SRF_TORUS`—A torus
- `PRO_SRF_COONS`—A Coons patch
- `PRO_SRF_SPL`—A spline surface

- `PRO_SRF_FIL`—A fillet surface
- `PRO_SRF_RUL`—A ruled surface
- `PRO_SRF_REV`—A surface of revolution
- `PRO_SRF_TABCYL`—A tabulated cylinder
- `PRO_SRF_B_SPL`—A nonuniform rational B-spline (NURBS)
- `PRO_SRF_CYL_SPL`—A cylindrical spline surface

The relevant field in the `ProGeomitemdata` structure is `p_surface_data`, of type `ProSurfacedata`.

The structure `ProSurfacedata` contains information applicable to surfaces of all types, such as the maximum and minimum values of *u* and *v*, and of *X*, *Y*, and *Z* for the surface, and a union that contains a field for each type of surface geometry.

As with edges, these structures contain fields for the coefficients and constants in the relevant equations, described in the [Geometry Representations on page 2078](#) appendix.

These functions are also applicable to datum surfaces, and to datum planes (in which the surface type will always be `PRO_SRF_PLANE`).

The function `ProSurfaceIsDatumPlane()` identifies if the given surface is a datum plane.

The function `ProSurfaceSameSrfsFind()` finds and returns an array of surfaces that are the same as the input surface. For example, in case of a cylinder, Creo Parametric creates two half cylindrical surfaces. If you obtain one half, the other half is returned by this function.

The function `ProSldsurfaceVolumesFind()` analyzes and returns the number of connect volumes of a part and the surfaces that bound them.

The function `ProSurfacePeriodicityGet()` gets information about the periodicity of a surface. The output arguments are:

- *periodic\_in\_u*—Specifies if the surface is periodic in U-direction.
- *period\_in\_u*—Specifies the value of period in U-direction.
- *periodic\_in\_v*—Specifies if the surface is periodic in V-direction.
- *period\_in\_v*—Specifies the value of period in V-direction.

The function `ProSurfaceNextGet()` returns the next surface in the surface list or returns `NULL` if there is no next surface. The input argument `this_surface` is the surface for which the next surface is queried and can be `NULL`.

---

The output argument `p_next_surface` is a non-Null pointer for returning the next surface. If the surface passed through the input argument `this_surface` is the last surface in the list, then the returned surface is `NULL`.

---

 **Note**

For a solid body part with multiple bodies, this function does not return a surface that is outside the body.

---

### Example 3: Getting the Angle of a Conical Surface

The sample code in `UgGeomConeAngDisp.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_geometry` shows how to read the geometry equation of a surface.

## Geometry of Axes

Function Introduced:

- **ProAxisDataGet()**

An axis is treated in the same way as a solid edge. The function `ProAxisDataGet()` allocates and fills a `ProGeomitemdata` structure for a `ProAxis` object. The relevant field in the union is `p_curve_data`, but the type of the contained edge is always a line.

## Geometry of Coordinate System Datums

Function Introduced:

- **ProCsysDataGet()**

The function `ProCsysDataGet()` provides a `ProGeomitemdata` structure in which the field `p_csys_data` is set. This is a pointer to a structure called `ProCsysdata`, declared in `ProCsysdata.h`, that contains the location of the origin, and the directions of the three axes, of the coordinate system datum.

## Geometry of Datum Planes

Datum planes are treated exactly like surfaces, so you can use `ProSurfaceDataGet()`.

Their type is always `PRO_SRF_PLANE`.

## Geometry of Quilts

Functions Introduced:

- **ProQuiltdataGet()**
- **ProQuiltdataSurfArrayGet()**
- **ProQuiltdataSurfArraySet()**
- **ProQuiltdataMemoryFree()**
- **ProQuiltdataFree()**
- **ProQuiltdataTypeGet()**
- **ProQuiltdataTypeSet()**
- **ProQuiltVolumeEval()**
- **ProQuiltIsBackupgeometry()**
- **ProQuiltIsInternal()**

A quilt represents a "patchwork" of connected nonsolid surfaces. A quilt may consist of a single surface or a collection of surfaces. A quilt contains information describing the geometry of all the surfaces that compose a quilt and information on how quilt surfaces are "stitched" (joined or intersected). A part can contain several quilts. You can create or manipulate quilts using a surface feature.

To find the surfaces it contains, use `ProQuiltSurfaceVisit()` and analyze the geometry of each surface.

The function `ProQuiltdataGet()` retrieves information from the quilt data structure. The helper functions `ProQuiltdataSurfArrayGet()` and `ProQuiltdataSurfArraySet()` return or define, respectively, an array of pointers to the datum surfaces in the quilt data structure.

The function `ProQuiltdataMemoryFree()` releases the top-level memory associated with the quilt data structure. The function `ProQuiltdataFree()` releases the underlying memory of the data structure.

The function `ProQuiltdataTypeGet()` returns the type of quilt data. If the type of quilt data is a body, the output argument `p_body_or_quilt` returns `PRO_BODY` and returns `PRO_QUILT` if the type is quilt.

Use the function `ProQuiltdataTypeSet()` to set the type of quilt data as `PRO_BODY` or `PRO_QUILT`. The input arguments follow:

- `p_quilt_data`—The quilt data.
- `body_or_quilt`—Type of quilt data as `PRO_BODY` or `PRO_QUILT`.

The function `ProQuiltVolumeEval()` calculates the volume of a closed quilt.

The function `ProQuiltIsBackupgeometry()` identifies if the specified quilt belongs to the invisible Copy Geometry backup feature. Its input argument is a pointer to the quilt's handle of the type `ProQuilt`. If the quilt belongs to the invisible Copy Geometry backup feature, the function returns a `ProBoolean` with the value `PRO_B_TRUE`; otherwise, the value is `PRO_B_FALSE`.

---

The function `ProQuiltIsInternal()` checks whether a quilt is created for internal use only. If the quilt is created for internal use only, the function returns a `ProBoolean` with the value `PRO_B_TRUE`; otherwise, the value is `PRO_B_FALSE`.

## Geometry of Datum Surfaces

Because the system treats datum surfaces exactly like surfaces, you can use `ProSurfaceDataGet()`.

They can have any type of geometry.

## Geometry of Datum Points

Functions Introduced:

- **`ProPointCoordGet()`**

The function `ProPointCoordGet()` provides the X, Y, and Z coordinates of the specified `ProPoint` object.

## Geometry of Datum Curves

Functions Introduced:

- **`ProCurveTypeGet()`**
- **`ProCurveDataGet()`**
- **`ProComponentCurvedataAlloc()`**
- **`ProComponentCurvedataFree()`**
- **`ProComponentCurvedataGet()`**
- **`ProComponentCurvedataInit()`**
- **`ProCurvedataMemoryFree()`**
- **`ProCurvedataFree()`**

Datum curves use the same data structure as edges, with the same possible types of geometry. Because they are stored in a different location in the Creo Parametric database, they need their own functions:

- `ProCurveTypeGet()` is analogous to `ProEdgeTypeGet()`.
- `ProCurveDataGet()` is analogous to `ProEdgeDataGet()`.

The enumerated type `ProEnttype` is used to get the type of curve.

- The value `PRO_ENT_CMP_CRV` specifies a composite curve.
- The value `PRO_ENT_PARAM_CRV` specifies a parametrized curve  $(x(t), y(t), z(t))$ , where  $x$ ,  $y$ , and  $z$  are user-defined functions.

- 
- The value `PRO_ENT_SRF_CRV` specifies a parameterized curve  $(u(t), v(t))$  that exists on a surface, where  $u$  and  $v$  are user-defined functions.

Use the function `ProComponentCurvedataAlloc()` to allocate memory for a component of a composite curve. The output argument `pp_component` is the component of a composite curve.

Use the function `ProComponentCurvedataFree()` to free the memory of a component of a composite curve. The input argument `p_component` is the component of a composite curve.

The function `ProComponentCurvedataGet()` gets information from a component of a composite curve.

### Note

The function ignores the output arguments with null pointers.

---

The input argument `p_component` is the component of the composite curve.

The output arguments are:

- `p_curve`—The component curve
- `p_direction`—The direction of the component.

The function `ProComponentCurvedataInit()` initializes a component of a composite curve data structure.

The input arguments are:

- `p_curve`—The component curve data structure
- `direction`—The direction of the component

The output argument `p_component` is the component of the composite curve

Use function `ProCurvedataMemoryFree()` to free the top-level memory associated with the curve data structure. Function `ProCurvedataFree()` frees the underlying memory of the data structure.

## Geometry of Composite Curves

A composite curve does not have geometry of its own. Find the member curves using `ProCurveCompVisit()` and analyze their geometry in the usual way.

## Ray Tracing

Functions Introduced:

- **`ProSolidRayIntersectionCompute()`**
- **`ProSelectionDepthGet()`**

---

The function `ProSolidRayIntersectionCompute()` finds the intersections between a ray and a solid.

The ray is defined in terms of a start location and direction vector. The intersections are described in terms of an array of `ProSelection` objects to show their context in an assembly.

The function finds intersections in both directions from the start point of the ray, and assigns each intersection a depth—the distance from the ray start point in the direction defined (intersections in the reverse direction have a negative depth). You can extract the depth of each intersection using the function `ProSelectionDepthGet()`. The intersections are ordered from the most negative depth to the most positive.

The function processes all solid surfaces and datum surfaces, but not datum planes. It also includes edges that lie within a certain critical distance, called the aperture radius, of the ray. Such an edge is shown as intersected, even if a neighboring surface is also intersected. This implies that several entries in the array may represent a single “piercing,” in geometrical terms.

The aperture radius is an optional input to the function, defined in terms of pixels. If you supply a value less than  $-1.0$ , the value is taken from the Creo Parametric configuration file option `pick_aperture_radius`. If that option is not set, the function uses the default value of  $7.0$ .

In an assembly, each component is processed separately, so if two coincident mating faces are hit, the function records two separate intersections.

Surfaces and edges that are not displayed because they are assigned to a blanked layer are not intersected.

This function is most often used in optical analysis, when calculating the path of a ray of light through an assembly whose parts represent lenses or mirrors. In this case, you want to find the closest intersecting surface in the positive direction, then calculate the normal to the surface at that point, in assembly coordinates.

## Measurement

Functions Introduced:

- **`ProSurfaceAreaEval()`**
- **`ProContourAreaEval()`**
- **`ProSurfaceExtremesEval()`**
- **`ProSurfacePrincipalCrvtEval()`**
- **`ProEdgeLengthEval()`**
- **`ProCurveLengthEval()`**
- **`ProEdgeLengthT1T2Eval()`**

- **ProCurveLengthT1T2Eval()**
- **ProEdgeParamByLengthEval()**
- **ProCurveParamByLengthEval()**
- **ProGeomitemDistanceEval()**
- **ProGeomitemAngleEval()**
- **ProSurfaceDiameterEval()**
- **ProGeomitemDiameterEval()**
- **ProContourBoundbox3dCompute()**
- **ProContourBoundbox2dCompute()**
- **ProSelectionWithOptionsDistanceEval()**

The function `ProSurfaceAreaEval()` evaluates the surface areas of a specified surface. It is not valid for datum planes.

Function `ProContourAreaEval()` outputs the inside surface area of a specified outer contour. Note it takes into account internal voids.

The function `ProSurfaceExtremesEval()` finds the coordinates of the face edges at the extremes in the specified direction. The accuracy of the result is limited to the accuracy of edge tessellation.

Function `ProSurfacePrincipalCrvtEval()` outputs the curvatures and directions of the specified surface at a given UV point. The `u` and `v` values are obtained by specifying the projection type as `PRO_SRFTESS_NO_PROJECTION` for the function `ProSurfacetessellationinputUvprojectionSet()`.

The function `ProEdgeLengthEval()` evaluates the length of a solid edge, and `ProCurveLengthEval()` does the same for a datum curve.

Function `ProEdgeLengthT1T2Eval()` finds the length of a specified edge between two parameters. Use function `ProCurveLengthT1T2Eval()` to do the same for a curve.

`ProEdgeParamByLengthEval()` finds the parameter value of the point located a given length from the specified start parameter. Use function `ProCurveParamByLengthEval()` to do the same for a curve.

The function `ProGeomitemDistanceEval()` measures the distance between two geometry items. The geometry items are expressed as `ProSelection` objects, so you can specify any two objects in an assembly. Each object can be an axis, plane surface, or datum point.

The function `ProGeomitemAngleEval()` measures the angle between two geometry items expressed as `ProSelection` objects. Both objects must be straight, solid edges.

---

The function `ProSurfaceDiameterEval()` measures the diameter of a surface, expressed as a `ProSelection` object. The surface type must be one of the following:

- Cylinder—The cylinder radius
- Torus—The distance from the axis to the generating arc
- Cone—The distance of the point specified from the axis
- Surface of revolution—The distance of the point specified from the axis

The `u` and `v` values are obtained by specifying the projection type as `PRO_SRFTESS_NO_PROJECTION` for the function `ProSurfaceTessellationInputUvProjectionSet()`.

---

 **Note**

In the case of a sphere made by revolving an arc, the Creo Parametric command **Analysis ► Diameter** gives the real spherical diameter, whereas `ProGeomItemDiameterEval()` gives the distance of the specified point from the axis of revolution.

---

The functions `ProContourBoundingBox2dCompute()` and `ProContourBoundingBox3dCompute()` output a bounding box for the inside surface of the specified outer contour.

---

 **Note**

- Only the `ProContourBoundingBox3dCompute()` function takes into account internal voids.
  - The outline returned by the function `ProContourBoundingBox3dCompute()` represents the outline box used by Creo Parametric embedded algorithms, and hence it can be slightly bigger than the outline computed directly from the surface parameters.
- 

The function `ProSelectionWithOptionsDistanceEval()` evaluates the distance between two items. You can evaluate distance between surfaces, edges, entities, vertices, curves, datums, and so on. The initial selection of the item is used to guess the type of geometry. In case of error types `PRO_TK_BAD_INPUTS` or `PRO_TK_BAD_CONTEXT`, the output argument `p_result` is set to `-1.0` and all parameters are set to `0.0`.

---

The input arguments `option1` and `option2` are analogous to **Options** in the **Measure** dialog box in Creo Parametric user interface. You can specify `PRO_B_TRUE` if you want to turn on the following options for the selected items:

- If the selected item is a cylindrical surface, measures the distance from the central axis of the cylindrical surface. Specify `PRO_B_FALSE` to measure from the surface instead of the axis.
- If the selected item is an arc, measures the distance from the center of a circle or an arc-shaped curve or edge. Specify `PRO_B_FALSE` to measure from the edge instead of the center.
- If the selected item is a planar surface or a plane, extends the selected surface or plane to infinity in both directions only for the purpose of measuring distance. You can now measure the distance normal to the reference entity.
- If the selected item is linear, extends the selected straight edge or curve to infinity in both directions only for the purpose of measuring distance. You can now measure the distance normal to the reference entity.

The output arguments return the following values:

- `p_result`—Distance between the two items
- `pnt_1` and `pnt_2`—Critical point for the first and second selected items. Critical point is the actual point used for measurement.
- `param_1` and `param_2`—UV parameter of the critical point for the first and second selected items

## Geometry as NURBS

Functions Introduced:

- **ProSurfaceToNURBS()**
- **ProEdgeToNURBS()**
- **ProCurveToNURBS()**

A common reason for extracting the solid geometry of a Creo Parametric model is to pass it to another MCAE tool for some kind of engineering analysis. Not all of the other MCAE tools share the rich variety of geometry equation types supported by Creo Parametric, and therefore may not be able to import all the surface descriptions directly. Because many MCAE systems use nonuniform rational B-splines (NURBS) to model surfaces and edges, you frequently need to convert many or all of the Creo Parametric surface descriptions to NURB splines.

The function `ProSurfaceToNURBS()` operates on a surface of any type. The function makes an accurate approximation of the shape of the surface using a NURBS, and outputs a pointer to the structure `ProSurfacedata`. This structure contains the surface type `PTC_B_SPLSRF`, which describes the form of the NURBS.

---

The function `ProEdgeToNURBS()` finds a one-dimensional NURBS that approximates a Creo Parametric solid edge. The function outputs a pointer to the `ProCurvedata` union whose `b_spline` field contains the NURBS description.

The function `ProCurveToNURBS()` provides the same functionality as `ProEdgeToNURBS()`, but for a datum curve.

Both `ProSurfacedata` and `ProCurvedata` are declared in the Creo TOOLKIT header file `ProGeomitem.h`.

## Interference

Functions Introduced:

- **`ProFitClearanceCompute()`**
- **`ProFitGlobalinterferenceCompute()`**
- **`ProFitInterferenceCompute()`**
- **`ProFitInterferencevolumeCompute()`**
- **`ProFitInterferencevolumeDisplay()`**
- **`ProInterferenceDataFree()`**
- **`ProInterferenceInfoProarrayFree()`**
- **`ProVolumeInterferenceCompute()`**
- **`ProVolumeInterferenceDisplay()`**
- **`ProVolumeInterferenceBodiesGet()`**
- **`ProVolumeInterferenceDisplayForBody()`**
- **`ProVolumeInterferenceInfoArrayFree()`**

The function `ProFitClearanceCompute()` computes the clearance between two objects. When the function computes clearance between two parts, it also tries to determine if there is interference between them.

Use the function `ProFitGlobalinterferenceCompute()` to compute the interference in the specified assembly. If the assembly is regenerated, the interference must be recalculated. The enumerated data type `ProFitComputeSetup` specifies the set up to compute the interference for parts or subassemblies. The valid values are:

- `PRO_FIT_PART`—Computes interference between the pairs of parts in an assembly. The interference is computed only for those pairs whose volume can be calculated. The pairs whose volume could not be calculated are removed.

- 
- `PRO_FIT_SUB_ASSEMBLY`—Computes interference between the pairs of subassemblies in an assembly, that is, computes interference between parts of different subassemblies. The interference is computed only for pairs whose volume can be calculated. The pairs whose volume could not be calculated are removed.
  - `PRO_FIT_PART_DETAILED`—Computes interference between the pairs of parts in an assembly. The interference is computed for all the pairs irrespective of whether the volume can be calculated.
  - `PRO_FIT_SUB_ASSEMBLY_DETAILED`—Computes interference between the pairs of subassemblies in an assembly, that is, computes interference between parts of different subassemblies. The interference is computed for all the pairs irrespective of whether the volume can be calculated.

The function `ProFitInterferenceCompute()` returns the interference information specified between two items. In assembly mode, each item is either a component part or a solid body of a part. In Part mode, each item is a solid body of the current part. If the items are regenerated, the interferences must be recalculated. The input arguments follow:

- `sel_1`—The first part or solid body.
- `sel_2`—The second part or solid body.
- `set_facets`—The option to include facets for parts.
- `set_quilts`—The option to include quilts for parts.

---

 **Note**

Set the `ProBoolean` arguments `set_facets` and `set_quilts` to `PRO_B_TRUE` to include facets or quilts in the model, respectively.

---

---

 **Note**

The interference data obtained from the functions `ProFitGlobalInterferenceCompute()` and `ProFitInterferenceCompute()` must be passed as input to the functions `ProFitInterferenceVolumeCompute()` and `ProFitInterferenceVolumeDisplay()`. The interference data must not include facets or quilts. They must include information about only interfering solids.

---

---

The function `ProFitInterferenceCompute()` returns an error `PRO_TK_NOT_EXIST` if one or more items specified by either of the input arguments `sel_1` and `sel_2` could not be found or does not contain any geometry with which to compute interference.

The function returns the error `PRO_TK_GENERAL_ERROR` if the interference could not be computed. The function returns the error `PRO_TK_NOT_VALID` if the value of the interference volume is invalid.

The function `ProFitInterferencevolumeCompute()` calculates volume of interference between two specified components. Use the function `ProFitInterferencevolumeDisplay()` to display the volume of interference between the two specified components.

Use the functions `ProInterferenceDataFree()` and `ProInterferenceInfoProarrayFree()` to free the interference data obtained from the functions `ProFitInterferenceCompute()` and `ProFitGlobalinterferenceCompute()` respectively.

The function `ProVolumeInterferenceCompute()` calculates the volume interference between the selected closed quilt and an assembly. The output argument `p_intf_infos` is a pointer to the `ProArray`, where the interference results are stored. The interference data is returned as a `ProVolumeInterferenceInfo` structure.

Use the function `ProVolumeInterferenceInfoArrayFree()` to free the interference data obtained from the function `ProVolumeInterferenceCompute()`. The function is supported only in DLL mode.

The function `ProVolumeInterferenceDisplay()` displays the curves and surfaces that interfere with the selected quilt in the specified color or hides them. This function must be called after the interference data is computed. The input arguments are:

- *inetr<sub>f</sub>\_data* — Specifies a pointer to the interference data.
- *color*— Specifies the color to use for highlighting the interference.
- *hilite*— Specifies if the curves and surfaces that interfere with the selected quilt must be displayed or hidden. Specify `PRO_B_TRUE` for displaying the interfering component and `PRO_B_FALSE` for hiding it.

Use the function `ProVolumeInterferenceBodiesGet()` to obtain the solid bodies of the specified component that participate in the interference with the selected closed quilt. The input argument *inter<sub>f</sub>\_data* specified through the structure `ProVolumeInterferenceData` is the pointer to the interference data for the corresponding component that interferes with the quilt. The output argument `r_bodies` returns an array of the bodies through the structure `ProSolidBody` which is allocated by the function.

---

Call the function `ProVolumeInterferenceCompute()` before using `ProVolumeInterferenceBodiesGet()`.

The function `ProVolumeInterferenceBodiesGet()` returns an error `PRO_TK_E_NOT_FOUND` if there are no solid bodies in the interference data.

The function `ProVolumeInterferenceDisplayForBody()` displays or hides the curves and surfaces of the specified solid body that interfere with the quilt that is selected. The input arguments follow:

- *interf\_data*—Pointer to the interference data for the corresponding component that interferes with the quilt.
- *p\_body*—Pointer to the solid body in the specified component.
- *color*—Specifies the color to be used for highlighting the interference and is defined by the enumerated data type `ProColorType`.
- *hilite*—Specifies if the curves and surfaces that interfere with the selected quilt must be displayed or hidden. Specify `PRO_B_TRUE` for displaying the interference geometry of the specified body and `PRO_B_FALSE` for hiding it.

The function `ProVolumeInterferenceDisplayForBody()` returns an error `PRO_TK_E_NOT_FOUND` if the given body does not interfere with the quilt.

Call the function `ProVolumeInterferenceInfoArrayFree()` to remove the interference highlighted by the function `ProVolumeInterferenceDisplay()` or partially highlighted by the function `ProVolumeInterferenceDisplayForBody()`.

## Faceted Geometry

Creo Parametric allows you to build a surface CAD model on top of faceted or triangular data. Each facet is uniquely identified by a face normal and three vertices.

A facet is represented by the opaque handle `ProFacet`, while a set of facets is represented by the DHandle `ProFacetSet`. `ProFacetSet` has the same structure as the object `ProModelItem` and is defined as follows:

```
typedef struct pro_model_item
{
 ProType type;
 int id;
 ProMdl owner;
} ProFacetSet;
```

## Visiting Facets and Facet Sets

The functions described below enable you to find all the facet sets in a model and visit the facets stored in those sets.

---

Functions Introduced:

- **ProSolidFacetsetVisit()**
- **ProFacetsetFacetVisit()**

The function `ProSolidFacetsetVisit()` visits each of the facet sets in a given model. This function takes the filter function `ProFacetsetFilterAction()` and the visit function `ProFacetsetVisitAction()` as its input arguments. The function `ProFacetsetFilterAction()` is a generic action function for filtering the facet sets from a model. It returns the filter status of the facet sets. This status is used as an input argument by the visit action function `ProFacetsetVisitAction()`.

The function `ProFacetsetFacetVisit()` visits the facets in the faceted geometry set. This function takes the filter function `ProFacetFilterAction()` and the visit function `ProFacetVisitAction()` as its input arguments. The function `ProFacetFilterAction()` is a generic action function for filtering a facet from the faceted geometry set. It returns the filter status of the facet. This status is used as the input argument by the visit action function `ProFacetVisitAction()`.

## Accessing Facet Properties

The functions described below allow you to access the face normal and three vertices or corners of a facet. A facet vertex is given by the object `ProFacetVertex`.

Functions Introduced:

- **ProFacetVerticesGet()**
- **ProFacetverticesFree()**
- **ProFacetvertexPointGet()**
- **ProFacetNormalGet()**

The function `ProFacetVerticesGet()` obtains the vertices of a specified facet.

Use the function `ProFacetverticesFree()` to release the memory allocated for the vertices of a facet.

The function `ProFacetvertexPointGet()` returns the location of the facet vertex in the model coordinate system.

The function `ProFacetNormalGet()` returns the normal vector of a facet in the model coordinate system.

---

# Core: Relations

## Relations

This section describes how to access relations on all models and model items in Creo Parametric using the functions provided in Creo TOOLKIT.

Functions Introduced:

- **ProModelitemToRelset()**
- **ProSolidRelsetVisit()**
- **ProRelsetToModelitem()**
- **ProRelsetPostregenerationInit()**
- **ProRelsetRegenerate()**
- **ProRelsetCreate()**
- **ProRelsetDelete()**
- **ProRelsetRelationsGet()**
- **ProRelsetRelationsSet()**
- **ProRelationEvalWithUnitsRefResolve()**
- **ProRelsetUnitsSensitiveSet()**
- **ProRelsetIsUnitsSensitive()**

Superseded Functions:

- **ProRelationEvalWithUnits()**

The object `ProRelset` represents the entire set of relations on any model or model item. It is an opaque handle whose contents can be accessed only through the functions described in this section.

Creo TOOLKIT can only access the relations of the models and model item types as listed in the table below:

| Model Types  | Description          |
|--------------|----------------------|
| PRO_PART     | Part                 |
| PRO_ASSEMBLY | Assembly             |
| PRO_DRAWING  | Drawing              |
| PRO_REPORT   | Report               |
| PRO_DIAGRAM  | Diagram              |
| PRO_DWGFORM  | Format               |
| PRO_UDF      | User-defined feature |
| PRO_FEATURE  | Feature              |
| PRO_SURFACE  | Surface              |
| PRO_EDGE     | Edge                 |

| Model Types               | Description         |
|---------------------------|---------------------|
| PRO_WELD_PARAMS           | Weld parameters     |
| PRO_BND_TABLE             | Bend table          |
| PRO_EXTOBJ                | External objects    |
| PRO_PATREL_FIRST_DIR      | Pattern direction 1 |
| PRO_PATREL_SECOND_DIR     | Pattern direction 2 |
| PRO_RELOBJ_QUILT          | Quilt               |
| PRO_RELOBJ_CRV            | Curve               |
| PRO_RELOBJ_COMP_CRV       | Compound curve      |
| PRO_RELOBJ_ANNOT_ELEM     | Annotation Element  |
| PRO_RELOBJ_NC_STEP_OBJECT | NC Step Table Entry |
| PRO_RELOBJ_NC_STEP_MODEL  | NC Step Table Model |

The function `ProModelItemToRelset()` outputs a `ProRelset` object that contains the set of initial relations owned by the given model item. (Note that not all model items can have relations sets associated with them—only the types listed in the table.)

Use the function `ProRelsetPostregenerationInit()` to initialize the post-regeneration data object `ProRelset`. The object contains post-regeneration relations in the specified model.

### Note

According to your requirement you can pass the initial relations, or the post-regeneration relations data object, `ProRelset` as input to the functions `ProRelsetRelationsGet()`, `ProRelsetRelationsSet()`, `ProRelsetRegenerate()` and `ProRelsetDelete()`.

To get the relations of a feature pattern, the model item type should be either `PRO_PATREL_FIRST_DIR` or `PRO_PATREL_SECOND_DIR`, and the identifier should be that of the dimension on the pattern leader that drives the pattern in that direction. To find the identifiers of the pattern dimension, use the functions described in the section [Manipulating Patterns on page 149](#).

The function `ProSolidRelsetVisit()` enables you to visit all the relation sets on every model item in a model. Like other visit functions, it calls a user-supplied action function for each relation set, although there is no filter function. If the user-supplied function returns any status other than `PRO_TK_NO_ERROR`, visiting will stop. The model types `PRO_PART`, `PRO_ASSEMBLY`, and `PRO_DRAWING` are supported.

The function `ProRelsetToModelItem()` outputs the model item that is the owner of the specified `ProRelset`.

---

You can regenerate a relation set using the function `ProRelsetRegenerate()`. This function also determines whether the specified relation set is valid. If an error occurred, the function returns a status other than `PRO_TK_NO_ERROR`.

To create a new relation set for a model item, use the function `ProRelsetCreate()`. If a relation set already exists for that item, the function returns `PRO_TK_E_FOUND`.

To delete all the relations in a specified relation set, call the function `ProRelsetDelete()`.

The function `ProRelsetRelationsGet()` extracts the text of a set of relations described by a `ProRelset` object. This function takes two arguments: the `ProRelset` for the relation set and a preallocated expandable array. The elements of the expandable array are of type `ProLine` (wide strings).

The function `ProRelsetRelationsSet()` creates a `ProRelset` object from an expandable array of `ProLine` objects that describes the relations as text. For details of the syntax and use of relations, see the Creo Parametric help.

#### Note

Existing relations will be overwritten by a call to `ProRelsetRelationsSet()`.

---

The function `ProRelationEvalWithUnits()` evaluates a line of a relation set and outputs the resulting value in the form of a `ProParamvalue` structure. Specify the input argument `consider_units` as `true` if you want the units of the relation to be considered while evaluating the relation. In this case, the result of the relation is returned along with its unit. See the section [Core: Parameters on page 216](#) for a description of this data structure. The use of special pattern relation symbols such as `memb_v` or `idx1` is not supported; instead, replace these symbols with the corresponding dimension value or number, and evaluate them individually.

The function `ProRelationEvalWithUnits()` cannot be used for referencing external symbols.

In Creo Parametric 8.0.0.0 and later, the function `ProRelationEvalWithUnits()` is deprecated. Use the function `ProRelationEvalWithUnitsRefResolve()` instead.

The function `ProRelationEvalWithUnitsRefResolve()` evaluates the expression that is specified on the right side of a relation line and returns the value in the form of `ProParamvalue` structure. Relations with symbols that are referenced by parameters or dimensions on a different model can be evaluated using the function `ProRelationEvalWithUnitsRefResolve()`. Specify

---

the input argument `consider_units` as `true` if you want the units of the relation to be considered while evaluating the relation. In this case, the result of the relation is returned along with its unit. See the section [Core: Parameters on page 216](#) for a description of this data structure. The use of special pattern relation symbols such as `memb_v` or `idx1` is not supported; instead, replace these symbols with the corresponding dimension value or number, and evaluate them individually.

The function `ProRelsetUnitsSensitiveSet()` specifies that units must be considered while solving the specified relation. Use the function `ProRelsetIsUnitsSensitive()` to check if units must be considered while solving the relation.

## Adding a Customized Function to the Relations Dialog in Creo Parametric

Functions Introduced:

- **`ProRelationFunctionRegister()`**
- **`ProRelationReadFunction()`**
- **`ProRelationWriteFunction()`**
- **`ProRelationArgscheckFunction()`**

The function `ProRelationFunctionRegister()` registers a custom function that is visible to users in the Creo Parametric relations dialog. To register a custom function you may supply the following:

- An array of expected arguments. The arguments are described by their type (double, integer, etc) and attributes indicating if the argument can be skipped when the user calls the relations function. These optional arguments must fall at the end of the argument list.
- A Boolean indicating whether or not to check argument types internally. If the Boolean is set not to check the argument types internally, Creo Parametric does not need to know the contents of the arguments array. The custom function you create must handle all the user errors in this situation.
- An arguments check function, which can be used to verify the input arguments.
- A read function, which provides the value of the function when used in the right-hand side of a relation. For example  

```
d12 = ptk_user_function (0.5, 5, true, inch)
```
- A write function, which receives the value when the function is used in the left-hand side of the relation. For example:  

```
ptk_user_function (assigned_value) = 14.0;
```
- All the callback functions are optional and may be `NULL`.

---

 **Note**

Creo TOOLKIT registered relations are valid only when the function has been registered by the application. If the application is not running or not present, models that contain user-defined relations cannot evaluate these relations. In this situation, the relations are marked as errors, however, they can be commented until needed at a later time when the relation functions are reactivated.

---

The function type `ProRelationReadFunction()` is called when a custom relation function is used on the right-hand side of the relation. You should output the computed value of the custom relation function which is used to complete evaluation of the relation.

The function `ProRelationWriteFunction()`, is called when a custom function is used on the left hand side of a relation. The value of the right-hand side of the relation is provided as an input. You can use this type of function to initialize properties to be stored and used by your Creo TOOLKIT application.

The function `ProRelationArgscheckFunction()` performs the argument check function for a custom relation function. Return `PRO_TK_NO_ERROR` to indicate that the arguments passed to the relation are valid. Any other error causes an error to be displayed in the Relations dialog.

The following example creates three externally defined functions to be available in the relations dialog:

`ptk_set_a` and `ptk_set_b` are used from the left-hand side of relations to initialize double values to stored "A" and "B" variables.

`ptk_eval_ax_plus_b` returns the computation of  $Ax+B$ , where  $x$  is an input to the function.

These functions are available only while the Creo TOOLKIT application is running. Models can be saved with relations referencing these functions, but these models will have relation errors if retrieved while the application is not running.

## Code Example

The sample code in the file `UgCustomRelationFunction.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_param` shows how to use the "Write" function for the assignment of the parameters used for calculation.

---

# Core: Parameters

## Parameter Objects

This section describes the Creo TOOLKIT functions that give access to parameters and geometric tolerances.

The object `ProParameter` describes the contents and ownership of a parameter. *ProParameter* is a DHandle whose declaration is as follows:

```
typedef struct proparameter
{
 ProType type;
 ProName id;
 ProParamowner owner;
} ProParameter;
typedef struct proparamowner
{
 ProParamfrom type;
 union
 {
 ProModelitem item;
 ProMdl model;
 } who;
} ProParamowner;
typedef enum proparamfrom
{
 PRM_MODEL,
 PRM_ITEM
} ProParamfrom;
```

A structure called `ProParamvalue` is used to represent the value of a parameter. Its declaration is as follows:

```
typedef struct Pro_Param_Value
{
 ProParamvalueType type;
 ProParamvalueValue value;
} ProParamvalue;
typedef enum param_value_types
{
 PRO_PARAM_DOUBLE,
 PRO_PARAM_STRING,
 PRO_PARAM_INTEGER,
 PRO_PARAM_BOOLEAN,
 PRO_PARAM_NOTE_ID,
 PRO_PARAM_VOID
} ProParamvalueType;
typedef union param_value_values
{
 double d_val;
 int i_val;
```

```

short l_val;
ProLine s_val;
} ProParamvalueValue;

```

## Parameter Values

Functions introduced:

- **ProParamvalueSet()**
- **ProParamvalueValueGet()**
- **ProParamvalueTypeGet()**
- **ProParameterIsListValue()**
- **ProParameterListValueGet()**
- **ProParameterListValueSet()**
- **ProParameterListTypeSet()**
- **ProParameterEnumeratedSet()**
- **ProParameterRangeSet()**

These three functions are utilities to help you manipulate the `ProParamvalue` structure. They do not directly affect any parameter in Creo Parametric .

The function `ProParamvalueSet ()` sets the value type of a `ProParamvalue` structure, and writes a value of that type to the object.

The function `ProParamvalueTypeGet ()` provides the type of a `ProParamvalue` object.

The function `ProParamvalueValueGet ()` reads a value of the specified type from a `ProParamvalue` structure.

The function `ProParameterIsListValue ()` provides the information if the parameter value type is a list or not. The output argument `is_list` is a `ProBoolean` and returns `PRO_B_TRUE`, if the specified parameter value type is a list, if not it returns `PRO_B_FALSE`.

Use the function `ProParameterListValueGet ()` to get the list values and units for the specified parameter handle. The function returns the following output arguments:

- `proval`—`ProArray` of `ProParamvalue`. The values are assumed to be in the units specified by the `units` argument (when the `units` argument is not `NULL`) or in the units of the owner model, when argument `units` is `NULL`.
- `units`—The units in which the values are expressed. Pass `NULL` if units is not required. If none found, an empty string will be returned.

---

Use the function `ProParameterListValueSet()` to set the list values for the specified `ProParameter` handle with the given units. The input arguments are as follows:

- *param*—Specify the handle to the parameter.
- *proval*—Specify the `ProArray` of `ProParamvalue`. The values are assumed to be in the units specified by the *units* argument (when the *units* argument is not `NULL`) or in the units of the owner model, when argument *units* is `NULL`.
- *units*—Specify the new units. The units must be the same quantity type as the units of the parameter (i.e. if the units are "inch", a value can be expressed in "cm"). Can be `NULL`. If you pass `NULL`, the function will assume the units of the owner model.

Use the function `ProParameterListTypeSet()` to set the value type as list for the specified parameter.

Use the function `ProParameterEnumeratedSet()` to set a parameter as enumerated(parameter restricted by a list of values) and to provide a list of allowed values. The input arguments are:

- *param*—Handle to the parameter.
- *valid\_values*—Specify the valid values that should be assigned to this parameter. Cannot be `NULL`.
- *p\_default*—The default (current) value for the parameter.

Use the function `ProParameterRangeSet()` to identify the value to be restricted to a certain range for the specified parameter. The input arguments are as follows:

- *param*—Handle to the parameter.
- *minimum* —The minimum value for this parameter that is specified using the object `ProParamLimit`.
- *maximum* —The maximum value for this parameter that is specified using the object `ProParamLimit`.
- *p\_default*—The default (current) value for the parameter.

## Accessing Parameters

Functions introduced:

- **`ProParameterInit()`**
- **`ProParameterValueWithUnitsGet()`**
- **`ProParameterValueWithUnitsSet()`**
- **`ProParameterIsModified()`**
- **`ProParameterValueReset()`**

- 
- **ProParameterDelete()**
  - **ProParameterSelect()**
  - **ProParameterTableExport()**
  - **ProParameterVisit()**
  - **ProParameterReorder()**
  - **ProParameterToFamtableItem()**
  - **ProParameterUnitsGet()**
  - **ProParameterUnitsAssign()**
  - **ProParameterWithUnitsCreate()**
  - **ProParameterScaledvalueGet()**
  - **ProParameterScaledvalueSet()**
  - **ProParameterDescriptionGet()**
  - **ProParameterDescriptionSet()**
  - **ProParameterLockstatusGet()**
  - **ProParameterLockstatusSet()**
  - **ProParameterIsInactive()**

The function `ProParameterInit()` initializes a `ProParameter` object by defining its name and owner. The owner is expressed in terms of a `ProModelitem` object, and can be a Creo Parametric model, feature, surface, or edge.

If the owner is a model, use `ProMdlToModelitem()` to create the `ProModelitem` object; in other cases, use `ProModelitemInit()`.

The function `ProParameterValueWithUnitsGet()` reads the value of a parameter specified by a `ProParameter` object into a `ProParamvalue` object provided by the application. The function also retrieves the units in which the parameter value was expressed. The output arguments of this function are as follows:

- `proval`—The value held in the `ProParameter` object and is assumed to be in the specified units. Pass this as `NULL` to get the value in owner model units.
- `units`—The units in which the value is expressed. Pass this as `NULL` if unit is not required. If the value is not found, an empty string is returned.

---

The function `ProParameterValueWithUnitsSet()` sets the value of a Creo Parametric parameter identified by a `ProParameter` object to a value specified in a `ProParamvalue` structure. The parameter is expressed using the value specified for the input parameter *units*.

---

 **Note**

If the input argument *units* is passed as `NULL`, then the parameter will have the same units as that of the owner model.

---

The `ProParameterIsModified()` function returns a boolean value that indicates whether the value of the specified parameter has been modified since the last successful regeneration of the parameter owner. This function works successfully for solid models only.

The function `ProParameterValueReset()` sets the value of a parameter to the one it had at the end of the last regeneration.

The function `ProParameterDelete()` deletes a parameter, specified by a `ProParameter` object, from the Creo Parametric database.

The function `ProParameterSelect()` allows the user to select one or more parameters of a specified model or database item from the **Parameters** dialog box in Creo Parametric. The top model from which the parameters will be selected must be displayed in the current window. The input argument *context* allows you to select parameters by context. It takes the following values:

- `PRO_PARAMSELECT_ANY`—Specifies any parameter.
- `PRO_PARAMSELECT_MODEL`—Specifies the parameters of the top-level model.
- `PRO_PARAMSELECT_PART`—Specifies the parameters of any part.
- `PRO_PARAMSELECT_ASM`—Specifies the parameters of any assembly.
- `PRO_PARAMSELECT_FEATURE`—Specifies the parameters of any feature.
- `PRO_PARAMSELECT_EDGE`—Specifies the parameters of any edge.
- `PRO_PARAMSELECT_SURFACE`—Specifies the parameters of any surface.
- `PRO_PARAMSELECT_QUILT`—Specifies the parameters of any quilt.
- `PRO_PARAMSELECT_CURVE`—Specifies the parameters of any curve.
- `PRO_PARAMSELECT_COMPOSITE_CURVE`—Specifies the parameters of any composite curve.
- `PRO_PARAMSELECT_INHERITED`—Specifies the parameters of any inheritance feature.

- 
- `PRO_PARAMSELECT_SKELETON`—Specifies the parameters of any skeleton.
  - `PRO_PARAMSELECT_COMPONENT`—Specifies the parameters of any component.
  - `PRO_PARAMSELECT_ALLOW_SUBITEM_SELECTION`—Specifies the parameters of all the subitems of the top model.

---

 **Note**

The signature of `ProParameterSelect()` has changed from `Pro/ENGINEER Wildfire 2.0` onward.

---

The function `ProParameterTableExport()` exports a file containing information from a parameter table in Creo Parametric in the CSV or TXT format. If the output type is CSV, the output file contains the columns specified by the input argument *column\_list*, which is a bitmask of columns. In the CSV format, only the local parameters are exported. However, if the output type is TXT, then a default set of columns is exported. In the TXT format, all the parameters in the specified model are exported.

The function `ProParameterVisit()` visits all the parameters on a specified database item.

---

 **Note**

- The parameters are returned in the order that they appear in the parameter dialog box for the database item.
  - `ProParameterVisit()` does not visit mass property parameters.
- 

The function `ProParameterReorder()` reorders the given parameter to come just after the indicated parameter.

The function `ProParameterToFamtableItem()` converts `ProParameter` objects to `ProFamtableItem` objects. You may need to call `ProParameterToFamtableItem()` after calling `ProParameterSelect()` that allows you to select parameters from a menu.

The function `ProParameterUnitsGet()` fetches the units assigned to a parameter.

---

The function `ProParameterUnitsAssign()` assigns the specified unit to a parameter. If the parameter already has a unit assigned to it, the function will reassign the specified unit to it. The function can reassign unit only from the same quantity type. To convert a parameter with unit to a unitless parameter, pass the input argument *units* as `NULL`.

The function `ProParameterWithUnitsCreate()` enables the creation of a new parameter with the assigned units. To create a parameter without units, pass the input argument *units* as `NULL`.

The function `ProParameterScaledvalueGet()` retrieves the parameter value in terms of the units of the parameter, instead of the units of the owner model.

The function `ProParameterScaledvalueSet()` sets the parameter value in terms of the units provided, instead of using the units of the owner model.

The function `ProParameterDescriptionGet()` obtains the description of the parameter. The function `ProParameterDescriptionSet()` assigns the description of the parameter.

The function `ProParameterLockstatusGet()` returns the access state of the specified parameter. Use the function `ProParameterLockstatusSet()` to set the access state for the specified parameter. The access state is defined in the enumerated data type `ProLockstatus`. The valid values are:

- `PRO_PARAMLOCKSTATUS_UNLOCKED`—Parameters with full access are user-defined parameters, that can be modified from any application.
- `PRO_PARAMLOCKSTATUS_LIMITED`—Full access parameters can be set to have limited access. Limited access parameters can be modified by user, family tables and programs. These parameters cannot be modified by relations.
- `PRO_PARAMLOCKSTATUS_LOCKED`—Parameters with locked access are parameters that can be locked either by an external application, or by the user. If you have set the access state for a parameter using the function `ProParameterLockstatusSet()` and need to modify the parameter, you can change the access state from locked status to full access and then edit the parameter value. This can be done from an external application or an open Creo session.

The function `ProParameterIsInactive()` determines if the specified parameter is inactive.

---

#### **Note**

The function supports symbol instance and surface finish annotation element parameters only.

---

---

If the parameter is inactive due to current customization of symbol, the function outputs a `ProBoolean` with the value `PRO_B_TRUE`. Otherwise the function returns `PRO_B_FALSE`.

## Notification Functions

The parameter notification functions support the parameters owned by an annotation element. These functions are call back functions and are accessible by calling the function `ProNotificationSet()`.

- **`ProParameterCreateWithUnitsPreAction()`**
- **`ProParameterDeletePreAction()`**
- **`ProParameterModifyWithUnitsPreAction()`**
- **`ProParameterCreatePostAction()`**
- **`ProParameterModifyWithUnitsPostAction()`**
- **`ProParameterDeleteWithUnitsPostAction()`**

The notification function `ProParameterCreateWithUnitsPreAction()` is called before the parameter is created in the Creo Parametric user interface. This function is available by calling `ProNotificationSet()` with the value of the notify type as `PRO_PARAM_CREATE_W_UNITS_PRE`. You can specify the units for the parameter.

The notification function `ProParameterDeletePreAction()` is called before the parameter is deleted. This function is available by calling `ProNotificationSet()` with the value of the notify type as `PRO_PARAM_DELETE_PRE`.

The notification function `ProParameterModifyWithUnitsPreAction()` is called before a parameter is modified in the Creo Parametric user interface. This function is available by calling `ProNotificationSet()` with the value of the notify type as `PRO_PARAM_MODIFY_W_UNITS_PRE`. The function returns the old and new units of the parameter along with the values.

You can use the `PreAction` functions to cancel any changes made to the parameters. If any value except `PRO_TK_NO_ERROR` is returned, then the change is not permitted. The application must provide appropriate messaging to the user to explain the reason for which the change was rejected.

---

### **Note**

You are not permitted to cancel the parameter modification events when modifying multiple parameters as a group.

---

---

The notification function `ProParameterCreatePostAction()` is called after a parameter has been created. This function is available by calling `ProNotificationSet()` with the value of the notify type as `PRO_PARAM_CREATE_POST`.

The notification function

`ProParameterModifyWithUnitsPostAction()` is called after a parameter has been modified in the Creo Parametric user interface. This function is available by calling `ProNotificationSet()` with the value of the notify type as `PRO_PARAM_MODIFY_W_UNITS_POST`. The function returns the old and modified units of the parameter along with the values.

The notification function

`ProParameterDeleteWithUnitsPostAction()` is called after a parameter has been deleted in the Creo Parametric user interface. This function is available by calling `ProNotificationSet()` with the value of the notify type as `PRO_PARAM_DELETE_W_UNITS_POST`.

## Example 1: Labeling a Feature with a String Parameter

The sample code in `UgParamFeatLabel.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_param` shows how to label the selected feature with the specified string parameter. The program calls `ProParameterInit()` to find out whether the parameter already exists.

## Designating Parameters Windchill Servers

Functions introduced:

- **`ProParameterDesignationAdd()`**
- **`ProParameterDesignationVerify()`**
- **`ProParameterDesignationRemove()`**

These functions control the designation of parameters for Windchill servers. A designated parameter will become visible within these management systems as an attribute on the owning model when it is next submitted.

The function `ProParameterDesignationAdd()` designates an existing parameter, referred to by its `ProParameter` object.

The function `ProParameterDesignationRemove()` removes the designation.

---

 **Note**

PTC does not recommend undesignating or deleting a parameter that is already exposed to a Product Data Management system, such as Windchill PDMLink or Pro/INTRALINK.

---

The function `ProParameterDesignationVerify()` tells you whether a specified model parameter is currently designated or not.

## Restricted Parameters

Restricted parameters can have either:

- an enumeration which limits values only to those specified in advance; or
- a range which limits numerical values to fall within that range.

Functions introduced:

- **ProParameterIsEnumerated()**
- **ProParameterRangeGet()**

Use the function `ProParameterIsEnumerated()` to identify if a parameter is enumerated, and provides the values that may be assigned to it. If the parameter is enumerated then it gives the `ProArray` of values that are assigned to this parameter.

Use the function `ProParameterRangeGet()` to identify if a parameter's value is restricted to a certain range. If the parameter is restricted by a range then it gives the maximum and minimum value of the parameter.

## Table-Restricted Parameters

A parameter table is made up of one or more parameter table sets. Each set represents one or more parameters with their assigned values or assigned ranges. A given parameter owner (model, feature, annotation element, geometry item) can only have one parameter table set applied that creates a given parameter. In Creo TOOLKIT, a parameter table set is represented by the type `ProParamtableSet` and is made up of entries, represented by `ProParamtableEntry`. A single entry represents a parameter with an assigned value or range.

Functions introduced:

- **ProParameterTablesetGet()**
- **ProMdlParamtablesetsCollect()**

- **ProParamtablesetEntriesGet()**
- **ProParamtablesetTablepathGet()**
- **ProParamtablesetLabelGet()**
- **ProParamtablesetFree()**
- **ProParamtablesetProarrayFree()**
- **ProParamtableentryValueGet()**
- **ProParamtableentryRangeGet()**
- **ProParamtableentryNameGet()**
- **ProParamtableentryProarrayFree()**
- **ProParamtablesetApply()**
- **ProRelsetConstraintsGet()**

Use the function `ProParameterTablesetGet()` to obtain the governing parameter table set for this parameter, if it's a member of a set.

Use the function `ProMdlParamtablesetsCollect()` to obtain an array of all the table sets that are available for use in the given model. This includes all sets that are loaded from table files that are set up in this session, and any other sets that were previously stored in the model.

Use the function `ProParamtablesetFree()` to free the parameter table set and the function `ProParamtablesetProarrayFree()` to free an array of parameter table sets.

Use the function `ProParamtablesetEntriesGet()` to obtain the entries that are contained in a parameter table set.

Use the function `ProParamtablesetTablepathGet()` to obtain the name of the table that owns this parameter table set. If the set is loaded from a certain table file, this is the full path. If the set has been stored in the model directly, this is the table name.

Use the function `ProParamtablesetLabelGet()` to obtain the set label for a given parameter table set.

Use the function `ProParamtableentryNameGet()` to obtain the name for the parameter in this table set.

Use the function `ProParamtableentryValueGet()` to obtain the value for the parameter in this table set. If the parameter also has a range applied, this is the default value for the parameter. Use the function

`ProParamtableentryRangeGet()` to obtain the permitted range for the parameter in this table set. The output arguments for this function are:

- *minimum*—The minimum value for this parameter as set by the parameter set.
- *maximum*—The maximum value for this parameter as set by the parameter set

---

You can use the function `ProParamtableentryProarrayFree()` to free an array of table entries.

The function `ProParamtablesetApply()` assigns this parameter set to the given parameter owner. Parameters used by the set are created or modified, as appropriate. The parameter values are set to the default values. This function does not regenerate the model and may fail if the parameter owner already has one or more of the set's required parameters defined which are not driven by this table.

The function `ProRelsetConstraintsGet()` obtains the constraints applied to a given relation set. Constraints may be assigned when one or more parameters of the set is governed by an external parameter file.

## Driven Parameters

The functions described below provide access to the item (parameter or function) driving model parameters.

Functions Introduced:

- **ProParameterDrivertypeGet()**
- **ProParameterDrivingsymbolGet()**
- **ProParameterDrivingparamSet()**
- **ProParameterDrivingFunctionGet()**
- **ProParameterDrivingFunctionSet()**

The function `ProParameterDrivertypeGet()` retrieves the type of operation that is driving a model parameter in the form of `ProParameterDriver` object. In assemblies, you can refer to a parameter that belongs to another model. The function `ProParameterDrivertypeGet()` returns information for such parameters, which are referenced in the current model but belong to another model. The types of drivers are as follows:

- `PRO_PARAMDRIVER_PARAM`—Specifies the parameter driving the model parameter.
- `PRO_PARAMDRIVER_FUNCTION`—Specifies the function driving the model parameter.
- `PRO_PARAMDRIVER_RELATION`—Specifies the relation driving the model parameter.

The function `ProParameterDrivingsymbolGet()` retrieves the driving parameter for a model parameter, if the driver type is `PRO_PARAMDRIVER_PARAM`. The function `ProParameterDrivingsymbolGet()` also returns information for parameters, which are referenced in the current model but belong to another model.

---

The function `ProParameterDrivingparamSet()` sets the driver type for a material parameter to the value `PRO_PARAMDRIVER_PARAM`.

The function `ProParameterDrivingFunctionGet()` obtains the driving function for a material parameter, if the driver type is `PRO_PARAMDRIVER_FUNCTION`.

The function `ProParameterDrivingFunctionSet()` sets the driver type for a material parameter to the value `PRO_PARAMDRIVER_FUNCTION`.

## Core: Coordinate Systems and Transformations

### Coordinate Systems

This section describes the various coordinate systems used by Creo Parametric and Creo TOOLKIT, and how to transform coordinates from one to another.

Creo Parametric and Creo TOOLKIT use the following coordinate systems:

- [Solid coordinate system on page 228](#)
- [Screen coordinate system on page 229](#)
- [Window coordinate system on page 229](#)
- [Drawing coordinate system on page 229](#)
- [Drawing and drawing view coordinate system on page 229](#)
- [Assembly coordinate system on page 230](#)
- [Datum coordinate system on page 230](#)
- [Section coordinate system on page 230](#)

### Solid Coordinate System

The solid coordinate system is the three-dimensional, Cartesian coordinate system used to describe the geometry of a Creo Parametric solid model. In a part, the solid coordinate system describes the geometry of the surfaces and edges. In an assembly, the solid coordinate system also describes the locations and orientations of the assembly members.

You can visualize the solid coordinate system in Creo Parametric by creating a coordinate system datum with the option **Model ► Coordinate System**. Distances measured in solid coordinates correspond to the values of dimensions as seen by the Creo Parametric user.

Solid coordinates are used by Creo TOOLKIT for all the functions that look at geometry, and most of the functions that draw three-dimensional graphics.

---

## Screen Coordinate System

The screen coordinate system is a two-dimensional coordinate system that describes locations in a Creo Parametric window. This is an intermediate coordinate system after which the screen points are transformed to screen pixels. All the models are first mapped to the screen coordinate system. When the user zooms or pans the view, the screen coordinate system follows the display of the solid, so a particular point on the solid always maps to the same screen coordinate. The mapping changes only when the view orientation is changed.

Screen coordinates are used by some of the graphics functions, the mouse input functions, and all the functions that draw graphics or manipulate items on a drawing.

## Window Coordinate System

The window coordinate system is similar to the screen coordinate system. After mapping the models to the screen coordinate system, they are mapped to the window coordinate before being drawn to screen pixels based on screen resolution. When pan or zoom values are applied to the coordinates in the screen coordinate system, they result in window coordinates. When an object is first displayed in a window, or the option **View ► Refit** is used, the screen and window coordinates are the same.

You can use the function `ProWindowCoordinatePixelGet()` to get the window point in pixel coordinates.

The 3D point that is projected to 2D will be visible on the screen only if it lies within the outline that is returned by the function `ProWindowPixelOutlineGet()`. If not, it will be clipped and will not be visible on the screen.

## Drawing and Drawing View Coordinate System

The drawing coordinate system is a two-dimensional system that describes the location on a drawing relative to the bottom, left corner, and measured in drawing units. For example, on a U.S. letter-sized, landscape-format drawing sheet that uses inches, the top, right corner is (11, 8.5) in drawing coordinates.

The Creo TOOLKIT functions that manipulate drawings generally use screen coordinates.

## Drawing View Coordinate System

This drawing view coordinate system is used to describe the locations of entities in a drawing view.

---

## Assembly Coordinate System

An assembly has its own coordinate system that describes the positions and orientations of the member parts and subassemblies, and the geometry of datum features created in the assembly.

When an assembly is retrieved into memory, each member is loaded too, and continues to use its own solid coordinate system to describe its geometry.

This is important when you are analyzing the geometry of a subassembly, and want to extract or display the results relative to the coordinate system of the parent assembly.

## Datum Coordinate System

A coordinate system datum can be created anywhere in any part or assembly, and represents a user-defined coordinate system. It is often a requirement in a Creo TOOLKIT application to describe geometry relative to such a datum.

## Section Coordinate System

Every sketch has a coordinate system used to locate entities in that sketch. Sketches used in features will use a coordinate system different from that of the solid model.

## Coordinate System Transformations

Functions Introduced:

- **ProPntTrfEval()**
- **ProVectorTrfEval()**

All coordinate systems are treated in Creo TOOLKIT as if they were three-dimensional. Therefore, a point in any of the coordinate systems described is always represented in C by the following type:

```
typedef double ProPoint3d[3]
```

Vectors are distinguished for clarity by a different, though equivalent, declaration:

```
typedef double ProVector[3]
```

, Screen, window and section coordinates contain a Z value whose positive direction is normal to the screen or the sketch. The value of Z is not generally important when specifying a screen location as an input to a function, but it is useful in other situations. For example, if the user selects a datum plane, you can find out which side is towards the user by calculating the normal to the plane, transforming to screen coordinates, then looking at the sign of the Z coordinate.

A transformation between two coordinate systems is represented by a 4x4 matrix, with the following type:

```
typedef double ProMatrix[4][4];
```

---

This combines the conventional 3x3 matrix that describes the relative orientation of the two systems, and the vector that describes the shift between them.

### Transformation Matrix

Creo TOOLKIT provides two utilities for performing coordinate transformations. The function `ProPntTrfEval()` transforms a three-dimensional point, and `ProVectorTrfEval()` transforms a three-dimensional vector.

The source code for other utilities that manipulate transformation matrices is located in the file `Matrix.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_examples/pt_utils/Util`.

## Transforming Solid to Screen Coordinates

Functions Introduced:

- **ProViewMatrixGet()**
- **ProViewMatrixSet()**

The view matrix describes the transformation from solid to screen coordinates. The function `ProViewMatrixGet()` provides the view matrix for the specified view. [Example 1: Solid Coordinates to Screen Coordinates on page 231](#) shows a function that transforms a point, using the `ProViewMatrixGet()` function, and an example user function.

The function `ProViewMatrixSet()` changes the orientation of the solid model on the screen.

### Example 1: Solid Coordinates to Screen Coordinates

The sample code in the file `UgFundSolid2Screen.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_fundament` shows how to transform solid coordinates to screen coordinates.

---

## Example 2: Transform from Solid Coordinates to Screen Coordinates

The sample code in the file `UgFundCsysTrf.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_fundament` shows how to extract a selected point from the surface of a solid model, transform it from solid coordinates to screen coordinates, write the results into a file and display it.

## Transforming Screen to Window Coordinates

Functions Introduced:

- **ProWindowCurrentMatrixGet()**
- **ProWindowPanZoomMatrixSet()**

Transformation from screen to window coordinates consists solely of a zoom factor and pan in X and Y.

The function `ProWindowCurrentMatrixGet()` gets the transformation matrix for the window. A pan and zoom transformation matrix consists of:

- The scale factor, running down the diagonal of the matrix. For example, to zoom in by a factor of 2, the value 2.0 will be down the diagonal in the elements (0,0), (1,1), and (2,2).
- The translation factor (pan) in the elements (3,0) - X and (3,1) - Y.
- The element at (3,3) should be 1.0.

The function `ProWindowPanZoomMatrixSet()` can change the pan and zoom of the window. The matrix should contain only the elements listed above, for function `ProWindowCurrentMatrixGet()`.

## Transforming from Drawing View to Screen Coordinates in a Drawing

Function Introduced:

- **ProDrawingViewTransformGet()**

The function `ProDrawingViewTransformGet()` performs the transformation from drawing view coordinates (solid) to screen coordinates. It describes where a particular point on the solid will be in the drawing for a particular view of the solid.

## Transforming from Screen to Drawing Coordinates in a Drawing

Function Introduced:

- **ProDrawingSheetTrfGet()**

---

The function `ProDrawingSheetTrfGet()` returns the matrix that transforms screen coordinates to drawing coordinates. The function performs this transformation for the first sheet.

### Example 3: Screen Coordinates to Drawing Coordinates

The sample code in the file `UgFundScreen2Drw.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_fundament` allows you to transform the screen coordinates to drawing coordinates.

### Example 4: Transform from Screen Coordinates to Drawing Coordinates

The sample code in the file `UgFundCsysTrf.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_fundament` allows you to select a point from the screen, transform it from screen coordinates to drawing coordinates, write the results into a file and display it.

## Transforming Coordinates of an Assembly Member

Function Introduced:

- **ProAsmcomppathTrfGet()**

The function `ProAsmcomppathTrfGet()` provides the matrix for transforming from the solid coordinate system of the assembly member to the solid coordinates of the parent assembly, or the reverse.

## Transforming to Coordinate System Datum Coordinates

Functions Introduced:

- **ProCsysDataGet()**
- **ProMatrixInit()**

The function `ProCsysDataGet()` provides the location and orientation of the coordinate system datum in the solid coordinate system of the solid that contains it. The location is in terms of the directions of the three axes, and the position of the origin. When these four vectors are made into a transformation matrix using the function `ProMatrixInit()`, that matrix defines the transformation of a point described relative to the coordinate system datum back to solid coordinates. To transform the other way, which is the more usual requirement, you need to invert the matrix. The example function `ProUtilMatrixInvert()`, inverts the specified matrix.

---

## Transforming Coordinates of Sketched Entities

Function Introduced:

- **ProSectionLocationGet()**

The function `ProSectionLocationGet()` provides the matrix for transforming from the solid coordinate system to the sketch coordinate system, or the reverse.

### Example 5: Using Several Coordinate Transforms

The sample code in the file `UgGraphZoomAtPoint.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_graphics` demonstrates how to use several coordinate transformations. The function will zoom in on a solid model, with the results centered at the selected location.

## Core: Family Tables

### Family Table Objects

This section describes how to use Creo TOOLKIT functions to manipulate the family table for an object.

To enable access to family tables, Creo TOOLKIT implements the following objects (all DHandles):

- `ProFamtable`—A structure that contains the owner, type, and integer identifier of a family table.
- `ProFaminstance`—A structure that contains the name of a family table instance and the handle of the family table to which it belongs.
- `ProFamtableItem`—A structure that contains the type, name, and owner of a family table item (or column).

### Family Table Utilities

Functions Introduced:

- **ProFamtableInit()**
- **ProFamtableCheck()**
- **ProFamtableEdit()**
- **ProFamtableShow()**
- **ProFamtableErase()**

---

- **ProFamtableIsModifiable()**

Before you can manipulate the family table information stored in an object, you must get the handle to its family table using the function

`ProFamtableInit()`. Then use `ProFamtableCheck()` to determine whether the family table is empty (for a `ProSolid`, `ProPart`, or `ProAssembly` object, use `ProSolidFamtableCheck()`

The function `ProFamtableEdit()` opens a Pro/TABLE window for editing the specified family table, producing the same effect as the Creo Parametric command **Edit** in the **Family Table** dialog box.

Similarly, a call to `ProFamtableShow()` presents the family table in the same manner as the Creo Parametric command **Family Tab, Show**.

The function `ProFamtableErase()` clears the family from the current session, similar to the Creo Parametric command **Family Tab, Erase Table**.

The function `ProFamtableIsModifiable()` checks whether the specified family table can be modified.

## Visiting Family Tables

Functions Introduced:

- **ProFamtableInstanceVisit()**
- **ProFamtableItemVisit()**

As with the other Creo TOOLKIT traversal functions, the traversal functions for family tables visit family table objects and pass each object to action and filter functions that you supply.

For example, the function `ProFamtableInstanceVisit()` visits all the family's instances and calls the user-supplied functions of type `ProFamtableInstanceAction()` and `ProFamtableInstanceFilter()`.

The function `ProFamtableItemVisit()` visits each family table item (or column) and calls the user-supplied functions of type `ProFamtableItemAction()` and `ProFamtableItemFilter()`.

## Operations on Family Table Instances

Functions Introduced:

- **ProFaminstanceValueGet()**
- **ProFaminstanceValueSet()**
- **ProFaminstanceFamtableItemIsDefault()**
- **ProFaminstanceAdd()**

- 
- **ProFaminstanceCheck()**
  - **ProFaminstanceIsModifiable()**
  - **ProFaminstanceInit()**
  - **ProFaminstanceRemove()**
  - **ProFaminstanceSelect()**
  - **ProFaminstanceMdlGet()**
  - **ProFaminstanceErase()**
  - **ProFaminstanceLock()**
  - **ProFaminstanceRetrieve()**
  - **ProFaminstanceGenericGet()**
  - **ProFaminstanceImmediategenericinfoGet()**
  - **ProFaminstanceIsVerified()**
  - **ProFaminstanceIsExtLocked()**
  - **ProFaminstanceIsFlatState()**

The functions in this section enable you to programmatically manipulate instances that appear in a family table.

The function `ProFaminstanceValueGet()` retrieves the value of the family table item for the specified family table instance. Use the function `ProFaminstanceValueSet()` to change the value of the specified family table item.

For the specified instance, use the function `ProFaminstanceFamtableItemIsDefault()` to determine if the specified item has the default value, which is the value of the specified item in the generic model.

The functions `ProFaminstanceValueGet()`, `ProFaminstanceValueSet()`, and `ProFaminstanceFamtableItemIsDefault()` require the instance and the item handles as input values, both of which are available via the visit functions.

The function `ProFaminstanceAdd()` adds an instance to a family table. Note that you must initialize the handle to the new instance (using `ProFaminstanceInit()`) before adding the instance to the table.

Use the function `ProFaminstanceRemove()` to remove the specified instance from the family table.

The function `ProFaminstanceMdlGet()` retrieves the handle to the instance model for the given instance that is in session.

---

To erase an instance model from memory, call the function `ProFaminstanceErase()`.

The function `ProFaminstanceCheck()` checks the existence and lock status of the specified instance. Use the function `ProFaminstanceLock()` to make changes to the lock status of an instance.

The function `ProFaminstanceIsModifiable()` checks whether the given instance of a family table can be modified.

Given the instance handle, the function `ProFaminstanceRetrieve()` retrieves an instance of a model from disk. Note that you must allocate space for the resulting `ProMdl` object. In addition, you must call `ProSolidDisplay()` to display the instance model.

The function `ProFaminstanceGenericGet()` retrieves the generic model handle for a given instance model. This function includes the ability to choose between the immediate and the top-level generic models.

From Pro/ENGINEER Wildfire 4.0 onwards, the behavior of the function `ProFaminstanceGenericGet()` has changed as a result of performance improvement in family table retrieval. When you now call the function `ProFaminstanceGenericGet()` with the flag `immediate` set to `TRUE`, the function returns a new error code `PRO_TK_CANT_OPEN` if the immediate generic is currently not in session. Use the function `ProFaminstanceImmediategenericinfoGet()` to get the name and model type of the immediate generic model. This information can be used to retrieve the immediate generic model.

If you wish to turn-off this behavior and continue to run legacy applications in the pre-Wildfire 4.0 mode, set the configuration option `retrieve_instance_dependencies` to `instance_and_generic_deps`.

The function `ProFaminstanceIsVerified()` identifies whether the instance has been verified, and whether the verification succeeded or failed.

The function `ProFaminstanceIsExtLocked()` identifies whether the instance has been locked by an external application.

The function `ProFaminstanceIsFlatState()` identifies whether an instance is a sheetmetal flat state instance.

## Operations on Family Table Items

Functions Introduced:

- **`ProFamtableItemAdd()`**
- **`ProFamtableItemRemove()`**
- **`ProFamtableItemToModelitem()`**
- **`ProModelitemToFamtableItem()`**

- 
- **ProFamtableItemToParameter()**
  - **ProParameterToFamtableItem()**

These functions enable you to programmatically manipulate family table items (column values).

The function `ProFamtableItemAdd()` adds the specified item to a family table. Similarly, `ProFamtableItemRemove()` removes the specified item from the family table.

The functions `ProFamtableItemToModelitem()` and `ProModelitemToFamtableItem()` convert between `ProFamtableItem` and `ProModelitem` objects. Note that user selections (`ProSelection` objects) can be converted to `ProFamtableItem` objects by calling the functions `ProSelectionModelitemGet()` and `ProModelitemToFamtableItem()`.

The functions `ProFamtableItemToParameter()` and `ProParameterToFamtableItem()` convert between `ProFamtableItem` and `ProParameter` objects. Note that you might need to call `ProParameterToFamtableItem()` after calling `ProParameterSelect()` (which enables users to select parameters from a menu).

### Column Name Size in Family Tables

`#define PRO_FAMTAB_FIELDNAME_SIZE` changes field limit for the family table column name to `PRO_PATH_SIZE`.

So applications built on and after Creo 11.0.0.0 can work with longer family table columns names.

## Core: External Data

### Introduction to External Data

This section describes how to store and retrieve external data. External data is a Creo TOOLKIT application to be stored in the Creo Parametric database in a way that is invisible to the Creo Parametric user.

External data provides a way for the Creo TOOLKIT application to store its own private information about a Creo Parametric model within the model file. The data is built and interrogated by the Creo TOOLKIT application as a workspace data structure. It is saved to the model file when the model is saved, and retrieved when the model is retrieved. The external data is otherwise ignored by Creo Parametric, so the Creo TOOLKIT application has complete control over the form and content.

---

The external data for a particular Creo Parametric model is broken down into classes and slots. A class is a named “bin” for your data, and simply identifies it as yours so no other Creo TOOLKIT application (or other classes in your own application) will use it by mistake. A Creo TOOLKIT application usually needs only one class. The class name should be unique for each model, and describe the role of the data in your application.

Each class contains a list of data slots. Each slot is identified by either a name or an identifier, and contains a single data item of one of the following types:

- Integer
- Double
- Wide string (maximum length = 512 characters)
- Stream (maximum size = 512 kilobytes). A slot of type stream contains a completely unformatted sequence of bytes with unrestricted values. The slot also records the number of bytes in the stream, so no termination rules are assumed. The stream type should be used only when the format is completely controlled by your application in a platform-independent way. For example, if the volume of external data is very large, the stream format might be used to store the data in a more compressed form for greater efficiency.
- section. The section data type is similar to the stream data. It has the following advantages as compared to stream data type:
  - section data type has no limit on data length.
  - The name of the slot is used as the name of the section.

Stream and section slots could also be used as a shortcut way to store, for instance, an entire C structure, or an array of C structures, without any formatting. However, if you are supporting more than one platform with your Creo TOOLKIT application, remember that the mapping of a C structure may differ between platforms.

If external data is stored during a Creo Parametric session on one platform and retrieved on another, the values of integer, double, and wide string slots will be preserved correctly, regardless of any differences in the coding of those data types by the two C compilers. Stream and section slots will be preserved with exactly the same byte values and sequence that was saved, regardless of byte-swap conventions on the two platforms.

External data is stored in the workspace and is accessible only through the functions provided for that purpose. Two objects are used to reference the data contents: `ProExtdataClass` and `ProExtdataSlot`. These are both declared as `DHandles`—visible data structures. The declarations are as follows:

```
typedef struct pro_extdata_class
{
 ProMdl p_model;
 ProName class_name;
```

---

```

} ProExtdataClass;

typedef struct pro_extdata_slot
{
 ProExtdataClass *p_class;
 ProName slot_name;
 int slot_id;
} ProExtdataSlot;

```

Each slot has two ways to be identified: a name, which is defined by the application when the slot is created, or an identifier, which is allocated automatically. You can choose which kind of identifier to use for each slot. The Creo TOOLKIT functions for external data do not use the usual return type `ProError`. Instead, they use an enumerated type called `ProExtdataErr` that contains error statuses that are more specific to the needs of those functions. All the declarations relevant to external data are in the header file `ProExtdata.h`.

## Storing External Data

Functions Introduced:

- **ProExtdataInit()**
- **ProExtdataClassRegister()**
- **ProExtdataClassUnregister()**
- **ProExtdataSlotCreate()**
- **ProExtdataSlotWrite()**
- **ProExtdataSlotDelete()**
- **ProExtdataTerm()**

---

### Note

For the functions `ProExtdataClassRegister()` and `ProExtdataSlotCreate()`, the combined length of the class and slot names must not exceed `PRO_NAME_SIZE - 2`. `PRO_NAME_SIZE` is 32 character and is defined in file `ProSizeConst.h`.

---

The first step in manipulating external data for a model in a Creo Parametric session is to call the initialize function `ProExtdataInit()` for that model.

Next, set up a class using the function `ProExtdataClassRegister()`. The inputs are the `ProMdl` object and the class name, in the form of a wide string. The function outputs a `ProExtdataClass` used thereafter by the application to reference the class.

---

You can delete a class that is no longer needed using the function `ProExtdataClassUnregister()`.

The function `ProExtdataSlotCreate()` creates an empty data slot. The inputs are the `ProExtdataClass` object and the slot name, in the form of a wide string. The function outputs a `ProExtdataSlot` object to identify the new slot. You can use `NULL` as the value of the slot name argument, in which case the function allocates a unique integer identifier for the slot (which becomes the value of the field `slot_id` in the `ProExtdataSlot` structure).

### Consider this information about slots:

- Slot names cannot begin with a number.
- If you do not specify a slot name or pass `NULL` for the input argument `slot_name` in `ProExtdataSlotCreate()`, the slot name will be internally managed to be unique to avoid overwriting the slot data.
- If the slot data type is `PRO__CHAPTER__TYPE`, the following is true: If you pass a valid string value for the input argument `slot_name` in `ProExtdataSlotCreate()`, then the slot is created under Global workspace and not in the individual Class workspaces. Hence, you should pass a unique slot name that is not used anywhere across all the classes. For example, you can append the class name to the slot name to make it unique.
- Although class and slot names are individually restricted to a length of `PRO__NAME__SIZE`, they must also have a combined length shorter than `PRO__NAME__SIZE—2`. If you try to use combined names longer than `PRO__NAME__SIZE—2`, the function `ProExtdataSlotCreate()` returns the error `PROEXTDATA__TK__NAMES__TOO__LONG`.

The function `ProExtdataSlotWrite()` specifies the slot data type and writes an item of that type to the slot. The inputs are:

- The slot object `ProExtdataSlot`
- A flag showing whether the slot is identified by name or integer
- The data type of the slot
- The number of bytes in the data. Specify this argument only when the data type is stream or section.
- A pointer to the data (cast to `void*`)

A slot of type stream has a maximum size of 512 kilobytes. If this size is exceeded, `ProExtdataSlotWrite()` returns the status `PROEXTDATA__TK__STREAM__TOO__LARGE`. For data of size larger than 512 kilobytes, use the slot of type section.

You can delete an unused slot using the function `ProExtdataSlotDelete()`.

---

If the user and application no longer need external data in session, call `ProExtdataTerm()` to clean the external data from memory.

---

 **Note**

`ProExtdataTerm()` does not affect the contents of any file on the disk. It only removes all external data from the memory. Changes made to external data during the current session are not stored in the file until you save the model. If you call `ProExtdataTerm()` after making changes to the model, all external data changes (such as newly created slots, changed slot value, and deleted slot) made since the last `ProMdlSave()` are lost.

---

## Retrieving External Data

Functions Introduced:

- **`ProExtdataLoadAll()`**
- **`ProExtdataClassNamesList()`**
- **`ProExtdataSlotIdsList()`**
- **`ProExtdataSlotNamesList()`**
- **`ProExtdataSlotRead()`**
- **`ProExtdataFree()`**

For improved performance, external data is not loaded automatically into memory with the model. When the model is in session, call the function `ProExtdataLoadAll()` to retrieve all the external data for the specified model from the Creo Parametric model file and put it in the workspace. The function needs to be called only once to retrieve all the data.

Note that the function `ProExtdataLoadAll()` provides better performance than `ProExtdataClassNamesList()`, `ProExtdataSlotNamesList()`, and `ProExtdataSlotRead()` because these functions load only specific information (class names, slot names, and slot files, respectively), which can be slow.

The `ProExtdataClassNamesList()` function provides an array of the names of all the external data classes registered in a specified model.

The function `ProExtdataSlotIdsList()` provides an array of the integer identifiers of all the slots in a specified class. The input is a `ProExtdataClass` structure that must be set up manually or programmatically. The function `ProExtdataSlotNamesList()` provides an array of the names of the slots in the specified class. The function allocates a term in the array for each slot, even if you did not assign a name to the slot.

---

The function `ProExtdataSlotRead()` reads the data type and data from a specified slot. Its input is a `ProExtdataSlot` structure that must be set up manually. There is also an input argument to show whether the slot is identified by name or by integer. The function outputs the data type, the number of bytes (if the data type is stream or section), and a pointer to the data itself.

The `ProExtdataSlotRead()` function allocates memory for the data it outputs. To free this memory, call `ProExtdataFree()`.

#### Note

If you call `ProExtdataSlotRead()` multiple times and do not free the memory, the function uses the same memory for each call.

---

## Core: Cross Sections

### Listing Cross Sections

The functions in this section enable you to access, modify, and delete cross sections, and create planar cross sections.

Functions Introduced:

- **ProXsecRename()**
- **ProXsecTypeGet()**

The function `ProXsecRename()` renames a specified cross section.

Use function `ProXsecTypeGet()` to retrieve the type of cross section. The input argument for this function is a handle to the specified cross section. The output argument *p\_type* is a `ProXsecType` structure, which contains the following fields:

- *cutter*—Specifies the cutting object type. The valid cutting object types are contained in the enumerated type `ProXsecCut` and are as follows:
  - `PRO_XSEC_PLANAR`
  - `PRO_XSEC_OFFSET`
  - `PRO_XSEC_PATTERN`
- *cut\_object*—Specifies the object that was cut. The valid object types are contained in the enumerated type `ProXsecCutobj` and are as follows:
  - `PRO_XSECTYPE_MODEL`—Specifies that the cross section was created on solid geometry.

- `PRO_XSECTYPE_QUILTS`—Specifies that the cross section was created on one quilt surface.
- `PRO_XSECTYPE_MODELQUILTS`—Specifies that the cross section was created on solid geometry and all quilt surfaces.
- `PRO_XSECTYPE_ONEPART`—Specifies that the cross section was created on one component in the assembly.

## Extracting Cross-Sectional Geometry

Functions Introduced:

- **`ProXSectionItemDataGet()`**
- **`ProXSectionItemFree()`**
- **`ProXSectionItemsArrFree()`**
- **`ProXSectionItemsCollect()`**
- **`ProXsecGeometryArrayFree()`**
- **`ProXsecGeometryFree()`**
- **`ProXsecRegenerate()`**
- **`ProXsecDisplay()`**
- **`ProXsecPlaneGet()`**
- **`ProOffsetXsecInfoGet()`**
- **`ProXsecGet()`**
- **`ProXsecMdlnameAlloc()`**
- **`ProXsecMdlnameFree()`**
- **`ProXsecMdlnameNameGet`**
- **`ProXsecMdlnameNameSet()`**
- **`ProXsecMdlnameSolidOwnerGet()`**
- **`ProXsecMdlnameSolidOwnerSet()`**
- **`ProXsecAsModelitemGet()`**
- **`ProXsecFlipGet()`**
- **`ProXSectionExcludeCompGet()`**
- **`ProAsmpathProarrayFree()`**

Superseded Functions:

- **`ProXsecGeometryRetrieve()`**
- **`ProXsecGeometryCollect()`**
- **`ProXsecExcludeCompGet()`**

---

- **ProOffsetXsecGet()**

The geometry of a cross section in an assembly is divided into components. Each component corresponds to one of the parts in the assembly that is intersected by the cross section, and describes the geometry of that intersection. A component can have disjoint geometry if the cross section intersects a given part instance in more than one place.

A cross section in a part has a single component.

The components of a cross section are identified by consecutive integer identifiers that always start at 0.

The function `ProXSectionItemsCollect()` returns an array of `ProXSectionItem`. An array item is created for each body. If no bodies are created, an array contains one item for each component. The function returns the error `PRO_TK_E_NOT_FOUND` when the input argument `p_view` is a drawing view and the input cross section is not found in the view.

The function `ProXSectionItemDataGet()` returns the data from the cross section body specified using the structure `ProXSectionItem`. The output arguments follow:

- `r_path`—Path to the component being cut by the cross section.
- `r_id_type`—Body or quilt type.
- `r_id`—Id of the body or the quilt being cut.
- `r_geom`—Geometry created by the cross section by cutting the specific body or quilt.

Use the function `ProXSectionItemFree()` to free the memory allocated to the `ProXSectionItem` structure.

Use the function `ProXSectionItemsArrFree()` to free the `ProArray` of cross section data allocated by the function `ProXSectionItemsCollect()`.

The function `ProXsecGeometryRetrieve()` returns an array containing the geometry of all components in the specified cross section and retrieves the following information about a specified cross-sectional component:

- The *memb\_num* and *memb\_id\_tab* for the intersected part, with respect to the assembly that contains the cross section.
- A handle to the geometry of the intersection.

The geometry handle can be treated as an ordinary face pointer. Extract its contours with function `ProSurfaceContourVisit()`.

Use the function `ProXsecGeometryArrayFree()` to free the memory allocated to the array of cross section data and use the function `ProXsecGeometryFree()` to free memory allocated to the cross section data.

---

The geometry of a cross section is not maintained constantly by Creo Parametric—it is regenerated only when the user requests to see the cross section. Use function `ProXsecRegenerate()` to regenerate the cross section of a part or an assembly. Use function `ProXsecDisplay()` to display a cross section. `ProXsecDisplay()` does not add the cross section to the associated objects list, and the displayed cross section disappears on the first screen redraw.

The function `ProXsecPlaneGet()` returns the plane geometry for a specified cross section.

In Creo Parametric 9.0, the function `ProOffsetXsecGet()` is deprecated. Use the function `ProOffsetXsecInfoGet()` instead.

The function `ProOffsetXsecInfoGet()` returns the following parameters for a specified offset cross section.

- *p\_ent\_arr*—Specifies a `ProArray` of `Pro2dLinedef` structures for the cross section entities.
- *plane*—Specifies an entity plane.
- *p\_one\_sided*—If this output argument is `true`, the cross section lies on one side of the entity plane, if it is `false`, the cross section is both-sided.
- *p\_flip*—If this output argument is `false`, Creo Parametric removes material from the left of the cross section entities if the viewing direction is from the positive side of the entity plane. If *p\_flip* is `true`, Creo Parametric retains the material from the left of the cross section entities and removes the rest of the material.
- *p\_side\_xsec\_mode*—Specifies the side to which the cross-section is oriented. The side is specified by the enumerated data type `ProXsecOffsetSide`. The valid values are:
  - `PRO_XSEC_OFFSET_BOTH_SIDES`—Orients the cross section to both sides of entity plane.
  - `PRO_XSEC_OFFSET_SIDE_1`—Orients the cross section to the positive normal of entity plane.
  - `PRO_XSEC_OFFSET_SIDE_2`—Orients the cross section to the negative normal of entity plane.

The function `ProXsecGet()` retrieves the cross section handle based on the specified solid model and cross section ID.

The function `ProXsecMdlnameAlloc()` allocates the `ProXsecMdlname` handle. The input arguments follow:

- *solid\_owner*—Specifies the model where the cross section will be created.

- 
- *xsec\_name*—The name to set in the cross section. Maximum name size should be `PRO_MDLNAME_SIZE`.

---

 **Note**

The function `ProXsecMdlnameAlloc()` returns the error `PRO_TK_LINE_TOO_LONG` if the name of the cross section is longer than `PRO_NAME_SIZE`.

---

Use the function `ProXsecMdlnameFree()` to free the memory allocated to the `ProXsecMdlname` handle.

The function `ProXsecMdlnameNameGet()` returns the name of the cross section handle.

Use the function `ProXsecMdlnameNameSet()` to set the name of the cross section. Maximum name size should be `PRO_NAME_SIZE`.

---

 **Note**

The function `ProXsecMdlnameNameSet()` returns the error `PRO_TK_LINE_TOO_LONG` if the name of the cross section is longer than `PRO_NAME_SIZE`.

---

The functions `ProXsecMdlnameSolidOwnerGet()` and `ProXsecMdlnameSolidOwnerSet()` get and set the owner of the cross section.

The function `ProXsecAsModelitemGet()` converts a cross section handle into an appropriate model item.

The function `ProXsecFlipGet()` returns a integer value that indicates the direction in which the cross section has been clipped. Depending on the type of cross section, the integer value indicates different direction of clipping as below:

- Planar cross section—The integer value:
  - 1 indicates that the cross section has been clipped in the direction of the positive normal to the cross section plane.
  - -1 indicates that the cross section has been clipped in the opposite direction of the positive normal.
- Offset cross section—The integer value:
  - 1 indicates that material has been removed from the left of the cross section entities if the viewing direction is from the positive side of the entity plane.

- -1 indicates that the material has been retained from the left of the cross section entities and rest of the material has been removed.

In Creo Parametric 7.0.0.0 the function `ProXsecExcludeCompGet()` is deprecated. Use the function `ProXSectionExcludeCompGet()` instead.

The function `ProXSectionExcludeCompGet()` returns the status and an array of paths to the assembly components and bodies that have been included and excluded for the specified cross section. The assembly paths are returned as a `ProArray` of type `ProSelection`. The status of the assembly components and bodies is returned by the enumerated type `ProXsecExcludeModels` and the valid values are:

- `PRO_XSEC_MODEL_EXCLUDE`—Specifies that the assembly components and bodies have been excluded.
- `PRO_XSEC_MODEL_INCLUDE`—Specifies that the assembly components and bodies have been included.

Use the function `ProSelectionarrayFree()` to free the memory allocated to the `ProArray` of type `ProSelection`.

## Visiting Cross Sections

Function Introduced:

- **`ProSolidXsecVisit()`**
- **`ProSolidXsecVisitAction()`**

The function `ProSolidXsecVisit()` enables you to visit all named cross sections in the specified solid. Use `ProSolidXsecVisitAction()` to supply the function to be performed when visiting part or assembly cross sections.

## Creating and Modifying Cross Sections

Functions Introduced:

- **`ProXsecParallelCreate()`**
- **`ProXSectionItemXhatchScaleUp()`**
- **`ProXSectionItemXhatchScaleDown()`**
- **`ProXSectionItemXhatchScaleSet()`**
- **`ProXSectionItemXhatchRotate()`**
- **`ProXSectionItemXhatchRotateClockwise()`**
- **`ProXSectionItemXhatchRotateCounterClockwise()`**
- **`ProXSectionItemXhatchRotateAngleSet()`**
- **`ProXSectionItemXhatchTranslateHorizontal()`**

- 
- **ProXSectionItemXhatchHorizontalOffsetSet()**
  - **ProXSectionItemXhatchTranslateVertical()**
  - **ProXSectionItemXhatchVerticalOffsetSet()**
  - **ProXSectionItemXhatchColorSet()**
  - **ProXSectionOffsetCreate()**
  - **ProXSectionPlanarCreate()**
  - **ProXSectionCreateDataAlloc()**
  - **ProXSectionCreateDataFree()**
  - **ProXSectionCreateDataQuiltSelSet()**
  - **ProXSectionCreateDataQuiltSelGet()**
  - **ProXSectionCreateDataQuiltTypeSet()**
  - **ProXSectionCreateDataQuiltTypeGet()**
  - **ProXsecMakeVisible()**
  - **ProXsecIsVisible()**
  - **ProXsecActiveSet()**
  - **ProXsecActiveGet()**
  - **ProXsecCanCreateAsFeature()**
  - **ProXsecOldToNewConvert()**
  - **ProXsecIsFeature()**
  - **ProXsecFeatureGet()**
  - **ProXsecDelete()**

Superseded Functions:

- **ProXsecOffsetCreate()**
- **ProXsecPlanarWithoptionsCreate()**

The function `ProXsecParallelCreate()` creates a cross section feature parallel to a given plane.

In Creo Parametric 7.0.0.0 the function

`ProXsecPlanarWithoptionsCreate()` is deprecated. Use the function `ProXSectionPlanarCreate()` instead.

Use the function `ProXSectionItemXhatchScaleUp()` to double the hatch scale of `xsec_item`. The input arguments are:

- *xsec\_item*—Specifies the xsec handle of the specified body using the `ProXSectionItem` object.
- *view*—Specifies the view handle using the `Proview` object. It can be `NULL` if not a drawing.

---

Use the function `ProXSectionItemXhatchScaleDown()` to scale down the hatch of `xsec_item` in half. The input arguments are:

- *xsec\_item*—Specifies the xsec handle of the specified body using the `ProXSectionItem` object.
- *view*—Specifies the view handle using the `Proview` object. It can be `NULL` if not a drawing.

The function `ProXSectionItemXhatchScaleSet()` sets the hatch scale value of `xsec_item`. The input arguments are:

- *xsec\_item*—Specifies the xsec handle of the specified body using the `ProXSectionItem` object.
- *view*—Specifies the view handle using the `Proview` object. It can be `NULL` if not a drawing.
- *scale\_val*—Specifies the scale value.

The function `ProXSectionItemXhatchRotate()` rotates the hatch of `xsec_item` using the `rotate_by` object. The input arguments are:

- *xsec\_item*—Specifies the xsec handle of the specified body using the `ProXSectionItem` object.
- *view*—Specifies the view handle using the `Proview` object. It can be `NULL` if not a drawing.
- *rotate\_by*—Specifies the angle rotation increment.

The function `ProXSectionItemXhatchRotateClockwise()` rotates the hatch of `xsec_item` clockwise using the `hatch_pattern_rotation_interval`. The input arguments are:

- *xsec\_item*—Specifies the xsec handle of the specified body using the `ProXSectionItem` object.
- *view*—Specifies the view handle using the `Proview` object. It can be `NULL` if not a drawing.

The function `ProXSectionItemXhatchRotateCounterClockwise()` rotates the hatch of `xsec_item` counter clockwise using the `hatch_pattern_rotation_interval`. The input arguments are:

- *xsec\_item*—Specifies the xsec handle of the specified body using the `ProXSectionItem` object.
- *view*—Specifies the view handle using the `Proview` object. It can be `NULL` if not a drawing.

The function `ProXSectionItemXhatchRotateAngleSet()` rotates the hatch of `xsec_item` to `rotate_val`. If `XCH` is specified, it rotates the first line to that value and adjusts all other lines accordingly. The input arguments are:

- *xsec\_item*—Specifies the xsec handle of the specified body using the `ProXSectionItem` object.

- *view*—Specifies the view handle using the `Proview` object. It can be `NULL` if not a drawing.
- *rotate\_val*—Sets the value of the hatch angle.

Use the function `ProXSectionItemXhatchTranslateHorizontal()` to translate the hatch horizontally using the `translate_by` object. The input arguments are:

- *xsec\_item*—Specifies the `xsec` handle of the specified body using the `ProXSectionItem` object.
- *view*—Specifies the view handle using the `Proview` object. It can be `NULL` if not a drawing.
- *translate\_by*—Sets value of the horizontal translate.

The function `ProXSectionItemXhatchHorizontalOffsetSet()` sets the hatch horizontal offset to the `horizon_offset`. The input arguments are:

- *xsec\_item*—Specifies the `xsec` handle of the specified body using the `ProXSectionItem` object.
- *view*—Specifies the view handle using the `Proview` object. It can be `NULL` if not a drawing.
- *horizon\_offset*—Sets the value of the horizontal offset.

Use the function `ProXSectionItemXhatchTranslateVertical()` to translate the hatch vertically by `translate_by`. The input arguments are:

- *xsec\_item*—Specifies the `xsec` handle of the specified body using the `ProXSectionItem` object.
- *view*—Specifies the view handle using the `Proview` object. It can be `NULL` if not a drawing.
- *translate\_by*—Sets value of the vertical translate.

The function `ProXSectionItemXhatchVerticalOffsetSet()` sets the hatch vertical offset to the `vertical_offset`. The input argument are:

- *xsec\_item*—Specifies the `xsec` handle of the specified body using the `ProXSectionItem` object.
- *view*—Specifies the view handle using the `Proview` object. It can be `NULL` if not a drawing.
- *vertical\_offset*—Sets value of the horizontal offset.

The function `ProXSectionItemXhatchColorSet()` sets the color of the hatch pattern. The input argument are:

- *xsec\_item*—Specifies the `xsec` handle of the specified body using the `ProXSectionItem` object.
- *view*—Specifies the view handle using the `Proview` object. It can be `NULL` if not a drawing.

- 
- *color*—Specifies the color of the values using the object `ProColor`.

The function `ProXSectionPlanarCreate()` creates a cross section feature through a datum plane and also makes the cross section visible. The input arguments are:

- *solid\_owner*—Specifies the model where the cross section will be created.
- *xsec\_name*—Specifies the name of the cross section.
- *cutting\_plane*—Specifies the selection of the cutting plane. The cutting plane must belong to the top-level part or assembly.
- *xsec\_type*—Specifies the type of object that will be cut by the cross section. It is specified by the enumerated type `ProXsecCutobj`.
- *quilt\_or\_one\_part*—Specifies the selection of the quilt or component depending on type of object specified by *xsec\_type*.
- *flip*—Specifies the direction in which the cross section will be clipped. The value 1 indicates that the cross section will be clipped in the direction of the positive normal to the cutting plane. -1 indicates that the cross section will be clipped in the opposite direction of the positive normal.
- *excl\_d\_incl\_opt*—Specifies the items to exclude, specified by the input parameter *exclude\_items* from cutting by the cross section and is defined by the enumerated data type `ProXsecExcludeModels`.
- *exclude\_items*—Specifies a `ProArray` of selected bodies or parts to be included or excludes from the cross section.
- *data*—Reserved for future use.

---

### Note

- From Creo Parametric 4.0 F000 onward, when a cross section is created, it is not displayed by default in the model. You must call the function `ProXsecMakeVisible()` to display the cross section.
- While porting Creo TOOLKIT applications, which have used the function `ProXsecPlanarWithoptionsCreate()` and have been created in releases prior to Creo Parametric 4.0 F000, depending on whether you want the cross section to be displayed, call the function `ProXsecMakeVisible()` in your applications. `ProXsecMakeVisible()` displays the cross section in the model.
- From Creo Parametric 2.0 onward:
  - the legacy cross sections, that is, the cross sections created in Pro/ENGINEER, Creo Elements/Pro, and in releases prior to Creo Parametric 2.0 are not supported.
  - the functions `ProXsecParallelCreate()` and `ProXsecPlanarWithoptionsCreate()` create cross sections as features.
  - the functions `ProXsecParallelCreate()` and `ProXsecPlanarWithoptionsCreate()` automatically convert the legacy cross sections to new cross section features as defined in Creo Parametric 2.0 before creating any new cross section feature.

---

The function `ProXsecOffsetCreate()` is deprecated. Use the function `ProXSectionOffsetCreate()` instead.

The function `ProXSectionOffsetCreate()` creates an offset cross section from a polyline. The polyline lies on a plane and the plane is defined by a local coordinate system. Offset cross section is created by extruding the polyline perpendicular to the sketching plane. The input arguments are:

- *solid\_owner*—Specifies the model where the cross section will be created.
- *xsec\_name*—Specifies the name of the cross section.
- *trf*—Specifies the local coordinate system of the plane which contains the polyline.
- *ent\_arr*—Specifies a `ProArray` of `Pro2dEntdef` structure. The structure contains information about the entities of the polyline.

- 
- *side*—Specifies the side to which the cross section must be extended. The cross section is extended normal to the polyline plane. The side is specified using the enumerated data type `ProXsecOffsetSide`. The valid values are:
    - `PRO_XSEC_OFFSET_BOTH_SIDES`—Extends the cross section to both sides of polyline plane.
    - `PRO_XSEC_OFFSET_SIDE_1`—Extends the cross section to the positive normal of polyline plane.
    - `PRO_XSEC_OFFSET_SIDE_2`—Extends the cross section to the negative normal of polyline plane.
  - *flip*—Specifies the direction in which the cross section will be clipped. The value `False` indicates that the material on the right side of the polyline plane is retained. When the argument *side* is set to `PRO_XSEC_OFFSET_SIDE_1` or `PRO_XSEC_OFFSET_SIDE_2` then the material is retained from positive or negative side of polyline plane respectively.

---

When the value is set to `True` the above area is removed. The remaining material is retained.

---

 **Note**

If the polyline from which the cross section has been created is closed, then flip works a little different.

| Polyline Direction                        | Flip Value | Description                                                                                                                                                                                                                                                                                 |
|-------------------------------------------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Closed polyline created clockwise         | False      | <p>The material inside of the closed polyline is retained.</p> <p>When the argument <code>side</code> is set to <code>PRO_XSEC_OFFSET_SIDE_1</code> or <code>PRO_XSEC_OFFSET_SIDE_2</code> then the material is retained from positive or negative side of polyline plane respectively.</p> |
| Closed polyline created clockwise         | True       | <p>The material described in above case is removed. The remaining material is retained.</p>                                                                                                                                                                                                 |
| Closed polyline created counter clockwise | True       | <p>The material inside of the closed polyline is retained.</p> <p>When the argument <code>side</code> is set to <code>PRO_XSEC_OFFSET_SIDE_1</code> or <code>PRO_XSEC_OFFSET_SIDE_2</code> then the material is retained from positive or negative side of polyline plane respectively.</p> |
| Closed polyline created counter clockwise | False      | <p>The material described in above case is removed. The remaining material is retained.</p>                                                                                                                                                                                                 |

- *excl<sub>d</sub>incl<sub>d</sub>opt*—Specifies the items to be excluded from cutting by the cross section and is defined by the enumerated data type `ProXsecExcludeModels`. The items to be excluded are specified by the input parameter *exclude\_items*.
- *exclude\_items*—Specifies a `ProArray` of selected bodies or parts to include or exclude from the cross section.
- *data*—This option is specified using the data structure `ProXSectionCreateData` and is used to set quilt cross section type as `PRO_XSECTYPE_QUILTS` or `PRO_XSECTYPE_MODELQUILTS` for offset cross section. . This input argument is optional. If you do not want to offset cross section to cut quilts, set this as `Null`.

The functions `ProXSectionPlanarCreate()` and `ProXSectionOffsetCreate()` return an error `PRO_TK_LINE_TOO_LONG`, when the *xsec\_name* is longer than `PRO_NAME_SIZE`.

The function `ProXSectionCreateDataAlloc()` allocates memory for the `ProXSectionCreateData` data structure.

Use the function `ProXSectionCreateDataFree()` to free the `ProXSectionCreateData` data structure memory.

The data structure `ProXSectionCreateData` is defined as follows:

Use the function `ProXSectionCreateDataQuiltSelGet()` to retrieve the quilt selection data. The output argument *r\_quilt\_sel* is the address of the quilt selection pointer given through the `ProSelection` object.

The function `ProXSectionCreateDataQuiltSelSet()` sets the quilt selection data using the structure `ProXSectionCreateData`.

The function `ProXSectionCreateDataQuiltTypeGet()` gets the quilt cross section type using the structure `ProXSectionCreateData`. The output argument *r\_xsec\_type* is defined by the enumerated data type `ProXsecCutobj`. The valid values can be `PRO_XSECTYPE_QUILTS` or `PRO_XSECTYPE_MODELQUILTS`.

Use the function `ProXSectionCreateDataQuiltTypeSet()` to set the quilt cross section type using the structure `ProXSectionCreateData`.

The function `ProXsecMakeVisible()` displays the specified cross section in the model. Use the function `ProXsecIsVisible()` to check if the specified cross section is displayed in the model.

The function `ProXsecActiveSet()` sets the specified cross section as active in the current view. Use the function `ProXsecActiveGet()` to retrieve the cross section, which is active in the current view.

Use the function `ProXsecCanCreateAsFeature()` to check if new cross section features can be created in the specified model. The function returns `PRO_B_FALSE` if the specified model has legacy cross sections.

---

The function `ProXsecOldToNewConvert()` converts the legacy cross sections to new cross section features as defined in Creo Parametric 2.0 for the specified model.

Use the function `ProXsecIsFeature()` to check whether the cross section is a feature.

The function `ProXsecFeatureGet()` returns a pointer to the cross section feature. The function returns the error type `PRO_TK_BAD_CONTEXT` for legacy cross sections.

The function `ProXsecDelete()` deletes a given cross section from a part or assembly.

## Mass Properties of Cross Sections

Function Introduced:

- **`ProXsecMassPropertyCompute()`**

The function `ProXsecMassPropertyCompute()` calculates the mass properties of the cross section in the specified coordinate system. The function needs the name of a coordinate system datum whose X- and Y-axes are parallel to the cross section. The output from this function also refers to the coordinate system datum. Call `ProXsecRegenerate()` before `ProXsecMassPropertyCompute()`.

### Note

The function `ProXsecMassPropertyCompute()` is not supported for offset and quilt type of cross sections.

---

## Line Patterns of Cross Section Components

Functions Introduced:

- **`ProXsecCompXhatchGet()`**
- **`ProXsecCompXhatchAdd()`**
- **`ProXsecCompXhatchReplace()`**
- **`ProXsectionCompXhatchStyleGet()`**
- **`ProXSectionItemXhatchStyleGet()`**
- **`ProXsecNewXhatchStyleCreateFromName()`**
- **`ProXsectionCompXhatchStyleSet()`**
- **`ProXSectionItemXhatchStyleSet()`**

---

Superseded Functions:

- **ProXsecCompNewXhatchStyleSetByName()**
- **ProXsecCompNewXhatchStyleSet()**
- **ProXsecCompXhatchStyleSet()**
- **ProXsecCompXhatchStyleGet()**
- **ProXsecCompNewXhatchStyleGet()**

Creo Parametric supports hatch pattern files of the \*.pat file format. The new hatch supports nonlinear hatching styles.

The old hatch uses the Xhatch \*.xch file format. It is recommended to use the \*.pat files. Refer to the Creo Parametric Online Help for more information.

The function `ProXsecCompXhatchGet()` returns the line patterns of a cross section component based on the specified cross section handle and the ID of the cross section component. The line patterns obtained are `ProXsecXhatch` structures that contain the following fields:

- `angle`—Specifies the angle of the line patterns.
- `spacing`—Specifies the distance between the line patterns.
- `offset`—Specifies the offset of the first line in the pattern.

---

 **Note**

The functions `ProXsecCompXhatchGet()`, `ProXsecCompXhatchAdd()`, and `ProXsecCompXhatchReplace()` support only the old hatching styles, that is, the \*.xch file format.

---

The function `ProXsecCompXhatchAdd()` adds a line pattern to a specified cross section component. This function takes the handle to the cross section, the ID of the cross section component, the handle to the drawing view containing the cross section component and a pointer to the `ProXsecXhatch` object as its input arguments.

---

 **Note**

If the cross section component already includes a line pattern, then the function `ProXsecCompXhatchAdd()` does not add a line pattern.

---

The function `ProXsecCompXhatchReplace()` replaces all existing line patterns of a specified cross section component with a new one.

---

In Creo Parametric 7.0.0.0 the functions `ProXsecCompXhatchStyleGet()` and `ProXsecCompNewXhatchStyleGet()` are deprecated. Use the function `ProXsectionCompXhatchStyleGet()` to get `p_xhatch_style` from a component and `ProXsectionItemXhatchStyleGet()` to get `p_xhatch_style` from a body.

The function `ProXsectionItemXhatchStyleGet()` returns the cross section `p_xhatch_style` for the cross section handle of the body. The output argument `p_xhatch_style` returns a `ProXsecNewXhatchStyle` handle.

The function `ProXsectionCompXhatchStyleGet()` returns information about the style of hatch pattern in the specified cross section component. The output argument `p_xhatch_style` returns a `ProXsecNewXhatchStyle` handle. The structure `ProXsecNewXhatchStyle` specifies the following information:

- `type`—Type of hatch. Specify the following values:
  - `PRO_XHATCH`—Cross section component is appears as a hatch.
  - `PRO_XSEC_EXCLUDED`—Cross section is excluded for the specified assembly component.
  - `PRO_XSEC_FILL`—Cross section component appears as a solid.
  - `PRO_XHATCH_ERASED`—Cross section component is erased, that is, neither hatched nor filled.
- `ProXsecXhatchPattern`—Structure that contains information about the old hatch pattern in a cross section. It specifies the following information:
  - `angle`—Angle of the lines in the patterns.
  - `spacing`—Distance between the lines in the patterns.
  - `offset`—Offset of the first line in the pattern.
  - `font`—Line style for the line pattern.
  - `color`—Color for the line pattern.

---

 **Note**

When the cross section has old hatch patterns, the field `*new_lines` in the structure `ProXsecNewXhatchStyle` is returned as `NULL`.

---

- `ProXsecNewXhatchPattern`—Structure that contains information about the new hatch pattern in a cross section. It specifies the following information:

- 1 X-Origin, Y-Origin
- 2 Angle
- 3 Delta X
- 4 Delta Y
- `angle`—Angle of the lines in the patterns.
- `x_origin`—Origin of the first pattern line along the x-axis.
- `y_origin`—Origin of the first pattern line along the y-axis.
- `delta_x`—For a dashed line pattern, the distance after which the next dashed line starts in a pattern.
- `delta_y`—For a continuous and dashed line pattern, the distance between the pattern lines.
- `dash`—Dashed line pattern.
- `num_dash`—Number of dashes for the line pattern. Max number of dashes is 6.
- `color`—Color for the line pattern.

---

 **Note**

When the cross section has new hatch patterns, the field `*old_lines` in the structure `ProXsecNewXhatchStyle` is returned as `NULL`.

---

In Creo Parametric 7.0.0.0 the function

`ProXsecCompNewXhatchStyleSetByName()` is deprecated. Use the function `ProXsecNewXhatchStyleCreateFromName()` to create `ProXsecNewXhatchStyle`. Use the functions `ProXsectionCompXhatchStyleSet()` and `ProXsectionItemXhatchStyleSet()` to set `ProXsecNewXhatchStyle`.

Use the function `ProXsecNewXhatchStyleCreateFromName()` to create a `ProXsecNewXhatchStyle` structure using the hatch pattern specified by the input argument *hatch\_name*. This function supports only new, that is, PAT hatch patterns. The input arguments follows:

- *hatch\_name*—Name of the existing PAT hatch.
- *color*—Color of the newly created pattern.
- *type*—Type of the hatch specified by structure `ProXsecNewXhatchStyle` and has the following values:
  - `PRO_XHATCH`—Cross section component appears as a hatch.
  - `PRO_XSEC_EXCLUDED`—Cross section is excluded for the specified assembly component.
  - `PRO_XSEC_FILL`—Cross section component appears as a solid.
  - `PRO_XHATCH_ERASED`—Cross section component is erased, that is, neither hatched nor filled.

After creating the `ProXsecNewXhatchStyle` structure using the function `ProXsecNewXhatchStyleCreateFromName()`, either of the following situations might occur:

- The new PAT hatch that is created using the function `ProXsectionItemXhatchStyleSet()` is available in the hatch edit dialog in the part and assembly mode and a suffix `_TK` is added to the hatch name.
- If the hatch name is used as the input parameter to the function `ProXsectionItemXhatchStyleSet()` is used, then a new hatch is not added.

The output argument `p_xhatch_style` can be set by the functions `ProXsectionItemXhatchStyleSet()` and `ProXsectionCompXhatchStyleSet()`.

---

The function `ProXSectionItemXhatchStyleSet()` sets the cross section `p_xhatch_style` for the cross section handle of the body, using the `ProXsecNewXhatchStyle` structure. The input arguments follow:

- `xsec_item`—Cross section handle of the specific body.
- `p_view`—View handle.
- `hatch_name`—Name of the nonlinear hatch.
- `p_xhatch_style`—Handle to `ProXsecNewXhatchStyle`. The unused hatch field must be set to `NULL`.

In Creo Parametric 7.0.0.0 the function `ProXsecCompXhatchStyleSet()` is deprecated. Use the function `ProXsectionCompXhatchStyleSet()` to set `p_xhatch_style` on a component and `ProXSectionItemXhatchStyleSet()` to set `p_xhatch_style` on a body.

---

 **Note**

Use the function `ProXsecCompNewXhatchStyleGet()` for nonlinear hatch support.

---

The function `ProXsectionCompXhatchStyleSet()` sets the cross section `p_xhatch_style` for the specified component using the `ProXsecNewXhatchStyle` structure. The input arguments follow:

- `xsec`—Cross section handle of the specific body.
- `path`—Path to the specified component.
- `p_view`—View handle.
- `hatch_name`—Name of the nonlinear hatch.
- `p_xhatch_style`—Handle to `ProXsecNewXhatchStyle`. The unused hatch field must be set to `NULL`.

---

 **Note**

`PRO_XSEC_EXCLUDED` type is applied only in the drawing environment.

---

When parts with multiple solid bodies are being cut by the cross section, the following functions return the error `PRO_TK_MULTIBODY_UNSUPPORTED`:

- `ProXsecCompNewXhatchStyleSetByName`
- `ProXsecCompNewXhatchStyleSet()`
- `ProXsecCompXhatchStyleSet()`
- `ProXsecCompNewXhatchStyleGet()`

- `ProXsecCompXhatchStyleGet()`

## Core: Utilities

### Configuration Options

This section describes the Creo TOOLKIT utility functions.

Functions Introduced:

- **`ProConfigoptionGet()`**
- **`ProConfigoptSet()`**
- **`ProConfigoptArrayGet()`**
- **`ProDisplstInvalidate()`**

The functions `ProConfigoptionGet()` and `ProConfigoptSet()` enable you to retrieve and set the current value for the specified configuration file option. Use the function `ProConfigoptionGet()` instead. The function `ProConfigoptionGet()` returns the value of configuration option as a `ProPath` object.

To use `ProConfigoptSet()` on a configuration option that affects the display of Creo Parametric, you must call the function `ProDisplstInvalidate()` before you repaint the screen. This function makes sure Creo Parametric invalidates the two- or three-dimensional display list. The calling sequence of functions is as follows:

```
ProConfigoptSet (woption, value);
ProMdlCurrentGet (&model);
ProDisplstInvalidate (model)
ProWindowRepaint (-1);
```

The function `ProConfigoptSet()`, when applied to a multi string configuration option like "search\_path", adds a new path entry into the session. It does not affect existing values. When applied to a single-valued configuration option, `ProConfigoptSet()` modifies the value of the configuration option.

The function `ProConfigoptArrayGet()` retrieves the value of a specified configuration file option. The function returns an array of values assigned to the configuration file. It returns a single value if the configuration file option is not a multi-valued option.

### Registry File Data

Functions Introduced:

- **`ProToolkitApplExecPathGet()`**
- **`ProToolkitApplTextPathGet()`**

---

The function `ProToolkitApplExecPathGet()` returns the path to the Creo TOOLKIT executable file (`exec_file`) from the registry file.

The function `ProToolkitApplTextPathGet()` returns the path to the directory containing the "text" directory for the application.

## Trail Files

Function Introduced:

- **ProTrailfileCommentWrite()**

To append a comment to the end of the current trail file, call the function `ProTrailfileCommentWrite()`. The comment should not be longer than  $(\text{PRO\_COMMENT\_SIZE} - 2)$  characters, and should not contain any nonprintable characters, such as "\n."

## License Data

Function Introduced:

- **ProOptionOrderedVerify()**

The function `ProOptionOrderedVerify()` reports whether a specified Creo Parametric license option (such as Pro/MESH) is currently available in the Creo Parametric session.

## Current Directory

Functions Introduced;

- **ProDirectoryCurrentGet()**
- **ProDirectoryChange()**

These two functions are concerned with the current default directory in Creo Parametric—the one in which it searches when you retrieve an object, for example. The Creo Parametric user changes this directory using the command **File ► Manage Session ► Working Directory**.

The function `ProDirectoryChange()` enables you to do the exact equivalent of **File ► Manage Session ► Working Directory** in Creo Parametric. Use this function if you need to save and retrieve objects in a directory other than the one the user chose.

The function `ProDirectoryCurrentGet()` returns the whole path to the directory, as a wide string.

---

## File Handling

Functions Introduced:

- **ProFilesList()**
- **ProFileMdlnameOpen()**
- **ProFileMdlfiletypeOpen()**
- **ProFileOpenRegister()**
- **ProFileMdlnameSave()**
- **ProFileMdlfiletypeSave()**
- **ProFileSaveRegister()**
- **ProDirectoryChoose()**
- **ProFileMdlnameParse()**
- **ProPathMdlnameCreate()**
- **ProInfoWindowDisplay()**
- **ProFileEdit()**
- **ProTexturePathGet()**

The function `ProFilesList()` provides a list of the contents of a directory, given the directory path. You can filter the list to include only files of a particular type, as specified by the file extension. Use the `PRO_FILE_LIST_ALL` option to include all versions of a file in the list; use `PRO_FILE_LIST_LATEST` to include only the latest version. In addition to an array of file names, the function returns an array of subdirectory names, regardless of the filter used.

Starting with Pro/ENGINEER Wildfire 5.0, the function `ProFilesList()` can also list instance objects when accessing Windchill workspaces or folders. A PDM location (for workspace or commonspace) must be passed as the directory path. The following options have been added in the `ProFileListOpt` enumerated type that can be passed as the `listing_option` argument to `ProFilesList()`:

- `PRO_FILE_LIST_ALL_INST`—Same as the `LIST_ALL` option. It returns instances only for PDM locations.
- `PRO_FILE_LIST_LATEST_INST`—Same as the `LIST_LATEST` option. It returns instances only for PDM locations.
- `PRO_FILE_LIST_ALL_SORTED_INST`—Same as the `LIST_ALL_SORTED` option. It returns instances only for PDM locations.
- `PRO_FILE_LIST_LATEST_SORTED_INST`—Same as the `LIST_LATEST_SORTED` option. It returns instances only for PDM locations.
- `PRO_FILE_LIST_LATEST_SORTED_INST`—Same as the `LIST_LATEST_SORTED` option. It returns instances only for PDM locations.

---

The function `ProFileMdlnameOpen()` opens the dialog box to browse directories and open files. The function lets you specify the title of the dialog box, a set of shortcuts to other directories, and the name of a file to be preselected. This function uses the same filtering method as `ProFilesList()`. You can set a filter in the dialog box to include files of a particular type. In the input argument *filter\_string* specify all types of files extensions with wildcards separated by commas, for example, `*.prt, *.asm, *.txt, *.avi`, and so on.

You can also use the function `ProFileMdlfiletypeOpen()` to browse directories and open files. You can set a filter in the dialog box to include files of a particular type. In the input argument *file\_types*, you can specify an array of file types using the enumerated data type `ProMdlfileType`.

---

 **Note**

The functions `ProFileMdlnameOpen()` and `ProFileMdlfiletypeOpen()` do not actually open the file, but return the file path of the selected file. For example, to open a text file, use the function `ProFileEdit()` or `ProInfoWindowDisplay()`.

---

The function `ProFileOpenRegister()` registers a new file type in the **File ► Open** dialog box in Creo Parametric. This function takes the access function `ProFileOpenAccessFunction()` and the action function `ProFileOpenOperationAction()` as its input arguments.

The function `ProFileOpenAccessFunction()` is called to determine whether the new file type can be opened using the **File ► Open** dialog box. The function `ProFileOpenOperationAction()` is called on clicking **Open** for the newly registered file type.

The function `ProFileMdlnameSave()` opens the save dialog box. This function has input arguments similar to `ProFileMdlnameOpen()`.

You can also use the function `ProFileMdlfiletypeSave()` to open the save dialog box. You can set a filter in the dialog box to include files of a particular type. In the input argument *file\_types*, you can specify an array of file types using the enumerated data type `ProMdlfileType`.

---

### Note

- The functions `ProFileMdlnameSave()` and `ProFileMdlfiletypeSave()` do not actually save the file, but return the file path of the selected file.
- For multi-CAD models, in a linked session of Creo Parametric with Windchill, the functions `ProFileMdlnameSave()` and `ProFileMdlfiletypeSave()` do not support a file path location on local disk.

---

The function `ProFileSaveRegister()` registers a new file type in the **File ► Save a Copy** dialog box in Creo Parametric. This function takes the access function `ProFileSaveAccessFunction()` and the action function `ProFileSaveOperationAction()` as its input arguments.

The function `ProFileSaveAccessFunction()` is called to determine whether the new file type can be saved using the **File ► Save a Copy** dialog box. The function `ProFileSaveOperationAction()` is called on clicking OK for the newly registered file type.

The function `ProDirectoryChoose()` prompts the user to select a directory using the Creo Parametric dialog box for browsing directories. Specify the title of the dialog box, a set of shortcuts to other directories, and the default directory path to start browsing. If the default path is specified as null, the current directory is used. The function returns the selected directory path as output.

In general, the file utility functions refer to files using a single wide character string, which contains four, distinct pieces of information that uniquely identify the file: the directory path, file name, extension, and version. The function `ProFileMdlnameParse()` takes such a string as input, and returns the four segments as separate arguments.

---

### Note

The function `ProFileMdlnameParse()` returns the file version as -1, if the input argument `file_name_w_path` has the path specified as the path to a Windchill model. This function does not support fetching of model version of a Windchill model.

---

The function `ProPathMdlnameCreate()` performs the opposite operation—it builds the single wide string that identifies the file, given the path, file name, extension, and version.

---

The function `ProInfoWindowDisplay()` creates a text information window. It reads the contents from a text file in the current directory whose name is an input to the function. The function can also override the default size, shape, and location of the window. (These do not affect the properties of the Creo Parametric Information Window.)

The function `ProFileEdit()` opens an edit window on a specified text file. The editor used is the current default editor for Creo Parametric.

The function `ProTexturePathGet()` looks for the full path to the specified texture, decal, or bump map files and loads them from the texture path.

---

 **Note**

For textures embedded inside a Creo Parametric model, if the `create_temp_file` is set to `true` the `ProTexturePathGet()` function writes a temporary copy of the specified files.

---

## Wide Strings

Functions Introduced:

- **`ProStringToWstring()`**
- **`ProWstringToString()`**
- **`ProWcharSizeVerify()`**

These three utilities are described in the topic [Wide Strings on page 69](#) in the [Fundamentals on page 30](#) section.

## Freeing String Outputs

Many Creo TOOLKIT functions provide outputs of non-fixed length strings or wide strings. These outputs must be freed using a special set of functions, because they have been allocated by a special function internally.

---

 **Note**

These functions must be only used for strings and string arrays output from Creo TOOLKIT functions. Check the function description to determine the function to use when freeing the output.

---

Functions Introduced:

- **`ProStringFree()`**

- 
- **ProWstringFree()**
  - **ProStringarrayFree()**
  - **ProWstringarrayFree()**
  - **ProStringproarrayFree()**
  - **ProWstringproarrayFree()**

Use the functions `ProStringFree()` and `ProWstringFree()` to free a single `char*` or `wchar_t*` output from a Creo TOOLKIT function.

Use the functions `ProStringarrayFree()` and `ProWstringarrayFree()` to free a standard array of `char*` or `wchar_t*` output from a Creo TOOLKIT function.

Use the functions `ProStringproarrayFree()` and `ProWstringproarrayFree()` to free a `ProArray` of `char*` or `wchar_t*` output from a Creo TOOLKIT function.

## Freeing Integer Outputs

Functions Introduced:

- **ProIntArrayFree()**

Use the function `ProIntArrayFree()` to free a plain integer array, which has been returned from a Creo TOOLKIT function.

## Running Creo ModelCHECK

Creo ModelCHECK is an integrated application that runs transparently within Creo Parametric. Creo ModelCHECK uses a configurable list of company design standards and best modeling practices. You can configure Creo ModelCHECK to run interactively or automatically when you regenerate or save a model.

Functions Introduced:

- **ProModelcheckExecute()**

You can execute Creo ModelCHECK from an external application using the function `ProModelcheckExecute()`. The input parameters of this function are:

- `mdl`—Specifies the model on which you want to execute Creo ModelCHECK.

- 
- `show_ui`—Specifies True to display the Creo ModelCHECK report in the Web browser.

---

 **Note**

The configuration option `SHOW_REPORT` in the `config_init.mc` file overrides the `show_ui` value.

---

- `mcMode`—Specifies the mode in which you want to run Creo ModelCHECK. The modes are:
  - `PRO_MODELCHECK_GRAPHICS`—Interactive mode
  - `PRO_MODELCHECK_NO_GRAPHICS`—Batch mode
- `config_dir`—Specifies the location of the configuration files. If this parameter is set to NULL, the default Creo ModelCHECK configuration files are used.
- `output_dir`—Specifies a location for the reports. If this parameter is set to NULL, the default Creo ModelCHECK output directory is used.

The output parameters of this function are:

- `errors`—Specifies the number of errors found.
- `warnings`—Specifies the number of warnings found.
- `model_saved`—True if the model is saved with updates, else false.

## Creating Custom Checks

This section describes how to define custom checks in Creo ModelCHECK that users can run using the standard Creo ModelCHECK interface in Creo Parametric.

To define and register a custom check:

1. Set the `CUSTOMTK_CHECKS_FILE` configuration option in the start configuration file to a text file that stores the check definition. For example:  
`CUSTOMTK_CHECKS_FILE text/custmtk_checks.txt.`
2. Set the contents of the `CUSTOMTK_CHECKS_FILE` file to define the checks. Each check should list the following items:
  - `DEF_<checkname>`—Specifies the name of the check. The format must be `CHKTK_<checkname>_<mode>`, where `mode` is PRT, ASM, or DRW.

- **TAB\_<checkname>**—Specifies the tab (category) in the Creo ModelCHECK report under which the check is classified. All the custom checks are stored in the **Miscellaneous** category.
- **MSG\_<checkname>**—Specifies the description of the check that appears in the lower part of the Creo ModelCHECK report when you select the name.
- **DSC\_<checkname>**—Specifies the name of the check as it appears in the Creo ModelCHECK report table.
- **ERM\_<checkname>**—If set to INFO, the check is considered an INFO check and the report table will display the text from the first item returned by the check, instead of a count of the items. Otherwise, this value must be included, but is ignored by Creo Parametric.

See [Example 1: Text File for Custom Checks on page 274](#) for a sample custom checks text file.

1. Add the check and its values to the Creo ModelCHECK configuration file. For an example of how this is done, see the sample code at the end of this section.
2. Register the Creo ModelCHECK check from the Creo TOOLKIT application.

---

#### **Note**

Other than the requirements listed above, Creo TOOLKIT custom checks do not have access to the rest of the values in the Creo ModelCHECK configuration files. All the custom settings specific to the check such as start parameters, constants, and so on, must be supported by the user application and not Creo ModelCHECK. In the custom checks text file, separate options and values for options with a space, not by a tab character.

---

#### Functions Introduced

- **ProModelcheckCheckRegister()**
- **ProModelcheckCheckFunction()**
- **ProModelcheckUpdateFunction()**
- **ProModelcheckCleanupFunction()**

The function `ProModelcheckCheckRegister()` registers the callback functions for each custom check. The following arguments are available:

- The custom check name. This name must match the name given to the check in the Creo ModelCHECK configuration file, and must begin with "CHKTK\_".

- The check label. Currently unused; the label is taken from the check configuration file.
- The check options. Currently unused, specify the value as `NULL`.
- The check callback functions, described in details below.
- Labels for the action and update buttons, or specify `NULL` if these buttons should not be shown.
- Application data to pass to the callback functions.

The check callback functions are as follows:

- The check function (required)—This function, whose signature matches `ProModelcheckCheckFunction()`, should calculate the results of the check and provide them to Creo ModelCHECK through the function output arguments.
- The action and update functions (optional)—These functions are called when users choose the action or update button when viewing the Creo ModelCHECK report. These have the signature of the `ProModelcheckUpdateFunction()` function.
- The cleanup function (optional)—Gives your application a chance to free memory allocated by the check function. This has the signature of the `ProModelcheckCleanupFunction()` function.

Each callback function receives the following inputs:

- The name of the custom check, as defined in the original call to `ProModelcheckCheckRegister()`.
- The model being checked.
- A pointer to the application data, set during the call to `ProModelcheckCheckRegister()`.

The function whose prototype matches `ProModelcheckCheckFunction()` is used to evaluate the custom defined checks. The user application runs the check on the specified model and populates the following output arguments:

- *results\_count*—Specifies an integer indicating the number of errors found by the check.
- *results\_url*—Specifies the link to an application-owned page that contains information specific to the check.
- *results\_table*—Specifies an array of data for each error encountered that will be shown along with the results.

The function whose prototype matches `ProModelcheckCleanupFunction()` is used to release memory allocated for the check callback function.

---

The functions whose prototypes matches

`ProModelcheckUpdateFunction()` are used for the following:

- To execute a check-defined action on a given item.
- To automatically update a given item to fix errors, if any.

The selected item's description string is passed as an argument to the update function.

Creo ModelCHECK checks may have one "action" function to highlight the problem, and possibly an update function, to fix it automatically. The following figure displays the Creo ModelCHECK report with an action button that invokes the action callback function.

## Example 1: Text File for Custom Checks

The following is the text file for the custom check examples.

```
UG CustomCheck: MDL PARAM NOT FOUND
Parameter %0w is not found in the model %1w
#
#
UG CustomCheck: MDL PARAM OK
Parameter %0w is set correctly in the model %1w
#
#
UG CustomCheck: MDL PARAM INV TYPE
Parameter %0w in %1w is not a String parameter
#
#
Parameter %0w value does not match model name %1w
UG CustomCheck: MDL PARAM INCORRECT
#
#
UG CustomCheck: MDL PARAM NAME
Parameter %0w value matches model name
#
#
UG CustomCheckUpdate: MDL PARAM NAME
Fix Parameter
#
#
%CIUG CustomCheck: MDL PARAM UPDATED
Mdl name parameter %0w has been updated.
#
#
%CEUG CustomCheck: MDL PARAM UPDATE TYPE

## Example 2: Registering Custom Creo ModelCheck Checks

The sample code in `UgModelCheck.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_main` shows how to register custom Creo ModelCHECK checks using Creo TOOLKIT. The following custom checks are registered:

- `CHKTK_MDL_NAME_PARAM`—Determines if the model has a parameter whose value is equal to the model name
- `CHKTK_MDL_REFC_SCOPE`—Info check that prints the model reference control settings
- `CHKTK_DWVIEW_GENERIC`—Drawing mode check that looks for views that use generic models

## Example 3: Implementing a Model Name Parameter Check

The sample code in `UgModelCheck.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_main` shows the implementation for the model name parameter check. This check has a check function callback and an update function callback. Also included is the cleanup callback used for all of the custom checks.

---

## Example 4: Implementing a Reference Control Info Check

The sample code `UgModelCheck.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_main` shows the implementation for an info check that will report on the reference control setting applied to the model. This check has a check function callback but no action or update function (because it is an info-only check).

## Example 5: Implementing a Check Looking for Drawing Views Using Generics

The sample code in `UgModelCheck.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_main` shows the implementation for the drawing view using generics check. This check has a check function callback and an action function used to highlight the views that have this error.

## Example 6: Changes to the Creo ModelCheck Configuration Files to enable Custom Checks

The following show the changes made to the Creo ModelCHECK configuration files to enable the custom checks.

```

## Core: Asynchronous Mode

### Overview

This section explains using Creo TOOLKIT in Asynchronous Mode.

Asynchronous mode is a multiprocess mode in which the Creo TOOLKIT application and Creo Parametric can perform concurrent operations. Unlike synchronous mode, the asynchronous mode uses remote procedure calls (rpc) as the means of communication between the application and Creo Parametric.

Another important difference between synchronous and asynchronous modes is in the startup of the Creo TOOLKIT application. In synchronous mode, the application is started by Creo Parametric, based on information contained in the registry file. In asynchronous mode, the application is started independently of Creo Parametric and subsequently either starts or connects to a Creo Parametric process. The application can contain its own `main()` or `wmain()` function. Use `wmain()` if the application needs to receive command-line arguments as `wchar_t`, for example if the input contains non-ascii characters. Note that an asynchronous application will not appear in the Auxiliary Applications dialog box.

The section [How Creo Toolkit Works on page 40](#) in [Fundamentals on page 30](#) section describes two modes—DLL and multiprocess (or “spawned”). These modes are synchronous modes in the sense that the Creo TOOLKIT application and Creo Parametric do not perform operations concurrently. In spawn mode, each process can send a message to the other to ask for some operation, but each waits for a returning message that reports that the operation is complete. Control alternates between the two processes, one of which is always in a wait state.

Asynchronous mode applications operate with the same method of communication as spawn mode (multiprocess). The use of rpc in spawn mode causes this mode to perform significantly slower than DLL communications. For this reason, you should be careful not to apply asynchronous mode when it is not needed. Note that asynchronous mode is not the only mode in which your application can have explicit control over Creo Parametric. You can also run Creo

---

Parametric in batch mode using Creo TOOLKIT applications; for more information on batch mode operation, refer to the section [Using Creo Toolkit to Make a Batch Creo Parametric Session on page 58](#).

## Setting up an Asynchronous Creo Toolkit Application

For your asynchronous application to communicate with Creo Parametric, you must set the environment variable `PRO_COMM_MSG_EXE` to the full path of the executable `pro_comm_msg.exe`, that is, `<creo_loadpoint>\<datecode>\Common Files\<machine>\obj\pro_comm_msg.exe`

Set `PRO_COMM_MSG_EXE` in the **Environment Variables** section of the **System** window (which can be accessed from the Control Panel).

Depending on how your asynchronous application handles messages from Creo Parametric, your application can be classified as either “simple” or “full”. The following sections describe simple and full asynchronous mode.

The environment variable `RPC_TIMEOUT` sets the maximum time limit in which the remote procedure calls must be executed. The variable sets the time in seconds. The default value is set to 2000 seconds. The functions return the error `PRO_TK_COMM_ERROR`, when the application times out without complete execution. If your application requires more time for execution, you must set this variable to a higher value.

---

### Note

For asynchronous mode applications, you are not required to supply `user_initialize()` and `user_terminate()`, Creo TOOLKIT will supply a default implementation for these functions. If you do wish to include a custom version of either function, both the functions `user_initialize()` and `user_terminate()` must be supplied in the application. A custom `user_initialize()` will make it possible to access the `user_initialize()` input arguments and to reuse code from a synchronous application without making modifications.

---

## Starting Asynchronous Applications in Creo+

As is auto updated, it is difficult to find and update path of `creoplus.exe`. To overcome this problem, you need to set the value of the new environment variable `TK_ASYNC_CREO_AUTO_LOCATE`, which will auto locate the path for `creoplus.exe`. If you set this environment variable, you don't need to set the value of the environment variable `PRO_COMM_MSG_EXE` explicitly.

---

Pass the arguments to the function `ProEngineerStart()` along with new argument *profile* as `creoplus.exe -g:no_graphics -profile automation`, `text_path`, where *profile* is the profile name with which is launched.

To automate the launch of , pass the inputs arguments as follows:

- `-profile` as `profile_name`, to specify profile.
- `-cwd` as `directory`, to specify working directory.
- `++creo_tk` as `args_to_creo_in` double\_quotes, to specify arguments to be used by Creo Parametric.

For example, if you run the function `ProEngineerStart()` with `creoplus.exe --profile profile --cwd D:/ ++creo_tk "-g:no_graphics -i:rpc_input"`, will launch with the profile name as `profile` and Creo Parametric will receive the arguments as `-g:no_graphics -i:rpc_input`.

#### Note

You need to ensure that the profile is valid and does not have a space in the name.

---

## Simple Asynchronous Mode

A simple asynchronous application does not implement a way to handle requests from Creo Parametric. Therefore, Creo Parametric cannot call functions in the Creo TOOLKIT application. Consequently, Creo Parametric cannot invoke the callback functions that must be supplied when you add, for example, menu buttons or notifications to Creo Parametric.

Despite this limitation, Creo Parametric running with graphics is still an interactive process available to the user.

When you design a Creo TOOLKIT application to run in simple asynchronous mode, keep the following in mind:

- The Creo Parametric process and the application perform operations concurrently.
- None of the application's functions are invoked by Creo Parametric.
- Simple asynchronous mode supports Creo TOOLKIT visit functions (`ProSolidFeatVisit()`, for example), but does not support notification callbacks.

---

These considerations imply that the Creo TOOLKIT application does not know the state (the current mode, for example) of the Creo Parametric process at any moment.

## Starting and Stopping Creo Parametric

Functions introduced:

- **ProEngineerStart()**
- **ProEngineerConnectionStart()**
- **ProEngineerEnd()**

A simple asynchronous application can spawn and connect to a Creo Parametric process via the function `ProEngineerStart()`. During this startup, Creo Parametric calls `user_initialize()` if it is present in the application. The Creo Parametric process “listens” for requests from the application and acts on the requests at suitable breakpoints—normally between commands.

The function `ProEngineerConnectionStart()` performs the same task as `ProEngineerStart()`, except that `ProEngineerConnectionStart()` outputs a `ProProcessHandle` which can be used for later connect and disconnect operations. Using this function requires building with a C++ compiler—see the description of `ProEngineerConnect()` for more information.

To connect to an existing Creo Parametric process from an asynchronous application, see the section [Connecting to a Creo Parametric Process on page 280](#).

Unlike applications running in synchronous mode, asynchronous applications are not terminated when Creo Parametric terminates. This functionality is useful when the application needs to perform Creo Parametric operations only intermittently, and therefore start and stop Creo Parametric more than once during a session. To end a Creo Parametric process, call the function `ProEngineerEnd()`.

## Connecting to a Creo Parametric Process

Functions introduced:

- **ProEngineerConnectIdGet()**
- **ProEngineerConnect()**
- **ProEngineerDisconnect()**
- **ProEngineerConnectIdExtract()**

The function `ProEngineerConnectIdGet()` returns the asynchronous connection id of the Creo Parametric session that the application is running with. This function can be called from any synchronous (DLL or spawn mode) or asynchronous application. It allows the application to send the connection id to any other asynchronous application that needs to connect to this specific Creo Parametric session.

---

A simple asynchronous application can also connect to a Creo Parametric process that is already running on that machine. The function `ProEngineerConnect()` performs this function. It allows you to specify the name of the user who owns the Creo Parametric process to which you want to connect, and the name of the machine used for the display. If multiple Creo Parametric sessions meet this specification, `ProEngineerConnect()` can optionally choose one process at random or return an error status.

To disconnect from a Creo Parametric process, call `ProEngineerDisconnect()`.

The connection to a Creo Parametric process uses information that is provided by the name service daemon. The name service daemon accepts and supplies information about the processes running on the specified hosts. The application manager, for example, uses name service when it starts up Creo Parametric and other processes. The name service daemon is set up as part of the Creo Parametric installation.

The function `ProEngineerConnectIdExtract()` returns a string connection identifier for the Creo Parametric process. This identifier can be used later to connect to the same process using a call to `ProEngineerConnect()`. Pass the connection id as the first argument to the connection function.

To use the functions in this section, and also the function `ProEngineerConnectionStart()`, you must link your application with the library `pt_asynchronous.lib`, which is in the following location:  
`<creo_toolkit_loadpoint>/<Machine>/obj`

Because this is a C++ library, you must use a C++ compiler to build your application. For sample makefiles containing C++ settings, see the makefiles under the directory `<creo_toolkit_loadpoint>/<Machine>/obj`

---

### Note

You do not have to link with `pt_asynchronous.lib` (or use a C++ compiler) if you do not use the functions just described or `ProEngineerConnectionStart()`.

---

## Status of a Process

Function introduced:

- **ProEngineerStatusGet()**

It might be useful for your application to know whether a Creo Parametric process is running. The function `ProEngineerStatusGet()` returns this information.

---

## Full Asynchronous Mode

Functions introduced:

- **ProEventProcess()**
- **ProAsynchronousEventLoop()**
- **ProAsynchronousEventLoopInterrupt()**
- **ProTermFuncSet()**
- **ProTerminationAction()**

Full asynchronous mode is identical to simple asynchronous mode except in the way the Creo TOOLKIT application handles requests from Creo Parametric. In simple asynchronous mode, it is not possible to process such requests. In full asynchronous mode, the application must implement a control loop that “listens” for messages that arrive from Creo Parametric. As a result, Creo Parametric can call functions in the application, including callback functions for menu buttons and notifications.

The control loop of an application running in full asynchronous mode must contain a call to the function `ProEventProcess()`, which takes no arguments. This function responds to Creo Parametric messages in a manner similar to synchronous mode. For example, if the user selects a menu button that is added by your application, `ProEventProcess()` processes the call to your callback function and returns when the call completes. (For more information on callback functions and adding menu buttons, see the [User Interface: Menus, Commands, and Popupmenus on page 320](#) section.)

The function `ProAsynchronousEventLoop()` provides an alternative to the development of an event processing loop in a full asynchronous mode application. Call this function to have the application wait in a loop for events to be passed from Creo Parametric. No other processing will take place while the application is waiting. The loop will continue until `ProAsynchronousEventLoopInterrupt()` is called from a Creo TOOLKIT callback action, or until the application detects that Creo Parametric has terminated.

It is often necessary for your full asynchronous application to be notified of the termination of the Creo Parametric process. In particular, your control loop need not continue to listen for Creo Parametric messages if Creo Parametric is no longer running. The function `ProTermFuncSet()` binds a termination action to be executed when Creo Parametric is terminated. The termination action is a function that you supply and identify in the input of `ProTermFuncSet()` by a function pointer of type `ProTerminationAction`. The input to the termination action is the termination type, which is one of the following:

- `PROTERM_EXIT`—Normal exit (the user picks **Exit** from the menu).
- `PROTERM_ABNORMAL`—Exit with error status.

- `PROTERM_SIGNAL`—Fatal signal raised.

Your application can interpret the termination type and take appropriate action.

## Setting Up a Non-Interactive Session

You can spawn a Creo Parametric session that is both noninteractive and nongraphical. In asynchronous mode, include the following arguments in the call to `ProEngineerStart()`:

- `-g:no_graphics`—Turn off the graphics display.
- `-i:rpc_input`—Cause Creo Parametric to expect input from your asynchronous application only.

Both of these arguments are required, but the order is not important. The syntax of the call for a noninteractive, nongraphical session is as follows:

```
ProEngineerStart ("parametric -g:no_graphics -i:rpc_input", <text_dir>);
```

In the syntax, `parametric` is the command to start Creo Parametric.

# Composite Design

## Composite Design

### Introduction to Composite Design

In Creo Parametric 10.0.1.0 and later, the composite functionality is added. To set up the composite design environment, you need to complete the following steps:

- **Add Composite Materials** — The Composite Design environment uses composite materials of the top part, to create plies and cores.
- **Define the Layup Surface**—A layup surface is defined by selecting an individual surface, a complete quilt, or multiple surfaces of the same quilt or the same body. You can define only one layup surface in a Composite feature.
- **Define a Rosette**—A rosette is a reference coordinate system that defines the primary fiber orientation of the plies and cores. You must define a layup surface before defining the rosette.

For more details about Creo Composite Design and the user interface, refer to the Composite Design module in the Creo online help.

### Non-Compatible APIs in Composite Models

The functions that do not support composite models return the error type `PRO_TK_UNSUPPORTED`, when a composite model is passed as the input model.

---

## Non-Compatible APIs for read-only/locked models

The functions that do not support read-only/locked models return the error type `PRO_TK_CANT_MODIFY` or `PRO_TK_BAD_INPUTS` when a read-only/locked model is passed as the input model.

## Composite Feature

The feature type `PRO_FEAT_CMPST_DESIGN` represents the composite feature. You can create a composite feature using the function `ProCompositeFeatureCreate()`.

---

### Note

Always regenerate the composite model and top part using the `ProSolidRegenerate()`.

---

Functions Introduced:

- **ProCompositeMdlGet()**
- **ProCompositeFeatureCreate()**
- **ProMdlIsComposite()**
- **ProRosetteDefaultSet()**
- **ProRosetteDefaultGet()**
- **ProCompositePlyVisit()**
- **ProPlyColorGet()**
- **ProPlyFeatureGet()**
- **ProSolidBodyIsComposite()**

The function `ProCompositeMdlGet()` retrieves the composite model for the specified composite feature.

The function `ProCompositeFeatureCreate()` creates an empty composite feature with the specified model handle.

Use the function `ProMdlIsComposite()` to check if model is a composite model.

The function `ProRosetteDefaultSet()` sets the specified rosette feature as default.

The function `ProRosetteDefaultGet()` returns the default rosette feature for the specified composite model.

The function `ProCompositePlyVisit()` visits all the plies in the specified composite solid. The input arguments are as follows:

- *composite*—Handle to composite solid.
- *action*—Visiting function defined by `ProModelitemVisitAction()`. If it returns anything other than `PRO_TK_NO_ERROR`, visiting stops.
- *filter*—Filter function defined by `ProModelitemFilterAction()`. If it is `NULL`, all the features in the specified solid are visited using the action function.
- *appdata*—Application data passed to the filter and action functions.

Use the function `ProPlyColorGet()` to retrieve the color of the ply.

Use the function `ProPlyFeatureGet()` to retrieve the feature that created the specified ply.

## Composite Feature Types

The following feature types are supported in Composite Design:

| Feature Type                             | Description         | New/Existing |
|------------------------------------------|---------------------|--------------|
| <code>PRO_FEAT_CMPST_DESIGN</code>       | Composite Design    | New          |
| <code>PRO_FEAT_CSYS</code>               | Coordinate System   | Existing     |
| <code>PRO_CSYS_SUB_TYPE_ROSETTE</code>   | Rosette             | New          |
| <code>PRO_FEAT_GEOM_COPY</code>          | Copy Geometry       | Existing     |
| <code>PRO_E_CMPST_DESIGN_SURF_DIR</code> | Layup Surface       | New          |
| <code>PRO_FEAT_REMOVE_PLY</code>         | Remove Ply          | New          |
| <code>PRO_FEAT_CMPST_MAN_PLY</code>      | Manual Ply          | New          |
| <code>PRO_FEAT_CMPST_CORE</code>         | Core Ply            | New          |
| <code>PRO_FEAT_CMPST_PLIES_TRANS</code>  | Transition Plies    | New          |
| <code>PRO_FEAT_CMPST_SPLC</code>         | Splice Plies        | New          |
| <code>PRO_FEAT_CMPST_DRAPE</code>        | Composite Drape     | New          |
| <code>PRO_FEAT_CMPST_DESIGN_SURF</code>  |                     | New          |
| <code>PRO_FEAT_DATUM</code>              | All types of Datums | Existing     |
| <code>PRO_FEAT_CURVE</code>              | All types of Curves | Existing     |
| <code>PRO_CURVE_TYPE_CLOSED_LOOP</code>  | Closed Loop Curve   | New          |

| Feature Type         | Description  | New/Existing |
|----------------------|--------------|--------------|
| PRO_FEAT_DATUM_POINT | Datum Points | Existing     |
| PRO_FEAT_DATUM_AXIS  | Datum Axis   | Existing     |

## Materials for Composite Feature

By default, Creo assigns the initial material to the new composite feature automatically provided a composite material exists in the top part of your composite feature. If you want to assign composite materials to a composite feature, you can add the materials to the top part. These materials assigned to the top part are listed in the composite material tree which you select and assign to a ply or a core feature. You can also set a default material to the composite feature. If you change the composite materials in the top model, you are prompted to regenerate the composite feature. When you create a new composite feature, the default material is the first component material in the list of materials.

When you create a composite feature without materials, the first composite material added to the model becomes the default material of the active composite feature.

### Note

You cannot add or edit a material in the composite material tree. You can add and assign materials only to the top part to your composite feature.

## Properties of a Composite Material

You can use the enumerated data type `ProMaterialPropertyType` to define the properties of the composite material:

- `PRO_MATPROP_SPECIFICATION`
- `PRO_MATPROP_FABRIC_ARCHITECTURE`
- `PRO_MATPROP_CONSTIT_FIBER_ANGLES`
- `PRO_MATPROP_CURED_THICKNESS`
- `PRO_MATPROP_UNCURED_THICKNESS`
- `PRO_MATPROP_ROLL_WIDTH`
- `PRO_MATPROP_WARN_ANGLE`
- `PRO_MATPROP_LIMIT_ANGLE`
- `PRO_MATPROP_AREAL_MASS`
- `PRO_MATPROP_AREAL_COST`

---

## Mass Properties of a Composite Feature

The mass properties computation in the Composite Design environment is similar to the standard mass properties computation. You can compute the mass properties of a single laminate object similar to a ply or a core, or the full laminate. Before you compute the mass properties of the whole laminate, make sure that you setup a mass properties computation method as follows:

- Based on layup surface
- Based on underlying plies

Functions Introduced:

- **ProCompositeMassPropertyOptionGet()**
- **ProCompositeMassPropertyOptionSet()**

The function `ProCompositeMassPropertyOptionGet()` retrieves the mass property calculation option for the specified composite model. The input argument *composite\_md1* is specified using the `ProMdl` object. The function returns the output the mass property calculation option using the enumerated data type `ProCompositeMassPropertyOption`. The valid values are:

- `PRO_CMPST_MP_LAYUP_BASED`—Calculates mass properties of plies and cores based on their geometry on the layup surface.
- `PRO_CMPST_MP_PLIES_BASED`—Calculates mass properties of a laminate object based on the effect of underlying plies in the laminate stack on its 3D position from the layup surface. With the underlying plies option specified, all mass properties calculations are shared with the draping simulation analysis. This allows to leverage intermediate results to improve the performance.

Use the function `ProCompositeMassPropertyOptionSet()` to set mass property calculation option on composite solid. The input arguments are *composite\_md1*, the composite model specified using the `ProMdl` object and *opt*, the option to calculate mass property.

## Ply Objects

The term “Ply” denotes a single layer of material such as foam, paper, aluminum, or honeycomb structure in the Composite Design environment. A ply is defined using the object `ProPly` with the type as `PRO_CMPST_PLY_DEF`. You can use the `ProPly` object to set and get the color of the ply.

### Ply View and Flat Ply View

You can create and view the scaled-up section of a model along a particular direction. You can also create multiple composite sections in a Composite Design. For this, you must have ply objects in your Composite Design environment.

Functions Introduced:

- **ProDrawingFlatPlyViewCreate()**
- **ProDrawingPlyViewCreate()**

Use the function `ProDrawingFlatPlyViewCreate()` to create a flat ply view in a specified drawing. The drawing must be displayed. The input arguments are as follows:

- *drawing*—The drawing on which you want to create a flat ply view and is defined using `ProDrawing` object.
- *composite*—The composite solid defined using `ProSolid`.
- *sheet\_number*—Reserved for future use.
- *ply*—Active ply defined using the `ProPly` feature type.
- *position*—The position of the view on the screen and is defined using the `ProPoint3d` object.
- *scale*—Scale defined as double value. If scale is  $>0$ , the view has an associated scale. If scale is  $\leq 0$ , the view has a default scale.

Use the function `ProDrawingPlyViewCreate()` to create a ply view in a specified drawing. The drawing must be displayed. The input arguments are as follows:

- *drawing*—The drawing on which you want to create a flat ply view and is defined using `ProDrawing` object.
- *composite*—The composite solid defined using `ProSolid`.
- *sheet\_number*—The number of the sheet on which to place the view.
- *ply*—Active ply defined using the `ProPly` feature type.
- *position*—The position of the view on the screen and is defined using the `ProPoint3d` object.
- *scale*—Scale defined as double value. If scale is  $>0$ , the view has an associated scale. If scale is  $\leq 0$ , the view has a default scale.

The output of both the functions `ProDrawingFlatPlyViewCreate()` and `ProDrawingPlyViewCreate()` is the view specified by the `ProView` handle.

## Laminate Cross Section

Functions Introduced:

- **ProXSectionLaminateCreate()**
- **ProXSectionLaminateScaleGet()**
- **ProXSectionLaminateScaleModify()**

---

The function `ProXSectionLaminateCreate()` creates a cross section through a datum plane and makes it visible. The input arguments are as follows:

- *solid\_owner*—Specifies the model where the cross section will be created.
- *xsec\_name*—Specifies the name of the cross section.
- *cutting\_plane*—Specifies the selection of the cutting plane. The cutting plane must belong to the solid owner.
- *flip*—Specifies the cross section flip with respect to cutting plane positive normal.

The output argument `r_xsec` is the handle to the cross section specified using `ProXsecMdlname`.

The function `ProXSectionLaminateCreate()` returns the error `PRO_TK_BAD_CONTEXT`, if the solid owner is not a composite design model.

Use the function `ProXSectionLaminateScaleGet()` to get the value of the ply section exaggerated scale.

Use the function `ProXSectionLaminateScaleModify()` to modify the value of the ply section exaggerated scale.

## Limitations of Composite Mode in Creo Toolkit

- If Composite mode is active, you cannot load a Creo TOOLKIT application.
- If you have loaded a Creo TOOLKIT application already and you switch to the Composite mode:
  - Your application becomes inaccessible. For example, the commands/buttons that are added by the application are disabled and cannot be executed.
  - Notifications registered by your application will not get called while Composite mode is active.

## Element Tree: Remove Ply

This section introduces and shows how to create, redefine and access remove ply features in Creo TOOLKIT.

### Introduction to Remove Ply

You can remove cores and plies created in the Composite Design using the Remove Ply feature. You cannot use a remove ply in your composite design again.

## Feature Element Tree for the Remove Ply Feature

The element tree for the Remove Ply feature is documented in the header file `ProCmpstRemovePly.h` and has a simple structure. The following figure demonstrates the element tree structure:

The following table describes the elements in the element tree:

| Element ID             | Element Name | Data Type                |
|------------------------|--------------|--------------------------|
| PRO_E_FEATURE_TYPE     | Feature Type | PRO_VALUE_TYPE_INT       |
| PRO_E_REMOVE_PLY_TYPE  | Type         | PRO_VALUE_TYPE_INT       |
| PRO_E_STD_FEATURE_NAME | featname     | PRO_VALUE_TYPE_WSTRING   |
| PRO_E_REMOVE_PLY_REF   | ply_ref      | ProArray of ProReference |

The elements in this tree are described as follows:

- `PRO_E_FEATURE_TYPE`—Specifies the feature type and the valid value is `PRO_FEAT_REMOVE_PLY`.
- `PRO_E_REMOVE_PLY_TYPE`—Specifies the objects to be removed and is defined using the enumerated data type `ProRemovePlyType`. The valid values are:
  - `PRO_REMOVE_PLY_REMOVE`—All selected plies are removed.
  - `PRO_REMOVE_PLY_KEEP`—All selected plies are kept, and unselected plies are removed.
- `PRO_E_STD_FEATURE_NAME`—Specifies the feature name.
- `PRO_E_REMOVE_PLY_REF`—Specifies the laminate objects to be removed and is defined using the `ProArray` of `ProReference`.

## Element Tree: Manual Ply

This section introduces and shows how to create, redefine and access manual ply features in Creo TOOLKIT.

## Introduction to Manual Ply

Create a manual ply by defining its material and properties. To create a manual ply, you must first set up the Composite Design environment.

### Feature Element Tree for the Manual Ply Feature

The element tree for the Manual Ply feature is documented in the header file `ProCmpstManPly.h`. The following figure demonstrates the element tree structure:

```
--PRO_E_FEATURE_TYPE
|--PRO_E_STD_FEATURE_NAME
|--PRO_E_CMPST_PLY_BASE_QUILT
|--PRO_E_AREA_BOUNDARY
| |--PRO_E_AREA_BOUNDARY_LOOPS
| |--PRO_E_AREA_BOUNDARY_LOOP
| |--PRO_E_STD_LOOP_COLLECTION_APPL

--PRO_E_DSGNTAREA_CREATION_FLIP
--PRO_E_CMPST_MAN_PLY_CMPND
| |--PRO_E_CMPST_MAN_PLY_MTRL
| |--PRO_E_CMPST_MAN_PLY_ORNT
| |--PRO_E_CMPST_MAN_PLY_DROP_OFF
| |--PRO_E_CMPST_MAN_PLY_NAME
| |--PRO_E_CMPST_MAN_PLY_SEQ

--PRO_E_CMPST_PLY_ROSETTE|
```

The following table describes the elements in the element tree:

| Element ID                 | Element Name  | Data Type                |
|----------------------------|---------------|--------------------------|
| PRO_E_FEATURE_TYPE         | Feature Type  | PRO_VALUE_TYPE_INT       |
| PRO_E_STD_FEATURE_NAME     | featname      | PRO_VALUE_TYPE_WSTRING   |
| PRO_E_CMPST_PLY_BASE_QUILT | layup surface | PRO_VALUE_TYPE_SELECTION |
| PRO_E_CMPST_MAN_PLY_TYPE   | Ply_type      | Optional element         |
| PRO_E_AREA_                | Boundary      | Compound element.        |

| Element ID                     | Element Name         | Data Type                |
|--------------------------------|----------------------|--------------------------|
| BOUNDARY                       |                      |                          |
| PRO_E_AREA_BOUNDARY_LOOPS      | Loops                | ProArray of Loops        |
| PRO_E_AREA_BOUNDARY_LOOP       | Loop                 | Compound element.        |
| PRO_E_STD_LOOP_COLLECTION_APPL | Boundary chains      | PRO_VALUE_TYPE_POINTER   |
| PRO_E_DSGNTAREA_CREATION_FLIP  | Creation Flip        | PRO_VALUE_TYPE_INT       |
| PRO_E_CMPST_MAN_PLY_ZONES      | Zones                | PRO_VALUE_TYPE_SELECTION |
| PRO_E_CMPST_MAN_PLY_CMPND      | PlyCompound          | Compound element.        |
| PRO_E_CMPST_MAN_PLY_MTRL       | Material             | PRO_VALUE_TYPE_INT       |
| PRO_E_CMPST_MAN_PLY_ORNT       | Orientation          | PRO_VALUE_TYPE_DOUBLE    |
| PRO_E_CMPST_MAN_PLY_DROP_OFF   | Drop-Off             | PRO_VALUE_TYPE_DOUBLE    |
| PRO_E_CMPST_MAN_PLY_NAME       | Name                 | PRO_VALUE_TYPE_WSTRING   |
| PRO_E_CMPST_PLY_ROSETTE        | CmpstPlyRosette Step | PRO_VALUE_TYPE_SELECTION |

The elements in this tree are described as follows:

- PRO\_E\_FEATURE\_TYPE—Specifies the feature type and the valid value is PRO\_FEAT\_CMPST\_MAN\_PLY.
- PRO\_E\_STD\_FEATURE\_NAME—Specifies the feature name.
- PRO\_E\_CMPST\_PLY\_BASE\_QUILT—Specifies the selection of layup surfaces.
- PRO\_E\_CMPST\_MAN\_PLY\_TYPE—Specifies the manual ply type. The ply type is defined using the enumerated data type ProCmpst\_man\_ply\_type and has the valid values as:
  - PRO\_CMPST\_MAN\_PLY\_TYPE\_OPT\_MANUAL\_PLY—Use PRO\_E\_AREA\_BOUNDARY to specify the boundary.
  - PRO\_CMPST\_MAN\_PLY\_TYPE\_OPT\_ZONE\_BASED\_PLY—Use PRO\_E\_CMPST\_MAN\_PLY\_ZONES to specify the boundary zones.
- PRO\_E\_AREA\_BOUNDARY—Specifies the boundary.

- `PRO_E_AREA_BOUNDARY_LOOPS`—Specifies the loops that represent the outer boundary of the ply and its inner islands.
- `PRO_E_AREA_BOUNDARY_LOOP`—Specifies the loops from multiple edges, curves, or loops.
- `PRO_E_STD_LOOP_COLLECTION_APPL`—Specifies the boundary chains using the `ProCrvcollection` object.
- `PRO_E_DSGNTAREA_CREATION_FLIP`—Specifies the flip direction.
- `PRO_E_CMPST_MAN_PLY_ZONES`—Specifies the boundary zones. The valid value is `PRO_QUILT` for laminate zone feature.
- `PRO_E_CMPST_MAN_PLY_CMPND`
  - `PRO_E_CMPST_MAN_PLY_MTRL`—Specifies the material of the ply.
  - `PRO_E_CMPST_MAN_PLY_ORNT`—Specifies the angle of the ply with respect to X-axis of the rosette. The valid range is  $-360.0$  to  $+360.0$ .
  - `PRO_E_CMPST_MAN_PLY_DROP_OFF`—Specifies the drop-off. The valid range is  $0$  to `MAX_DIM_VALUE`.
  - `PRO_E_CMPST_MAN_PLY_NAME`—Specifies the name of the ply object that is shown in the Laminate tree.
  - `PRO_E_CMPST_MAN_PLY_SEQ`—Specifies the ply sequence.
- `PRO_E_CMPST_PLY_ROSETTE`—Specifies the selection of `PRO_SURFACE`, `PRO_QUILT`, `PRO_CSYS`, `PRO_LOG_CSYS`.

## Element Tree: Core Ply

This section introduces and shows how to create, redefine and access core ply features in Creo TOOLKIT.

### Introduction to Core Ply

A core ply is a thick ply made up of materials such as foam, paper, aluminum, or honeycomb structure. It is extracted from a large sheet and cut along a boundary. To create a core ply, you must first set up the Composite Design environment.

### Feature Element Tree for the Core Ply Feature

The element tree for the Core Ply feature is documented in the header file `ProCmpstCore.h`. The following figure demonstrates the element tree structure:

```

|--PRO_E_FEATURE_TYPE
|--PRO_E_STD_FEATURE_NAME
|--PRO_E_CMPST_PLY_BASE_QUILT
|--PRO_E_AREA_BOUNDARY
 |--PRO_E_AREA_BOUNDARY_LOOPS
 |--PRO_E_AREA_BOUNDARY_LOOP
 |--PRO_E_STD_LOOP_COLLECTION_APPL

|--PRO_E_DSGNTAREA_CREATION_FLIP
|--PRO_E_CMPST_MAN_PLY_CMPND
 |--PRO_E_CMPST_MAN_PLY_MTRL
 |--PRO_E_CMPST_MAN_PLY_ORNT
 |--PRO_E_CMPST_MAN_PLY_DROP_OFF
 |--PRO_E_CMPST_MAN_PLY_NAME
 |--PRO_E_CMPST_MAN_PLY_SEQ

|--PRO_E_CMPST_PLY_ROSETTE
|--PRO_E_CMPST_CORE_SET_ARR
 |--PRO_E_CMPST_CORE_SET
 |--PRO_E_CMPST_CORE_D1
 |--PRO_E_CMPST_CORE_D2
 |--PRO_E_CMPST_CORE_HEIGHT
 |--PRO_E_STD_CURVE_COLLECTION_APPL

```

The following table describes the elements in the element tree:

| Element ID                 | Element Name           | Data Type                |
|----------------------------|------------------------|--------------------------|
| PRO_E_FEATURE_TYPE         | Feature Type           | PRO_VALUE_TYPE_INT       |
| PRO_E_STD_FEATURE_NAME     | featname               | PRO_VALUE_TYPE_WSTRING   |
| PRO_E_CMPST_PLY_BASE_QUILT | CmpstPlyBaseQuilt Step | PRO_VALUE_TYPE_SELECTION |
| PRO_E_CMPST_MAN_PLY_TYPE   | Ply_type               | Optional element         |
| PRO_E_AREA_BOUNDARY        | Boundary               | Compound element.        |

| Element ID                      | Element Name         | Data Type                |
|---------------------------------|----------------------|--------------------------|
| PRO_E_AREA_BOUNDARY_LOOPS       | Loops                | ProArray of Loops        |
| PRO_E_AREA_BOUNDARY_LOOP        | Loop                 | Compound element.        |
| PRO_E_STD_LOOP_COLLECTION_APPL  | Boundary chains      | PRO_VALUE_TYPE_POINTER   |
| PRO_E_DSGNTAREA_CREATION_FLIP   | Creation Flip        | PRO_VALUE_TYPE_INT       |
| PRO_E_CMPST_MAN_PLY_ZONES       | zones                | PRO_VALUE_TYPE_SELECTION |
| PRO_E_CMPST_MAN_PLY_CMPND       | PlyCompound          | Compound element.        |
| PRO_E_CMPST_MAN_PLY_MTRL        | Material             | PRO_VALUE_TYPE_INT       |
| PRO_E_CMPST_MAN_PLY_ORNT        | Orientation          | PRO_VALUE_TYPE_DOUBLE    |
| PRO_E_CMPST_MAN_PLY_DROP_OFF    | Drop-Off             | PRO_VALUE_TYPE_DOUBLE    |
| PRO_E_CMPST_MAN_PLY_NAME        | Name                 | PRO_VALUE_TYPE_WSTRING   |
| PRO_E_CMPST_MAN_PLY_SEQ         | Sequence             | PRO_VALUE_TYPE_WSTRING   |
| PRO_E_CMPST_PLY_ROSETTE         | CmpstPlyRosette Step | PRO_VALUE_TYPE_SELECTION |
| PRO_E_CMPST_CORE_SET_ARR        | Taper Sets           | ProArray of Sets         |
| PRO_E_CMPST_CORE_SET            | Taper Set            | Compound element         |
| PRO_E_CMPST_CORE_D1             | D1                   | PRO_VALUE_TYPE_DOUBLE    |
| PRO_E_CMPST_CORE_D2             | D2                   | PRO_VALUE_TYPE_DOUBLE    |
| PRO_E_STD_CURVE_COLLECTION_APPL | Taper Chain          | PRO_VALUE_TYPE_SELECTION |

The elements in this tree are described as follows:

- PRO\_E\_FEATURE\_TYPE—Specifies the feature type and the valid value is PRO\_FEAT\_CMPST\_MAN\_PLY.
- PRO\_E\_STD\_FEATURE\_NAME—Specifies the feature name.

- `PRO_E_CMPST_PLY_BASE_QUILT`—Specifies the selection of layup surfaces.
- `PRO_E_CMPST_MAN_PLY_TYPE`—Specifies the core ply type. The ply type is defined using the enumerated data type `ProCmpst_man_ply_type` and has the valid values as:
  - `PRO_CMPST_MAN_PLY_TYPE_OPT_MANUAL_PLY`—Use `PRO_E_AREA_BOUNDARY` to specify the boundary.
  - `PRO_CMPST_MAN_PLY_TYPE_OPT_ZONE_BASED_PLY`—Use `PRO_E_CMPST_MAN_PLY_ZONES` to specify the boundary zones.
- `PRO_E_AREA_BOUNDARY`—Specifies the boundary.
- `PRO_E_AREA_BOUNDARY_LOOPS`—Specifies the loops that represent the outer boundary of the ply and its inner islands.
- `PRO_E_AREA_BOUNDARY_LOOP`
- `PRO_E_STD_LOOP_COLLECTION_APPL`—Specifies the boundary chains using the `ProCrvcollection` object.
- `PRO_E_DSGNTAREA_CREATION_FLIP`—Specifies the flip direction.
- `PRO_E_CMPST_MAN_PLY_ZONES`—Specifies the boundary zones. The valid value is `PRO_QUILT` for laminate zone feature.
- `PRO_E_CMPST_MAN_PLY_CMPND`
  - `PRO_E_CMPST_MAN_PLY_MTRL`—Specifies the material of the ply.
  - `PRO_E_CMPST_MAN_PLY_ORNT`—Specifies the angle of the ply with respect to X-axis of the rosette. The valid range is  $-360.0$  to  $+360.0$ .
  - `PRO_E_CMPST_MAN_PLY_DROP_OFF`—Specifies the drop-off. The valid range is  $0$  to `MAX_DIM_VALUE`.
  - `PRO_E_CMPST_MAN_PLY_NAME`—Specifies the name of the ply object that is shown in the Laminate tree.
  - `PRO_E_CMPST_MAN_PLY_SEQ`—Specifies the ply sequence.
- `PRO_E_CMPST_PLY_ROSETTE`—Specifies the selection of `PRO_SURFACE`, `PRO_QUILT`, `PRO_CSYS`, `PRO_LOG_CSYS`.
- `PRO_E_CMPST_CORE_SET_ARR`—Specifies the array of loop or an edge to which the taper dimensions will be applied to.
- `PRO_E_CMPST_CORE_SET`—Specifies a loop or an edge to which the taper dimensions will be applied to. The reference selected to apply the taper dimensions can only be a sub-set of the selected boundary references.
  - `PRO_E_CMPST_CORE_D1`—Specifies the horizontal taper direction.

- `PRO_E_CMPST_CORE_D2`—Specifies the vertical taper direction. The valid range is 0 to material thickness
- `PRO_E_STD_CURVE_COLLECTION_APPL`—Specifies the taper chains using the `ProCrvcollection` object.

## Element Tree: Transition Plies

This section introduces and shows how to create, redefine and access transition plies features in Creo TOOLKIT.

### Introduction to Transition Plies

Transition between plies is a way to shorten and extend plies created from the same boundary to create a transition effect relative to a transition chain. For the transition curve, you must select a chain of edges that is common to all the selected plies.

### Feature Element Tree for the Transition Plies Feature

The element tree for the Transition Ply feature is documented in the header file `ProCmpstPliesTrans.h` and has a simple structure. The following figure demonstrates the element tree structure:

```

|--PRO_E_FEATURE_TYPE
|--PRO_E_STD_FEATURE_NAME
|--PRO_E_CMPST_PLIES_TRANS_TYPE
|--PRO_E_CMPST_PLIES_TRANS_REFS
|--PRO_E_STD_CURVE_COLLECTION_APPL
|--PRO_E_CMPST_PLIES_TRANS_PAT_SETT
|--PRO_E_CMPST_PLIES_TRANS_OFFSET
|--PRO_E_CMPST_PLIES_TRANS_OFFS_ARR
| |--PRO_E_CMPST_PLIES_TRANS_ARR_CMPD
| | |--PRO_E_CMPST_PLIES_TRANS_PLY_ARR
| | |--PRO_E_CMPST_PLIES_TRANS_OFF_ARR

```

The following table describes the elements in the element tree:

| Element ID                          | Element Name    | Data Type                       |
|-------------------------------------|-----------------|---------------------------------|
| <code>PRO_E_FEATURE_TYPE</code>     | Feature Type    | <code>PRO_VALUE_TYPE_INT</code> |
| <code>PRO_E_STD_FEATURE_NAME</code> | featname        | DATATYPE                        |
| <code>PRO_E_CMPST_</code>           | transition_type | Specified using the             |

| Element ID                               | Element Name     | Data Type                                                                            |
|------------------------------------------|------------------|--------------------------------------------------------------------------------------|
| PLIES_TRANS_TYPE                         |                  | enumerated data type<br>ProCmpst_plies_transTransition_type.                         |
| PRO_E_CMPST_PLIES_TRANS_REFS             | plies_refs       | ProArray of<br>ProReference                                                          |
| PRO_E_CMPST_PLIES_TRANS_OFFSETS_ARR      | offsets_arr      | ProArray of<br>ProCmpst_plies_transOffsets_cmpd                                      |
| PRO_E_CMPST_PLIES_TRANS_ARR_CMPD         | offsets_cmpd     | Specified using the<br>enumerated data type<br>ProCmpst_plies_transOffsets_cmpd.     |
| PRO_E_CMPST_PLIES_TRANS_PLY_REF_ARR      | plies_ref        | ProReference                                                                         |
| PRO_E_CMPST_PLIES_TRANS_OFFSET_ARR       | offset_arr_col   | PRO_VALUE_TYPE_DOUBLE                                                                |
| PRO_E_STD_CURVE_COLLECTION_APPL          | transition_ref   | ProCollection                                                                        |
| PRO_E_CMPST_PLIES_TRANS_PATTERN_SETTINGS | pattern_settings | Specified using the<br>enumerated data type<br>ProCmpst_plies_transPattern_settings. |
| PRO_E_CMPST_PLIES_TRANS_OFFSET           | offset           | PRO_VALUE_TYPE_DOUBLE                                                                |

The elements in this tree are described as follows:

- PRO\_E\_FEATURE\_TYPE—Specifies the feature type and the valid value is PRO\_FEAT\_CMPST\_PLIES\_TRANS.
- PRO\_E\_STD\_FEATURE\_NAME—Specifies the feature name.
- PRO\_E\_CMPST\_PLIES\_TRANS\_TYPE—Specifies the transition type and is defined using the enumerated data type ProCmpst\_plies\_transTransition\_type. The valid values are:
  - PRO\_CMPST\_PLIES\_TRANS\_TRANSITION\_TYPE\_PATTERN=1
  - PRO\_CMPST\_PLIES\_TRANS\_TRANSITION\_TYPE\_CUSTOM=2

- `PRO_E_CMPST_PLIES_TRANS_REFS`—Specifies the reference to the transition plies using `ProArray` of `ProReference`.
- `PRO_E_CMPST_PLIES_TRANS_OFF_ARR`—Specifies the transition offsets of the selected plies relative to the selected reference.
- `PRO_E_CMPST_PLIES_TRANS_ARR_CMPD`—Specifies the constant offset between the edges of subsequent plies.
  - `PRO_E_CMPST_PLIES_TRANS_PLY_REF_ARR`—Specifies a chain of edges to define the reference for transition offsets. You can select only chain that is common to all the selected plies. When you move the cursor over a chain it will highlight when it is a transition chain.
  - `PRO_E_CMPST_PLIES_TRANS_OFFS_ARR`—Specifies a chain from the highlighted chains.
- `PRO_E_STD_CURVE_COLLECTION_APPL`—Specifies the transition references using the `ProCollection` object.
- `PRO_E_CMPST_PLIES_TRANS_PAT_SETT`—Specifies the pattern settings using the enumerated data type `ProCmpst_plies_transPattern_settings`. The valid values are:
  - `PRO_CMPST_PLIES_TRANS_PATTERN_SETTINGS_BACKSLASH=1`
  - `PRO_CMPST_PLIES_TRANS_PATTERN_SETTINGS_SLASH=2`
- `PRO_E_CMPST_PLIES_TRANS_OFFSET`—Specifies a chain of edges to define the reference for transition offsets. You can select only a chain that is common to all the selected plies. The system highlights the possible transition chains.

## Element Tree: Splice Plies

This section introduces and shows how to create, redefine, and access splice plies features in Creo TOOLKIT.

### Introduction to Splice Plies

You can splice one or several plies in 2 pieces by defining whether the spliced plies are touching or overlapping each other. For overlapping splice plies, you need to define the overlapping direction and offset. For multiple splice plies, you need to define the stagger, its direction and offset.

### Feature Element Tree for the Splice Plies Feature

The element tree for the Splice Plies feature is documented in the header file `ProCmpstSplc.h` and has a simple structure. The following figure demonstrates the element tree structure:

```

|--PRO_E_FEATURE_TYPE
|--PRO_E_STD_FEATURE_NAME
|--PRO_E_PLIES_REF
|--PRO_E_STD_CURVE_COLLECTION_APPL
|--PRO_E_CMPST_PLY_OVERLAP_OPT
|--PRO_E_CMPST_PLY_OVERLAP_DIM
|--PRO_E_CMPST_PLY_STG_OPT
|--PRO_E_CMPST_PLY_STG_DIM
|--PRO_E_CMPST_PLY_SPLC_FLIP

```

The following table describes the elements in the element tree:

| Element ID                      | Element Name          | Data Type                |
|---------------------------------|-----------------------|--------------------------|
| PRO_E_FEATURE_TYPE              | Feature Type          | PRO_VALUE_TYPE_INT       |
| PRO_E_STD_FEATURE_NAME          | featname              | DATATYPE                 |
| PRO_E_PLIES_REF                 | plies_coll            | ProArray of ProReference |
| PRO_E_STD_CURVE_COLLECTION_APPL | chain_coll            | ProCollection            |
| PRO_E_CMPST_PLY_OVERLAP_OPT     | cmpst_ply_overlap_opt | PRO_VALUE_TYPE_INT       |
| PRO_E_CMPST_PLY_OVERLAP_DIM     | cmpst_ply_overlap_dim | PRO_VALUE_TYPE_DOUBLE    |
| PRO_E_CMPST_PLY_STG_OPT         | cmpst_ply_stg_opt     | PRO_VALUE_TYPE_INT       |
| PRO_E_CMPST_PLY_STG_DIM         | cmpst_ply_stg_dim     | PRO_VALUE_TYPE_DOUBLE    |
| PRO_E_CMPST_PLY_SPLC_FLIP       | cmpst_ply_splc_flip   | PRO_VALUE_TYPE_INT       |

The elements in this tree are described as follows:

- PRO\_E\_FEATURE\_TYPE—Specifies the feature type and the valid value is PRO\_FEAT\_CMPST\_SPLC.
- PRO\_E\_STD\_FEATURE\_NAME—Specifies the feature name.

- 
- `PRO_E_PLIES_REF`—Specifies the plies to splice or dart.

---

 **Note**

Splice plies does not support external references. If you want to use external references for creating a Splice Plies feature, you need to use the External Copy Geometry feature which is created in the composite solid as a local reference.

---

- `PRO_E_STD_CURVE_COLLECTION_APPL`—The curve that defines the splicing or darting trajectory.
- `PRO_E_CMPST_PLY_OVERLAP_OPT`—The plies that are created as a result of splicing the original ply, touch each other but do not overlap. This element is defined by the enumerated data type `ProCmpst_splc_overlap` and has the following valid values:
  - `PRO_CMPST_SPLC_OVERLAP_NO=0`
  - `PRO_CMPST_SPLC_OVERLAP_YES=1`
- `PRO_E_CMPST_PLY_OVERLAP_DIM`—Value or dimension of the overlapping offset.
- `PRO_E_CMPST_PLY_STG_OPT`—The plies that are created as a result of splicing the original ply, are staggered. This element is defined by the enumerated data type `ProCmpst_splc_stagger` and has the following valid values:
  - `PRO_CMPST_SPLC_STAGGER_NO=0`
  - `PRO_CMPST_SPLC_STAGGER_YES=1`
- `PRO_E_CMPST_PLY_STG_DIM`—Value or dimension of the staggering offset.
- `PRO_E_CMPST_PLY_SPLC_FLIP`—Toggles the direction of both the overlapping offset and the stagger offset.

## Element Trees: Composite Drape

This section introduces and shows how to create, redefine and access drape feature in Creo TOOLKIT.

### Introduction to Drape Feature

You can run the draping simulation to analyze the ply producibility and to create the ply flat patterns. You can create only one drape feature in a composite feature.

## Feature Element Tree for the Drape Feature

The element tree for the Drape feature is documented in the header file `ProCmpstDrape.h`. The following figure demonstrates the element tree structure:

The following table describes the elements in the element tree:

| Element ID               | Element Name         | Data Type                                  |
|--------------------------|----------------------|--------------------------------------------|
| PRO_E_FEATURE_TYPE       | Feature Type         | PRO_VALUE_TYPE_INT                         |
| PRO_E_STD_FEATURE_NAME   | featname             | PRO_VALUE_TYPE_WSTRING                     |
| PRO_E_DRAPE_SETS         | Sets                 | Compound element<br>ProArray               |
| PRO_E_DRAPE_SET          | Set                  | Mandatory element                          |
| PRO_E_DRAPE_PLY_REF      | Ply Reference        | Mandatory element<br>ProReference          |
| PRO_E_DRAPE_SEED_PNT     | Seed Point           | Optional element<br>ProReference           |
| PRO_E_DRAPE_STEP_LENGTH  | Step length          | Mandatory element<br>PRO_VALUE_TYPE_DOUBLE |
| PRO_E_DRAPE_ANGLE        | Draping angle        | PRO_VALUE_TYPE_DOUBLE                      |
| PRO_E_DRAPE_POLYLINE_ANG | Simplification angle | PRO_VALUE_TYPE_DOUBLE                      |
| PRO_E_DRAPE_3D           | Drape in 3D space    | ProDrapeIn3d                               |

|                         |                 |                                         |
|-------------------------|-----------------|-----------------------------------------|
| PRO_E_DRAPE_REFINEMENT  | Refinement      | Mandatory element<br>ProDrapeRefinement |
| PRO_E_DRAPE_CURED_THICK | Drape all plies | ProDrapeThicknessOpt                    |

The elements in this tree are described as follows:

- PRO\_E\_FEATURE\_TYPE—Specifies the feature type and the valid value is PRO\_FEAT\_CMPST\_DRAPE.
- PRO\_E\_STD\_FEATURE\_NAME—Specifies the feature name.
- PRO\_E\_DRAPE\_SETS—Specifies the ProArray of draping simulation definitions.
- PRO\_E\_DRAPE\_SET—Specifies the draping simulation definition applied to a single ply.
- PRO\_E\_DRAPE\_PLY\_REF—Specifies the ply to perform a draping simulation on.
- PRO\_E\_DRAPE\_SEED\_PNT—Specifies the position on the mould surface or previous ply on which the drape starts (i.e. the first point of contact between the ply and previous ply or mould).
- PRO\_E\_DRAPE\_STEP\_LENGTH—Specifies the distance between adjacent drape points / fibers i.e. the resolution of the fishnet drape mesh.
- PRO\_E\_DRAPE\_ANGLE—Specifies the angle with respect to the material roll direction of the fixed warp and weft fibers (i.e. the orientation that the drape progresses).
- PRO\_E\_DRAPE\_POLYLINE\_ANG—Specifies the angle between the polyline segments.
- PRO\_E\_DRAPE\_3D—Specifies the height of the ply in the laminate stack when performing draping analysis. This element is defined using the enumerated data type ProDrapeIn3d and valid values are:
  - PRO\_DRAPE\_IN3D\_DISABLED—0.
  - PRO\_DRAPE\_IN3D\_ENABLED—1.
- PRO\_E\_DRAPE\_REFINEMENT—Specifies the option for additional refinements by using the property parameters for the step length, drape angle offset, and simplification angle for each set. This element is defined using the enumerated data type ProDrapeRefinement and the valid values are:
  - PRO\_DRAPE\_REFINEMENT\_DISABLED—0
  - PRO\_DRAPE\_REFINEMENT\_ENABLED—1

- **PRO\_E\_DRAPE\_CURED\_THICK**—Specifies the option to drape the plies using cured or uncured thickness. This element is defined using the enumerated data type `ProDrapeThicknessOpt` and the valid values are:
  - **PRO\_DRAPE\_OPTION\_CURED\_THICKNESS**—0
  - **PRO\_DRAPE\_OPTION\_UNCURED\_THICKNESS**—1

## Element Tree: Solidify Plies

This section introduces and shows how to create, redefine and access solidify plies features in Creo TOOLKIT.

### Introduction to Solidify Plies

Solidifying plies is the creation of solid geometry from laminate objects. You can create only one solidify plies feature in a composite feature. The feature is updated automatically when the laminate is updated.

When the individual entities are merged completely, a single body is generated in the part. Otherwise, multiple individual bodies might be generated. The system generated composite material is assigned to the generated bodies.

Optionally, you can generate an IML quilt. The IML quilt is generated only when all entities are merged completely. The generated IML quilt consists of all the surfaces; however, the side of the IML quilt facing the layup surface is open.

### Feature Element Tree for the Solidify Ply Feature

The element tree for the Solidify Ply feature is documented in the header file `ProSolidifyPlies.h`, and has a simple structure. The following figure demonstrates the element tree structure:

```

|--PRO_E_STD_FEATURE_NAME
|--PRO_E_OPT_CREATE_IML
|--PRO_E_OPT_CREATEDROPOFF
|--PRO_E_OPT_KEEP_SKIRTS

```

The following table describes the elements in the element tree:

| Element ID                          | Element Name                          | Data Type                           |
|-------------------------------------|---------------------------------------|-------------------------------------|
| <code>PRO_E_STD_FEATURE_Type</code> | Feature Type                          | <code>PRO_VALUE_TYPE_INT</code>     |
| <code>PRO_E_STD_FEATURE_NAME</code> | Feature Name                          | <code>PRO_VALUE_TYPE_WSTRING</code> |
| <code>PRO_E_OPT_CREATE_IML</code>   | Create IML(inner mold line) attribute | <code>PRO_VALUE_TYPE_BOOLEAN</code> |

| Element ID               | Element Name             | Data Type              |
|--------------------------|--------------------------|------------------------|
| PRO_E_OPT_CREATE_DROPOFF | Create Dropoff attribute | PRO_VALUE_TYPE_BOOLEAN |
| PRO_E_OPT_KEEP_SKIRTS    | Keep Skirts attribute    | PRO_VALUE_TYPE_BOOLEAN |

The elements in this tree are described as follows:

- PRO\_E\_FEATURE\_TYPE—Specifies the feature type and the valid value is PRO\_FEAT\_PLY\_SOLIDIFY.
- PRO\_E\_STD\_FEATURE\_NAME—Specifies the feature name.
- PRO\_E\_OPT\_CREATE\_IML—Specifies the inner mold line quilt attribute and is defined using PRO\_VALUE\_TYPE\_BOOLEAN.
- PRO\_E\_OPT\_CREATE\_DROPOFF—Specifies the dropoff attribute and is defined using PRO\_VALUE\_TYPE\_BOOLEAN.
- PRO\_E\_OPT\_KEEP\_SKIRTS—Specifies the keep skirt surface attribute and is defined using PRO\_VALUE\_TYPE\_BOOLEAN.

## User Interface: Messages

### Writing a Message Using a Popup Dialog

This section describes the functions used to communicate with the user through the text message area, including keyboard entry.

The function `ProUIMessageDialogDisplay()` displays the UI message dialog. The input arguments to the function are:

- The type of message to be displayed. It is defined by the enumerated data type `ProUIMessageType` and has the following valid values:
  - `PROUIMESSAGE_ERROR`—displays an error dialog box.
  - `PROUIMESSAGE_WARNING`—displays a warning dialog box.
  - `PROUIMESSAGE_INFO`—displays an information dialog box.
  - `PROUIMESSAGE_QUESTION`—displays a question dialog box.

#### Note

As per Microsoft Windows guidelines, the question mark symbol in the question dialog box is deprecated and is replaced by an information symbol that appears in the information dialog box.

- The text to display as the title of the dialog. If you want to support displaying localized text, use the message files and the function `ProMessageToBuffer()` to generate this string. Message files are described later in this section.
- The message text to be displayed in the dialog. If you want to support displaying localized text, use the message files and function `ProMessageToBuffer()` to generate this string. Message files are described later in this section.
- `ProArray` of possible button identifiers for the dialog.
- The identifier of the default button for the dialog.

The function outputs the button that the user selected.

### Example 1: Displaying the UI Message Dialog

The sample code in `UgUIMessageDisplay` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_message` shows how to display a hard coded confirmation message.

## Writing a Message to the Message Window

This section describes the following topics:

- Displaying and clearing messages
- The text message file

Functions Introduced:

- **`ProMessageDisplay()`**
- **`ProMessageClear()`**
- **`ProUIMessageDialogDisplay()`**
- **`ProUIMessagedialogCreate()`**
- **`ProUIMessagedialogShow()`**
- **`ProUIMessagedialogTitleSet()`**
- **`ProUIMessagedialogMessageSet()`**
- **`ProUIMessagedialogTransientSet()`**
- **`ProUIMessagedialogDurationSet()`**
- **`ProUIMessagedialogBalloonSet()`**

The function `ProMessageDisplay()` is similar to the C function `printf()`, but with some important differences:

- 
- The first argument is the name (as a wide string) of the message file. The name must include the file extension, but not the path. See the below topic [Text Message File Format and Restrictions on page 306](#).
  - The second argument, instead of being a format string, is a keyword used to look up the format string in the message file.
  - The subsequent arguments for the values inserted into the format string are pointers, not values. These values can be data inserted into the message or default values for the data to be read from user input. See the section [Getting Keyboard Input on page 311](#) for more information.
  - Although the list of arguments for the values is variable in number, there is a maximum of 9. See [Contents of the Message File on page 308](#) for more information on using these arguments with a message format.

The function `ProMessageClear()` scrolls the text in the message area up one line. This could be used to indicate that Creo Parametric has received the user's response to a message.

The function `ProUIMessageDialogCreate()` is used for transient and balloon message windows. The `ProUIMessageDialogDisplay` is used for regular message window. The input arguments to the function are:

- *name*—Specifies the name of the window.
- *type*—Specifies the type of message.

The function `ProUIMessageDialogShow()` displays a message window. The input argument *name* specifies the name of the window.

The function `ProUIMessageDialogTitleSet()` specifies the title for a message window. The input arguments to the function are:

- *name*—Specifies the name of the window.
- *title*—Specifies the title text.

The function `ProUIMessageDialogMessageSet()` specifies the message for the window. The input arguments to the function are:

- *name*—Specifies the name of the window.
- *message*—The text in the message.

The function `ProUIMessageDialogTransientSet()` makes a message window transient. The input argument *name* specifies the name of the window.

The function `ProUIMessageDialogDurationSet()` specifies the duration of a transient window. The default duration is 5 seconds. The input arguments to the function are:

- *name*—Specifies the name of the window.
- *duration*—Specifies the duration of the window in milliseconds.

---

The function `ProUIMessageDialogBalloonSet()` generates a message for a window balloon. The input arguments to the function are:

- *name*—Specifies the name of the window.
- *target\_dialog*—The window on which the balloon is displayed.
- *target\_component*—The component that is pointed by the balloon.

## Text Message File Format and Restrictions

The text message file enables you to provide your own translation of the text message, just as the menu files enable you to provide your own translation of the button name and the one-line command help.

## Restrictions on the Text Message File

You must observe the following restrictions when you name your message file:

- The name of the file must be 30 characters or less, including the extension.
- The name of the file must contain lowercase characters only.
- The file extension must be three characters.
- The version number must be in the range 1 to 9999.
- All message file names must be unique, and all message key strings must be unique across all applications that run with Creo Parametric. Duplicate message file names or message key strings can cause Creo Parametric to exhibit unexpected behavior. To avoid conflicts with the names of Creo Parametric or Creo TOOLKIT application message files or message key strings, PTC recommends that you choose a prefix unique to your application, and prepend that prefix to each message file name and each message key string corresponding to that application.

Creo Parametric looks for the message file using the following search path:

- The current Creo Parametric directory
- The directory text under the directory named in the `text_dir` statement in the registry file (`protk.dat`).

Note that message files are loaded into Creo Parametric only once during a session, during the first call to `ProMessageDisplay()`. Consequently, if you make a change to the message file while Creo Parametric is running, you must exit and restart Creo Parametric to have the changes take effect.

## Contents of the Message File

The message file consists of groups of four lines—one group for each message you want to write. The four lines are as follows:

1. A string that acts as the keyword to identify the message when you call `ProMessageDisplay()`. This keyword must be unique for all Creo Parametric messages.
2. A string that will be substituted for the first string when you call `ProMessageDisplay()`. This string acts like the format string in a `printf()` statement. By modifying this line in the message file, you can modify the text of the message without modifying your C code.
3. The translation of the message into another language (can be blank).
4. An intentionally blank line reserved for future extensions.

The format string (line 2 in the message file) differs from the format string of a `printf()` in the following respects:

- The conversion specifications (`%d`, `%s`, and so on) must include an argument number corresponding to the position of that argument in the subsequent list (starting at 0). For example, instead of `%d`, `%s`, you must have `%0d`, `%1s`, and so on. If you want to specify a field width, put it in parentheses between the position number and the type specifier; for example, `%0 (5.3) f`.
- The separator `|||` between message text and a conversion specification signifies that the conversion specification is for a default value for user input. This default value will appear in the text box created using the keyboard input functions, such as `ProMessageIntegerRead()`. Refer to [Using Default Values on page 312](#) for more on default values.
- The conversion character `w` is available for wide strings.
- You do not need the character constant (`\n`) at the end of the format. Creo Parametric automatically inserts a new line when necessary.

#### Note

The length of any line in the message file must not exceed 4096 wide characters.

The following table lists the conversion characters and their corresponding data types.

| Conversion Character | Data Type                                      |
|----------------------|------------------------------------------------|
| <code>f</code>       | Float (or double)                              |
| <code>d</code>       | Decimal integer                                |
| <code>s</code>       | Ordinary string (or type <code>char[]</code> ) |
| <code>w</code>       | Wide character strings                         |
| <code>e</code>       | Exponential                                    |
| <code>g</code>       | Either float or exponential, as appropriate    |

---

Ensure that the keyword string is similar to the format string to make your C code easy to interpret. Add a prefix that is unique to your application to the keyword string. The examples in this manual use the unique prefix “USER.”

## Message Classification

Messages displayed in Creo Parametric include a symbol which identifies the message type. Each message type is identified by a classification which begins with the characters %C. A message classification requires that the message key (line 1 in the message file) be preceded by the classification code. Note that the message key string used in the code should NOT contain the classification.

Creo TOOLKIT applications can now display any or all of these message symbols:

- Prompt—the Creo Parametric message displayed is preceded by a green arrow. The user must respond to this message type (to either input information, accept the default value offered, or cancel the application). Without such action, no progress can be made. The response may be either textual or in the form of a selection. The classification code for prompt messages is %CP.
- Info—the Creo Parametric message displayed is preceded by a blue dot. This message type contains information such as user requests or feedback from either Creo Parametric or the Creo TOOLKIT application. The classification code for prompt messages is %CI.

---

### Note

Do not classify as Info any message which informs users of a problem with an operation or process. These messages should be classified as Warnings.

---

- Warning—the Creo Parametric message displayed is preceded by a triangle containing an exclamation point. Warnings alert the user to situations which may lead to potentially erroneous situations at a later stage, for example, possible process restrictions imposed or a suspected data problem. However, warnings do not prevent or interrupt task completion, nor should they be used to indicate a failed operation. Warnings only caution the user that the operation has been completed, but may not have been performed in a completely desirable way. The classification code for prompt messages is %CW.
- Error—the Creo Parametric message is preceded by a broken square. This message type informs the user when a required task was not successfully completed. It may or may not require intervention or correction before work

---

can continue, depending on the application. Whenever possible, provide a path to redress this situation. The classification code for prompt messages is %CE.

- **Critical**—the Creo Parametric message displayed is preceded by a red X. This message type informs the user of extremely serious situations, especially those which could cause the loss of user data. Options for redressing the situation (if available) should be provided with the message. The classification code for prompt messages is %CC.

## Writing a Message to an Internal Buffer

Function Introduced:

- **ProMessageToBuffer()**
- **ProMessageWstringbufferAlloc()**

The functions `ProMessageToBuffer()` and `ProMessageWstringbufferAlloc()` have the same relationship to `ProMessageDisplay()` that the C library function `sprintf()` has to `printf()`: it enables you to write a message to an internal, wide-string buffer instead of to the Creo Parametric message area. These functions perform exactly the same argument substitution and translation as `ProMessageDisplay()`. You provide a wide-string buffer as the first argument, and the subsequent arguments are the same as those for `ProMessageDisplay()`.

The function `ProMessageToBuffer()` allows you to write a message with a maximum length of 80 characters to a wide-string buffer.

For a message of any length use the function `ProMessageWstringbufferAlloc()`. You must free the output string `translated_msg` using the function `ProWstringFree()`.

## Getting Keyboard Input

Functions Introduced:

- **ProMessageIntegerRead()**
- **ProMessageDoubleRead()**
- **ProMessageStringRead()**
- **ProMessagePasswordRead()**

These four functions obtain keyboard input from a text box at the bottom of the Creo Parametric window. The functions check the syntax of the user's entry and indicate when the entry is simply a carriage return. Each of the functions enable you to restrict numeric input to a specified range, or string input to a specified string length. The functions continue to prompt the user until a valid response is entered.

---

The function `ProMessageStringRead()` supports string lengths up to 127 characters.

## Using Default Values

Prior to Release 20, Pro/TOOLKIT applications implemented default values by checking for a user-entered carriage return. Beginning with Release 20, you can specify default values within the call to `ProMessageDisplay()`, provided that the separator `|||` appears in the format string in the message file. (See the section [Contents of the Message File on page 308](#) for the specific placement of the `|||` separator.)

### Note

You must call the function `ProMessageDisplay()` before calling the `ProMessage*Read` functions to specify the default values.

Default values are displayed in the text box as input. Note that this value will not be passed to the Creo TOOLKIT function if the user hits a carriage return; instead, the function will return `PRO_TK_GENERAL_ERROR` and the application must interpret that the user intends to use the default.

To specify a constant default value, the format string would appear as follows:

```
Enter a double: |||3.0
```

Specifying constant defaults is not recommended as changing the default requires revising the Creo TOOLKIT application. Specifying defaults that are variables is more flexible.

To specify a default integer that is a variable, for example, the format string in the message file would appear as follows:

```
Enter any integer: |||%0d
```

## Example 2: Displaying Messages and Retrieving Keyboard Input

The sample code in `UgMessageWindowUse.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_message` shows how to print messages and accept keyboard input with default values. The example also shows how to write a message to an internal, wide-string buffer. The name of the message file is `msg_ugmessage.txt`.

---

# User Interface: Ribbon Tabs, Groups and Menu Items

## User Interface: Ribbon Tabs, Groups, and Menu Items

This section describes theCreo TOOLKIT support for the Ribbon User Interface (UI). It also describes the impact of the ribbon user interface on legacy Pro/TOOLKIT applications and the procedure to place the commands, buttons, and menu items created by the legacy applications in the Creo Parametric ribbon user interface. Refer to the Creo Parametric Help for more information on the ribbon user interface and the procedure to customize the ribbon.

## Creating Ribbon Tabs, Groups, and Menu Items

Customizations to the ribbon user interface using the Creo TOOLKIT applications are supported through the **Customize Ribbon** tab in the **Creo Parametric Options** dialog box. You can specify the user interface layout for a Creo TOOLKIT application and save the layout definition in a ribbon definition file, `toolkitribbonui.rbn`. When you run Creo Parametric, the `toolkitribbonui.rbn` file is loaded along with the Creo TOOLKIT application and the commands created by the Creo TOOLKIT application appear in the ribbon user interface. Refer to the section [About the Ribbon Definition File on page 315](#) for more information on the `toolkitribbonui.rbn` file.

You can customize the ribbon user interface only for a particular mode in Creo Parametric. For example, if you customize the ribbon user interface and save it to the `toolkitribbonui.rbn` file in the Part mode, then on loading Creo Parametric the customized user interface will be visible only in the Part mode. To view a particular tab or group in all the modes, you must customize the ribbon user interface and save the `toolkitribbonui.rbn` file in each mode. Refer to the Creo Parametric help for more information on customizing the ribbon.

---

### Note

You can add a new group to an existing tab or create a new tab using the **Customize Ribbon** tab in the **Creo Parametric Options** dialog box. You will not be able to modify the tabs or groups that are defined by Creo Parametric.

---

---

## Workflow to Add Menu Items to the Ribbon User Interface

---

### Note

The instructions explained below are applicable only if the application is implemented in full asynchronous mode. This is because applications in simple asynchronous mode cannot handle requests, that is, command callbacks, from Creo Parametric. Refer to the section [Core: Asynchronous Mode on page 277](#), for more information.

---

You must have a Creo TOOLKIT development license to customize the ribbon user interface for Creo TOOLKIT applications. The steps to add commands to the Creo Parametric ribbon user interface are as follows:

1. Create a Creo TOOLKIT application with complete command definition, which includes specifying command label, help text, large icon name, and small icon name. Designate the command using the `ProCmdDesignate()`.

---

### Note

The labels and the text added using the `ProCmdDesignate()` function duplicate existing messages that are previously added in the Creo database. To display the correct label and text message, you can use a prefix or a suffix with the message names that will identify your Creo TOOLKIT application. You should avoid using generic names of Creo TOOLKIT buttons such as Point, Arc, Circle, Ellipse in the labels and text.

---

2. Start the Creo TOOLKIT application and ensure that it is started or connected to Creo Parametric. The commands created by the Creo TOOLKIT application will be loaded in Creo Parametric.
3. Click **File ► Options**. The **Creo Parametric Options** dialog box opens.
4. Click **Customize Ribbon**.
5. In the **Customize the Ribbon** list, select a tab and create a new group in it or create a new tab and a group in it.
6. In the **Choose commands from** list, select **TOOLKIT Commands**. The commands created by the Creo TOOLKIT application are displayed.
7. Click **Add** to add the commands to the new tab or group.
8. Click **Import/Export ► Save the Auxiliary Application User Interface**. The changes are saved to the `toolkitribbonui.rbn` file. The `toolkitribbonui.rbn` file is saved in the text folder specified in the Creo TOOLKIT application registry file. For more information refer to the section on [Ribbon Definition File on page 315](#).

9. Click **Apply**. The custom settings are saved to the `toolkitribbonui.rbn` file.
10. Reload the Creo TOOLKIT application or restart Creo Parametric. The `toolkitribbonui.rbn` file will be loaded along with the Creo TOOLKIT application.

If translated messages are available for the newly added tabs or groups, then Creo Parametric displays the translated strings by searching for the same string from the list of string based messages that are loaded. For more information refer to the section on Localizing the Ribbon User Interface Created by the Creo Parametric TOOLKIT Applications [Localizing the Ribbon User Interface Created by the Creo Parametric TOOLKIT Applications](#) on page 318.

## About the Ribbon Definition File

A ribbon definition file is a file that is created through the **Customize Ribbon** interface in Creo Parametric. This file defines the containers, that is, Tabs, Groups, or Cascade menus that are created by a particular Creo TOOLKIT application. It contains information on whether to show an icon or label. It also contains the size of the icon to be used, that is, a large icon (32X32) or a small icon (16x16).

The ribbon user interface displays the commands referenced in the ribbon definition file only if the commands are loaded and are visible in that particular Creo Parametric mode. If translated messages are available for the newly added tabs or groups, then Creo Parametric displays the translated strings by searching for the same string from the list of string based messages that are loaded. For more information refer to the section on [Localizing the Ribbon User Interface Created by the Creo Parametric TOOLKIT Applications](#) on page 318.

You need a Creo Parametric development license to create, modify, or save the `toolkitribbonui.rbn` file. You cannot edit it manually. To save the ribbon user interface layout definition to the `toolkitribbonui.rbn` file:

1. Click **File ► Options**. The **Creo Parametric Options** dialog box opens.
2. Click **Customize Ribbon**.
3. In the **Customize the Ribbon** list, select a tab and create a new group in it or create a new tab and a group in it.
4. In the **Choose commands from** list, select **TOOLKIT Commands**. The commands created by the Creo TOOLKIT application are displayed.
5. Click **Add** to add the commands to the new tab or group.
6. Click **Import/Export ► Save the Auxiliary Application User Interface**. The modified layout is saved to the `toolkitribbonui.rbn` file located in the text folder within the Creo TOOLKIT application directory, that is, `<protk_app_dir>/text`
7. Click **OK**.

---

## To Specify the Path for the Ribbon Definition File

You can rename the `toolkitribbonui.rbn` to another filename with the `.rbn` extension. To enable the Creo TOOLKIT application to read the ribbon definition file having a name other than `toolkitribbonui.rbn`, it must be available at the location `<protk_app_dir>/text/ribbon`. The function introduced in this section enables you to load the ribbon definition file from within a Creo TOOLKIT application.

Function Introduced:

- **ProRibbonDefinitionfileLoad()**

The function `ProRibbonDefinitionfileLoad()` loads a specified ribbon definition file from a default path into the Creo Parametric application. The input argument is as follows:

- *file\_name* - Specify the name of the ribbon definition file including its extension. The default search path for this file is:
  - The working directory from where Creo Parametric is loaded.
  - `<application_text_dir>/ribbon`
  - `<application_text_dir>/language/ribbon`

---

 **Note**

- ◆ The location of the application text directory is specified in the Creo TOOLKIT registry file.
  - ◆ A Creo TOOLKIT application can load a ribbon definition file only once. After the application has loaded the ribbon, calls made to the function `ProRibbonDefinitionfileLoad()` to load other ribbon definition files are ignored.
- 

## Loading Multiple Applications Using the Ribbon Definition File

Creo Parametric supports loading of multiple `.rbn` files in the same session. You can develop multiple Creo TOOLKIT applications that share the same tabs or groups and each application will have its own ribbon definition file. As each application is loaded, its `.rbn` file will be read and applied. When an application is unloaded, the containers and command created by its `.rbn` file will be removed.

For example, consider two Creo TOOLKIT applications, namely, `pt_geardesign` and `pt_examples` that add commands to the same group on a tab on the Ribbon user interface. The application `pt_geardesign` adds a command **Pro/TOOLKIT Gear Design** to the **Advanced Modeling** group on the **Model**

tab and the application `pt_examples` adds a command **TKPart** to the **Advanced Modeling** group on the **Model** tab. The ribbon definition file for each application will contain an instruction to create the **Advanced Modeling** group and if both the ribbon files are loaded, the group will be created only once and the two ribbon customizations will be merged into the same group.

That is, if both the applications are running in the same Creo Parametric session, then the commands, **Pro/TOOLKIT Gear Design** and **TKPart** will be available under the **Advanced Modeling** group on the **Model** tab.

---

 **Note**

The order in which the commands will be displayed within the group will depend on the order of loading of the `.rbn` file for each application.

---

The following image displays commands added by two Creo TOOLKIT applications to the same group.

To save the customization when multiple applications are loaded:

1. Click **File ► Options**. The **Creo Parametric Options** dialog box opens.
2. Click **Customize Ribbon**.
3. In the **Customize the Ribbon** list, select a tab and create a new group in it or create a new tab and a group in it.
4. In the **Choose commands from** list, select **TOOLKIT Commands**. The commands created by the TOOLKIT application are displayed.
5. Click **Add** to add the commands to the new tab or group.
6. Click **Import/Export ► Save the Auxiliary Application User Interface**. The **Save UI Customization** dialog box opens.

7. Select a Creo TOOLKIT application and Click **Save**. The modified layout is saved to the `.rbn` file of the specified Creo TOOLKIT application. The **Save UI Customization** dialog box is shown in the following image:

## Localizing the Ribbon User Interface Created by Creo Toolkit Applications

The labels for the custom tabs, groups, and cascade menus belonging to the Creo TOOLKIT application can be translated in the languages supported by Creo Parametric. To display localized labels, specify the translated labels in the `ribbonui.txt` file and save this file at the location `<application_text_dir>/<language>`. For example, the text file for German locale must be saved at the location `<application_text_dir>/german/ribbonui.txt`.

Create a file containing translations for each of the languages in which the Creo TOOLKIT application is localized. The Localized translation files must use the UTF-8 encoding with BOM character for the translated text to be displayed correctly in the user interface. For more information on UTF-8 encoding, refer to [Unicode Encoding on page 2021](#).

The format of the `ribbonui.txt` file is as shown below. Specify the following lines for each label entry in the file:

1. A hash sign (#) followed by the label, as specified in the ribbon definition file.
2. The label as specified in the ribbon definition file and as displayed in the ribbon user interface.
3. The translated label.
4. Add an empty line at the end of each label entry in the file.

---

For example, if the Creo TOOLKIT application creates a tab with the name TK\_TAB having a group with the name TK\_GROUP, then the translated file will contain the following:

```
#TK_TAB
TK_TAB
<translation for TK_TAB>
<Empty_line>
#TK_GROUP
TK_GROUP
<translation for TK_GROUP>
<Empty_line>
```

## Tab Switching Events

If tab switching happens at run-time in Creo Parametric, use the notification functions to trigger a call back function to manage the changes due to the tab switching.

Functions Introduced:

- **ProNotificationSet()**
- **ProRibbonTabSwitchAction()**
- **ProNotificationUnset()**

Use the function `ProNotificationSet()` to assign a callback function to be called when the application switches from one tab to the other.

If the notification argument type is set to `PRO_RIBBON_TAB_SWITCH`, a registered call back function whose signature matches `ProRibbonTabSwitchAction()` is called. The “(Switch) from Tab” and “(Switch) to Tab” information is provided to the call back function, through the function arguments, whenever a Tab switch happens.

Use the function `ProNotificationUnset()` to cancel a notification.

For more information on using notifications see the section [Event-driven Programming: Notifications on page 1974](#).

## Support for Legacy Pro/TOOLKIT Applications

The user interface for Creo Parametric 1.0 has been restructured to a ribbon user interface. This may affect the behavior of existing Pro/TOOLKIT applications that were designed to add commands to specific Pro/ENGINEER menus or toolbars. These menus or toolbars or both have been redesigned in Creo Parametric 1.0. The commands added by the Pro/TOOLKIT applications appear on the Creo Parametric ribbon in the **Home** tab under the **TOOLKIT** group. When you open a model, the **TOOLKIT** group is on the **Tools** tab.

---

You can also arrange the commands added by the Pro/TOOLKIT applications under a new tab or an existing tab by customizing the ribbon using the **Customize Ribbon** tab in the Creo Parametric **Options** dialog box. For a list of all the commands added by the Pro/TOOLKIT applications, follow this procedure:

1. Click **File ► Options**. The Creo Parametric **Options** dialog box opens.
2. Click **Customize Ribbon**.
3. In the **Choose commands from** list, select **TOOLKIT Commands**. All the commands added by legacy Pro/TOOLKIT applications are listed.

#### Note

Commands that have not been designated will not have an icon or will have a generic icon.

---

Refer to the Creo Parametric Help for more information on customizing the Ribbon.

## Migration of Legacy Pro/TOOLKIT Applications

To migrate existing Pro/TOOLKIT applications to the Creo Parametric Ribbon user interface without compiling the source code:

1. Load the Pro/TOOLKIT applications in Creo Parametric so that the commands created in these applications are available in the **Customize Ribbon** user interface.
2. Modify the ribbon user interface layout and save the changes to the `toolkitribbonui.rbn`.
3. Copy the `toolkitribbonui.rbn` to the location `<application_text_dir>/ribbon`.
4. Reload Pro/TOOLKIT application or restart Creo Parametric. The `.rbn` file will be loaded along with the Pro/TOOLKIT application and the commands will be visible in the ribbon user interface if its accessibility will be visible.

## User Interface: Menus, Commands and Popupmenus

### Introduction

This section describes all the functions provided by Creo TOOLKIT to create and manipulate menus and buttons in the Creo Parametric ribbon user interface.

---

Refer to the section [User Interface: Ribbon Tabs, Groups, and Menu Items](#) on [page 313](#) for more information. Also, refer to the Creo Parametric Help for more information on customizing the ribbon user interface.

Using Creo TOOLKIT, you can supplement the Creo Parametric ribbon user interface.

Once the Creo TOOLKIT application is loaded, you can add a new group to an existing tab or create a new tab using the **Customize Ribbon** tab in the **Creo Parametric Options** dialog box in Creo Parametric. You will not be able to modify the groups that are defined by Creo Parametric. If the translated messages are available for the newly added tabs or groups, then Creo Parametric will use them by searching for the same string in the list of sting based messages loaded.

You can customize the ribbon user interface only for a particular mode in Creo Parametric. For example, if you customize the ribbon user interface and save it to the `toolkitribbonui.rbn` file in the Part mode, then on loading Creo Parametric the customized user interface will be visible only in the Part mode. To view a particular tab or group in all the modes, you must customize the ribbon user interface and save the `toolkitribbonui.rbn` file in each mode. Refer to the Creo Parametric Fundamentals Help for more information on customizing the ribbon.

When you are designing your Creo TOOLKIT application, you should carefully consider the context of the buttons that you add to the Creo Parametric User Interface (UI). Buttons specific to a particular mode (such as PART) should be located on the ribbon related to that mode. Buttons that initiate some action on a part, for example, should be located on the **PART** ribbon.

There are fundamental differences in the files and functions used to manipulate Ribbon and Menu-Manager menus. For this reason, this manual describes these subjects in separate sections.

## Menu Buttons and Menus

The tabs in the Creo Parametric ribbon user interface contain groups composed of both buttons and submenus. Using Creo TOOLKIT, you can create similar structures in the Creo Parametric ribbon user interface. The object definitions are as follows:

- Push button—A named item in a group or menu that is used to launch a set of instructions. An example is the **Plane** button in the **Datum** group.  
Check button—An item in a group or menu that may be toggled on and off. An example is the **Plane Display** toggle in the **Model Display** group in the **View** tab.
- Radio group—An item in a group or menu that may be set to one and only one of any number of options. An example is the group of windows listed in the

---

**Window** group at the **Windows** tab which allow you to switch between different windows.

- **Command**—A procedure in Creo Parametric that may be activated from a button.
- **Command ID**—An opaque pointer to a command, used as an input to other Creo TOOLKIT functions.
- **Action command**—A command which executes a set of instructions. Launched by push buttons.
- **Option command**—A command which executes a set of instructions based on the state of a UI component. Commands are launched by check buttons and radio groups.

## Using the Trail File to Determine UI Names

Several functions dealing with UI components require the input of strings that Creo Parametric uses to identify commands and menu buttons.

To find the name of an action command, click the corresponding icon on the ribbon user interface and then check the last entry in the trail file. For example, for the save icon, the trail file will have the corresponding entry:

```
~ Command `ProCmdModelSave`
```

The command name for the save button is `ProCmdModelSave`. This string can be used as input to `ProCmdCmdIdFind()` to get the command ID.

## Adding a PushButton

To add a button to the ribbon user interface, your Creo TOOLKIT application must do the following:

1. Define the action command to be initiated by the button. The action is defined in a function known as the “callback function.”
2. Designate the command using the function `ProCmdDesignate()`.
3. Add the button to the ribbon user interface using the **Customize Ribbon** tab in the **File ► Options** dialog box. This operation binds the added action to the button.

### Adding an Action to the Creo Parametric Ribbon

Function Introduced:

- **ProCmdActionAdd()**

The function `ProCmdActionAdd()` adds an action to Creo Parametric. This action can be later associated with a push button command in the Creo Parametric user interface. The syntax of this function is as follows:

```

ProError ProCmdActionAdd (
 char *action_name,
 uiCmdCmdActFn action_cb,
 uiCmdPriority priority,
 uiCmdAccessFn access_func,
 ProBoolean allow_in_non_active_window,
 ProBoolean allow_in_accessory_window,
 uiCmdCmdId *action_id);

```

This function takes the following arguments:

- *action\_name*—The name of the command as it will be used in Creo Parametric. This name must be unique, and it must occur only once in your applications or in Creo Parametric. To prevent conflicts, PTC recommends prepending or appending a unique identifier to your command names, similar to `ptc_openfile` or `openfile_ptc`.
- *action\_cb*—The action function (callback function) that will be called when the command is activated by pressing the button, cast to a `uiCmdCmdActFn`:

```

typedef int (*uiCmdCmdActFn) (
 uiCmdCmdId command,
 uiCmdValue *p_value,
 void *p_push_command_data
);

```

  - *command*—Identifier of the action or option.
  - *p\_value*—For options passed to `ValueGet` functions. Ignored for actions.
  - *p\_push\_command\_data*—Not implemented in this release.
- *priority*—The command priority. The priority of the action refers to the level of precedence the added action takes over other Creo Parametric actions.

The available action priorities are defined in the enumerated type `uiCmdPriority`. The possible values are as follows:

```

typedef int uiCmdPriority;
#define uiCmdPrioDefault ((uiCmdPriority) 0)
#define uiProeImmediate ((uiCmdPriority) 2)
#define uiProeAsynch ((uiCmdPriority) 3)
#define uiProe2ndImmediate ((uiCmdPriority) 5)
#define uiProe3rdImmediate ((uiCmdPriority) 6)
#define uiCmdNoPriority ((uiCmdPriority) 999)

```

The following table describes the enumerated values in detail.

| Value                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| uiCmdPrioDefault                                            | Normal priority actions<br><br>Normal priority actions dismiss all other actions except asynchronous actions. Note that buttons of this priority can lead to the dismissal of Menu Manager menus. Dismissing these menus can result in unexpected behavior from functions that depend on the mode and the context of the Creo Parametric session. One example of a function which can exhibit unintended behavior is <code>ProSelect()</code> when selecting objects from an active simplified representation. Menu buttons should have lesser priority if they depend on the context of the Creo Parametric session. |
| uiProeImmediate, uiProe2ndImmediate, and uiProe3rdImmediate | Levels of immediate priority. Actions of each level of priority dismiss actions with lower level priorities.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| uiProeAsynch                                                | Asynchronous priority. Actions with asynchronous priority are independent of all other actions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

- *access\_func*—The access function (callback function) that determines if the menu button should be available, unavailable, or hidden. Action accessibility refers to whether an added button is available for user selection. This function is called each time the button is displayed. The accessibility is evaluated based on the conditions pertaining at the time the button is pressed. The access function must be cast to a `uiCmdAccessFn`:

```
typedef uiCmdAccessState (*uiCmdAccessFn)
(uiCmdAccessMode access_mode);
```

The potential return values are listed in the enumerated type `uiCmdAccessState`:

- `ACCESS_REMOVE`—The button is not visible, and the containing menus might also be removed from the menu, if all of the menu buttons in the containing menu possess an access function returning `ACCESS_REMOVE`.
- `ACCESS_INVISIBLE`—The button is not visible.
- `ACCESS_UNAVAILABLE`—The button is visible, but unavailable and cannot be selected.
- `ACCESS_DISALLOW`—The button shows as available, but the command will not be executed when it is chosen.
- `ACCESS_AVAILABLE`—The button is available and can be selected by the user.

---

 **Note**

When you add a button, all the return values for the enumerated type `uiCmdAccessState` work as documented. However, when you add a button to the Creo Parametric ribbon user interface, and the access function returns the value `ACCESS_REMOVE` or `ACCESS_INVISIBLE`, these values are ignored. The values are treated as `ACCESS_UNAVAILABLE` instead. The button is visible, but is unavailable.

---

- *allow\_in\_non\_active\_window*—A `ProBoolean` determining whether or not to show this command in any non active window. A non-active window is a window that exists and contains a model, but that is not the active window in the Creo Parametric session. A window becomes active when the user chooses **View ► Activate**. This functionality is equivalent to changing the active window by selecting and activating a window using the pull-down menu of **Windows** command under the **View** tab in Creo Parametric.
- *allow\_in\_accessory\_window*—A `ProBoolean` determining whether or not to show this command in an accessory window. An accessory window is smaller than a main Creo Parametric window and allows only the **File>Exit** command from the menu.
- *action\_id*—The function will return a `uiCmdCmdId`, the command identifier. This identifier can be used in additional Creo Parametric function calls, such as, `ProCmdDesignate`.

---

 **Note**

- The function `ProCmdActionAdd()` is executed only once per Creo Parametric session for each action. Subsequent calls to this function for a previously loaded action are ignored (therefore you cannot redefine an action within a Creo Parametric session).
- 

## Adding a Button to the Ribbon

You can add a button to the ribbon user interface using the **Customize Ribbon** tab in the **Creo Parametric Options** dialog box. Refer to the section on [User Interface: Ribbon Tabs, Groups, and Menu Items on page 313](#) for more information. Also, refer to the Creo Parametric Help for more information on customizing the Ribbon User Interface.

---

## Adding a Check Button to the Ribbon User Interface

To add a check button to the ribbon user interface, your Creo TOOLKIT application must do the following:

1. Define the option command to be initiated by the button. The definition of this command includes the definition of three callback functions.
2. Designate the command using the function `ProCmdDesignate()`.
3. Add the check button to the ribbon user interface. This operation binds the added action to the button.

These procedures are described in the sections that follow.

### Adding an Option Command to Creo Parametric —Check Button

Functions Introduced:

- **ProCmdOptionAdd()**
- **ProCmdChkbuttonValueGet()**
- **ProCmdChkbuttonValueSet()**

The function `ProCmdOptionAdd()` adds a command to Creo Parametric.

The syntax of this function is as follows:

```
ProError ProCmdOptionAdd (
 char *option_name,
 uiCmdCmdActFn option_cb,
 ProBoolean boolean_operation,
 uiCmdCmdValFn set_value_cb,
 uiCmdAccessFn access_func,
 ProBoolean allow_in_non_active_window,
 ProBoolean allow_in_accessory_window,
 uiCmdCmdId *option_id);
```

This function requires the following arguments:

- *option\_name*—The name of the option command. This must be unique, in the same way as action command.
- *option\_cb*—The action command to be executed when the check button is toggled, cast to a `uiCmdCmdActFn`. This function should include a call to `ProCmdChkbuttonValueGet()`, to determine the value of the check button.
- *boolean\_operation*—Specifies whether or not the option has two values. Set this to `PRO_B_TRUE` for a check button.
- *set\_value\_cb*—The callback function that sets the value of the check button, cast to a `uiCmdCmdValFn`:

```
typedef int (*uiCmdCmdValFn) (
 uiCmdCmdId command,
```

---

```
 uiCmdValue *p_value
);
```

This function should include a call to `ProCmdChkbuttonValueSet()` to set the value of the check button when the UI is displayed or refreshed.

- *access\_func*—The callback function that determines if the command is accessible.
- *allow\_in\_non\_active\_window*—A `ProBoolean` determining whether or not to show this command in any non-active window. A non-active window is a window that exists and contains a model, but that is not the active window in the Creo Parametric session. A window becomes active when the user activates a new window or opens a model in a new window.
- *allow\_in\_accessory\_window*—A `ProBoolean` determining whether or not to show this command in an accessory window. An accessory window is smaller than a main Creo Parametric window and allows only the **File>Exit** command from the ribbon user interface.

The functions `ProCmdChkbuttonValueGet()` and `ProCmdChkbuttonValueSet()` provide access to the value of the check button. These functions require the option command value (provided by the callback functions as input), and the value is expressed as a `ProBoolean`.

### Adding a Check Button to the Ribbon

You can add a check button to the ribbon user interface using the **Customize Ribbon** tab in the **Creo Parametric Options** dialog box. Refer to the section on [User Interface: Ribbon Tabs, Groups, and Menu Items on page 313](#) for more information. Also, refer to the Creo Parametric Help for more information on customizing the Ribbon User Interface.

## Adding a Radio Button Group to the Ribbon

To add a radio button group to the ribbon user interface, your Creo TOOLKIT application must:

1. Define the option command to be initiated by the group of buttons. The definition of this command includes the definition of three callback functions.
2. Designate the command using the function `ProCmdDesignate()`
3. Add the radio button group to the ribbon user interface. This operation binds the added action to the button.

## Adding an Option Command to Creo Parametric —Radio Group

Functions Introduced:

- **ProCmdOptionAdd()**
- **ProCmdRadiogrpValueGet()**
- **ProCmdRadiogrpValueSet()**

The function `ProCmdOptionAdd()` is used to create the option command corresponding to the button group.

The arguments should be similar to the usage for creating the option command for a check button, with the following exceptions:

- *output\_callback\_function*—Must include a call to `ProCmdRadiogrpValueGet()` to determine the selected value in the radio group.
- *boolean\_operations*—Must be `PRO_B_FALSE` for radio groups.
- *set\_value\_cb*—Must include a call to `ProCmdRadiogrpValueSet()` to set the value of the group upon redisplay of the radio group UI.

The functions `ProCmdRadiogrpValueGet()` and `ProCmdRadiogrpValueSet()` provide access to getting or setting the selected item in the group. They require the option command value (provided by the callback functions) as an input. The selected value is returned as a `ProMenuItemName` string.

### Adding a Radio Button Group

You can add a button to the ribbon user interface using the **Customize Ribbon** tab in the **Creo Parametric Options** dialog box. Refer to the section on [User Interface: Ribbon Tabs, Groups, and Menu Items on page 313](#) for more information. Also, refer to the Creo Parametric Help for more information on customizing the Ribbon User Interface.

### Manipulating Existing Commands

Functions Introduced:

- **ProCmdCmdIdFind()**
- **ProCmdAccessFuncAdd()**
- **ProCmdAccessFuncRemove()**
- **ProCmdBracketFuncAdd()**

The function `ProCmdCmdIdFind()` allows you to find the command ID for an existing command so you can add an access function or bracket function to the command. You must know the name of the command in order to find its ID. See section [Using the Trail File to Determine UI Names on page 322](#) to determine UI names in order to determine the name of the command.

---

The functions `ProCmdAccessFuncAdd()` and `ProCmdAccessFuncRemove()` allow you to impose an access function on a particular command. (See function `ProCmdActionAdd()` for a description of access functions.) The Add function provides an `access_id`. This ID must be saved for later use when you deactivate the access function.

The function `ProCmdBracketFuncAdd()` allows the creation of a function that will be called immediately before and after execution of a given command. This function would be used to add company logic to the start or end (or both) of an existing Creo Parametric command. It could also be used to cancel an upcoming command. This function is declared as:

```
ProError ProCmdBracketFuncAdd (
 uiCmdCmdId cmd_id,
 uiCmdCmdBktFn bracket_func,
 char *bracket_func_name,
 void **pp_bracket_data);
```

The function takes the following arguments:

- *cmd\_id*—The command identifier.
- *bracket\_func*—The callback function to be called before and after the command, cast to a `uiCmdCmdBktFn`:

```
typedef int (*uiCmdCmdBktFn)
(uiCmdCmdId command,
 uiCmdValue *p_new_value,
 int entering_command,
 void **pp_bracket_data);
```

The entering command argument will be 1 before execution and 0 after. If the operation is before the upcoming command execution, and you want to cancel the upcoming command execution, return 0. Otherwise, return non-zero.

- *bracket\_func\_name*—The name of the bracket function.
- *pp\_bracket\_data*—A `void**` containing data to be passed to the bracket function.

---

#### **Note**

Model tree commands that use the model tree action functions cannot be used as bracket functions. Such commands exit before the redefinition starts. You can use the notification function `ProNotificationSet()` to get and set the notifications for the pre and post redefinition callbacks, respectively. You need to set the value of the enumerated data type `ProNotifyType` to `PRO_FEATURE_REDEFINE_PRE` or `PRO_FEATURE_REDEFINE_POST`.

---

---

## Designating the Command

Function Introduced:

- **ProCmdDesignate()**
- **ProCmdRadiogrpDesignate()**
- **ProCmdAlwaysAllowValueUpdate()**

The function `ProCmdDesignate()` allows you to designate a command or check button to be available in the **Customize Ribbon** tab in the **Creo Parametric Options** dialog of Creo Parametric.

After a Creo TOOLKIT application has used the function `ProCmdDesignate()` on a command, the user can add the button associated with this command into the Creo Parametric ribbon user interface.

If this function is not called, the button will not be visible in the **TOOLKIT Commands** list in the **Customize Ribbon** tab in the **Creo Parametric Options** dialog of Creo Parametric.

The syntax of the function `ProCmdDesignate()` is:

```
ProError ProCmdDesignate (uiCmdCmdId cmd_id,
 ProMenuItemLabel button_label,
 ProMenuLineHelp one_line_help,
 ProMenuDescription description,
 ProFileName msg_file);
```

The arguments to this function are:

- *cmd\_id*—The command identifier.
- *button\_label*—The message string that refers to the icon label. This label (stored in the message file) identifies the text seen when the button is displayed. If the command is not assigned an icon, the *button\_label* string appears on the button by default.
- *one\_line\_help*—The one-line Help for the icon. This label (stored in the message file) identifies the help line seen when the mouse moves over the icon.
- *description*—The message appears in the **Customize Ribbon** tab in the **Creo Parametric Options** dialog and also when "Description" is clicked in Creo Parametric.
- *msg\_file*—The message file name. All the labels including the one-line Help labels must be present in the message file.

---

 **Note**

This file must be in the directory <text\_path>/text or <text\_path>/text/<language>.

---

The function `ProCmdRadiogrpDesignate` designates the radio button to be available in the **TOOLKIT Commands** list in the **Customize Ribbon** tab in the **Creo Parametric Options** dialog box of Creo Parametric. The input arguments of this function are:

- *option\_id*—The option identifier.
- *number\_radio\_group\_items*—Specifies the number of options in the radio group
- *radio\_group\_items*—Specifies an array of items in the radio group.
- *radio\_group\_labels*—Specifies the labels for the radio buttons. This label (stored in the message file) identifies the text seen when the button is displayed. If the command is not assigned an icon, the label string appears on the menu by default.
- *one\_line\_helps*—The one-line Help for the icon. This label (stored in the message file) identifies the help line seen when the mouse moves over the icon.
- *radio\_group\_icons*—Specifies an array of icon file names, including the extension. A valid format for the icon file is a standard .GIF, .JPG, or .PNG. PTC recommends using .PNG format. All icons in the Creo Parametric ribbon are either 16x16 (small) or 32x32 (large) size. The naming convention for the icons is as follows:

- Small icon—<icon\_name\_16X16.ext>
- Large icon—<icon\_name\_32X32.ext>

The application searches for the icon files in the following locations:

- <creo\_loadpoint>\<datecode>\Common Files\text\resources
- <application\_text\_dir>\resource
- <application\_text\_dir>\<language\_dir>\resource

The location of the application text directory is specified in the Creo TOOLKIT registry file.

- *description*—The message appears in the **Customize Ribbon** tab in the **Creo Parametric Options** dialog and also when "Description" is clicked in Creo Parametric.
- *msg\_file*—The message file name. All the labels including the one-line Help labels must be present in the message file.

---

### **Note**

This file must be in the directory <text\_path>/text or <text\_path>/text/<language>.

---

The function `ProCmdAlwaysAllowValueUpdate()` allows the value of the command to be updated always, even when the command is not accessible. By default, `set_value_cb` is called only when the command is accessible. The input arguments follow:

- `cmd_id`—The command identifier.
- `allow`—Specify as `PRO_B_TRUE` for the value of the command to be updated always. Specify it as `PRO_B_FALSE`, only when the command is accessible.

## Adding the Command

Functions Introduced:

- **`ProCmdActionAdd()`**
- **`ProCmdOptionAdd()`**

The functions `ProCmdActionAdd()` and `ProCmdOptionAdd()` allow you to define or register a Creo Parametric command. See the section [Adding an Action to the Creo Parametric Ribbon on page 322](#) for more information on the function `ProCmdActionAdd()` and the section [Adding an Option Command to Creo Parametric —Check Button on page 326](#) for more information on the function `ProCmdOptionAdd()`.

## Providing the Icon

Function Introduced:

- **`ProCmdIconSet()`**

The function `ProCmdIconSet()` allows you to provide an icon to be used with the command you created. The function adds the icon to the Creo Parametric command. The function takes the command identifier as one of the inputs and the name of the icon file, including the extension as the other input. A valid format for the icon file is a standard .GIF, .JPG, or .PNG. PTC recommends using .PNG format. All icons in the Creo Parametric ribbon are either 16x16 (small) or 32x32 (large) size. The naming convention for the icons is as follows:

- Small icon—<iconname.ext>

- 
- Large icon—<iconname\_large.ext>

---

 **Note**

The legacy naming convention for icons <icon\_name\_icon\_size.ext> will not be supported in future releases of Creo Parametric. The icon size was added as a suffix to the name of the icon. For example, the legacy naming convention for small icons was iconname16X16.ext. It is recommended to use the standard naming conventions for icons, that is, iconname.ext or iconname\_large.ext.

---

The application searches for the icon files in the following locations:

- <creo\_loadpoint>\<datecode>\Common Files\text\resources
- <application\_text\_dir>\resource
- <application\_text\_dir>\<language\_dir>/resource

The location of the application text directory is specified in the Creo TOOLKIT registry file.

The Creo Parametric button is replaced with the icon image.

Commands that do not have an icon assigned to them display the button label.

You may also use this function to assign a small icon to a button.

## Designating Commands

Using Creo TOOLKIT you can designate Creo Parametric commands. These commands can later appear in the Creo Parametric ribbon user interface.

In Creo TOOLKIT you can set a button to refer to a command and subsequently drag this button on to the Creo Parametric ribbon user interface. When the button is clicked, the command is executed.

To add a command, your Creo TOOLKIT application must do the following:

1. Define or add the command to be initiated on clicking the icon.
2. Optionally designate an icon button to be used with the command defined by you.
3. Designate the command (icon) to appear in the **Customize Ribbon** tab in the **Creo Parametric Options** dialog box.

---

### **Note**

Refer to the section on [User Interface: Ribbon Tabs, Groups, and Menu Items on page 313](#) for more information. Also, refer to the Creo Parametric Help for more information on customizing the Ribbon User Interface.

---

4. Save the configuration in Creo Parametric so that changes to the ribbon user interface appear when a new session of Creo Parametric is started.

## Placing the Button

Once the button has been created using the functions discussed, place the button on the Creo Parametric ribbon user interface. Refer to the section on [User Interface: Ribbon Tabs, Groups, and Menu Items on page 313](#) for more information. Also, refer to the Creo Parametric Help for more information on customizing the Ribbon User Interface.

### Example 1: Designating a Command

The example code in the file `UgMain.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_main` illustrates how to designate a command to be available for placement as a button.

## Popup Menus

Creo Parametric provides shortcut menus that contain frequently used commands appropriate to the currently selected items. You can access a shortcut menu by clicking the right mouse button (RMB) after selecting an item. Shortcut menus are accessible in:

- Graphics window
- Model tree
- Some dialog boxes
- Any area where you can perform an object-action operation by selecting an item and then choosing a command to perform on the selected item.

Creo TOOLKIT provides different procedures to add custom buttons to popup menus, depending on the buttons' context. To add to the model tree popup menu, use the procedure described in [Adding a Button to the Model Tree Popup Menu on page 339](#). To add a popup menu to a custom dialog box, see the [User Interface: Dialogs on page 362](#) section (you cannot modify the popup menus in an existing UI dialog box). To add to a graphics window popup menu, refer to [Adding a Popup Menu to the Graphics Window on page 335](#).

---

## Adding a Popup Menu to the Graphics Window

Different popup menus can be activated during a given session of Creo Parametric. Every time the Creo Parametric context changes (by opening a different model type, by entering different tools, or by entering special modes like "Edit") a different popup menu is created. When Creo Parametric moves to the next context, the popup menu may be destroyed.

Because of this, Creo TOOLKIT applications must attach a button to the popup menu during initialization of the popup menu. The Creo TOOLKIT application is notified each time a particular popup menu is created, which then allows the user to add to the popup menu.

Use the following procedure to add items to graphics window popup menus:

1. Obtain the name of the existing popup menus to which you want to add a new menu using the trail file.
2. Register the Creo TOOLKIT notifications for creation and destruction of popup menus.
3. Create commands for the new popup menu items.
4. Implement access functions to provide visibility information for the items.
5. When the notification is called for the desired popup menu, add the custom buttons to the menu.
6. When the destroy notification is called, free the associated memory for the custom buttons.

The following sections describe each of these steps in detail. You can add push buttons, check buttons, and cascade menus to the popup menus. You can add popup menu items only in the active window. You cannot use this procedure to remove items from existing menus. To remove items using an access function see the section on [Manipulating Existing Commands on page 328](#).

## Using the Trail File to Determine Existing Popup Menu Names

The trail file in Creo Parametric contains a comment that identifies the name of the popup menu if the configuration option `auxapp_popup_menu_info` is set to `yes`.

For example, the popup menu, **Edit Properties**, has the following comment in the trail file:

```
~ Close `rmb_popup` `PopupMenu`
~ Command `ProCmdEditProperties`
```

---

## Registering Notifications to Create and Destroy Popup Menus

Popup menus are created at runtime in Creo Parametric and only when the required menus exist in the active window. Hence it is not possible to pre-register the custom buttons. Notification functions notify applications to add a new popup menu. For more information on using notifications see the section [Event-driven Programming: Notifications on page 1974](#).

Functions Introduced:

- **ProNotificationSet()**
- **ProPopupmenuCreatePostAction()**
- **ProPopupmenuDestroyPreAction()**

If the notification value argument type is set to `PRO_POPMENU_CREATE_POST`, a registered callback function whose signature matches `ProPopupmenuCreatePostAction()` is called. This function is called after the popup menu is created internally in Creo Parametric and must be used to assign application-specific buttons to the popup menu.

If the notification value argument type is set as `PRO_POPUPMENU_DESTROY_PRE`, a registered callback notification function `ProPopupmenuDestroyPreAction()` is called before the popup menu is destroyed. Use this function to free memory allocated by the application for the custom buttons in the popup menu.

## Accessing the Popup Menus

The functions described in this section provide the name and ID of the popup menus that are used to access these menus while using other functions.

Functions Introduced:

- **ProPopupmenuIdGet()**
- **ProPopupmenuNameGet()**

The function `ProPopupmenuIdGet()` returns the popup menu ID for a given popup menu name. The popup menu ID is required for the functions that add buttons to the popup menu. IDs are dependent on the context of Creo Parametric and are not maintained between sessions.

The function `ProPopupmenuNameGet()` returns the name of the popup menu assigned to a given ID.

## Creating Commands for the New Popup Menu Buttons

Functions Introduced:

- **ProCmdActionAdd()**

- **ProCmdOptionAdd()**
- **ProCmdCmdIdFind()**

The functions `ProCmdActionAdd()` or `ProCmdOptionAdd()` are used to create commands for the popup menus. Only push buttons (action commands) and check buttons (option commands) are supported in popup menus. Commands with a given name are created only once in a session of Creo Parametric. Hence PTC recommends that you create the required commands in the `user_initialize()` function of the application.

Use `ProCmdCmdIdFind()` to obtain the command ID for the command (in the notification callback for `PRO_POPUPMENU_CREATE_POST`) to add the button to the popup menu.

## Checking the Access State of a Popup Menu Item

Functions Introduced:

- **ProPopupmenuAccessFunction()**

A popup menu uses an additional access function to determine whether the popupmenu must be visible based on the currently selected items. Use the function whose signature matches `ProPopupmenuAccessFunction()` to set the access state of the button in the popup menu.

The syntax for this function is as follows:

```
typedef uiCmdAccessState (*ProPopupmenuAccessFunction)
(uiCmdCmdId command,
 ProAppData appdata,
 ProSelection* sel_buffer);
```

The last argument contains an array of selected items that are used to determine the visibility of the popup menu button. It is PTC standard practice to remove popup menu buttons using `ACCESS_REMOVE` instead of graying them out using `ACCESS_UNAVAILABLE` when unusable item types have been selected. This is to minimize the size of the popup menu.

## Adding Creo Parametric Popup Menus

Functions Introduced:

- **ProPopupmenuButtonAdd()**
- **ProPopupmenuCascadebuttonAdd()**

Use `ProPopupmenuButtonAdd()` to add a new item to a popup menu. The input arguments are:

- *menu\_ID*—Specifies the ID of the popup menu obtained from `ProPopupmenuIdGet()`.

- 
- *position*—Specifies the position in the popup menu at which to add the menu button. Pass `PRO_VALUE_UNUSED` to add to the bottom of the menu.
  - *button\_name*—Specifies the name of the added button. The button name is placed in the trail file when the user selects the menu button. For more information on valid characters that you can use to specify the name, refer to the topic [Naming Convention for UI Components on page 365](#).
  - *button\_label*—Specifies the message that refers to the button label. This label identifies the text seen when the button is displayed. To localize this text, obtain and pass a string from `ProMessageToBuffer()`.

---

 **Note**

The labels and the text added using the `ProCmdDesignate()` function duplicate existing messages that are previously added in the Creo database. To display the correct label and text message, you can use a prefix or a suffix with the message names that will identify your Creo TOOLKIT application. You should avoid using generic names of Creo TOOLKIT buttons such as Point, Arc, Circle, Ellipse in the labels and text.

---

- *button\_helptext*—Specifies the help message associated with the button. This label acts as a keyword that identifies the help text in the message file. To localize this text, obtain and pass a string from `ProMessageToBuffer()`.
- *cmd\_ID*—Specifies the command identifier for the action or option.
- *access\_status*—Specifies the callback function used to determine the visibility status of the added button.
- *appdata*—Specifies the user application data.

Use the function `ProPopupmenuCascadebuttonAdd()` to add a new cascade menu to an existing popup menu.

The input arguments are:

- *menu\_ID*—Specifies the ID of the popup menu obtained from `ProPopupmenuIdGet()`.
- *position*—Specifies the position in the menu at which to add the cascade button. Pass `PRO_VALUE_UNUSED` to add to the bottom of the menu.
- *cascade\_menu\_name*—Specifies the name of the cascade menu. The name is placed in the trail file when the user selects the menu button. For more information on valid characters that you can use to specify the name, refer to the topic [Naming Convention for UI Components on page 365](#).

- *cascade\_menu\_label*—Specifies the message that refers to the cascade menu label. This label identifies the text seen when the menu is displayed. To localize this text, obtain and pass a string from `ProMessageToBuffer()`.
- *cascade\_menu\_helptext*—Specifies the help message associated with the cascade menu. This label acts as a keyword that identifies the help text in the message file. To localize this text, obtain and pass a string from `ProMessageToBuffer()`.
- *access\_status*—Specifies the callback function used to determine the visibility status of the added item.
- *appdata*—Specifies the user application data.

The output argument is *casc\_menuId*, the menu ID of the cascade menu.

## Adding a Button to the Model Tree Popup Menu

To add a button to the ribbon user interface, refer to the section [Menu Bar Buttons and Menus on page 321](#). Ensure that the following conditions are met:

- The menu name used should be “ActionMenu.”
- The command access function should be configured to read the selection buffer using `ProSelbufferSelectionsGet()`. If the buffer is inactive or empty, the access function should make the menu item invisible.

## Example 2: Assigning the Creo Parametric command to popup menus

The example in the file `UgPopupmenus.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_main` demonstrates how to assign a Creo Parametric command to the popup menus in the graphics window and the model tree. It adds the example `UserAsmcompConstraintsHighlight()` to the popup menu (see the section on [Assembly: Basic Assembly Access on page 1115](#) for details). The popup menus use an access function to check the currently selected item in the selection buffer that is an assembly component. If it is not an assembly component, the button will be removed from the menu. The example adds the popup menu button using `ProPopupmenuButtonAdd()` if the menu name is the name of the current main popup menu in assembly mode.

---

## Menu Manager Buttons and Menus

Very few modes in Creo Parametric display a menu manager. For example, the **ASM PROCESS** menu is displayed only when Creo Parametric is in the Process Plan Assembly mode, which occurs when a Process-Plan Assembly has been created or retrieved. Modifying and supplementing the menu manager interface is fundamentally different from similar operations on the ribbon.

This section describes the files and functions necessary to manipulate the menu manager buttons and menus of Creo Parametric. This section covers the following topics:

- [Menu Files on page 340](#)
- [Adding a Menu Button on page 342](#)
- [New Menus on page 344](#)
- [Preempting Creo Parametric Commands on page 349](#)
- [Submenus on page 350](#)
- [Manipulating Menus on page 350](#)
- [Data Menus on page 351](#)
- [Setting Menu Buttons on page 352](#)
- [Controlling Accessibility of Menu Buttons on page 352](#)
- [Pushing and Popping Menus on page 353](#)
- [Run-time Menus on page 353](#)

### Menu Files

Menu files enable you to specify your own text for the name of a menu button and the one-line help text that appears when you place the cursor over that button, along with translations for both of these.

Creo Parametric looks for the Creo TOOLKIT menu files in the following locations:

- The current Creo Parametric startup directory
- The subdirectory `text/menus` under the directory named by the `text_dir` statement in the registry file

PTC recommends that during development you place your menu files in `text/menus` under your working directory and specify the following registry file entry:

```
text_dir .
```

### Names and Contents of Menu Files

There are two conventional extensions used in naming menu files:

- `.mnu`—Files that describe complete menus

- 
- `.aux`—Files that describe new buttons to be added to existing Creo Parametric menus

The following restrictions apply to file names:

- The name must be unique through out Creo Parametric.
- The name must have no more than 30 characters, including the extension.

To find out what menu file names are used by Creo Parametric, look in the Creo Parametric menu directory at `<creo_loadpoint>\<datecode>\Common Files\text\<language_dir>\menus`.

When you create an `.aux` file to extend an existing Creo Parametric menu, use the same file name root as Creo Parametric used for that menu.

### Syntax and Semantics of Menu Files

The two types of files—`.mnu` and `.aux`—have identical formats.

The format consists of groups of three lines (one group for each menu button) and a group at the top for the menu title. The title group contains the menu title on the first line, and then two blank lines.

The menu title is the name that appears at the top of the menu when you run Creo Parametric in English. The menu title is also used to refer to the menu from your Creo TOOLKIT code, so it is essential that this name is unique in all Creo Parametric menus. For example, if you are writing an `.aux` file to add buttons to a Creo Parametric menu, make sure you use the title that appears in the corresponding `.mnu` file in Creo Parametric. If you are creating a new menu, make sure that the title you use has not already been used in Creo Parametric.

If the menu title is followed by a second word, Creo Parametric displays the second word instead of the first one. This is how a translation is provided. If there is no second word, Creo Parametric displays the first word.

Each menu button group consists of the following three lines:

- Button name—If the button name as it appears on the Creo Parametric screen contains spaces, each space must be replaced by the character `#` in the menu file. If the button name is followed by another name, separated by white space, the second name will be what is actually displayed.

The first name is still used to refer to the button from your Creo TOOLKIT code. The second provides an optional translation of that button name.

- One-line Help—This is a single line of text that explains what the menu button does. When you place the mouse pointer on the menu button, Creo Parametric displays the one-line Help text in the Message Window.
- Alternate Help—If this line is not blank (or does not start with the comment character `"#"`), it will be used in place of the one-line Help. This provides a translation of the Help message.

---

### Example 3: Sample Menu File

The following example code shows the menu file you would create to add a new button, **Check Part**, to the Creo Parametric **PART** menu.

```
Menu file "part.aux":
[Start of file on next line]
PART
<blank line>
<blank line>
Check#Part
Check the validity of the current part.
<blank line>
[End of file on previous line]
```

### Example 4: Adding Alternate Names and Help Text to a Button

This example code creates an alternate button name and Help text for the previous example.

```
Menu file "part.aux":
[Start of file on next line]
PART
<blank line>
<blank line>
Check#Part DRC#Check
Check the validity of the current part.
Perform a DRC (Design Rule Check) on the part.
[End of file on previous line]
```

## Adding a Menu Button

Functions Introduced:

- **ProMenuFileRegister()**
- **ProMenuAuxfileRegister()**
- **ProMenubuttonActionSet()**
- **ProMenubuttonGenactionSet()**

When you add a new button to an existing menu in `user_initialize()`, you are modifying the Creo Parametric definition of the menu in its memory before that menu has been used by Creo Parametric, and therefore before Creo Parametric has loaded it from its menu file. You must call the function `ProMenuFileRegister()` to tell Creo Parametric to load its own menu file before you can add your own buttons.

To add a button to a menu, first write a menu file, and then add the following calls to `user_initialize()`:

1. Load the Creo Parametric menu into memory, using `ProMenuFileRegister()`.

- 
2. Add the buttons in your menu file to the menu, using `ProMenuAuxfileRegister()`.
  3. Define the actions of the new buttons, using `ProMenubuttonActionSet()`.

## Calling ProMenuFileRegister()

The input arguments to `ProMenuFileRegister()` are as follows:

- `ProMenuName` *menuname*—The unique title of the menu that appears as the first word on the first line of the menu file and on the heading of the menu on the screen when you run Creo Parametric in English. This argument is case-insensitive.
- `ProMenufileName` *filename*—The name of the menu file, including the extension but not the directory.

The function outputs the integer identifier of the menu, which you do not normally need. If the function fails for some reason (for example, the menu file did not exist), it returns `PRO_TK_GENERAL_ERROR`. If you call this function a second time on the same menu file, it has no effect.

## Calling ProMenuAuxfileRegister()

This function has the same arguments and return value as `ProMenuFileRegister()`. Instead of loading a new menu into memory, the function adds the buttons in the file to a menu already in memory.

## Calling ProMenubuttonActionSet()

The first three arguments to `ProMenubuttonActionSet()` are as follows:

- `ProMenuName` *menuname*—The title of the menu that contains the button.
- `ProMenubuttonName` *button*—The first name for the button in the menu file (not the second, which provides the translation), but with spaces instead of pound signs (#). This argument is case-insensitive.
- `ProMenubuttonAction` *action*—A pointer to the Creo TOOLKIT callback function to be called when the user selects this menu button. To pass a pointer to a function, supply the name of the function without the following parentheses. If your function does not precede the call to `ProMenubuttonActionSet()` in the same file, you must add a declaration of it to show the compiler that this is a function.

The other two arguments, *app\_data* and *app\_int*, are optional arguments to your command function. These arguments enable your command function to be more flexible in what it does. If you do not want to use *app\_data* and *app\_int*, supply the values `NULL` and `0`, respectively.

---

Sample declarations and the use of the optional arguments is shown in Example 5: Adding a Button to the Creo Parametric Ribbon, and [Example 6: Defining a New Menu that Closes Itself on page 345](#), [Example 7: Defining a New Menu the User Must Close on page 346](#).

### Example 5: Adding a Button to the Creo Parametric Ribbon

The example code in the file `UgMenuMenuButtonAdd.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_menu` adds the button **Check Part** to the Creo Parametric **PART** tab. The example uses the menu file from the previous examples.

## New Menus

Functions Introduced:

- **ProMenuProcess()**
- **ProMenuDelete()**
- **ProMenuCreate()**
- **ProMenuHold()**
- **ProMenuDeleteWithStatus()**

Creo TOOLKIT enables you to create new menus. Defining a new menu differs from adding buttons to an existing menu in the following ways:

- The menu file you supply should end in `.mnu`, not `.aux`. (It has the same syntax, though.)
- You do not need to call `ProMenuAuxfileRegister()` because the whole menu is defined in a single menu file.
- You need to define an exit action for the menu, in addition to an action for each button on the menu.
- You can either specify the new menu in `user_initialize()` or you can set up the new menu locally before you use it.

## Exit Actions

You must not only tell the menu manager inside Creo Parametric which function to call for each button on your menu, but also which function to call if the user selects a button on another menu. This function is called an exit action because it is often used to close the menu.

---

## Note

If you do not define an exit action, Creo Parametric's behavior is undefined if the user selects from another menu.

---

There are two types of exit action:

- Nothing—The menu selection is ignored. This is useful if you want the user to take some definite action before leaving the current menu.
- Close the current menu—The menus unwind to the level of the menu selected and the selected command is entered. This is the usual way to leave a menu.

## Defining a New Menu

To define a new menu, first write a menu file. Before you need to use the menu, add the following calls to your Creo TOOLKIT program:

1. Load the Creo Parametric menu into memory, using `ProMenuFileRegister()`.
2. Define the actions of the new buttons, using the function `ProMenubuttonActionSet()`.
3. Define the exit action of the new menu, using the functions `ProMenubuttonActionSet()` and one of the exit action functions described in the following section.

## Example 6: Defining a New Menu that Closes Itself

This example code defines a new menu, MYMENU, that closes itself using the function `ProMenuDelete()`.

```
[Start of file on next line]
MYMENU
<blank line>
<blank line>
Partial#Check
Perform a partial check on the part.
<blank line>
Full#Check
Perform a full check on the part.
<blank line>
[End of file on previous line]
```

The following code sets up the menu:

```
int menuId;
ProMenuFileRegister ("mymenu", "mymenu.mnu", &menuId);
```

---

```

 ProMenubuttonActionSet ("mymenu", "Partial Check",
ProCheckPart,
 NULL, 0);
 ProMenubuttonActionSet ("mymenu", "Full Check", ProCheckPart,
NULL,
 1);
 ProMenubuttonActionSet ("mymenu", "Quit Checks",
 (ProMenubuttonAction)ProMenuDelete, NULL, 0);
 ProMenubuttonActionSet ("mymenu", "mymenu",
 (ProMenubuttonAction)ProMenuDelete, NULL, 0);

```

## Example 7: Defining a New Menu the User Must Close

In the following example code, the user has to close MYMENU.

```

int menuId;
ProMenuFileRegister ("mymenu", "mymenu.mnu", &menuId);
ProMenubuttonActionSet ("mymenu", "Partial Check",
ProCheckPart,
 NULL, 0);
ProMenubuttonActionSet ("mymenu", "Full Check", ProCheckPart,
 NULL, 1);
ProMenubuttonActionSet ("mymenu", "Quit Checks",
 (ProMenubuttonAction)ProMenuDelete, NULL, 0);
ProMenubuttonActionSet ("mymenu", "mymenu",
 (ProMenubuttonAction)ProMenuHold, NULL, 0);

```

## Defining an Exit Action

To define an exit action, make an extra call to `ProMenubuttonActionSet()`, but instead of the button name (the third argument), specify the menu name.

If you want the menus to unwind and the new command to be entered, use `ProMenuDelete()` as the action function.

If you want the selection to be ignored, use the function `ProMenuHold()` as the exit action. If you use this function, you must provide some other exit route for the menu. For example, you can specify an explicit menu button (such as **Done**) whose command function calls `ProMenuDelete()`.

If you want to perform some additional action in these cases (such as sending a warning to the user), you can provide your own exit function that performs the action and then calls `ProMenuHold()`.

## Using a New Menu

After you have defined your new menu, you need to know how to use it. This is normally done inside the command function of another menu button.

To Use a New Menu

- 
1. Display the menu, using `ProMenuCreate()`.
  2. Make the menu active so the user can select from it, using `ProMenuProcess()`.

### Calling ProMenuCreate()

The first argument to `ProMenuCreate()` is either `PROMENUTYPE_MAIN` or `PROMENUTYPE_SUB`. The usual choice is `PROMENUTYPE_MAIN` (see the section [Submenus on page 350](#) for detailed information about submenus). The second argument is the title of the menu. The last argument is the identifier of the displayed menu.

### Calling ProMenuProcess()

The function `ProMenuProcess()` takes a single input argument—the title of the menu. If the menu is the last one displayed, you can pass an empty string. The return value is meaningful only if you use the function `ProMenuDeleteWithStatus()` as the exit action for the menu.

The function `ProMenuProcess()` returns only when the menu is closed, as the result of a call to either `ProMenuDelete()` or `ProMenuDeleteWithStatus()`. The following is true for any code following the call to `ProMenuProcess()`:

1. The code does not get executed until the menu is closed.
2. The code gets executed before any command that causes an exit from the menu. When the user closes a menu by selecting another command, that command is put into the input buffer and is not executed until control passes from your application back to Creo Parametric.

## Example 8: Using a New Menu

The following example code shows how to use the functions `ProMenuProcess()` and `ProMenuCreate()`. The example builds on the previous examples.

```
int action, menuId;
.
.
.
ProMenuCreate (PROMENUTYPE_MAIN, "mymenu", &menuId);
ProMenuProcess ("", &action);
.
.
```

## Creating a Menu for Selecting a Single Value

Function Introduced:

- **ProMenuDeleteWithStatus()**
- **ProMenubuttonActionSet()**
- **ProMenuProcess()**

## Use of ProMenubuttonActionSet() Final Arguments

The two last arguments of `ProMenubuttonActionSet()` are *app\_data*, of type `ProAppData` and *app\_int*, of type integer. These arguments are passed directly to your callback function when it is invoked. Because Creo TOOLKIT and Creo Parametric do not look at these arguments, you can use them for any information that you want to pass to or from your function.

[Example 9: Creating a Menu that Selects a Value on page 348](#) uses the final argument of `ProMenubuttonActionSet()` to distinguish between several menu buttons that share the same command function. Inside the command function, this value appears as the second argument. It is used to determine which button was selected and then perform the appropriate action. The command function does not use the fourth argument of `ProMenubuttonActionSet()`, but includes a dummy first argument of type `ProAppData` to match it, so that the second argument is received correctly.

## Returning a Value from ProMenuProcess()

The function `ProMenuDelete()` closes the current menu and causes control to return from the call to `ProMenuProcess()` that made that menu active. If you want to close the menu under more than one condition and react to that condition in the code that follows the return from `ProMenuProcess()`, use `ProMenuDeleteWithStatus()` instead of `ProMenuDelete()`. The `ProMenuDeleteWithStatus()` function takes a single integer argument, which is the value returned by `ProMenuProcess()`.

## Example 9: Creating a Menu that Selects a Value

The example code in the file `UgMenuValueSelect.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_menu` shows several new techniques for using the menu functions. This example shows how to use `ProMenuDeleteWithStatus()` and uses more of the arguments to `ProMenubuttonActionSet()`.

## Compound Menus

Function Introduced:

- **ProCompoundmenuCreate()**

The `ProCompoundmenuCreate()` function enables you to take an array of previously loaded menu names and append them together into one menu.

---

To Create a Compound Menu:

1. Specify which submenus to include in the compound menu, as follows:  

```
static char **compound_menu = {"MENU_1", "MENU_2", "MENU_3", ""};
```
2. Load the actions on the buttons.
3. Set the button visibility and accessibility.
4. Generate the compound menu, as follows:  

```
ProCompoundmenuCreate (compound_menu, n_submenus);
```
5. Get user input, as follows:  

```
ProMenuProcess (compound_menu[0], action);
```

## Preempting Creo Parametric Commands

Functions Introduced:

- **ProMenubuttonPreactionSet()**
- **ProMenubuttonPostactionSet()**

In addition to adding your own menus and menu buttons, it is sometimes useful to be able to modify the effect of an existing Creo Parametric menu button. The function `ProMenubuttonPreactionSet()` enables you to call your function before the Creo Parametric command is executed. If the operation is before the upcoming command execution, and you want to cancel the upcoming command execution, return 1. Otherwise, return zero.

You could also cancel the Creo Parametric command, so only your function gets called. Similarly, the function `ProMenubuttonPostactionSet()` enables you to call your function after the Creo Parametric command is executed.

You can use the `ProMenubuttonPreactionSet()` function to protect certain commands, so that the user can use them only under certain circumstances specified by your Creo TOOLKIT application. For example, you may want to prevent the user from saving a model unless it has passed a certain validity check.

## Calling ProMenubutton\*actionSet()

The functions `ProMenubuttonPreactionSet()` and `ProMenubuttonPostactionSet()` have the same arguments as `ProMenubuttonActionSet()`. The function `ProMenubuttonPreactionSet()` inserts your function before an existing Creo Parametric command instead of assigning it to a new button. The function `ProMenubuttonPostactionSet()` inserts your function after an existing Creo Parametric command.

Because you are changing the definition of the menu in Creo Parametric, you must make sure the menu is loaded into memory first, by calling `ProMenuFileRegister()`.

---

If the command function you load returns the value 0, the Creo Parametric command for that menu button will be executed immediately. If your function returns any other value, the Creo Parametric command will not be performed.

## Example 10: Asking for Confirmation on Quit Window

The example code in the file `UgMenuConfirmGet.c` located at `<creo_toolkit_loadpoint>protk_appls/pt_userguide/ptu_menu` shows how to use `ProMenubuttonPreactionSet()` to ask the user to confirm a selection. The example uses `ProMenubuttonPreactionSet()` to protect **Quit Window**

## Submenus

Function Introduced:

- **ProMenuCreate()**

All the menus described so far have been main menus. The other type of menu is called a submenu. A submenu differs from a main menu in the following ways:

- A submenu is active at the same time as the menu above it. Selecting from the menu above does not close the submenu.
- A submenu does not display its title.

In effect, a submenu acts as an extension to the menu above it. This enables you to display two active menus at the same time, such as if you want the user to choose two options from two exclusive groups of values.

## Making a Menu a Submenu

To make a Main Menu a Submenu:

1. Display the menu above the submenu, using `ProMenuCreate()`.
2. Display the submenu, using `ProMenuCreate()`, but make the first argument `PROMENUTYPE_SUB` instead of `PROMENUTYPE_MAIN`.
3. Call `ProMenuProcess()` for the submenu only. Because it is a submenu, the menu above it will become active at the same time.
4. Close both menus, using either `ProMenuDelete()` or `ProMenuDeleteWithStatus()`.

## Manipulating Menus

Function Introduced:

- **ProMenubuttonLocationSet()**

---

The function `ProMenubuttonLocationSet()` provides the ability to move a Creo Parametric menu button to a different location on its menu, or to add new menu buttons to a Creo Parametric menu somewhere other than at the bottom of the menu.

Before you call `ProMenubuttonLocationSet()`, you must make sure the menu you are modifying has been fully loaded into memory. Make sure `ProMenuFileRegister()` has been called, and, where appropriate, `ProMenuAuxfileRegister()`.

The first two arguments of the `ProMenubuttonLocationSet()` function identify the menu and the button, as in `ProMenubuttonActionSet()`.

The final argument is a switch that specifies where to move the button. The possible values are as follows:

- 0—The button becomes the first in the menu.
- 1—The button is inserted after the current first button.
- 2—The button is inserted after the current second button.
- -1—The button becomes the last button on the menu.

## Data Menus

Functions Introduced:

- **ProMenuModeSet()**
- **ProMenuDatamodeSet()**

Menus can operate in two modes:

- `PROMENUMODE_OPERATIONAL`—The default mode. This mode is used in all the previous examples. On an operational menu, only one button is ever set (that is, displayed with a red background) while that command is in progress.
- `PROMENUMODE_DATA`—Each button remains set until you select it again. This is useful when the buttons do not represent commands, but, for example, a set of independently selectable options.

The function `ProMenuModeSet()` sets the menu mode. For a `PROMENUMODE_DATA` menu, you can choose to indicate the set buttons with a check mark instead of the usual red background by using the function `ProMenuDatamodeSet()`.

## Calling ProMenuModeSet() and ProMenuDatamodeSet()

The function `ProMenuModeSet()` has two arguments:

- The menu title

- The menu mode (either `PROMENU_MODE_OPERATIONAL` or `PROMENUMODE_DATA`)

The function `ProMenuDatamodeSet()` has two arguments:

- The menu title.
- The set indicator, which indicates which buttons are set. This argument can have either of the following values:
  - `TRUE`—Use a check mark.
  - `FALSE`—Use a red background. This is the default value.

Both of these functions must be called after the menu has been loaded into memory (using `ProMenuFileRegister()`), and before the menu has been displayed (using `ProMenuCreate()`).

If you want to create a menu whose buttons are dependent on run-time data, use the function `ProMenuStringsSelect()`, described later in this section.

## Setting Menu Buttons

Functions Introduced:

- **`ProMenubuttonHighlight()`**
- **`ProMenubuttonUnhighlight()`**

Sometimes it is useful to be able to set and unset menu buttons from the Creo TOOLKIT application. For example, if you are using data menus, you can set the appropriate buttons when the menu is displayed to show the current options.

### Calling `ProMenubuttonHighlight()` and `ProMenubuttonUnhighlight()`

Both `ProMenubuttonHighlight()` and `ProMenubuttonUnhighlight()` take two arguments—the menu title and button name. Both functions must be called after the menu has been displayed (using `ProMenuCreate()`), but before making the menu interactive (using `ProMenuProcess()`). Contrast these rules to the rules for using `ProMenuModeSet()` and `ProMenuDatamodeSet()`.

## Controlling Accessibility of Menu Buttons

Functions Introduced:

- **`ProMenubuttonActivate()`**
- **`ProMenubuttonDeactivate()`**

A menu button that is inaccessible is one that, though currently displayed on a menu, is gray and has no effect when it is selected. Creo Parametric uses this facility for options that are temporarily unavailable for some reason. For example, you cannot create a hole until you have created the first protrusion.

---

You can control the accessibility of your own menu buttons from Creo TOOLKIT using `ProMenubuttonActivate()` and `ProMenubuttonDeactivate()`. Each function takes two arguments: the menu title and button name. These functions must be called when the menu is displayed (after calling `ProMenuCreate()`).

## Pushing and Popping Menus

Functions Introduced:

- **ProMenuVisibilityGet()**
- **ProMenuPush()**
- **ProMenuPop()**

Sometimes Creo Parametric temporarily hides certain menus, even though they are still in context, to make room for lower-level menus. An example of this is when you select **Make Datum** during feature creation. This process is called pushing menus, because they are put on a stack from which they can be popped to make them reappear.

The function `ProMenuVisibilityGet()` tells you whether the specified menu is currently displayed. It takes one input argument—the menu title.

The function `ProMenuPush()` pushes the current lowest menu. It takes no arguments.

The function `ProMenuPop()` pops the menu from the top of the stack. It takes no arguments.

## Run-time Menus

Functions Introduced:

- **ProMenuStringsSelect()**
- **ProMenuFromStringsRegister()**

The `ProMenuStringsSelect()` function enables you to set up a menu at run time. You do not need to supply a menu file because the buttons are defined when you display the menu. You cannot attach command functions to the button; a run-time menu simply returns a list of the buttons selected.

A run-time menu is displayed together with a submenu that contains the following buttons:

- **Done Select**
- **Quit Select**
- **List**

The default option, **List**, causes the string menu itself to be displayed.

---

You can set the maximum number of items you want to be selectable. The function returns when the user has selected the maximum number of items you specified, or has selected **Done** or **Quit**. Creo Parametric uses this type of menu to select a disk file to be retrieved after the user selects **Search/Retr**.

The maximum size of the string you assign to a button is `PRO_NAME_SIZE - 1`. `PRO_NAME_SIZE` is defined in file `ProSizeConst.h`.

The function `ProMenuFromStringsRegister()` creates menus at run time and attaches actions to the menu buttons. The function takes as arguments all the information required to create auxiliary (\*.aux) and user-defined (\*.mnu) menu files. The first argument is the default menu name. The next argument enables you to specify an alternate name for the menu if, for instance, your application supports a foreign language. The list of button labels is passed to the function as an array of wide character strings. As with the menu name, you can provide alternate button labels for foreign language support. You can also provide one-line Help for each button.

After you have registered the menu with a call to the function `ProMenuFromStringsRegister()`, you can attach actions to the buttons by calling the function `ProMenuButtonActionSet()` for each button. You must also define an exit action for your run-time menu. To do this, call `ProMenuButtonActionSet()` and supply the name of the menu instead of a button name. Finally, create the menu by calling `ProMenuProcess()`, and then `ProMenuCreate()`.

## Customizing the Creo Parametric Navigation Area

The Creo Parametric navigation area includes the **Model Tree** and **Layer Tree** pane, **Folder Browser** pane, and **Favorites** pane. The functions described in this topic enable Creo TOOLKIT applications to add custom panes to the Creo Parametric navigation area. The custom panes can contain custom dialog box components or WEB pages.

### Adding Custom Web Pages

To add custom web pages to the navigation area, the Creo TOOLKIT application must:

1. Add a new pane to the navigation area.
2. Set an icon for this pane.
3. Set the URL of the location that will be displayed in the pane.

Functions Introduced:

- **ProNavigatorpaneBrowserAdd()**
- **ProNavigatorpaneBrowsericonSet()**

---

- **ProNavigatorpaneBrowserURLSet()**

The function `ProNavigatorpaneBrowserAdd()` adds a new pane that can display a web page to the navigation area. The input arguments are:

- *pane\_name*—Specify a unique name for the pane. Use this name in subsequent calls to `ProNavigatorpaneBrowsericonSet()` and `ProNavigatorpaneBrowserURLSet()`.
- *icon\_file\_name*—Specify the name of the icon file, including the extension. A valid format for the icon file is .GIF, .JPG, or .PNG. The new pane is displayed with the icon image. If you specify the value as NULL, the default Creo Parametric icon is used.
- *url*—Specify the URL of the location to be accessed from the pane.

Use the function `ProNavigatorpaneBrowsericonSet()` to set or change the icon of a specified browser pane in the navigation area.

Use the `ProNavigatorpaneBrowserURLSet()` to change the URL of the page displayed in the browser pane in the navigation area.

## Adding Custom Dialog Box Components

To add a new pane to the navigation area based on Creo TOOLKIT dialog box components:

1. Add a new pane to the navigation area.
2. Assign an icon for the pane.
3. Add the Creo TOOLKIT dialog box components using one of the following methods:
  - Assign resource files that describe the overall structure of the new navigation pane. To customize the components after placement in the navigation pane, get the window device name and component name using the Creo TOOLKIT functions described in this topic and set the necessary values using the Creo TOOLKIT functions described in the section [User Interface: Dialogs on page 362](#)
  - To build the layout of the dialog box programmatically, obtain the window device name and layout name. Add each component to the layout as desired using Creo TOOLKIT user interface functions described in the [User Interface: Dialogs on page 362](#).

Functions Introduced:

- **ProNavigatorpanePHolderAdd()**
- **ProNavigatorpanePHolderDelete()**
- **ProNavigatorpanePHolderShow()**

- 
- **ProNavigatorpanePHolderHide()**
  - **ProNavigatorpanePHolderDevicenameGet()**
  - **ProNavigatorpanePHolderLayoutGet()**
  - **ProNavigatorpanePHolderComponentnameGet()**
  - **ProNavigatorpanePHolderHelptextSet()**

The function `ProNavigatorpanePHolderAdd()` adds a layout that will be displayed in the new pane in the navigation area. The input arguments are:

- *pane\_name*—Specify a unique name for the pane.
- *resource\_name*—Specify the name of the resource file to use (whose top component must be a layout, not a dialog box). The contents of the layout from the specified resource file will be inserted into the custom pane.
- *icon\_file\_name*—Specify the name of the icon file, including the extension. A valid format for the icon file is .GIF, .JPG, or .PNG. The new pane is displayed with the icon image. If you specify the value as NULL, the default Creo Parametric icon is used.

The function `ProNavigatorpanePHolderDelete()` deletes the specified pane from the navigation area.

Use the functions `ProNavigatorpanePHolderShow()` and `ProNavigatorpanePHolderHide()` to show and hide the specified pane in the navigation area.

The function `ProNavigatorpanePHolderLayoutGet()` returns the layout name for the specified pane in the navigation area. You can create and place the user interface components within this layout.

Components added to the custom pane actually belong to the Creo Parametric main window dialog. Creo Parametric automatically modifies the names of components loaded from resource files to ensure that no name collisions occur when the components are added. The functions `ProNavigatorpanePHolderDevicenameGet()` and `ProNavigatorpanePHolderComponentnameGet()` allow you to locate the names of components that you need to access.

Use the function `ProNavigatorpanePHolderDevicenameGet()` to obtain name of the Creo Parametric window owning the new pane in the navigation area.

Use the function `ProNavigatorpanePHolderComponentnameGet()` to obtain the complete name of the component in the navigation pane, if loaded from a layout.

---

Use the device name and the component name to add or update the placement of the components in the layout with the help of the `ProUI*` functions. For more information on the user interface functions, refer to the section [User Interface: Dialogs on page 362](#).

The function `ProNavigatorpanePHolderHelptextSet()` sets the popup help text, which is displayed when you point over the navigator pane component.

### Example 11: Customizing the Creo Parametric Navigation Pane

The sample code in the file `UgNavigatorPane.c` located at `<creo_toolkit_loadpoint>protk_appls/pt_userguide/ptu_menu` shows you how to customize the Creo Parametric navigation pane.

## Registering Notifications to Add and Destroy Content to a New Pane

The navigation panes are available in every window within a Creo Parametric session. Notifications are provided to the Creo TOOLKIT application when a Creo Parametric window populated with a model so that the application can add the necessary contents to the new pane upon this event. Similarly, notifications are provided before a model is removed from a Creo Parametric window so that the application can cleanup resources related to added panes. For more information on using notifications see the section [Event-driven Programming: Notifications on page 1974](#).

Functions Introduced:

- **ProNotificationSet()**
- **ProWindowOccupyPostAction()**
- **ProWindowVacatePreAction()**

Specify the argument *type* of the function `ProNotificationSet()` to `PRO_WINDOW_OCCUPY_POST`, to call the callback function whose signature matches `ProWindowOccupyPostAction()`. This function is called when a new Creo Parametric window is created, or when the base window is populated and is used by the application to add the necessary content to the new pane in the navigation area.

Specify the argument *type* of the function `ProNotificationSet()` to `PRO_WINDOW_VACATE_PRE`, to call the callback function whose signature matches `ProWindowVacatePreAction()`. This function is called when a Creo Parametric window is closed, or when the base window gets cleared. Use this function to free memory allocated by the Creo TOOLKIT application to add content in the navigation pane.

---

## Entering Creo Parametric Commands

Functions Introduced:

- **ProMacroLoad()**
- **ProMacroExecute()**
- **ProMenuCommandPush()**

The function `ProMacroLoad()` loads a macro string or a mapkey onto a stack of macros that are executed after control returns to Creo Parametric. A Creo TOOLKIT macro is a string. The macro string is equivalent to a mapkey without the key sequence and the mapkey name.

---

### Note

`ProMacroLoad()` fails if a macro string contains a backslash or if a command splits over two lines with or without a backslash. A macro string can contain multiple commands separated by semicolons. However, each command should entirely appear in a single line.

---

The function `ProMacroLoad()` enables you to execute the commands created by the Creo TOOLKIT application using the following macro:

```
~ Command `<command name>`
```

Click **Mapkeys Settings** in the **Environment** tab of the **Creo Parametric Options** dialog box to create a mapkey in the Creo Parametric user interface. Copy the value of the generated mapkey option from the **Configuration Editor** in the **Creo Parametric Options** dialog box. An example of a created mapkey is as follows:

```
$F2 @MAPKEY_LABELtest;~ Command `ProCmdModelNew`~ Activate `new`
`OK`
```

The key sequence is `$F2`. The remainder of the string after the first semicolon is the macro string. In this case, it is as follows:

```
~ Command `ProCmdModelNew`~ Activate `new` `OK`
```

You can either pass the mapkey directly or the generated macro string to `ProMacroLoad()`. Pass the mapkey directly as *%key\_sequence*.

---

### Note

Creating or editing the macro string manually is not supported, as mapkeys are not a supported scripting language. The syntax is not defined for users and may not remain constant across different datecodes of Creo Parametric.

---

---

## Execution Rules

Consider the following rules about the execution of macros:

- In asynchronous mode, macros are executed as soon as they are loaded with `ProMacroLoad()`.
- In synchronous mode, the mapkey or the macro strings are pushed onto a stack and are popped off and executed only when control returns to Creo Parametric from the Creo TOOLKIT program. Due to the last in, first out nature of the stack, macros that cannot be passed entirely in one `ProMacroLoad()` call should have the strings loaded in reverse order of desired execution.
- To execute a macro from within Creo TOOLKIT, call the function `ProMacroExecute()`. The function runs the Creo Parametric macro and returns the control to the Creo TOOLKIT application. It executes the macros previously loaded using the function `ProMacroLoad()`. The function works only in the synchronous mode.
- Do not call the function `ProMacroExecute()` during the following operations:
  - Activating dialog boxes or setting the current model
  - Erasing the current model
  - Replaying a trail file
- Clicking the **OK** button on the dialog box to complete the command operation. In this case, the dialog box may be displayed momentarily without completing the command operation.

---

### Note

- You can execute only the dialog boxes with built-in exit confirmation as macros, by canceling the exit action.
  - It is possible that a macro may not be executed because a command specified in the macro is currently inaccessible in the menus. The functional success of `ProMacroExecute()` depends on the priority of the executed command against the current context.
- 
- If some of the commands ask for an input to be entered from the keyboard (such as a part name), the macro continues execution after you type the input and press ENTER. However, if you must select something with the mouse (such as selecting a sketching plane), the macro is interrupted and ignores the remaining commands in the string.

---

This allows the application to create object-independent macros for long sequences of repeating choices (as long as the user does not have to select any geometry).

A `ProStringToWstring()` call for defining the macro string must be followed by the following calls:

- `ProMacroLoad(macro wstring)` to load the macro strings or the mapkey
- `ProMacroExecute()` to execute the macro

Some sample macros in various scenarios are given below.

## Ribbon User Interface Macros

The following single entry and exit type of interactions are supported by `ProMacroExecute()`.

- To switch the wireframe display of model, use the macro:  
`Command `ProCmdEnvWireframe` 1`
- To switch the shaded display of model, use the macro:  
`~ Command `ProCmdEnvShaded` 1`
- You can switch the display for datum planes and datum axes using the following macros:
  - Datum Planes  
`~ Command `ProCmdEnvDtmDisp` 1`
  - Datum Axes  
`~ Command `ProCmdEnvAxisDisp` 0`
- To repaint a model, use the macro:  
`~ Command `ProCmdViewRepaint``
- To get the default model orientation, use the macro:  
`~ Command `ProCmdNamedViewsGalSelect` `Default``
- To get the model information, use the macro:  
`~ Command `ProCmdInfoModel``

## Macros For Feature Creation

The following macros are used while creating the following features.

- To create a hole feature, use the macro:  
`~ Command `ProCmdHole``
- To extrude a feature, use the macro:  
`~ Command `ProCmdFtExtrude``
- To create a datum plane, use the macro:  
`~ Command `ProCmdDatumPlane``

---

## Creo Parametric Navigator Macros

The following macros are provided for Creo Parametric navigator:

- For folder navigator:  
~ Select `main\_dlg\_cur` `PHTLeft.ProExplorerTab` 1 `PHTLeft.Folders`
- For Favorites navigator:  
~ Select `main\_dlg\_cur` `PHTLeft.ProExplorerTab` 1 `PHTLeft.FavLay`
- For the Model Tree:  
~ Select `main\_dlg\_cur` `PHTLeft.ProExplorerTab` 1 `PHTLeft.MdlTreeLay`

The function `ProMenuCommandPush()` places the name of a specific menu button in the command input buffer for Creo Parametric. This command is executed after control returns to Creo Parametric from the Creo TOOLKIT application, as if you have selected that menu button. This menu button must be from the menu that is currently displayed in the Creo Parametric user interface.

## Specifying Keyboard Input

You can specify keyboard input within the command string. As previously specified, a macro must be preceded by a pound sign (#) and terminated by a semicolon. If the field after the semicolon does not start with a pound sign, the data up to the next semicolon is used as input at the next keyboard prompt. If the command currently being executed does not request keyboard input, the system ignores this keyboard data. Note that keyboard data is case-sensitive and spaces are not ignored. A carriage return is indicated when no data appears between the semicolons.

### Note

Note that the correctness of the sequence is the responsibility of the user. PTC does not guarantee that a sequence will be valid from one version of Creo Parametric to another.

---

---

# User Interface: Dialogs

## Introduction

This section describes the User Interface (UI) components available in Pro/TOOLKIT for Pro/ENGINEER Wildfire 3.0 onwards. The following topics introduce each of the dialog component types, operations and callbacks available for each component, and the methods and techniques that can be used to instantiate and show customized user interface dialogs.

This section includes documentation for each UI component. The documentation is divided into the following sections:

- **Attributes**—Defines the names and functions that affect attributes on the UI component. Each component supports its own set of unique attributes; however, some attributes are supported by more than one component. Because of the fact that attributes typically work on more than one component, detailed documentation for the attributes is included in a master table at the end of this topic.
- **Operations**—Defines the component-specific functions that make more detailed modifications to the components.
- **Actions**—Defines the functions that register action callbacks on a component.

### Note

From Creo 3.0 onward, a new tool, Creo UI Editor, allows you to interactively create and edit dialog boxes for Creo Object TOOLKIT C++ and Creo Object TOOLKIT Java customizations. It provides a library of graphical user interface components such as buttons, lists, and so on. The new framework, User Interface Foundation Classes (UIFC), provides enhanced attributes and actions for the user interface components. The UIFC framework is available in Creo Object TOOLKIT C++ and Creo Object TOOLKIT Java. You can generate callbacks in Creo Object TOOLKIT C++ or Creo Object TOOLKIT Java. Refer to the *Creo UI Editor User's Guide*, for more information.

---

## About Creo Toolkit Support for User Interface

Creo TOOLKIT allows applications to create dialogs and dashboards with the same look and feel as those in Creo Parametric. Creo TOOLKIT users can accomplish this task by following the following steps:

- 
- Establish the main UI container object. This is either a dialog or a dashboard. Optionally, this can be read from a resource file to prepopulate the container with specific components.
  - Add components to the container (if they do not already exist).
  - Set attributes on components in the container.
  - Execute operations on components in the container. Operations also modify the component, but typically make more detailed or sophisticated changes than setting an individual attribute.
  - Establish action function callbacks on components in the container. Action functions are called when the user interacts with the component in some way. They allow the application to react to user events.
  - Show the dialog or dashboard.
  - Based on user actions, eventually you will need to close the container.
  - "Destroy" the container to free up the resources it uses.

---

 **Note**

The functions described in this topic do not support using Creo TOOLKIT to modify standard Creo Parametric dialogs.

---

The UI function library is integral to Creo Parametric, not the Creo TOOLKIT libraries; thus, the library can only be used while a Creo Parametric session is active. The library cannot be used to display user interfaces when the application is not connected to Creo Parametric running interactively.

## UI Components

The behavior and uses of the different component types is introduced briefly below, and described in more detail in later sections. The component types are:

- **Tab**—part of a dialog that can contain several groups of components, formatted such that only one group is visible at a time. A Tab component must always contain a set of Layout components; each layout contains the components that must be displayed at one time. The Figure - ‘All Components Dialog’ shows a decorated Tab which displays a handle on each layout to allow the user to select which layout is visible.
- **Layout**—an area of a dialog which can contain any number of other dialog components. A Layout can be used to better control the relative position of components in a dialog, by allowing the grids in different parts of the dialog to

---

adopt unaligned rows or columns. A layout can also be used inside a Tab component.

- **Check Button**—a button which toggles between a `TRUE` and `FALSE` state each time the user selects it.
- **Drawing Area**—a component which allows points, lines, shapes, images and text (including symbols) to be drawn in a variety of colors.
- **Input Panel**—a box containing a single line of text. The Input Panel may be set to expect text in different formats, for example a real number or an integer. The Input Panel may also be set to be read-only, when it is used by the application to show information to the user.
- **Label**—a text string used to label the other components.
- **List**—a box containing a list of text strings, which can be selected by the user. Users can set the List to allow selection of only one item at a time, or more than one.
- **Option Menu**—a single-line box which allows selection of a single text string from a list of options. The selection is done using a pull-down menu, which appears when a button next to the text box is selected.
- **Progress Bar**—a component which shows the progress of a time-consuming action.
- **Push Button**—a button which performs some action when it is selected. It does not contain any remembered state. Push Buttons appear on almost every dialog as `OK` and `Cancel` buttons.
- **Radio Group**—a set of buttons which individually act like check buttons, but which are connected to each other such that only one can be set to `TRUE` at any time. Selecting one button sets that button and unsets all others in the group.
- **Separator**—a separator is for cosmetic purposes only, and helps to visually divide components into logical groups.
- **Slider**—a device which allows the user to set a value in a predefined range by moving a handle with the mouse. Use sliders in situations where an exact value may not be needed. A slider should usually be tied programmatically with a read-only input panel to show the current value.
- **Spin-Box**—a box containing a single numerical value that can be directly edited. The spin box also has up- and down-arrow buttons for increasing or decreasing the value in steps. A single click increments or decrements by a single step. Holding a button down makes the value change in repeated steps, first small steps and then large steps. The step sizes can be set for each spin box.

- 
- **Table**—a set of tabulated rows and columns containing text and other components.
  - **Text Area**—a box containing unformatted text containing any number of lines. It may be set to be read-only and used by the application to output information to the user.
  - **Thumbwheel**—a thumbwheel is similar to slider but provides finer control over a wider range of values. Unlike the slider, it does not provide a visual indication of the current value.
  - **Tree**—a tree contains nodes which are structured and displayed in a hierarchical formation.

## Naming Convention for UI Components

The valid characters for naming UI components are:

- A to Z (uppercase)
- a to z (lowercase)
- 0 to 9
- Underscore( \_ )
- Hyphen(-)

Using any other characters in UI component names may result in an error.

## Menubars and Menubar Components

A dialog can also contain its own menubar. These menubars support cascading menus.

See [Example 15: Resource File for Dialog with Menubar on page 472](#) for resource file code for this example.

The following components are used to define menu bars and their dependent menus:

- **Menubar**—The menubar itself is just a container for the menu panes. A dialog can contain only one menubar, and it must contain at least one other component at the top level.
- **MenuPane**—A menu pane describes a button on a menubar and also acts as a container for the components on the pull-down menu that appears when the user selects the menu pane button.
- **Cascade button**—A button on a pull-down menu that contains its own menupane. Selecting the cascade button pulls out the menu described by the menupane.

The following components described in the previous topic can also be added to menu panes, but in this case their appearance is automatically modified to suit the style of pull-down menus:

- **Check Button**—This looks like a regular menu button, but in fact toggles its state. When TRUE, it shows a check mark next to the label.
- **Push Button**—When added to a menu pane a pushbutton represents a command that causes some action.
- **Radio Group**—A radio group on a menu pane behaves exactly as it would in the body of a dialog, although the appearance is rather different, as shown in the picture above.
- **Separator**—A separator can be used to group buttons on a menu pane.

## Dialog Attributes

| Attribute Name                         | Get Function                           | Set Function(s)                                                            |
|----------------------------------------|----------------------------------------|----------------------------------------------------------------------------|
| <a href="#">.AttachBottom on page</a>  | • <b>ProUIDialogIsAttachedBottom()</b> | • <b>ProUIDialogAttachBottom()</b><br>• <b>ProUIDialogUnattachBottom()</b> |
| <a href="#">.AttachTop on page</a>     | • <b>ProUIDialogIsAttachedTop()</b>    | • <b>ProUIDialogAttachTop()</b><br>• <b>ProUIDialogUnattachTop()</b>       |
| <a href="#">.AttachRight on page</a>   | • <b>ProUIDialogIsAttachedRight()</b>  | • <b>ProUIDialogAttachRight()</b><br>• <b>ProUIDialogUnattachRight()</b>   |
| <a href="#">.AttachLeft on page</a>    | • <b>ProUIDialogIsAttachedLeft()</b>   | • <b>ProUIDialogAttachLeft()</b><br>• <b>ProUIDialogUnattachLeft()</b>     |
| <a href="#">.BottomOffset on page</a>  | • <b>ProUIDialogBottomoffsetGet()</b>  | • <b>ProUIDialogBottomoffsetSet()</b>                                      |
| <a href="#">.Bitmap on page</a>        | • <b>ProUIDialogBitmapGet()</b>        | • <b>ProUIDialogBitmapSet()</b>                                            |
| <a href="#">.ChildNames on page</a>    | • <b>ProUIDialogChildnamesGet()</b>    | • Not Applicable                                                           |
| <a href="#">.ClassName on page</a>     | • <b>ProUIComponentClassnameGet()</b>  | • Not Applicable                                                           |
| <a href="#">.DefaultButton on page</a> | • <b>ProUIDialogDefaultbuttonGet()</b> | • <b>ProUIDialogDefaultbuttonSet()</b>                                     |
| <a href="#">.DialogStyle on page</a>   | • <b>ProUIDialogDialogstyleGet()</b>   | • <b>ProUIDialogDialogstyleSet()</b>                                       |
| <a href="#">.Focus on page</a>         | • Not Applicable                       | • <b>ProUIDialogFocusSet()</b>                                             |
| <a href="#">.Height on page</a>        | • <b>ProUIDialogHeightGet()</b>        | • <b>ProUIDialogHeightSet()</b>                                            |
| <a href="#">.HorzAtPoint on page</a>   | • <b>ProUIDialogHorzatpointGet()</b>   | • <b>ProUIDialogHorzatpointSet()</b>                                       |
| <a href="#">.HorzDialog on page</a>    | • <b>ProUIDialogHorzdialogGet()</b>    | • <b>ProUIDialogHorzdialogSet()</b>                                        |
| <a href="#">.HorzMethod on page</a>    | • <b>ProUIDialogHorzmethodGet()</b>    | • <b>ProUIDialogHorzmethodSet()</b>                                        |
| <a href="#">.HorzPoint on page</a>     | • <b>ProUIDialogHorzpointGet()</b>     | • <b>ProUIDialogHorzpointSet()</b>                                         |
| <a href="#">.HorzPosOffset</a>         | • <b>ProUIDialogHorzposoffsetGet()</b> | • <b>ProUIDialogHorzposoffsetSet()</b>                                     |

| Attribute Name            | Get Function                           | Set Function(s)                                                  |
|---------------------------|----------------------------------------|------------------------------------------------------------------|
| on page                   |                                        |                                                                  |
| .HorzSize on page         | • ProUIDialogHorzsizeGet()             | • ProUIDialogHorzsizeSet()                                       |
| .Labels on page           | • ProUIDialogTitleGet()                | • ProUIDialogTitleSet()                                          |
| .LeftOffset on page       | • ProUIDialogLeftoffsetGet()           | • ProUIDialogLeftoffsetSet()                                     |
| .Mapped on page           | • ProUIDialogIsMapped()                | • ProUIDialogMappedSet()<br>• ProUIDialogMappedUnset()           |
| .PopupMenu on page        | • ProUIDialogPopupmenuGet()            | • ProUIDialogPopupmenuSet()                                      |
| .RememberPosition on page | • ProUIDialogRemembersPosition()<br>() | • ProUIDialogRememberPosition()<br>• ProUIDialogForgetPosition() |
| .RememberSize on page     | • ProUIDialogRemembersSize()           | • ProUIDialogRememberSize()<br>• ProUIDialogForgetSize()         |
| .Resizable on page        | • ProUIDialogIsResizable()             | • ProUIDialogEnableResizing()<br>• ProUIDialogDisableResizing()  |
| .RightOffset on page      | • ProUIDialogRightoffsetGet()          | • ProUIDialogRightoffsetSet()                                    |
| .StartLocation on page    | • ProUIDialogStartlocationGet()        | • ProUIDialogStartlocationSet()                                  |
| .TopOffset on page        | • ProUIDialogTopoffsetGet()            | • ProUIDialogTopoffsetSet()                                      |
| .VertAtPoint on page      | • ProUIDialogVertatpointGet()          | • ProUIDialogVertatpointSet()                                    |
| .VertDialog on page       | • ProUIDialogVertdialogGet()           | • ProUIDialogVertdialogSet()                                     |
| .VertMethod on page       | • ProUIDialogVertmethodGet()           | • ProUIDialogVertmethodSet()                                     |
| .VertPoint on page        | • ProUIDialogVertpointGet()            | • ProUIDialogVertpointSet()                                      |
| .VertPosOffset on page    | • ProUIDialogVertposoffsetGet()        | • ProUIDialogVertposoffsetSet()                                  |
| .VertSize on page         | • ProUIDialogVertsizeGet()             | • ProUIDialogVertsizeSet()                                       |
| .Width on page            | • ProUIDialogWidthGet()                | • ProUIDialogWidthSet()                                          |

## Dialog Operations

### Functions Introduced

- ProUIDialogCreate()
- ProUIDialogActivate()
- ProUIDialogComponentsCollect()
- ProUIDialogMinimumsizeGet()
- ProUIDialogSizeGet()

- 
- **ProUIDialogPositionReset()**
  - **ProUIDialogReconfigure()**
  - **ProUIDialogScreenpositionGet()**
  - **ProUIDialogAboveactivewindowGet()**
  - **ProUIDialogAboveactivewindowSet()**
  - **ProUIDialogShow()**
  - **ProUIDialogHide()**
  - **ProUIDialogExit()**
  - **ProUIDialogDestroy()**
  - **ProUITimerCreate()**
  - **ProUIDialogTimerStart()**
  - **ProUIDialogTimerStop()**
  - **ProUITimerDestroy()**
  - **ProUIDialogMenupaneAdd()**

The function `ProUIDialogCreate()` loads a dialog from a resource file into memory. It can also create an empty dialog by passing a `NULL` value for the resource file name. The input arguments follow:

- *session\_dialog\_name*—Name of the dialog.
- *resource*—Name of the resource file.

---

 **Note**

- The function `ProUIDialogCreate()` requires that the resource file name input matches the case of the actual resource file.
- The dialog name specified in the resource file should match both the input argument *resource* and the name of the resource file without adding the suffix name.

---

The following points must be noted while developing Creo TOOLKIT applications:

- Resource names of dialogs resources must not coincide with the resources that are defined by PTC.
- Dialog instance or session names must not coincide with the instance or session names that are defined by PTC.
- You can ensure uniqueness in the dialog resource and session names by adding a prefix that specifies the name of the Creo TOOLKIT application.

---

Use the function `ProUIDialogActivate()` to display the dialog on the screen and makes it active by setting the key input focus on it. This function returns only after the function `ProUIDialogExit()` has been called on the same dialog.

Use the function `ProUIDialogComponentsCollect()` to return the names of components in this dialog. This function can also filter components by their type.

---

 **Note**

Refer to the topic [UI Components on page 363](#) for the predefined list of component types.

---

Use the function `ProUIDialogMinimumsizeGet()` to get the minimum size of the dialog in pixels.

Use the function `ProUIDialogSizeGet()` to get the size of the dialog.

Use the function `ProUIDialogPositionReset()` to reset the dialog in its previous screen position.

Use the function `ProUIDialogReconfigure()` to reset the size and position of the dialog.

Use the function `ProUIDialogScreenpositionGet()` get the screen position in pixels of the dialog component.

Use the function `ProUIDialogAboveactivewindowGet()` to checks if the dialog is always going to be above the Creo Parametric dialogs currently active in the Creo Parametric window.

Use the function `ProUIDialogAboveactivewindowSet()` to set focus of the dialog above any dialog in the currently active Creo Parametric window.

---

 **Note**

Using the `ProUIDialogAboveactivewindowSet()` allows Creo TOOLKIT applications to always stay in focus in the Creo Parametric window during opening and closing events of Creo Parametric.

---

Use the `ProUIDialogDestroy()` to remove the dialog instance from memory as it is not automatically removed.

Use the function `ProUIDialogShow()` to show a secondary window when the primary window is being restored.

---

Use the function `ProUIDialogHide()` to iconify a secondary window when the primary window is being minimized.

Use the function `ProUIDialogExit()` to terminate the activation of the named dialog window. The function causes a return from the call to `ProUIDialogActivate()` that make it active.

Use the function `ProUIDialogDestroy()` to remove the dialog from the memory.

You can set a timer to schedule an action to be executed later in Creo Parametric session. The function `ProUITimerCreate()` creates a timer and registers the action. If you call the function `ProUITimerCreate()` with `timer_name` that already exists in the session, it returns an error. The input arguments for the function are:

- *action*—Specifies call to the action callback function `ProUITimerAction()`. You can invoke the action callback only once from the function `ProUIDialogTimerStart()`. To run the action again, you must call `ProUIDialogTimerStart()` again.
- *appdata*—Specifies the data that will be passed to the action callback.
- *timer\_name*—Specifies the name of the timer.

The function returns the ID of the timer, which will be used to start and stop the timer.

Use the function `ProUIDialogTimerStart()` to start the timer. The action is executed after the specified interval of time. The input arguments are:

- *dialog*—Specifies the name of the dialog box. You can invoke only one timer at a time for a dialog box.
- *timer\_id*—Specifies the ID of the timer, which was returned by the function `ProUITimerCreate()`.
- *duration*—Specifies the time interval in milliseconds after which the action must be executed. The minimum value is set to 500 milliseconds.
- *write\_in\_trail\_file*—Specifies if the timer action must be recorded in a trail file.

The function `ProUIDialogTimerStop()` stops the timer and the action will not be executed. Specify the ID of the timer as the input argument.

The function `ProUITimerDestroy()` removes the specified timer, which was created using the function `ProUITimerCreate()`. If the timer to be removed has already been started, it is first stopped, and then removed. Pass the ID of the timer as the input argument. After the timer is removed, its name is available for use again. You can specify the name to a new timer.

---

## Note

You must use the functions `ProUITimerCreate()`, `ProUIDialogTimerStart()`, `ProUIDialogTimerStop()`, and `ProUITimerDestroy()` only in DLL mode.

---

The function `ProUIDialogMenupaneAdd()` allows to create a menupane. After creating a menupane, you can add it to a cascade button in the menubar by using the `ProUICascadebuttonPopupmenuSet()` function. To add it directly to the menubar, use the `ProUIMenubarNamesSet()`. The input arguments for the function are:

- *dialog*—Specifies the name of the dialog box.
- *name*—Name of the menupane to be added.

## Example 1: Source for Dialog with Text Question, OK and Cancel Buttons

The example in the file `UgUIYesnoDialog.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_ui`, shows the source code that uses this dialog.

## Adding and Removing Components

| Component Name | Add Function                               | Remove Function                               |
|----------------|--------------------------------------------|-----------------------------------------------|
| Checkbutton    | • <code>ProUIDialogCheckbuttonAdd()</code> | • <code>ProUIDialogCheckbuttonRemove()</code> |
| Drawingarea    | • <code>ProUIDialogDrawingareaAdd()</code> | • <code>ProUIDialogDrawingareaRemove()</code> |
| Inputpanel     | • <code>ProUIDialogInputpanelAdd()</code>  | • <code>ProUIDialogInputpanelRemove()</code>  |
| Label          | • <code>ProUIDialogLabelAdd()</code>       | • <code>ProUIDialogLabelRemove()</code>       |
| Layout         | • <code>ProUIDialogLayoutAdd()</code>      | • <code>ProUIDialogLayoutRemove()</code>      |
| List           | • <code>ProUIDialogListAdd()</code>        | • <code>ProUIDialogListRemove()</code>        |
| Menubar        | • <code>ProUIDialogMenubarAdd()</code>     | • Not Applicable                              |
| Menupane       | • <code>ProUIDialogMenupaneAdd()</code>    | • <code>ProUIDialogMenupaneRemove()</code>    |
| Optionmenu     | • <code>ProUIDialogProgressbarAdd()</code> | • <code>ProUIDialogOptionmenuRemove()</code>  |
| Progressbar    | • <code>ProUIDialogProgressbarAdd()</code> | • <code>ProUIDialogProgressbarRemove()</code> |
| Pushbutton     | • <code>ProUIDialogPushbuttonAdd()</code>  | • <code>ProUIDialogPushbuttonRemove()</code>  |
| Radiogroup     | • <code>ProUIDialogRadiogroupAdd()</code>  | • <code>ProUIDialogRadiogroupRemove()</code>  |

| Component Name | Add Function                        | Remove Function                        |
|----------------|-------------------------------------|----------------------------------------|
| Separator      | • <b>ProUIDialogSeparatorAdd()</b>  | • <b>ProUIDialogSeparatorRemove()</b>  |
| Slider         | • <b>ProUIDialogSliderAdd()</b>     | • <b>ProUIDialogSliderRemove()</b>     |
| Spinbox        | • <b>ProUIDialogSpinboxAdd()</b>    | • <b>ProUIDialogSpinboxRemove()</b>    |
| Tab            | • <b>ProUIDialogTabAdd()</b>        | • <b>ProUIDialogTabRemove()</b>        |
| Table          | • <b>ProUIDialogTableAdd()</b>      | • <b>ProUIDialogTableRemove()</b>      |
| Textarea       | • <b>ProUIDialogTextareaAdd()</b>   | • <b>ProUIDialogTextareaRemove()</b>   |
| Thumbwheel     | • <b>ProUIDialogThumbwheelAdd()</b> | • <b>ProUIDialogThumbwheelRemove()</b> |
| Tree           | • <b>ProUIDialogTreeAdd()</b>       | • <b>ProUIDialogTreeRemove()</b>       |

Creo TOOLKIT provides functions to add components to a dialog. These functions accept an argument of type `ProUIGridopts` that determines the location and initial placement details of the component. In addition, a number of grid-specific attributes control the position and resizing of the newly created component within the grid of the Dialog.

These grid-specific attributes are listed as follows:

| Attribute   | Default Value            | Description                                                                                                                                                                                                      |
|-------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| column      | PRO_UI_INSERT_NEW_COLUMN | The column of the grid into which the component should be added. A value of PRO_UI_INSERT_NEW_COLUMN indicates that the component should be added to a newly created column to the left of any existing columns. |
| row         | PRO_UI_INSERT_NEW_ROW    | The row of the grid into which the component should be added. A value of PRO_UI_INSERT_NEW_ROW indicates that the component should be added to a newly created row to the left of any existing rows.             |
| horz_cells  | 1                        | The number of cells which the component should occupy in the existing grid in a horizontal direction.                                                                                                            |
| vert_cells  | 1                        | The number of cells which the component should occupy in the existing grid in a vertical direction.                                                                                                              |
| horz_resize | PRO_B_TRUE               | A flag indicating whether the grid cell containing the component should resize horizontally.                                                                                                                     |
| vert_resize | PRO_B_TRUE               | A flag indicating whether the grid cell containing the component should resize vertically.                                                                                                                       |
| attach_top  | PRO_B_TRUE               | Attach the item to the top neighbor                                                                                                                                                                              |

| Attribute     | Default Value            | Description                                                                                                           |
|---------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------|
| attach_bottom | PRO_B_TRUE               | Attach the item to the bottom neighbor                                                                                |
| attach_left   | PRO_B_TRUE               | Attach the item to the left neighbor                                                                                  |
| attach_right  | PRO_B_TRUE               | Attach the item to the right neighbor                                                                                 |
| top_offset    | PRO_UI_USE_DEVICE_OFFSET | Offset to the top neighbor. The default value PRO_UI_USE_DEVICE_OFFSET inherits the offset from the owning dialog.    |
| bottom_offset | PRO_UI_USE_DEVICE_OFFSET | Offset to the bottom neighbor. The default value PRO_UI_USE_DEVICE_OFFSET inherits the offset from the owning dialog. |
| left_offset   | PRO_UI_USE_DEVICE_OFFSET | Offset to the left neighbor. The default value PRO_UI_USE_DEVICE_OFFSET inherits the offset from the owning dialog.   |
| right_offset  | PRO_UI_USE_DEVICE_OFFSET | Offset to the right neighbor. The default value PRO_UI_USE_DEVICE_OFFSET inherits the offset from the owning dialog.  |

### Note

Components that are added to a dialog after it is displayed do not permit modification of all component attributes. When creating and displaying a dialog, it is preferable to use these functions to add the components before activating the dialog. If a component might be needed but should not be shown initially, add it before activation and set its `.Visible` attribute to false.

## Dialog Action Callbacks

### Functions Introduced

- **ProUIDialogPremanagenotifyActionSet()**
- **ProUIDialogPostmanagenotifyActionSet()**
- **ProUIDialogDestroynotifyActionSet()**
- **ProUIDialogCloseActionSet()**
- **ProUIDialogActivateActionSet()**
- **ProUIDialogAppActionSet()**
- **ProUIDialogAppActionRemove()**

---

Use the function `ProUIDialogPremanagenotifyActionSet()` to set the function to be called when the dialog is about to be managed. For example, when a dialog box is displayed or redisplayed.

Use the function `ProUIDialogPostmanagenotifyActionSet()` to set the function to be called when the dialog has just been managed. For example, when a dialog box is displayed.

Use the function `ProUIDialogDestroynotifyActionSet()` to set the function to be called when the dialog is about to be destroyed.

Use the function `ProUIDialogCloseActionSet()` to set the action function to be called when the user attempts to close the dialog using the window close icon in the upper right corner of the dialog.

Use the function `ProUIDialogActivateActionSet()` to set the function to be called when the dialog has just been activated and made the current foreground window. The action function for a given dialog can be called

- The dialog must not be the current foreground application.
- The dialog (when it is not the foreground application) is activated using one of the following methods:
  - When the user clicks on the taskbar button for the given dialog.
  - When the user switches to the given dialog using `Alt+Tab`.
  - When the user clicks within the given dialog.

Use the function `ProUIDialogAppActionSet()` to set a function to be called only once, when you return to or enter an event loop. The input arguments follow:

- *dialog*—Name of the dialog. The action is associated with the dialog and is automatically cancelled if the dialog is destroyed. The value can be `NULL`.
- *function*—Function to be called when you return to an event loop.
- *data*—Action data passed to the callback function. The value can be `NULL`.

Use the function `ProUIDialogAppActionRemove()` to remove a function added via `ProUIDialogAppActionSet()`. The input arguments follow:

- *dialog*—Name of the dialog passed to the function `ProUIDialogAppActionRemove()`.
- *function*—Function passed to `ProUIDialogActionSet()`.
- *data*—Action data passed to `ProUIDialogActionSet()`.

## Cascade\_Button

### Cascade Button Attributes

| Attribute Name                         | Get Function                                                                                           | Set Function(s)                                                                                                                                             |

---

## Checkbox Operations

### Functions Introduced

- **ProUICheckbuttonAnchorSet()**
- **ProUICheckbuttonSizeSet()**
- **ProUICheckbuttonMinimumsizeGet()**
- **ProUICheckbuttonPositionSet()**
- **ProUICheckbuttonPositionGet()**
- **ProUICheckbuttonSizeGet()**

Use the function `ProUICheckbuttonAnchorSet()` to set the position of the checkbox with respect to a given anchor location. This function is applicable only if the parent of the checkbox is a drawing area. The input argument *anchor* determines which part of the component is being positioned.

Use the function `ProUICheckbuttonSizeSet()` to set the size of the checkbox in pixels. This operation is applicable only if the parent is a drawing area. The function will fail, if you specify a value smaller than the minimum size for the input arguments *width* or *height*.

Use the function `ProUICheckbuttonMinimumsizeGet()` to retrieve the minimum size of the width and height of the check button in pixels. Use this function only if the parent is a drawing area.

Use the function `ProUICheckbuttonPositionSet()` to set the position to the checkbox with respect to its parent. This operation is applicable only if the parent is a drawing area.

Use the function `ProUICheckbuttonPositionGet()` to get the position of the checkbox with respect to its parent. This operation is applicable only if the parent is a drawing area.

Use the function `ProUICheckbuttonSizeGet()` to get the size of the checkbox. This operation is applicable only if the parent is a drawing area.

## Checkbox Action Callbacks

### Functions Introduced

- **ProUICheckbuttonActivateActionSet()**

The function `ProUICheckbuttonActivateActionSet()` sets the callback action to be invoked when the user toggles the state of the checkbox.

Components added to drawing areas are not managed in grids like components in most other containers. Instead, use the operations that set the component size and position to place the component how you wish in the drawing area.

### **Note**

This means that components may possibly overlap each other in a drawing area depending on their individual placement.

## **Drawing Area Action Callbacks**

### Functions Introduced

- **ProUIDrawingareaEnterActionSet()**
- **ProUIDrawingareaExitActionSet()**
- **ProUIDrawingareaMoveActionSet()**
- **ProUIDrawingareaLbuttonarmActionSet()**
- **ProUIDrawingareaLbuttondisarmActionSet()**

- 
- **ProUIDrawingareaLbuttonactivateActionSet()**
  - **ProUIDrawingareaLbuttondblclkActionSet()**
  - **ProUIDrawingareaMbuttonarmActionSet()**
  - **ProUIDrawingareaMbuttondisarmActionSet()**
  - **ProUIDrawingareaMbuttondisarmActionSet()**
  - **ProUIDrawingareaMbuttonactivateActionSet()**
  - **ProUIDrawingareaMbuttondblclkActionSet()**
  - **ProUIDrawingareaRbuttonarmActionSet()**
  - **ProUIDrawingareaRbuttondisarmActionSet()**
  - **ProUIDrawingareaRbuttonactivateActionSet()**
  - **ProUIDrawingareaRbuttondblclkActionSet()**
  - **ProUIDrawingareaUpdateActionSet()**
  - **ProUIDrawingareaResizeActionSet()**
  - **ProUIDrawingareaPostmanagenotifyActionSet()**

Use the function `ProUIDrawingareaEnterActionSet()` to set the action function to be called when the user has moved the cursor into the drawing area. This action will be generated only if tracking is enabled for the drawing area.

Use the function `ProUIDrawingareaExitActionSet()` to set the function to be called when the user has moved the cursor out of the drawing area. This action will be generated only if tracking is enabled for the drawing area.

Use the function `ProUIDrawingareaMoveActionSet()` to set the function to be called when the cursor is moved over the drawing area. This action will be generated only if tracking is enabled for the drawing area.

Use the function `ProUIDrawingareaLbuttonarmActionSet()` to set the function to be called when the left mouse button is clicked in the drawing area.

Use the function `ProUIDrawingareaLbuttondisarmActionSet()` to set the function to be called when the left mouse button is released in the drawing area.

Use the function `ProUIDrawingareaLbuttonactivateActionSet()` to set the function to be called when the left mouse button is clicked and released in the drawing area.

Use the function `ProUIDrawingareaLbuttondblclkActionSet()` to set the function to be called when the left mouse button is double-clicked in the drawing area.

Use the function `ProUIDrawingareaMbuttonarmActionSet()` to set the function to be called when the middle mouse button is clicked in the drawing area.

---

Use the function `ProUIDrawingareaMbuttondisarmActionSet()` to set the function to be called when the middle mouse button is released in the drawing area.

Use the function `ProUIDrawingareaMbuttonactivateActionSet()` to set the function to be called when the middle mouse button is clicked and released in the drawing area.

Use the function `ProUIDrawingareaMbuttondblclkActionSet()` to set the function to be called when the middle mouse button is double-clicked in the drawing area.

Use the function `ProUIDrawingareaRbuttonarmActionSet()` to set the function to be called when the right mouse button is clicked in the drawing area.

Use the function `ProUIDrawingareaRbuttondisarmActionSet()` to set the function to be called when the right mouse button is released in the drawing area.

Use the function `ProUIDrawingareaRbuttonactivateActionSet()` to set the function to be called when the right mouse button is clicked and released in the drawing area.

Use the function `ProUIDrawingareaRbuttondblclkActionSet()` to set the function to be called when the right mouse button is double-clicked in the drawing area.

Use the function `ProUIDrawingareaUpdateActionSet()` to set the function to be called when the drawing area needs to be updated due to a system-level color scheme change.

Use the function `ProUIDrawingareaResizeActionSet()` to set the function to be called when the drawing area is resized.

---

### **Note**

Any graphics, text or images added to the drawing area is typically cleared after a resize.

---

Use the function `ProUIDrawingareaPostmanagenotifyActionSet()` to set the function to be called when the drawing area has just been displayed. Use this callback to setup the initial graphics, text, and images in the drawing area.

## **Drawing Area Operations**

### Functions Introduced

- **`ProUIDrawingareaAnchorSet()`**
- **`ProUIDrawingareaSizeGet()`**

- 
- **ProUIDrawingareaSizeSet()**
  - **ProUIDrawingareaMinimumsizeGet()**
  - **ProUIDrawingareaPositionGet()**
  - **ProUIDrawingareaPositionSet()**
  - **ProUIDrawingareaClear()**
  - **ProUIDrawingareaCopyArea()**
  - **ProUIDrawingareaPointDraw()**
  - **ProUIDrawingareaPointsDraw()**
  - **ProUIDrawingareaLineDraw()**
  - **ProUIDrawingareaLinesDraw()**
  - **ProUIDrawingareaPolylineDraw()**
  - **ProUIDrawingareaRectDraw()**
  - **ProUIDrawingareaRectsDraw()**
  - **ProUIDrawingareaRectFill()**
  - **ProUIDrawingareaRectsFill()**
  - **ProUIDrawingareaShadowRectDraw()**
  - **ProUIDrawingareaShadowRectsDraw()**
  - **ProUIDrawingareaPolygonDraw()**
  - **ProUIDrawingareaPolygonFill()**
  - **ProUIDrawingareaArcDraw()**
  - **ProUIDrawingareaArcsDraw()**
  - **ProUIDrawingareaArcFill()**
  - **ProUIDrawingareaArcsFill()**
  - **ProUIDrawingareaEllipseDraw()**
  - **ProUIDrawingareaEllipsesDraw()**
  - **ProUIDrawingareaEllipseFill()**
  - **ProUIDrawingareaEllipsesFill()**
  - **ProUIDrawingareaImageDraw()**
  - **ProUIDrawingareaImagesDraw()**
  - **ProUIDrawingareaStringDraw()**
  - **ProUIDrawingareaStringsDraw()**
  - **ProUIDrawingareaStringsizedGet()**
  - **ProUIDrawingareaStringbaselineGet()**

- 
- **ProUIDrawingareaImagesizeGet()**
  - **ProUIDrawingareaCursorposGet()**
  - **ProUIDrawingareaCursorposSet()**

Use the function `ProUIDrawingareaAnchorSet()` to set the position of the drawing area with respect to a given anchor location. This function is applicable only if the parent of the drawing area is another drawing area.

Use the function `ProUIDrawingareaSizeGet()` to get the size of the drawing area. This operation is applicable only if the parent is a drawing area.

Use the function `ProUIDrawingareaSizeSet()` to set the size of the drawing area. This operation is applicable only if the parent is a drawing area. The function will fail, if you specify a value smaller than the minimum size for the input arguments *width* or *height*.

Use the function `ProUIDrawingareaMinimumsizeGet()` to retrieve the minimum size of the width and height of the drawing area in pixels. Use this function only if the parent is a drawing area.

Use the function `ProUIDrawingareaPositionGet()` to get the position of the drawing area with respect to its parent. This operation is applicable only if the parent is a drawing area.

Use the function `ProUIDrawingareaPositionSet()` to set the position to the drawing area with respect to its parent. This operation is applicable only if the parent is a drawing area.

Use the function `ProUIDrawingareaClear()` to clear the contents of the drawing area by painting it in the drawing background color.

Use the function `ProUIDrawingareaCopyArea()` to copy the contents within a given boundary at a location in the drawing area to another location.

Use the function `ProUIDrawingareaPointDraw()` to draw a point in the drawing area.

Use the function `ProUIDrawingareaPointsDraw()` to draw an array of points in the drawing area.

Use the function `ProUIDrawingareaLineDraw()` to draw a line in the drawing area.

Use the function `ProUIDrawingareaLinesDraw()` to draw a set of lines between in the drawing area. Each line will be drawn from the indicated start point in the array to the corresponding endpoint.

Use the function `ProUIDrawingareaPolylineDraw()` to draw a series of connected lines in the drawing area.

Use the function `ProUIDrawingareaRectDraw()` to draw a rectangle in the drawing area.

---

Use the function `ProUIDrawingareaRectsDraw()` to draw a set of rectangles in the drawing area.

Use the function `ProUIDrawingareaRectFill()` to draw a filled rectangle in the drawing area.

Use the function `ProUIDrawingareaRectsFill()` to draw a set of filled rectangles in the drawing area.

Use the function `ProUIDrawingareaShadowRectDraw()` to draw a rectangle with a shadow border.

Use the function `ProUIDrawingareaShadowRectsDraw()` to draw a set of rectangles with shadow borders.

Use the function `ProUIDrawingareaPolygonDraw()` to draw a polygon in the drawing area.

Use the function `ProUIDrawingareaPolygonFill()` to draw a filled polygon in the drawing area.

Use the function `ProUIDrawingareaArcDraw()` to draw an arc in the drawing area.

Use the function `ProUIDrawingareaArcsDraw()` to draw a set of arcs in the drawing area.

Use the function `ProUIDrawingareaArcFill()` to draw a filled arc in the drawing area.

Use the function `ProUIDrawingareaArcsFill()` to draw a set of filled arcs in the drawing.

Use the function `ProUIDrawingareaEllipseDraw()` to draw an ellipse in the drawing area.

Use the function `ProUIDrawingareaEllipsesDraw()` to draw a set of ellipses in the drawing area.

Use the function `ProUIDrawingareaEllipseFill()` to draw a filled ellipse in the drawing area.

Use the function `ProUIDrawingareaEllipsesFill()` to draw a set of filled ellipses in the drawing area.

Use the function `ProUIDrawingareaImageDraw()` to draw an image in the drawing area.

Use the function `ProUIDrawingareaImagesDraw()` to draw images at the given positions in the drawing area.

Use the function `ProUIDrawingareaStringDraw()` to draw a string at the given position in the drawing area.

Use the function `ProUIDrawingareaStringsDraw()` to draw strings at the given positions in the drawing.

Use the function `ProUIDrawingareaStringsizedGet()` to get the size that the given text string will occupy in the drawing area, given the current drawing area font settings.

Use the function `ProUIDrawingareaStringbaselineGet()` to get the height from the top of the string border to the string baseline for the given text string in the drawing area, given the current drawing area font settings.

Use the function `ProUIDrawingareaImagesizedGet()` to get the size of the image in the drawing area.

Use the function `ProUIDrawingareaCursorposGet()` to get the position of the cursor in the drawing area.

Use the function `ProUIDrawingareaCursorposSet()` to set the cursor at the given location in the drawing area.

## Input\_Panel

### Input Panel Attributes

## Input Panel Action Callbacks

Functions Introduced

- **ProUIInputpanelActivateActionSet()**
- **ProUIInputpanelFocusinActionSet()**
- **ProUIInputpanelFocusoutActionSet()**
- **ProUIInputpanelInputActionSet()**

Use the function `ProUIInputpanelActivateActionSet()` to set the action callback to be called when the user hits return in an input panel.

Use the function `ProUIInputpanelFocusinActionSet()` to set the focus in action for an input panel. This function is called when the user moves the cursor onto the input panel using the mouse or <TAB> key.

Use the function `ProUIInputpanelFocusoutActionSet()` to set the focus out action for an input panel. This function is called when the user moves the cursor off of the input panel using the mouse or <TAB> key.

Use the function `ProUIInputpanelInputActionSet()` to set the action callback to be called when the user enters a key in an input panel.

## Input Panel Operations

Functions Introduced

- **ProUIInputpanelAnchorSet()**
- **ProUIInputpanelSizeGet()**
- **ProUIInputpanelSizeSet()**
- **ProUIInputpanelMinimumsizeGet()**
- **ProUIInputpanelPositionGet()**
- **ProUIInputpanelPositionSet()**

Use the function `ProUIInputpanelAnchorSet()` to set the position of the input panel with respect to a given anchor location. This function is applicable only if the parent of the input panel is a drawing area.

Use the function `ProUIInputpanelSizeGet()` to get the size of the input panel. This operation is applicable only if the parent is a drawing area.

Use the function `ProUIInputpanelSizeSet()` to set the size of the input panel. This operation is applicable only if the parent is a drawing area. The function will fail, if you specify a value smaller than the minimum size for the input arguments *width* or *height*.

Use the function `ProUIInputpanelMinimumsizeGet()` to retrieve the minimum size of the width and height of the input panel in pixels. Use this function only if the parent is a drawing area.

Use the function `ProUIInputpanelPositionGet()` to get the position of the input panel with respect to its parent. This operation is applicable only if the parent is a drawing area.

Use the function `ProUIInputpanelPositionSet()` to set the position to the input panel with respect to its parent. This operation is applicable only if the parent is a drawing area.

## Label

### Label Attributes

## Label Operations

### Functions Introduced

- **ProUILabelAnchorSet()**
- **ProUILabelSizeSet()**
- **ProUILabelMinimumsizeGet()**
- **ProUILabelPositionGet()**
- **ProUILabelPositionSet()**
- **ProUILabelSizeGet()**

Use the function **ProUILabelAnchorSet()** to set the location to position the label with respect to its parent. This field is used only if the parent is a drawing area.

Use the function **ProUILabelSizeSet()** to set the size of the label. This field is used only if the parent is a drawing area. The function will fail, if you specify a value smaller than the minimum size for the input arguments *width* or *height*.

Use the function **ProUILabelMinimumsizeGet()** to retrieve the minimum size of the width and height of the label in pixels. Use this function only if the parent is a drawing area.

Use the function **ProUILabelPositionGet()** to get the position of the label with respect to its parent. This field is used only if the parent is a drawing area.

Use the function **ProUILabelPositionSet()** to set the position to the label with respect to its parent. This field is used only if the parent is a drawing area.

Use the function **ProUILabelSizeGet()** to get the size of the label. This field is used only if the parent is a drawing area.

## Layout\_2

### Layout Attributes

| Attribute Name                        | Get Function                           | Set Function(s)                                                            |
|---------------------------------------|----------------------------------------|----------------------------------------------------------------------------|
| <a href="#">.AttachBottom on page</a> | • <b>ProUILayoutIsAttachedBottom()</b> | • <b>ProUILayoutAttachBottom()</b><br>• <b>ProUILayoutUnattachBottom()</b> |
| <a href="#">.AttachTop on page</a>    | • <b>ProUILayoutIsAttachedTop()</b>    | • <b>ProUILayoutAttachTop()</b><br>• <b>ProUILayoutUnattachTop()</b>       |

See the topic on [Adding and Removing Components on page 415](#) for description of how to use the `ProUIGridopts` arguments when adding components to a layout.

## Layout Operations

### Functions Introduced

- **ProUILayoutAnchorSet()**
- **ProUILayoutSizeSet()**
- **ProUILayoutMinimumsizeGet()**
- **ProUILayoutPositionGet()**
- **ProUILayoutPositionSet()**
- **ProUILayoutSizeGet()**
- **ProUILayoutIsMapped()**
- **ProUILayoutMappedSet()**
- **ProUILayoutMappedUnset()**

Use the function `ProUILayoutAnchorSet()` to set the position of the layout with respect to a given anchor location. This function is applicable only if the parent of the layout is a drawing area.

Use the function `ProUILayoutSizeSet()` to set the size of the layout. This field is used only if the parent is a drawing area. The function will fail, if you specify a value smaller than the minimum size for the input arguments *width* or *height*.

---

Use the function `ProUILayoutMinimumsizeGet()` to retrieve the minimum size of the width and height of the layout in pixels. Use this function only if the parent is a drawing area.

Use the function `ProUILayoutPositionGet()` to get the position of the layout with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUILayoutPositionSet()` to set the position to the layout with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUILayoutSizeGet()` to get the size of the layout. This field is used only if the parent is a drawing area.

The function `ProUILayoutIsMapped()` specifies if the given layout component is mapped. The value of the output flag is `PRO_B_TRUE` if the layout is mapped, else it is `PRO_B_FALSE`.

The functions `ProUILayoutShow()` and `ProUILayoutHide()` show and hide the layout component respectively, along with its contents.

### Note

The function `ProUILayoutHide` does not hide layouts that are direct children of a tab.

---

Use the function `ProUILayoutMappedSet()` to keep the size of the layout unchanged while working with these functions. To collapse or expand the layout to its nominal size, use the function `ProUILayoutMappedUnset()`.

## List

### List Attributes

| Attribute Name                        | Get Function                                                                               | Set Function(s)                                                                                                                         |

## List Action Callbacks

Functions Introduced

- **ProUListActivateActionSet()**
- **ProUListSelectActionSet()**
- **ProUListTriggerhighlightActionSet()**
- **ProUListFocusinActionSet()**
- **ProUListFocusoutActionSet()**

---

Use the function `ProUIListActivateActionSet()` to set the activate action for a list. This function is called when the return key is pressed or the mouse is double-clicked in the list.

Use the function `ProUIListSelectActionSet()` to set the select action for a list component.

Use the function `ProUIListTriggerhighlightActionSet()` to set the trigger highlight action for a list. This function is called when the user moves the mouse over an item on the list.

Use the function `ProUIListFocusinActionSet()` to set the focus in action for a list. This function is called when the user moves the cursor onto of the list using the mouse or <TAB> key.

Use the function `ProUIListFocusoutActionSet()` to set the focus out action for a list. This function is called when the user moves the cursor off of the list using the mouse or <TAB> key.

## List Operations

### Functions Introduced

- **ProUIListAnchorSet()**
- **ProUIListSizeSet()**
- **ProUIListMinimumsizeGet()**
- **ProUIListPositionGet()**
- **ProUIListPositionSet()**
- **ProUIListSizeGet()**
- **ProUIListStateGet()**
- **ProUIListStateSet()**

Use the function `ProUIListAnchorSet()` to set the position of the list with respect to a given anchor location. This function is applicable only if the parent of the list is a drawing area.

Use the function `ProUIListSizeSet()` to set the size of the list. This field is used only if the parent is a drawing area. The function will fail, if you specify a value smaller than the minimum size for the input arguments *width* or *height*.

Use the function `ProUIListMinimumsizeGet()` to retrieve the minimum size of the width and height of the list in pixels. Use this function only if the parent is a drawing area.

Use the function `ProUIListPositionSet()` to set the position to the list with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUIListPositionGet()` to get the position of the list with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUIListSizeGet()` to get the size of the list. This field is used only if the parent is a drawing area.

Use the function `ProUIListStateGet()` to get the state of the item in the list. The state is applicable only for a "check" type of list and refers to the checked or unchecked status of the item.

Use the function `ProUIListStateSet()` to set the state of the item in the list. The state is applicable only for a "check" type of list and refers to the checked or unchecked status of the item.

## Example 2: To use UI List Functions

The sample code in `UgUIListImplement.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_ui` shows the source code for UI List functions. The application gets the names of the parts that constitute any given drawing and then populates the list area in a newly created dialog with those names.

## Menubar

## Optionmenu Action Callbacks

### Functions Introduced

- **`ProUIOptionmenuActivateActionSet()`**
- **`ProUIOptionmenuSelectActionSet()`**
- **`ProUIOptionmenuInputActionSet()`**
- **`ProUIOptionmenuTriggerhighlightActionSet()`**
- **`ProUIOptionmenuFocusinActionSet()`**
- **`ProUIOptionmenuFocusoutActionSet()`**

Use the function `ProUIOptionmenuActivateActionSet()` to set the activate action for an option menu. This function is called when the user modifies the contents of the option menu. The option menu must be editable. The action callback is called when you press the ENTER key in the input panel of the option menu.

Use the function `ProUIOptionmenuSelectActionSet()` to set the select action for a option menu component.

---

Use the function `ProUIOptionmenuInputActionSet()` to set the input action for an optionmenu. This function is called when the user changes the contents of the option menu. This is only valid for editable optionmenus.

Use the function `ProUIOptionmenuTriggerhighlightActionSet()` to set the trigger highlight action for an optionmenu. This function is called when the user moves the mouse on an item in the drop down list of the optionmenu.

Use the function `ProUIOptionmenuFocusinActionSet()` to set the focus in action for an optionmenu.

Use the function `ProUIOptionmenuFocusoutActionSet()` to set the focus out action for an optionmenu.

## Optionmenu Operations

### Functions Introduced

- **ProUIOptionmenuAnchorSet()**
- **ProUIOptionmenuSizeSet()**
- **ProUIOptionmenuMinimumsizeGet()**
- **ProUIOptionmenuPositionSet()**
- **ProUIOptionmenuPositionGet()**
- **ProUIOptionmenuSizeGet()**

Use the function `ProUIOptionmenuAnchorSet()` to the position of the option menu with respect to a given anchor location. This function is applicable only if the parent of the option menu is a drawing area.

Use the function `ProUIOptionmenuSizeSet()` to set the size of the optionmenu. This field is used only if the parent is a drawing area. The function will fail, if you specify a value smaller than the minimum size for the input arguments *width* or *height*.

Use the function `ProUIOptionmenuMinimumsizeGet()` to retrieve the minimum size of the width and height of the option menu in pixels. Use this function only if the parent is a drawing area.

Use the function `ProUIOptionmenuPositionSet()` to set the position to the optionmenu with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUIOptionmenuPositionGet()` to get the position of the optionmenu with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUIOptionmenuSizeGet()` to get the size of the optionmenu. This field is used only if the parent is a drawing area.

# Progressbar

## Progressbar Attributes

| Attribute Name                      | Get Function                                                                                      | Set Function(s)                                                                                                                                       |

## Progressbar Operations

Functions Introduced

- `ProUIProgressbarAnchorSet()`
- `ProUIProgressbarSizeSet()`

- **ProUIProgressbarMinimumsizeGet()**
- **ProUIProgressbarPositionSet()**
- **ProUIProgressbarPositionGet()**
- **ProUIProgressbarSizeGet()**

Use the function `ProUIProgressbarAnchorSet()` to set the position of the progressbar with respect to a given anchor location. This function is applicable only if the parent of the progressbar is a drawing area.

Use the function `ProUIProgressbarSizeSet()` to set the size of the progressbar. This field is used only if the parent is a drawing area. The function will fail, if you specify a value smaller than the minimum size for the input arguments *width* or *height*.

Use the function `ProUIProgressbarMinimumsizeGet()` to retrieve the minimum size of the width and height of the progress bar in pixels. Use this function only if the parent is a drawing area.

Use the function `ProUIProgressbarPositionSet()` to set the position to the progressbar with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUIProgressbarPositionGet()` to get the position to the progressbar with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUIProgressbarSizeGet()` to get the size of the progressbar. This field is used only if the parent is a drawing area.

## Pushbutton

### Pushbutton Attributes

| Attribute Name                        | Get Function                               | Set Function(s)                                                                    |
|---------------------------------------|--------------------------------------------|------------------------------------------------------------------------------------|
| <a href="#">.AttachBottom on page</a> | • <b>ProUIPushbuttonIsAttachedBottom()</b> | • <b>ProUIPushbuttonAttachBottom()</b><br>• <b>ProUIPushbuttonUnattachBottom()</b> |
| <a href="#">.AttachTop on page</a>    | • <b>ProUIPushbuttonIsAttachedTop()</b>    | • <b>ProUIPushbuttonAttachTop()</b><br>• <b>ProUIPushbuttonUnattachTop()</b>       |
| <a href="#">.AttachRight on page</a>  | • <b>ProUIPushbuttonIsAttachedRight()</b>  | • <b>ProUIPushbuttonAttachRight()</b><br>• <b>ProUIPushbuttonUnattachRight()</b>   |
| <a href="#">.AttachLeft on page</a>   | • <b>ProUIPushbuttonIsAttachedLeft()</b>   | • <b>ProUIPushbuttonAttachLeft()</b><br>• <b>ProUIPushbuttonUnattachLeft()</b>     |
| <a href="#">.BottomOffset on page</a> | • <b>ProUIPushbuttonBottomoffsetGet()</b>  | • <b>ProUIPushbuttonBottomoffsetSet()</b>                                          |
| <a href="#">.Bitmap on page</a>       | • <b>ProUIPushbuttonBitmapGet()</b>        | • <b>ProUIPushbuttonBitmapSet()</b>                                                |

| Attribute Name                      | Get Function                             | Set Function(s)                                                                       |
|-------------------------------------|------------------------------------------|---------------------------------------------------------------------------------------|
| <code>.ButtonStyle</code> on page   | • <b>ProUIPushbuttonButtonstyleGet()</b> | • <b>ProUIPushbuttonButtonstyleSet()</b>                                              |
| <code>.HelpText</code> on page      | • <b>ProUIPushbuttonHelptextGet()</b>    | • <b>ProUIPushbuttonHelptextSet()</b>                                                 |
| <code>.ModalOverride</code> on page | Not Applicable                           | • <b>ProUIPushbuttonModaloverrideSet()</b>                                            |
| <code>.Label</code> on page         | • <b>ProUIPushbuttonTextGet()</b>        | • <b>ProUIPushbuttonTextSet()</b>                                                     |
| <code>.LeftOffset</code> on page    | • <b>ProUIPushbuttonLeftoffsetGet()</b>  | • <b>ProUIPushbuttonLeftoffsetSet()</b>                                               |
| <code>.ParentName</code> on page    | • <b>ProUIPushbuttonParentnameGet()</b>  | • Not Applicable                                                                      |
| <code>.PopupMenu</code> on page     | • <b>ProUIPushbuttonPopupmenuGet()</b>   | • <b>ProUIPushbuttonPopupmenuSet()</b>                                                |
| <code>.Resizable</code> on page     | • <b>ProUIPushbuttonIsResizable()</b>    | • <b>ProUIPushbuttonEnableResizing()</b><br>• <b>ProUIPushbuttonDisableResizing()</b> |
| <code>.RightOffset</code> on page   | • <b>ProUIPushbuttonRightoffsetGet()</b> | • <b>ProUIPushbuttonRightoffsetSet()</b>                                              |
| <code>.Sensitive</code> on page     | • <b>ProUIPushbuttonIsEnabled()</b>      | • <b>ProUIPushbuttonEnable()</b><br>• <b>ProUIPushbuttonDisable()</b>                 |
| <code>.TopOffset</code> on page     | • <b>ProUIPushbuttonTopoffsetGet()</b>   | • <b>ProUIPushbuttonTopoffsetSet()</b>                                                |
| <code>.Visible</code> on page       | • <b>ProUIPushbuttonIsVisible()</b>      | • <b>ProUIPushbuttonShow()</b><br>• <b>ProUIPushbuttonHide()</b>                      |

## Pushbutton Operations

### Functions Introduced

- **ProUIPushbuttonAnchorSet()**
- **ProUIPushbuttonSizeSet()**
- **ProUIPushbuttonPositionSet()**
- **ProUIPushbuttonPositionGet()**
- **ProUIPushbuttonSizeGet()**

Use the function **ProUIPushbuttonAnchorSet()** to set the position of the pushbutton with respect to a given anchor location. This function is applicable only if the parent of the Pushbutton is a drawing area.

Use the function **ProUIPushbuttonSizeSet()** to set the size of the pushbutton. This field is used only if the parent is a drawing area.

Use the function **ProUIPushbuttonPositionSet()** to set the position to the pushbutton with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUIPushbuttonPositionGet()` to get the position to the pushbutton with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUIPushbuttonSizeGet()` to get the size of the pushbutton. This field is used only if the parent is a drawing area.

## Pushbutton Action Callbacks

Function Introduced

- **ProUIPushbuttonActivateActionSet()**

Use the function `ProUIPushbuttonActivateActionSet()` to set the activate action for a pushbutton. This function is called when the user selects the pushbutton.

### Example 3: Controlling Component Visibility or Sensitivity at Runtime

The sample code in `UgUIVisibility.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_ui` shows how to control component visibility or sensitivity at runtime.

## Radiogroup

### Radiogroup Attributes

| Attribute Name                     | Get Function                                     | Set Function(s)                                                                                |
|------------------------------------|--------------------------------------------------|------------------------------------------------------------------------------------------------|
| <code>.AttachBottom on page</code> | • <code>ProUIRadiogroupIsAttachedBottom()</code> | • <code>ProUIRadiogroupAttachBottom()</code><br>• <code>ProUIRadiogroupUnattachBottom()</code> |

| .Visible on page       | • <b>ProUIRadiogroupIsVisible()</b>        | • <b>ProUIRadiogroupShow()</b><br>• <b>ProUIRadiogroupHide()</b>                      |

## Radiogroup Operations

### Functions Introduced

- **ProUIRadiogroupAnchorSet()**
- **ProUIRadiogroupSizeSet()**
- **ProUIRadiogroupMinimumsizeGet()**
- **ProUIRadiogroupPositionSet()**
- **ProUIRadiogroupPositionGet()**
- **ProUIRadiogroupSizeGet()**

Use the function **ProUIRadiogroupAnchorSet()** to set the position of the radiogroup with respect to a given anchor location. This function is applicable only if the parent of the Radiogroup is a drawing area.

Use the function **ProUIRadiogroupSizeSet()** to set the size of the radiogroup. This field is used only if the parent is a drawing area. The function will fail, if you specify a value smaller than the minimum size for the input arguments *width* or *height*.

Use the function **ProUIRadiogroupMinimumsizeGet()** to retrieve the minimum size of the width and height of the radiogroup in pixels. Use this function only if the parent is a drawing area.

Use the function `ProUIRadiogroupPositionSet()` to set the position to the radiogroup with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUIRadiogroupPositionGet()` to get the position to the radiogroup with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUIRadiogroupSizeGet()` to get the size of the radiogroup. This field is used only if the parent is a drawing area.

## Radiogroup Action Callback

Function Introduced:

- **ProUIRadiogroupSelectActionSet()**

Use the function `ProUIRadiogroupSelectActionSet()` to set the select action for a radio group. This function is called when the user selects one of the buttons in the radio group.

### Slider Operations

Functions Introduced

- `ProUISliderAnchorSet()`
- `ProUISliderSizeSet()`

- **ProUISliderMinimumSizeGet()**
- **ProUISliderPositionSet()**
- **ProUISliderPositionGet()**
- **ProUISliderSizeGet()**

Use the function `ProUISliderAnchorSet()` to set the position of the slider with respect to a given anchor location. This function is applicable only if the parent of the Slider is a drawing area.

Use the function `ProUISliderSizeSet()` to set the size of the slider. This field is used only if the parent is a drawing area. The function will fail, if you specify a value smaller than the minimum size for the input arguments *width* or *height*.

Use the function `ProUISliderMinimumSizeGet()` to retrieve the minimum size of the width and height of the slider in pixels. Use this function only if the parent is a drawing area.

Use the function `ProUISliderPositionSet()` to set the position to the slider with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUISliderPositionGet()` to get the position to the slider with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUISliderSizeGet()` to get the size of the slider. This field is used only if the parent is a drawing area.

## Slider Action Callbacks

Function Introduced

- **ProUISliderUpdateActionSet()**

Use the function `ProUISliderUpdateActionSet()` to set the update action for the slider.

### Example 4: Source of Dialog with Slider and Linked InputPanel

The sample code in `UgUISlider.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_ui` shows code for use of a dialog with Slider and Linked InputPanel.

# Spinbox

## Spinbox Action Callbacks

Functions Introduced:

- **ProUISpinboxUpdateActionSet()**
- **ProUISpinboxActivateActionSet()**

Use the function `ProUISpinboxUpdateActionSet()` and `ProUISpinboxActivateActionSet()` to set the update and activate action for a spin box respectively.

## Spinbox Operations

Functions Introduced

- **ProUISpinboxAnchorSet()**
- **ProUISpinboxSizeSet()**
- **ProUISpinboxMinimumsizeGet()**
- **ProUISpinboxPositionSet()**
- **ProUISpinboxPositionGet()**
- **ProUISpinboxSizeGet()**

Use the function `ProUISpinboxAnchorSet()` to set the position of the spinbox with respect to a given anchor location. This function is applicable only if the parent of the Spinbox is a drawing area.

Use the function `ProUISpinboxSizeSet()` to set the size of the spinbox. This field is used only if the parent is a drawing area. The function will fail, if you specify a value smaller than the minimum size for the input arguments *width* or *height*.

Use the function `ProUISpinboxMinimumsizeGet()` to retrieve the minimum size of the width and height of the spin box in pixels. Use this function only if the parent is a drawing area.

Use the function `ProUISpinboxPositionSet()` to set the position to the spinbox with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUISpinboxPositionGet()` to get the position to the spinbox with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUISpinboxSizeGet()` to get the size of the spinbox. This field is used only if the parent is a drawing area.

## Tab Operations

### Functions Introduced

- 
- **ProUITabAnchorSet()**
  - **ProUITabSizeSet()**
  - **ProUITabMinimumsizeGet()**
  - **ProUITabPositionSet()**
  - **ProUITabPositionGet()**
  - **ProUITabSizeGet()**
  - **ProUITabLayoutAdd()**
  - **ProUITabLayoutsInsert()**
  - **ProUITabItemInsert()**
  - **ProUITabItemDelete()**
  - **ProUITabItemNameSet()**
  - **ProUITabItemLabelSet()**
  - **ProUITabItemImageSet()**
  - **ProUITabItemHelptextStringSet()**
  - **ProUITabItemLabelGet()**
  - **ProUITabItemImageGet()**
  - **ProUITabItemHelptextStringGet()**
  - **ProUITabItemExtentsGet()**

Use the function `ProUITabAnchorSet()` to set the position of the Tab with respect to a given anchor location. This function is applicable only if the parent of the Tab is a drawing area.

Use the function `ProUITabSizeSet()` to set the size of the Tab. This field is used only if the parent is a drawing area. The function will fail, if you specify a value smaller than the minimum size for the input arguments *width* or *height*.

Use the function `ProUITabMinimumsizeGet()` to retrieve the minimum size of the width and height of the tab in pixels. Use this function only if the parent is a drawing area.

Use the function `ProUITabPositionSet()` to set the position to the Tab with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUITabPositionGet()` to get the position to the Tab with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUITabSizeGet()` to get the size of the Tab. This field is used only if the parent is a drawing area.

Use the function `ProUITabLayoutAdd()` to add a new layout to the tab. Even if the layout has a label assigned, you must set the tab labels with `ProUITabLabelsSet()` for the decorated tab to show the appropriate labels.

---

Use the function `ProUITabLayoutsInsert()` to insert a new layout after an existing component in the tab. Even if the layouts have labels assigned, you must set the tab labels with `ProUITabLabelsSet()` for the decorated tab to show the appropriate labels.

Use this function `ProUITabItemInsert()` to insert a new item after an existing one in the tab. You can set the tab labels with the `ProUITabLabelsSet()` function (even if the layouts have already been assigned labels), so that the decorated tab displays the correct labels. The input arguments are:

- *dialog*—Specifies the name of the dialog box that contains the tab.
- *component*—Specifies the name of the tab component.
- *sibling*—Inserts the new item after the specified item name.
- *name*—Specifies the name of the new item.

Use this function `ProUITabItemDelete()` to delete an item from the tab. The input arguments are:

- *dialog*—Specifies the name of the dialog that contains tab.
- *component*—Specifies the name of the tab component.
- *name*—Specifies the name of the new item.

Use the function `ProUITabItemNameSet()` to set a new name to the item in the tab.

Use the function `ProUITabItemLabelSet()` to set the label of the item in the tab.

Use the function `ProUITabItemImageSet()` to set the image of the item in the tab.

Use the function `ProUITabItemHelptextStringSet()` to set the text that should be displayed when the cursor is over the item in the tab.

Use the function `ProUITabItemLabelGet()` to get the label of the item in the tab.

Use the function `ProUITabItemImageGet()` to get the image of the item in the tab.

Use the function `ProUITabItemHelptextStringGet()` to get the text that is displayed when the cursor is over the item in the tab.

Use the function `ProUITabItemExtentsGet()` to get the boundary of the item that is in the tab relative to the top left corner of the dialog.

## Tab Action Callbacks

Function Introduced

- **ProUITabSelectActionSet()**

Use the function `ProUITabSelectActionSet()` sets the select action for a tab. This function is called when the user selects the tab.

## Table Cell Functions

### Functions Introduced

- **ProUITableCellLabelSet()**
- **ProUITableCellLabelGet()**
- **ProUITableCellHelpTextSet()**
- **ProUITableIsCellSensitive()**
- **ProUITableCellEnable()**
- **ProUITableCellDisable()**
- **ProUITableCellComponentNameSet()**
- **ProUITableCellComponentNameGet()**
- **ProUITableCellComponentCopy()**
- **ProUITableCellComponentDelete()**
- **ProUITableAnchorCellSet()**
- **ProUITableAnchorCellGet()**
- **ProUITableFocusCellSet()**
- **ProUITableFocusCellGet()**
- **ProUITableCellAttachTop()**
- **ProUITableCellUnattachTop()**
- **ProUITableIsCellAttachedTop()**
- **ProUITableCellAttachBottom()**
- **ProUITableCellUnattachBottom()**
- **ProUITableIsCellAttachedBottom()**
- **ProUITableCellAttachLeft()**
- **ProUITableCellUnattachLeft()**

- 
- **ProUITableIsCellAttachedLeft()**
  - **ProUITableCellAttachRight()**
  - **ProUITableCellUnattachRight()**
  - **ProUITableIsCellAttachedRight()**
  - **ProUITableCellHelptextStringGet()**
  - **ProUITableCellHelptextStringSet()**
  - **ProUITableCellForegroundColorGet()**
  - **ProUITableCellForegroundColorSet()**
  - **ProUITableCellBackgroundColorGet()**
  - **ProUITableCellBackgroundColorSet()**

Use the function `ProUITableCellLabelSet()` to set the text contained in the table cell.

Use the function `ProUITableCellLabelGet()` to get the text contained in the table cell.

Use the function `ProUITableCellHelpTextSet()` to set the help text for the table cell.

Use the function `ProUITableIsCellSensitive()` to determine if the table cell is sensitive to user input.

Use the function `ProUITableCellEnable()` to set the table cell to be sensitive to user input.

Use the function `ProUITableCellDisable()` to set the table cell to be insensitive to user input.

Use the function `ProUITableCellComponentNameSet()` to set the component name contained in the table cell.

Use the function `ProUITableCellComponentNameGet()` to get the component name contained in the table cell.

Use the function `ProUITableCellComponentCopy()` to copy a predefined component and places it in the table in the designated cell. The component will be displayed in this cell.

Use the function `ProUITableCellComponentDelete()` to remove the component contained in the table cell.

Use the function `ProUITableAnchorCellSet()` to set the coordinates of the table selection anchor cell.

Use the function `ProUITableAnchorCellGet()` to get the coordinates of the table selection anchor cell.

Use the function `ProUITableFocusCellSet()` to set the coordinates of the table selection focus cell.

---

Use the function `ProUITableFocusCellGet()` to get the coordinates of the table selection focus cell.

Use the function `ProUITableCellAttachTop()` to attach the contents of the cell to the top of the cell.

Use the function `ProUITableCellUnattachTop()` to unattach the contents of the cell from the top of the cell.

Use the function `ProUITableIsCellAttachedTop()` to determine if the contents of the cell are attached to the top of the cell.

Use the function `ProUITableCellAttachBottom()` to attach the contents of the cell to the bottom of the cell.

Use the function `ProUITableCellUnattachBottom()` to unattach the contents of the cell from the bottom of the cell.

Use the function `ProUITableIsCellAttachedBottom()` to determine if the contents of the cell are attached to the bottom of the cell.

Use the function `ProUITableCellAttachLeft()` to attach the contents of the cell to the left of the cell.

Use the function `ProUITableCellUnattachLeft()` to unattach the contents of the cell from the left of the cell.

Use the function `ProUITableIsCellAttachedLeft()` to determine if the contents of the cell are attached to the left of the cell.

Use the function `ProUITableCellAttachRight()` to attach the contents of the cell to the right of the cell.

Use the function `ProUITableCellUnattachRight()` to unattach the contents of the cell from the right of the cell.

Use the function `ProUITableIsCellAttachedRight()` to determine if the contents of the cell are attached to the right of the cell.

Use the function `ProUITableCellHelptextStringGet()` to get the help-text that is displayed while the cursor is over the table cell.

Use the function `ProUITableCellHelptextStringSet()` to set the help-text to be displayed when the cursor is over the table cell.

Use the function `ProUITableCellForegroundColorGet()` to get the foreground color of the table cell.

Use the function `ProUITableCellForegroundColorSet()` to set the foreground color of the table.

Use the function `ProUITableCellBackgroundColorGet()` to get the background color of the table cell.

Use the function `ProUITableCellBackgroundColorSet()` to set the background color of the table cell.

---

## Example 5: To Assign Components into Table Cells

The sample code in `UgUITables.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_ui` shows how to assign components into table cells.

## Table Row Functions

Functions Introduced

- **ProUITableRowIndexGet()**
- **ProUITableRowRename()**
- **ProUITableRowLabelSet()**
- **ProUITableRowLabelGet()**
- **ProUITableRowsInsert()**
- **ProUITableRowsDelete()**
- **ProUITableRowCellsSelect()**
- **ProUITableRowCellsDeselect()**
- **ProUITableRowCellLabelsSet()**

Use the function `ProUITableRowIndexGet()` to get the index of the table row with the given name.

Use the function `ProUITableRowRename()` to rename the table row.

Use the function `ProUITableRowLabelSet()` to set the user-visible label for the table row.

Use the function `ProUITableRowLabelGet()` to get the user-visible label for the table row.

Use the function `ProUITableRowsInsert()` to insert one or more new rows into the table.

Use the function `ProUITableRowsDelete()` to delete one or more rows from the table.

Use the function `ProUITableRowCellsSelect()` to select the cells of the given rows of the table. The table selection policy must be either Multiple or Extended.

Use the function `ProUITableRowCellsDeselect()` to deselect the cells of the given rows of the table.

Use the function `ProUITableRowCellLabelsSet()` to set the contents of the cells of the rows using a single string.

---

## Table Column Functions

### Functions Introduced

- **ProUITableColumnIndexGet()**
- **ProUITableColumnRename()**
- **ProUITableColumnLabelSet()**
- **ProUITableColumnLabelGet()**
- **ProUITableColumnWidthSet()**
- **ProUITableColumnWidthGet()**
- **ProUITableColumnResizingFactorSet()**
- **ProUITableColumnResizingFactorGet()**
- **ProUITableColumnsInsert()**
- **ProUITableColumnsDelete()**
- **ProUITableColumnCellsSelect()**
- **ProUITableColumnCellsDeselect()**
- **ProUITableResetColumnWidth()**

Use the function `ProUITableColumnIndexGet()` to get the column index for a given column.

Use the function `ProUITableColumnRename()` to rename a table column.

Use the function `ProUITableColumnLabelSet()` to set the user visible label for the column.

Use the function `ProUITableColumnLabelGet()` to get the user-visible label for the column.

Use the function `ProUITableColumnWidthSet()` to set the width of the column in the table.

Use the function `ProUITableColumnWidthGet()` to get the width of the column in the table.

Use the function `ProUITableColumnResizingFactorSet()` to set the resizing factor of the column in the table.

Use the function `ProUITableColumnResizingFactorGet()` to get the resizing factor of the column in the table.

Use the function `ProUITableColumnsInsert()` to insert one or more columns into the table.

Use the function `ProUITableColumnsDelete()` to delete one or more columns from the table.

---

Use the function `ProUITableColumnCellsSelect()` to select the cells of the given columns in the table.

Use the function `ProUITableColumnCellsDeselect()` to deselect the cells of the given columns in the table.

Use the function `ProUITableResetColumnWidth()` to set the column width to the default.

### Example 6: To Access and Modify Names and Labels for the Table Rows and Columns

The sample code in `UgUITables.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_ui` shows how to access and modify names and labels for the Table rows and columns and also to access, allocate and free the string and wide string arrays.

## Table Operations

### Functions Introduced

- **`ProUITableAnchorSet()`**
- **`ProUITableSizeSet()`**
- **`ProUITableMinimumsizeGet()`**
- **`ProUITablePositionSet()`**
- **`ProUITablePositionGet()`**
- **`ProUITableSizeGet()`**
- **`ProUITableComponentCopy()`**
- **`ProUITableComponentDelete()`**

Use the function `ProUITableAnchorSet()` to set the position of the table with respect to a given anchor location. This function is applicable only if the parent of the table is a drawing area.

Use the function `ProUITableSizeSet()` to set the size of the table. This field is used only if the parent is a drawing area. The function will fail, if you specify a value smaller than the minimum size for the input arguments *width* or *height*.

Use the function `ProUITableMinimumsizeGet()` to retrieve the minimum size of the width and height of the table in pixels. Use this function only if the parent is a drawing area.

Use the function `ProUITablePositionSet()` to set the position to the table with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUITablePositionGet()` to get the position to the table with respect to its parent. This field is used only if the parent is a drawing area.

---

Use the function `ProUITableSizeGet()` to get the size of the table. This field is used only if the parent is a drawing area.

Use the function `ProUITableComponentCopy()` to copy a predefined component and place it in the table. The component is not displayed until it is assigned to a table cell using `ProUITableCellComponentNameSet()`. However, you can update the component's properties as needed and display it at a later time.

Use the function `ProUITableComponentDelete()` to delete a specified component from the table.

## Table Action Callbacks

### Functions Introduced

- **`ProUITableArmActionSet()`**
- **`ProUITableDisarmActionSet()`**
- **`ProUITableSelectActionSet()`**
- **`ProUITableActivateActionSet()`**
- **`ProUITableFocusinActionSet()`**
- **`ProUITableFocusoutActionSet()`**
- **`ProUITableColumnselectActionSet()`**

Use the function `ProUITableArmActionSet()` to set the arm action for a table. This function is called when the user changes the selection anchor cell and focus cell in the table.

Use the function `ProUITableDisarmActionSet()` to set the disarm action for a table. This function is called when the user changes the selection focus cell in the table.

Use the function `ProUITableSelectActionSet()` to set the select action for a table. This function is called when the user changes the selected cells in the table.

Use the function `ProUITableActivateActionSet()` to set the activate action for a table. This function is called when the user presses the return key or double-clicks the left mouse button in the table.

Use the function `ProUITableFocusinActionSet()` to set the focus in action for a table.

Use the function `ProUITableFocusoutActionSet()` to set the focus out action for a table.

Use the function `ProUITableColumnselectActionSet()` to set the column selection action for the table. This function is called when the user changes the currently selected table columns.

## Example 7: To Access Selected Names Array from Tables

The sample code in `UgUITables.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_ui` shows how to access selected names array from tables.

## Textarea

### Textarea Attributes

| Attribute Name                     | Get Function                                                                                 | Set Function(s)                                                                                                                             |

## Textarea Operations

### Functions Introduced

- 
- **ProUITextareaAnchorSet()**
  - **ProUITextareaSizeSet()**
  - **ProUITextareaMinimumsizeGet**
  - **ProUITextareaPositionGet()**
  - **ProUITextareaPositionSet()**
  - **ProUITextareaSizeGet()**

Use the function `ProUITextareaAnchorSet()` to set the position of the Textarea with respect to a given anchor location. This function is applicable only if the parent of the Textarea is a drawing area.

Use the function `ProUITextareaSizeSet()` to set the size of the Textarea. This operation is applicable only if the parent is a drawing area. The function will fail, if you specify a value smaller than the minimum size for the input arguments *width* or *height*.

Use the function `ProUITextareaMinimumsizeGet` to retrieve the minimum size of the width and height of the textarea in pixels. Use this function only if the parent is a drawing area.

Use the function `ProUITextareaPositionGet()` to get the position of the Textarea with respect to its parent. This operation is applicable only if the parent is a drawing area.

Use the function `ProUITextareaPositionSet()` to set the position to the Textarea with respect to its parent. This operation is applicable only if the parent is a drawing area.

Use the function `ProUITextareaSizeGet()` to get the size of the Textarea. This operation is applicable only if the parent is a drawing area.

## Textarea Action Callbacks

### Functions Introduced

- **ProUITextareaActivateActionSet()**
- **ProUITextareaFocusinActionSet()**
- **ProUITextareaFocusoutActionSet()**
- **ProUITextareaInputActionSet()**

Use the function `ProUITextareaActivateActionSet()` to set the action callback to be called when the user hits return in an Textarea.

Use the function `ProUITextareaFocusinActionSet()` to set the focus in action for an Textarea. This function is called when the user moves the cursor onto the Textarea using the mouse or <TAB> key.

Use the function `ProUITextareaFocusoutActionSet()` to set the focus out action for an Textarea. This function is called when the user moves the cursor off of the Textarea using the mouse or <TAB> key.

Use the function `ProUITextareaInputActionSet()` to set the action callback to be called when the user enters a key in an Textarea.

## Thumbwheel

### Thumbwheel Attributes

| Attribute Name                        | Get Function                                     | Set Function(s)                                                                                |
|---------------------------------------|--------------------------------------------------|------------------------------------------------------------------------------------------------|
| <a href="#">.AttachBottom on page</a> | • <code>ProUIThumbwheelIsAttachedBottom()</code> | • <code>ProUIThumbwheelAttachBottom()</code><br>• <code>ProUIThumbwheelUnattachBottom()</code> |
| <a href="#">.AttachTop on page</a>    | • <code>ProUIThumbwheelIsAttachedTop()</code>    | • <code>ProUIThumbwheelAttachTop()</code><br>• <code>ProUIThumbwheelUnattachTop()</code>       |
| <a href="#">.AttachRight on page</a>  | • <code>ProUIThumbwheelIsAttachedRight()</code>  | • <code>ProUIThumbwheelAttachRight()</code><br>• <code>ProUIThumbwheelUnattachRight()</code>   |
| <a href="#">.AttachLeft on page</a>   | • <code>ProUIThumbwheelIsAttachedLeft()</code>   | • <code>ProUIThumbwheelAttachLeft()</code><br>• <code>ProUIThumbwheelUnattachLeft()</code>     |
| <a href="#">.BottomOffset on page</a> | • <code>ProUIThumbwheelBottomoffsetGet()</code>  | • <code>ProUIThumbwheelBottomoffsetSet()</code>                                                |
| <a href="#">.HelpText on page</a>     | • <code>ProUIThumbwheelHelpTextGet()</code>      | • <code>ProUIThumbwheelHelpTextSet()</code>                                                    |
| <a href="#">.Integer on page</a>      | • <code>ProUIThumbwheelIntegerGet()</code>       | • <code>ProUIThumbwheelIntegerSet()</code>                                                     |
| <a href="#">.LeftOffset on page</a>   | • <code>ProUIThumbwheelLeftoffsetGet()</code>    | • <code>ProUIThumbwheelLeftoffsetSet()</code>                                                  |
| <a href="#">.MaxInteger on page</a>   | • <code>ProUIThumbwheelMaxintegerGet()</code>    | • <code>ProUIThumbwheelMaxintegerSet()</code>                                                  |
| <a href="#">.MinInteger on page</a>   | • <code>ProUIThumbwheelMinintegerGet()</code>    | • <code>ProUIThumbwheelMinintegerSet()</code>                                                  |
| <a href="#">.ParentName on page</a>   | • <code>ProUIThumbwheelParentnameGet()</code>    | • Not Applicable                                                                               |

## Thumbwheel Operations

### Functions Introduced

- **ProUIThumbwheelAnchorSet()**
- **ProUIThumbwheelSizeSet()**
- **ProUIThumbwheelMinimumsizeGet()**
- **ProUIThumbwheelPositionSet()**
- **ProUIThumbwheelPositionGet()**
- **ProUIThumbwheelSizeGet()**

Use the function `ProUIThumbwheelAnchorSet()` to set the position of the Thumbwheel with respect to a given anchor location. This function is applicable only if the parent of the Thumbwheel is a drawing area.

Use the function `ProUIThumbwheelSizeSet()` to set the size of the Thumbwheel. This field is used only if the parent is a drawing area. The function will fail, if you specify a value smaller than the minimum size for the input arguments *width* or *height*.

Use the function `ProUIThumbwheelMinimumsizeGet()` to retrieve the minimum size of the width and height of the thumb wheel in pixels. Use this function only if the parent is a drawing area.

Use the function `ProUIThumbwheelPositionSet()` to set the position to the Thumbwheel with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUIThumbwheelPositionGet()` to get the position to the Thumbwheel with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUIThumbwheelSizeGet()` to get the size of the Thumbwheel. This field is used only if the parent is a drawing area.

## Thumbwheel Action Callbacks

### Functions Introduced

- **ProUIThumbwheelUpdateActionSet()**

Use the function `ProUIThumbwheelUpdateActionSet()` to set the update action for the Thumbwheel.

### Note

Many of the properties of trees are currently only supported as a part of the resource file. Only very basic trees can be created using programmatic means.

## Adding and Removing Components

| Component Name | Adding Functions                   | Removing Functions                    |
|----------------|------------------------------------|---------------------------------------|
| Checkbutton    | • <b>ProUITreeCheckbuttonAdd()</b> | • <b>ProUITreeCheckbuttonRemove()</b> |
| Drawingarea    | • <b>ProUITreeDrawingareaAdd()</b> | • <b>ProUITreeDrawingareaRemove()</b> |
| Inputpanel     | • <b>ProUITreeInputpanelAdd()</b>  | • <b>ProUITreeInputpanelRemove()</b>  |
| Label          | • <b>ProUITreeLabelAdd()</b>       | • <b>ProUITreeLabelRemove()</b>       |
| Layout         | • <b>ProUITreeLayoutAdd()</b>      | • <b>ProUITreeLayoutRemove()</b>      |
| List           | • <b>ProUITreeListAdd()</b>        | • <b>ProUITreeListRemove()</b>        |
| Optionmenu     | • <b>ProUITreeOptionmenuAdd()</b>  | • <b>ProUITreeOptionmenuRemove()</b>  |
| Progressbar    | • <b>ProUITreeProgressbarAdd()</b> | • <b>ProUITreeProgressbarRemove()</b> |
| Pushbutton     | • <b>ProUITreePushbuttonAdd()</b>  | • <b>ProUITreePushbuttonRemove()</b>  |
| Radiogroup     | • <b>ProUITreeRadiogroupAdd()</b>  | • <b>ProUITreeRadiogroupRemove()</b>  |
| Slider         | • <b>ProUITreeSliderAdd()</b>      | • <b>ProUITreeSliderRemove()</b>      |
| Spinbox        | • <b>ProUITreeSpinboxAdd()</b>     | • <b>ProUITreeSpinboxRemove()</b>     |
| Tab            | • <b>ProUITreeTabAdd()</b>         | • <b>ProUITreeTabRemove()</b>         |
| Table          | • <b>ProUITreeTableAdd()</b>       | • <b>ProUITreeTableRemove()</b>       |
| Tree           | • <b>ProUITreeTreeAdd()</b>        | • <b>ProUITreeTreeRemove()</b>        |
| Textarea       | • <b>ProUITreeTextareaAdd()</b>    | • <b>ProUITreeTextareaRemove()</b>    |
| Thumbwheel     | • <b>ProUITreeThumbwheelAdd()</b>  | • <b>ProUITreeThumbwheelRemove()</b>  |

## Tree Column Functions

Functions Introduced

- **ProUITreeColumnCreate()**
- **ProUITreeColumnTitleGet()**
- **ProUITreeColumnWidthGet()**
- **ProUITreeColumnVisibilityGet()**
- **ProUITreeColumnJustificationGet()**
- **ProUITreeColumnTitleSet()**
- **ProUITreeColumnWidthSet()**
- **ProUITreeColumnVisibilitySet()**
- **ProUITreeColumnJustificationSet()**

---

Use the function `ProUITreeColumnCreate()` to create a column of the given name in the attribute window of the tree. The name must be unique within the scope of the columns of the tree.

Use the function `ProUITreeColumnTitleGet()` to obtain the title of a column in the tree.

Use the function `ProUITreeColumnWidthGet()` to obtain the width of a column in the tree.

Use the function `ProUITreeColumnVisibilityGet()` to obtain the visibility of a column in the tree.

Use the function `ProUITreeColumnJustificationGet()` to obtain the justification of a column in the tree.

Use the function `ProUITreeColumnTitleSet()` to set a title to the column in the tree.

Use the function `ProUITreeColumnWidthSet()` to set a width to the column in the tree.

Use the function `ProUITreeColumnVisibilitySet()` to set visibility of the column in the tree.

Use the function `ProUITreeColumnJustificationSet()` to set justification to the column in the tree.

## Tree Node Functions

### Functions Introduced

- **`ProUITreeNodeComponentSet()`**
- **`ProUITreeNodeChildrenGet()`**
- **`ProUITreeNodeLabelGet()`**
- **`ProUITreeNodeLabelSet()`**
- **`ProUITreeNodeParentGet()`**
- **`ProUITreeNodeTypeGet()`**
- **`ProUITreeNodeTypeSet()`**
- **`ProUITreeNodeExtentsGet()`**
- **`ProUITreeNodeNodesOfTypeGet()`**
- **`ProUITreeNodeAdd()`**
- **`ProUITreeNodeInsert()`**
- **`ProUITreeNodeCollapse()`**
- **`ProUITreeNodeDelete()`**
- **`ProUITreeNodeExists()`**

- 
- **ProUITreeNodeExpand()**
  - **ProUITreeNodeHelptextGet()**
  - **ProUITreeNodeIsVisible()**
  - **ProUITreeNodeIsExpanded()**
  - **ProUITreeNodeIsSelected()**
  - **ProUITreeNodeFontstyleGet()**
  - **ProUITreeNodeHelptextSet()**
  - **ProUITreeNodeShow()**
  - **ProUITreeNodeHide()**
  - **ProUITreeNodeSelect()**
  - **ProUITreeNodeDeselect()**
  - **ProUITreeNodeFontstyleSet()**
  - **ProUITreeNodeMove()**
  - **ProUITreeNodeRename()**
  - **ProUITreeNodeTypeAdd()**
  - **ProUITreeNodeTypeDelete()**
  - **ProUITreeNodeColumnTextSet()**
  - **ProUITreeNodesSelect()**
  - **ProUITreeNodeTypeSelect()**
  - **ProUITreeAllnodesSelect()**
  - **ProUITreeNodesDeselect()**
  - **ProUITreeNodeTypeDeselect()**
  - **ProUITreeAllnodesDeselect()**
  - **ProUITreeNodeVisitAction()**
  - **ProUITreeNodeFilterAction()**
  - **ProUITreeNodesVisit()**

Use the function `ProUITreeNodeComponentSet()` to set the component to be displayed in the given column corresponding to the given node name of the tree.

Use the function `ProUITreeNodeChildrenGet()` to get the child nodes for the node in the tree.

Use the function `ProUITreeNodeLabelGet()` to get the label of the node in the tree.

Use the function `ProUITreeNodeLabelSet()` to set the label of the node in the tree.

---

Use the function `ProUITreeNodeParentGet()` to get the parent of the node in the tree.

Use the function `ProUITreeNodeTypeGet()` to get the name of the node type associated with the node.

Use the function `ProUITreeNodeTypeSet()` to set the name of the node type associated with the node.

Use the function `ProUITreeNodeExtentsGet()` to get the boundary of the node of the tree relative to the top-left corner of the dialog.

Use the function `ProUITreeNodesOfTypeGet()` to get the name of all nodes of the tree associated with the node type.

Use the function `ProUITreeNodeAdd()` to add a new node to the tree.

Use the function `ProUITreeNodeInsert()` to insert a new node before a node in the tree.

Use the function `ProUITreeNodeCollapse()` to collapse a node in the tree making its children invisible.

Use the function `ProUITreeNodeDelete()` to delete the node in the tree.

Use the function `ProUITreeNodeExists()` to checks if the given node exists or not.

Use the function `ProUITreeNodeExpand()` to expand the node of the tree making all of its children visible.

Use the function `ProUITreeNodeHelptextGet()` to get the help text of the node in the tree.

Use the function `ProUITreeNodeIsVisible()` to checks if the node is shown or hidden.

Use the function `ProUITreeNodeIsExpanded()` to checks if the node is expanded or collapsed.

Use the function `ProUITreeNodeIsSelected()` to checks if the node is selected or not.

Use the function `ProUITreeNodeFontstyleGet()` to get the fontstyle of the node.

Use the function `ProUITreeNodeHelptextSet()` to set the helptext of the node in tree.

Use the function `ProUITreeNodeShow()` to display the node in a tree.

Use the function `ProUITreeNodeHide()` to hide the node in the tree.

Use the function `ProUITreeNodeSelect()` to select the node in the tree.

Use the function `ProUITreeNodeDeselect()` to unselect the node in the tree.

---

Use the function `ProUITreeNodeFontstyleSet()` to set fontstyle to the node in the tree.

Use the function `ProUITreeNodeMove()` to move the node in the tree to a child of the given parent node.

Use the function `ProUITreeNodeRename()` to rename the given node of the tree using the given name.

Use the function `ProUITreeNodeTypeAdd()` to add a new node type to the tree using the information supplied in the given data structure. Use `ProUITreeNodeTypeAlloc()` to fill the `ProUITreeNodeType()`.

Use the function `ProUITreeNodeTypeDelete()` to delete a node type from the tree using the information supplied in the given data structure.

Use the function `ProUITreeNodeColumnTextSet()` to set the given text to be displayed in the given column corresponding to the given node of the tree.

Use the function `ProUITreeNodesSelect()` to select an array of nodes in the tree.

Use the function `ProUITreeNodeTypeSelect()` to select all the nodes corresponding to a given node type.

Use the function `ProUITreeAllnodesSelect()` to select all nodes in the tree.

Use the function `ProUITreeNodesDeselect()` to unselect an array of nodes in the tree.

Use the function `ProUITreeNodeTypeDeselect()` to unselect all the nodes corresponding to a given node type.

Use the function `ProUITreeAllnodesDeselect()` to unselect all the nodes in the tree.

Use the function `ProUITreeParentnameGet()` to get the name of the parent to the tree component.

Use the function `ProUITreeChildnamesGet()` to get the name of the children to the tree component.

Use the function `ProUITreeNodeVisitAction()` for visiting nodes.

Use the function `ProUITreeNodeFilterAction()` for filtering nodes.

Use the function `ProUITreeNodesVisit()` to visits all the descendent nodes of the given node in the tree.

## Tree NodeType Functions

### Functions Introduced

- **ProUITreeNodeTypeAlloc()**

- 
- **ProUITreeNodeTypeFree()**
  - **ProUITreeNodeTypeExpandImageSet()**
  - **ProUITreeNodeTypeExpandImageGet()**
  - **ProUITreeNodeTypeCollapseImageSet()**
  - **ProUITreeNodeTypeCollapseImageGet()**
  - **ProUITreeNodeTypePrefixSet()**
  - **ProUITreeNodeTypePrefixGet()**
  - **ProUITreeNodeTypeAppendStringSet()**
  - **ProUITreeNodeTypeAppendStringGet()**
  - **ProUITreeNodeTypeNodesSet()**
  - **ProUITreeNodeTypeNodesGet()**

Use the function `ProUITreeNodeTypeAlloc()` to allocate `ProUITreeNodeType` data.

Use the function `ProUITreeNodeTypeFree()` to free `ProUITreeNodeType` data.

Use the function `ProUITreeNodeTypeExpandImageSet()` to set the image to appear when the nodetype is expanded.

Use the function `ProUITreeNodeTypeExpandImageGet()` to get the image that appears when the nodetype is expanded.

Use the function `ProUITreeNodeTypeCollapseImageSet()` to set the image to appear when the nodetype is collapsed.

Use the function `ProUITreeNodeTypeCollapseImageGet()` to get the image that appears when the nodetype is collapsed.

Use the function `ProUITreeNodeTypePrefixSet()` to set prefix to the nodetype.

Use the function `ProUITreeNodeTypePrefixGet()` to get prefix of the nodetype.

Use the function `ProUITreeNodeTypeAppendStringSet()` to append the string to the nodetype.

Use the function `ProUITreeNodeTypeAppendStringGet()` to get the appended string to the nodetype.

Use the function `ProUITreeNodeTypeNodesSet()` to set the nodes to the nodetype.

Use the function `ProUITreeNodeTypeNodesGet()` to get the nodes to the nodetype.

---

## Tree Operations

### Functions Introduced

- **ProUITreeAnchorSet()**
- **ProUITreeSizeSet()**
- **ProUITreeMinimumsizeGet()**
- **ProUITreePositionSet()**
- **ProUITreePositionGet()**
- **ProUITreeSizeGet()**
- **ProUITreeSashPositionGet()**
- **ProUITreeStateGet()**
- **ProUITreeStateSet()**
- **ProUITreeMixedStateGet()**
- **ProUITreeMixedStateSet()**
- **ProUITreeLastentereditemGet()**
- **ProUITreeNodescrollposSet()**

Use the function `ProUITreeAnchorSet()` to set the position of the Tree with respect to a given anchor location. This function is applicable only if the parent of the Tree is a drawing area.

Use the function `ProUITreeSizeSet()` to set the size of the Tree. This field is used only if the parent is a drawing area. The function will fail, if you specify a value smaller than the minimum size for the input arguments *width* or *height*.

Use the function `ProUITreeMinimumsizeGet()` to retrieve the minimum size of the width and height of the tree in pixels. Use this function only if the parent is a drawing area.

Use the function `ProUITreePositionSet()` to set the position to the Tree with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUITreePositionGet()` to get the position to the Tree with respect to its parent. This field is used only if the parent is a drawing area.

Use the function `ProUITreeSizeGet()` to get the size of the Tree. This field is used only if the parent is a drawing area.

Use the function `ProUITreeSashPositionGet()` to get the position of the sash between the tree hierarchy and the attribute window.

Use the function `ProUITreeStateGet()` to get the state of the item in the tree. The function `ProUITreeStateSet()` sets the state of an item in the tree. The state is applicable only for a "check" type of list and refers to the checked or unchecked status of the item in the tree.

---

The function `ProUITreeMixedStateGet()` returns if the specified item in the tree is in an indeterminate state. Use the function `ProUITreeMixedStateSet()` to set the specified item in the tree in an indeterminate state. An indeterminate state indicates that the component is in mixed state, that is, has no selection. The state is applicable only for a "check" type of tree.

The function `ProUITreeLastentereditemGet()` returns the name of the item, which is was last pointed to by the pointer.

Use the function `ProUITreeNodescrollposSet()` to scroll the window where the named item appears at a defined `ProUILocation`.

## Tree Action Callbacks

Functions Introduced

- **`ProUITreeSelectActionSet()`**
- **`ProUITreeActivateActionSet()`**
- **`ProUITreeFocusinActionSet()`**
- **`ProUITreeFocusoutActionSet()`**
- **`ProUITreeExpandActionSet()`**
- **`ProUITreeCollapseActionSet()`**
- **`ProUITreeTreecellselectActionSet()`**
- **`ProUITreeTreecellactivateActionSet()`**
- **`ProUITreeTreecellinputActionSet()`**
- **`ProUITreeTreecelldeleteActionSet()`**
- **`ProUITreeMoveActionSet()`**
- **`ProUITreeUpdateActionSet()`**

Use the function `ProUITreeSelectActionSet()` to set the select action for a Tree. This function is called when the user changes the selected cells in the Tree.

Use the function `ProUITreeActivateActionSet()` to set the activate action for a Tree. This function is called when the user presses the return key or double-clicks the left mouse button in the Tree.

Use the function `ProUITreeFocusinActionSet()` to set the focus in action for a Tree.

Use the function `ProUITreeFocusoutActionSet()` to set the focus out action for a Tree.

---

Use the function `ProUITreeSelectActionSet()` to set the action function to be called when the tree is selected. The left mouse button, the SPACE key and the navigation keys (if the selection policy is `PROUISELPOLICY_BROWSE` or `PROUISELPOLICY_EXTENDED`) can be used to make a selection in the tree.

Use the function `ProUITreeActivateActionSet()` to set the action function to be called when the tree is activated. The tree is activated by the press of RETURN key or the double click of LEFT mouse button over the node in the tree.

Use the function `ProUITreeExpandActionSet()` to set the action function to be called when the user attempts to expand a tree node by clicking on the '+' sign.

#### **Note**

You must make this callback call `ProUITreeNodeExpand()` to actually expand the node.

---

Use the function `ProUITreeCollapseActionSet()` to set the action function to be called when the user attempts to collapse a tree node by clicking on the '-' sign.

#### **Note**

You must make this callback call `ProUITreeNodeCollapse()` to actually collapse the node.

---

Use the function `ProUITreeFocusinActionSet()` to set the action function to be called when the tree has got keyboard input focus.

Use the function `ProUITreeFocusoutActionSet()` to set the action function to be called when the tree has lost keyboard input focus.

Use the function `ProUITreeTreecellselectActionSet()` to set the action function to be called when the cell of the attribute window of the tree has been selected.

Use the function `ProUITreeTreecellactivateActionSet()` to set the action function to be called when the cell of the attribute window of the tree has been activated.

Use the function `ProUITreeTreecellinputActionSet()` to set the action function to be called when text has been entered into a cell of the attribute window of the tree.

Use the function `ProUITreeTreecelldeleteActionSet()` to set the action function to be called when the DELETE key has been pressed in a cell of the attribute window of the tree.

Use the function `ProUITreeMoveActionSet()` to set the action function to be called when the sash of the tree between the tree hierarchy and the attribute window has been moved.

Use the function `ProUITreeUpdateActionSet()` to register a callback that executes when the user toggles a checkbox for an item.

### Note

When the update action callback runs, the application determines the name of the item by calling the `ProUITreeLastentereditemGet()` function.

## Master Table of Resource File Attributes

| Resource File Attribute | Permitted Values                                    | Description                                                                                                                                                                                                                                                                                             |
|-------------------------|-----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| .ActivateOnReturn       | Of Boolean type<br><br>TRUE (default)               | Flag indicating whether a RETURN key press should generate a UI_ACTIVATE_ACTION callback or whether it should cause the default button in the Dialog to be pressed.                                                                                                                                     |
| .ArcDirection           | Enumerated type<br>ProUIArcDirection                | The direction to use when drawing arcs in a drawing area:<br>PROUIARCDIR_CLOCKWISE draws in a clockwise direction between the two line segments in order to form the arc.<br>PROUIARCDIR_COUNTERCLOCKWISE Draws in a counterclockwise direction between the two line segments in order to form the arc. |
| .ArcFillMode            | Enumerated type<br>ProUIArcFillMode                 | The type of fill to generate for an arc drawn in a drawing area:<br>PROUIARCFILL_PIE—Fills the arc bounded by two line segments joining the endpoints of the arc and its center point.<br>PROUIARCFILL_CHORD—Fills the arc bounded by a single line segment that joins the two endpoints of the arc.    |
| .Alignment              | Enumerated type<br>ProUIAlignment.Default is "left" | The alignment of the text:                                                                                                                                                                                                                                                                              |

| .BackgroundColor        | Integer type based on <code>ProUIColorType</code> or a user defined color type. | The background color of the component as a user specified color or a window color of <code>ProUIColorType</code> .                                                                                                                                                                                                                                                                                                                                                                                            |
| .BgColor                | Integer type based on <code>ProUIColorType</code> or a user defined color type. | The background drawing color of the component as a user specified color or a window color of <code>ProUIColorType</code> . This cannot be set in a resource file.                                                                                                                                                                                                                                                                                                                                             |
| .BottomOffset           | Of Integer type<br>Default Value is -1                                          | The four Offset attributes describe the minimum gap, in pixels, between the component and the edge of the area available to it. The maximum value of an offset is 20. The default, -1, is equivalent to no offset. It is usual in Creo Parametric to put an offset of 4 around each component, so the minimum distance between components is 8 pixels. If you have a vertical column of components such as input panels in a single layout, you can reduce the overall vertical gap between them to 4 pixels. |
| .TopOffset              |                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| .RightOffset            |                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                         |                                          | <p>processing the action callbacks for the component. The following are the valid values:</p> <ul style="list-style-type: none"> <li>PROUIMODALOVERRIDE_NORMAL—The component is blocked whenever the Dialog is blocked. Callbacks are processed without an attempt to dismiss a blocking Dialog and menu.</li> <li>PROUIMODALOVERRIDE_ASYNC—The component is never blocked. Callbacks are processed without an attempt to dismiss a blocking Dialog and menu.</li> <li>PROUIMODALOVERRIDE_CAN_DISMISS_MENUS—The component is never blocked. Callbacks are processed only if a blocking Dialog and menu are successfully dismissed.</li> </ul> |
| .CascadeDirection       | Enumerated type<br>ProUICascadeDirection | <p>The direction in which the MenuPane should cascade when the CascadeButton is activated. Following are the possible values:</p> <p>PROUICASCADEDIR_TOP_LEFT—Up and to the left</p> <p>PROUICASCADEDIR_TOP_RIGHT—Up and to the right</p> <p>PROUICASCADEDIR_BOTTOM_LEFT—Down and to the left</p> <p>PROUICASCADEDIR_BOTTOM_RIGHT—Down and to the right</p>                                                                                                                                                                                                                                                                                   |
| .ChildNames             | Of String array type                     | Names of the children of the component. Read Only. This cannot be specified in a resource file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| .ClassName              | Of String type                           | Name of the class of the component. It is Read-only type. These are defined in the ProUI.h file. This cannot be specified in a resource file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| .ClipChildren           | Of Boolean type<br>TRUE (default), FALSE | Flag indicating whether drawing operations within a DrawingArea are clipped so that they do not overlap any children contained within the DrawingArea.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Resource File Attribute | Permitted Values                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| .Columns                | Of Integer type<br><br>Default Value is 16      | The width of the InputPanel, in character widths. Column widths are determined by the widest possible character in the font of the component (typically 'W'). Thus, a component with a width of 16 will likely hold words with more than 16 characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| .ColumnLabel            | Of WideString type                              | The tab-separated labels to be displayed as the column headers of a List.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

The only purpose of the other dialog style values is to be returned by the function <code>ProUIDialogDialogstyleGet ()</code> on a dialog created by Creo Parametric.</p> |
| .Digits                 | Of Integer type  | The number of digits to be                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Resource File Attribute | Permitted Values                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         | Default Value is -1                       | displayed if the contents are being treated as a number.<br><br>A value of 0 indicates that this attribute should be ignored when formatting the value.                                                                                                                                                                                                                                                                                   |
| .Double                 | Of Float type<br>Default Value is 0       | The double value of the contents of the component.                                                                                                                                                                                                                                                                                                                                                                                        |
| .DoubleFormat           | Of String type<br>Default Value is "%.1f" | The format of the contents of the component if they are being treated as a double. The value of this attribute is a C formatting string, which can handle the precision and value of the contents of the InputPanel.<br><br>Note: the formatting is not applied to values entered into the component until the component's Double value is accessed programmatically.                                                                     |
| .DoubleIncrement        | Of Float type<br>Default Value is 1       | Slow increment to be used when Spinbox value is a double.                                                                                                                                                                                                                                                                                                                                                                                 |
| .DrawingHeight          | Of Integer type<br>Default Value is 100   | Height in pixels of the drawing area.                                                                                                                                                                                                                                                                                                                                                                                                     |
| .DrawingMode            | Enumerated type<br>ProUIDrawingMode       | The drawing mode of the DrawingArea. Following are the possible values:<br><br>PROUIDRWMODE_COPY—Draw using the foreground drawing color.<br><br>PROUIDRWMODE_NOT—Draw, inverting the existing pixels of the component.<br><br>PROUIDRWMODE_AND—Draw using a combination of the foreground drawing color AND the existing pixels.<br><br>PROUIDRWMODE_OR—Draw using a combination of the foreground drawing color OR the existing pixels. |

| Resource File Attribute | Permitted Values                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         |                                          | PROUIDRWMODE_XOR—Draw using a combination of the foreground drawing color XOR the existing pixels.                                                                                                                                                                                                                                                                                                                                                                                                  |
| .DrawingWidth           | Of Integer type<br>Default Value is 100  | Width in pixels of the drawing area.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| .Editable               | Of Boolean type<br>TRUE (default), FALSE | Flag indicating whether the text contents of the component may be modified by the user.                                                                                                                                                                                                                                                                                                                                                                                                             |
| .FastDoubleIncrement    | Of Float type<br>Default Value is 10     | The fast increment to be used when the SpinBox value is a double                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| .FastIncrement          | Of Integer type<br>Default Value is 10   | The fast increment to be used when the SpinBox value is an integer.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| .FillMode               | Enumerated type<br>ProUIFillMode         | The current drawing fill mode of the DrawingArea. Following are the possible values:<br><br>PROUIFILLMODE_SOLID—Fill using the foreground drawing color.<br><br>PROUIFILLMODE_LIGHT_STIPPLE— Fill using a 75% stipple of the foreground and background drawing colors.<br><br>PROUIFILLMODE_MEDIUM_STIPPLE— Fill using a 50% stipple of the foreground and background drawing colors.<br><br>PROUIFILLMODE_HEAVY_STIPPLE— Fill using a 25% stipple of the foreground and background drawing colors. |
| .Focus                  | Of String type                           | The name of the component on which the cursor is positioned when the dialog is activated. If the Dialog is already active then this specifies the name of the component within the Dialog on which on which the focus is set and the cursor is positioned.                                                                                                                                                                                                                                          |
| .FontClass              | Enumerated type<br>ProUIFontClass        | The base font class to be used to draw text in the component.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| .FontSize               | Of Float type<br>Default Value is 0      | Point size of the font used to draw text in the component.                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Resource File Attribute | Permitted Values                                                      | Description                                                                                                                                                    |
|-------------------------|-----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| .FontStyle              | Enumerated type<br>ProUIFontStyle                                     | A bitwise OR of the styles of the font used to draw text in the component.<br><br>Note: All styles are not supported for a given font class and platform.      |
| .ForegroundColor        | Integer type based on<br>ProUIColorType or a user defined color type. | The foreground color of the component.                                                                                                                         |
| .FgColor                | Integer type based on<br>ProUIColorType or a user defined color type. | The foreground drawing color of the component as a user specified color or a window color of ProUIColorType.                                                   |

| Resource File Attribute | Permitted Values                        | Description                                                                                                                                                           |
|-------------------------|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         | 2147483647                              | contents of the component.                                                                                                                                            |
| .MaxLen                 | Of Integer type<br>Default Value is 32  | The maximum length of the text contents of the component.                                                                                                             |
| .MinColumns             | Of Integer type<br>Default Value is 4   | The minimum width of the component, in character widths.                                                                                                              |
| .MinDouble              | Of Float type<br>-8.507e+37             | The minimum double value of the contents of the component.                                                                                                            |
| .MinInteger             | Of Integer type<br>-2147483647          | The minimum integer value of the contents of the component.                                                                                                           |
| .MinRows                | Of Integer type<br>Default Value is 1   | The minimum number of visible rows of the component.                                                                                                                  |
| .MixedState             | Of Integer Array type                   | The indeterminate state of the items in a Tree.                                                                                                                       |
| .Names                  | Of String Array type                    | The names of the items of the component.                                                                                                                              |
| .Numerator              | Of Integer type<br>Default Value is 0   | The numerator value of the fractional contents of the InputPanel.                                                                                                     |
| .Ordinal                | Of Integer type<br>Default Value is 0   | The ordinal value of the fractional contents of the InputPanel.                                                                                                       |
| .Orientation            | Enumerated type<br>ProUIOrientation     | The orientation of the component. It is of the following types:<br><br>PROUI_HORIZONTAL<br><br>PROUI_VERTICAL                                                         |
| .ParentName             | Of String type                          | The name of the parent component of the component.                                                                                                                    |
| .Password               | Of Boolean type<br>FALSE (default)      | Flag indicating whether the component is used for password entry.                                                                                                     |
| .PolygonFillMode        | Enumerated type<br>ProUIPolygonFillMode | The fill mode to be used when drawing Polygons in the DrawingArea.                                                                                                    |
| .PopupMenu              | Of String type                          | Allows you to designate the popup menu for a component This is the name of a MenuPane component to use as a popup menu for the given component.                       |
| .PopupWhenInsen         | Of Boolean type                         | Flag indicating whether the component should display its popup menu when it is insensitive (TRUE) or whether no popup menu should be displayed at such times (FALSE). |
| .ProgressStyle          | Enumerated type<br>ProUIProgressstyle   | The display style of the ProgressBar. It is of the following                                                                                                          |

| Resource File Attribute | Permitted Values                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         |                                              | types: <ul style="list-style-type: none"> <li>• PROUIPROGRESS_NOTEXT</li> <li>• PROUIPROGRESS_VALUE</li> <li>• PROUIPROGRESS_PERCENT</li> <li>• PROUIPROGRESS_INTERVALS</li> </ul>                                                                                                                                                                                                                                                      |
| .RememberPosition       | Of Boolean type<br><br>TRUE (default), FALSE | Controls whether Creo Parametric should store the location of the dialog when it is destroyed, and apply the position to the dialog again if it is shown again.                                                                                                                                                                                                                                                                         |
| .RememberSize           | Of Boolean type<br><br>TRUE (default), FALSE | Controls whether Creo Parametric should store the size the dialog when it is destroyed, and apply the size to the dialog again if it is shown.                                                                                                                                                                                                                                                                                          |
| .Resizable              | Of Boolean type<br><br>TRUE (default), FALSE | Identifies whether a component is allowed to resize based on changing of content. If the content is larger than the component, set this to TRUE to resize to contain the new content. Set it to FALSE to truncate or shorten the content.                                                                                                                                                                                               |
| .ResizableCols          | Of Boolean type<br><br>TRUE (default), FALSE | Flag indicating whether the Tree columns may be resized using the column headers as draggable sashes.                                                                                                                                                                                                                                                                                                                                   |
| .Rows                   | Of Integer type<br><br>Default Value is 8    | The number of rows of the component.                                                                                                                                                                                                                                                                                                                                                                                                    |
| .RowLabels              | Of WideString Array type                     | The labels of the rows of the component. If labels are specified then the table will display row headers, otherwise no row headers are displayed.                                                                                                                                                                                                                                                                                       |
| .RowNames               | Of String Array type                         | The names of the rows of the component.                                                                                                                                                                                                                                                                                                                                                                                                 |
| .RowSelectionPolicy     | Enumerated type<br>ProUISelectionpolicy      | The types of selection supported for the rows of a table: <ul style="list-style-type: none"> <li>• PROUISELPOLICY_SINGLE—No item or one item can be selected at a time. Click to clear a selected item.</li> <li>• PROUISELPOLICY_BROWSE—Only one item can be selected at a time. You cannot clear the selection. You can replace the selected item with another selection.</li> <li>• PROUISELPOLICY_MULTIPLE—More than one</li> </ul> |

| Resource File Attribute | Permitted Values                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| .SelectByCell           | Of Boolean type                       | Flag indicating whether the Tree attribute window allows selection by cell (TRUE) or whether all the cells of the selected node of the Tree are selected when a node is selected (FALSE).                                                                                                                                                                                                                                                                                                                                                                                         |
| .SelectCBRegardless     | Of Boolean type                       | Flag indicating whether the Tree should generate a UI_SELECT_ACTION callback when the currently selected item is re-selected (TRUE) or whether such a selection should be ignored as the state has not changed.                                                                                                                                                                                                                                                                                                                                                                   |
| .Sensitive              | Of Boolean type                       | Flag indicating whether the component is disabled (FALSE) or sensitive to user input (TRUE).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| .Set                    | Of Integer type<br>Default Value is 0 | The state of the component.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| .ShowGrid               | Of Boolean type                       | Flag indicating whether to display the grid lines of the Table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| .StartLocation          | Enumerated type<br>ProUIStartLocation | <p>Following are the possible user defined start locations and anchor positions for a UI component:</p> <p>PROUIDEFAULT_LOCATION—default location</p> <p>PROUITOP_LEFT—top left-hand corner</p>                                                                                                                                                                                                                                                                                                                                                                                   |

| Resource File Attribute | Permitted Values   | Description                                                                                                                                                                                                                                                                                                                                   |
|-------------------------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         |                    | <p>PROUITOP_MIDDLE—top edge</p> <p>PROUITOP_RIGHT—top right-hand corner</p> <p>PROUIMIDDLE_LEFT—left-hand edge</p> <p>PROUIMIDDLE_MIDDLE—middle</p> <p>PROUIMIDDLE_RIGHT—right-hand edge</p> <p>PROUIBOTTOM_LEFT—bottom left-hand corner</p> <p>PROUIBOTTOM_MIDDLE—bottom edge</p> <p>PROUIBOTTOM_RIGHT—bottom right-hand corner</p>          |
| .String                 | Of String type     | The contents of the InputPanel as a string                                                                                                                                                                                                                                                                                                    |
| .TabCharsAllow          | Of Boolean type    | Flag indicating the behavior of the input panel when the TAB key is pressed. If the value is True, inserts a TAB key press into the text of input panel as a tab character. If the value is False, uses the TAB key press for focus traversal. The input panel ignores the tab key press. This attribute may not be set in the resource file. |
| .Tracking               | Of Boolean type    | Flag indicating whether the DrawingArea generates a UI_MOVE_ACTION whenever the pointer is moved over the visible region of the component.                                                                                                                                                                                                    |
| .TreeAttributeWindow    | Of Boolean type    | Flag indicating whether the Tree has an attribute window.                                                                                                                                                                                                                                                                                     |
| .TreeBoxNodes           | Of Boolean type    | Flag indicating whether the nodes of the Tree should be displayed with a bounding rectangle.                                                                                                                                                                                                                                                  |
| .TreeCellInput          | Of WideString type | The text entered by the user which caused a UI_TREE_CELL_INPUT_ACTION to be generated. This cannot be specified in the resource file.                                                                                                                                                                                                         |
| .TreeCellSelCol         | Of String type     | The name of the column of the selected cell of the attribute window of the Tree. This cannot be specified in the resource file.                                                                                                                                                                                                               |

| Resource File Attribute | Permitted Values                       | Description                                                                                                                                                                                                |
|-------------------------|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| .TreeCellSelNode        | Of String type                         | The name of the node of the selected cell of the attribute window of the Tree. This cannot be specified in the resource file.                                                                              |
| .TreeChildOrder         | Of Integer type<br>Default Value is 1  | The method used to order the children of a parent node of the Tree.                                                                                                                                        |
| .TreeColumnsJusts       | Of Integer Array type                  | The justifications of the text of the columns of the attribute window of the Tree.                                                                                                                         |
| .TreeColumnsNames       | Of String Array type                   | The names of the columns of the attribute window of the Tree.                                                                                                                                              |
| .TreeColumnsTitles      | Of WideStringArray type                | The labels of the column headers of the attribute window of the Tree.                                                                                                                                      |
| .TreeColumnsWidths      | Of Integer Array type                  | The widths of the columns of the attribute window of the Tree.                                                                                                                                             |
| .TreeColumnOrder        | Of String Array type                   | The display order of the columns of the attribute window of the Tree. An empty array indicates that the columns should be displayed in the order in which they were created.                               |
| .TreeCurrent            | Of String type                         | The name of the current node of the Tree. This is the node which is drawn with a dotted focus rectangle if the Tree component has the keyboard input focus. This cannot be specified in the resource file. |
| .TreeDisplayRoot        | Of Boolean type                        | Flag indicating whether the root node of the Tree should be displayed (TRUE) or whether it should be hidden from view (FALSE).                                                                             |
| .TreeExpColNode         | Of String type                         | The name of the node of the Tree which was expanded or collapsed to generate a UI_EXPAND_ACTION or a UI_COLLAPSE_ACTION, respectively. This cannot be specified in the resource file.                      |
| .TreeIndicateChildren   | Of Boolean type                        | Flag indicating whether the nodes of the Tree should be displayed with a "..." suffix to indicate that they have children when the nodes themselves are not expanded.                                      |
| .TreeInitialSashPercent | Of Integer type<br>Default Value is 50 | The initial percentage position of the sash of the Tree between the Tree hierarchy and the attribute window of the Tree.                                                                                   |
| .TreeKeyboardInput      | Of Boolean type                        | Flag indicating whether the attribute window of the Tree                                                                                                                                                   |

| Resource File Attribute                   | Permitted Values                                    | Description                                                                                                                                                                                                              |
|-------------------------------------------|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                           |                                                     | should respond to keyboard input and generate a <code>UI_TREE_CELL_INPUT_ACTION</code> .                                                                                                                                 |
| <code>.TreeLinkStyle</code>               | Of Integer type<br>Default Value is 2               | The link-style used to indicate the children of a parent node of the Tree.                                                                                                                                               |
| <code>.TreeNodeTypeAppends</code>         | Of WideStringArray type                             | The text to be appended to the labels of the nodes of the node types of the Tree.                                                                                                                                        |
| <code>.TreeNodeTypeCollapsedImages</code> | Of String Array type                                | The image to be displayed with the collapsed nodes of the node types of the Tree.                                                                                                                                        |
| <code>.TreeNodeTypeExpandedImages</code>  | Of String Array type                                | The image to be displayed with the expanded nodes of the node types of the Tree.                                                                                                                                         |
| <code>.TreeNodeTypeHelpTexts</code>       | Of WideStringArray type                             | The help text of the nodes of the node types of the Tree.                                                                                                                                                                |
| <code>.TreeNodeTypeNames</code>           | Of String Array type                                | The names of the node types of the Tree.                                                                                                                                                                                 |
| <code>.TreeNodeTypePrefixs</code>         | Of WideStringArray type                             | The text to be prepended to the labels of the nodes of the node types of the Tree.                                                                                                                                       |
| <code>.TreeRedraw</code>                  | Of Boolean type                                     | Flag indicating whether redraws are allowed in the Tree. This cannot be specified in the resource file.                                                                                                                  |
| <code>.TreeRootNode</code>                | Of String type                                      | The name of the root node of the Tree. This cannot be specified in the resource file.                                                                                                                                    |
| <code>.TreeState</code>                   | Of Integer Array type                               | The state of each of the items in the Tree.                                                                                                                                                                              |
| <code>.TreeVerticalSBPosition</code>      | Of Integer type<br>Default Value is 3.              | The position of the vertical scrollbar of the Tree.                                                                                                                                                                      |
| <code>.TruncateLabel</code>               | Of Boolean type                                     | Flag indicating whether to truncate the labels of newly created cells in the Table to the size of their cell.<br><br>Modifying this after adding rows and columns will have no effect on any existing cell's appearance. |
| <code>.UnitsPerRotation</code>            | Of Integer type<br>Default Value is 360.            | The amount by which the value of the thumbwheel should be incremented for each complete revolution of the wheel.                                                                                                         |
| <code>.Value</code>                       | Of WideString type                                  | The text contents of the component.                                                                                                                                                                                      |
| <code>.VertAtPoint</code>                 | Enumerated type<br><code>ProUIVertPosition</code> . | The vertical location from the existing dialog to which a new dialog is being positioned vertically.                                                                                                                     |

| Resource File Attribute | Permitted Values                           | Description                                                                                                            |
|-------------------------|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| .VertDialog             | Of String type                             | The name of the dialog to which the existing dialog is relatively being positioned.                                    |
| .VertMethod             | Enumerated type<br>ProUIPositioninMethod   | Vertical positioning method of the dialog.                                                                             |
| .VertPoint              | Enumerated type<br>ProUIVertPosition.      | The vertical location on the dialog, which is used for positioning.                                                    |
| .VertPosOffset          | Of Integer type<br><br>Default Value is -1 | The desired vertical offset between the dialog to which it is being relatively positioned and the existing dialog.     |
| .VertSize               | Of Integer type<br><br>Default Value is -1 | The desired height of the dialog.                                                                                      |
| .Visible                | Of Boolean type                            | Flag indicating whether the component is shown (TRUE) or hidden (FALSE).                                               |
| .VisibleNames           | Of String Array type                       | The names of the visible items of the component. An empty array indicates that every item of the component is visible. |
| .VisibleRows            | Of Integer type<br><br>Default Value is 4  | The number of visible rows of the component.                                                                           |
| .WideString             | Of WideString type                         | The contents of the InputPanel as a wide-string.                                                                       |
| .Width                  | Of Integer type<br><br>Default Value is -1 | Width of the component, in pixels.                                                                                     |

## Using Resource Files

Resource files are text files that describe the overall structure of a dialog box.

### Note

For most Creo TOOLKIT applications, it is not required to use resource files. Instead you can use the functions described in the previous sections to create, lay out, and populate dialog boxes directly. Information in this section is provided for the few applications that still require resource files.

When the Creo TOOLKIT application wants to show a dialog box to the Creo Parametric user, it simply asks Creo Parametric to load the dialog box from the resource file. The first task for the Creo TOOLKIT user who wants to display a dialog box is to write the resource file.

The resource file describes:

- Overall attributes of the dialog box.
- A list of components it contains.
- Attributes of the components themselves and the relative positions of the components.
- Rules for how they behave when the user resizes the dialog box.

Many of the dialog box and component attributes can also be read and modified programmatically with Creo TOOLKIT functions.

A resource file must be called `dialog_name.res` where `dialog_name` is the name of the dialog box. The name of the resource file should be in the lower case. Resource files used by the Creo TOOLKIT application must be stored under the `text` directory referred to by the `text_dir` statement in the Creo TOOLKIT registry file.

## Location and Translation of Resource Files

If the application uses language-specific directories, the resource file must be located in the `<application_text_dir>/<language_dir>/resource` directory. One resource file must exist for each language supported by the application. If the application supports only one language, then the resource file may be located in the `<application_text_dir>/resource` directory.

A Creo TOOLKIT application can optionally include only one resource file for all supported languages in the `<application_text_dir>/resource` directory. This application should also include a text file containing the translated entities and translated text for each additional language, in the format used by the function `ProMessageDisplay()`, in the `<application_text_dir>/resource/<language_dir>` directory. The translation text file should include the following items:

- The component and attribute for each translated item in line 1
- The English text in line 2
- The translated entities and translated text in line 3
- Line 4 should be left blank

Function Introduced:

- **ProUITranslationFilesEnable()**

Use the function `ProUITranslationFilesEnable()` to set your Creo TOOLKIT application to use the single resource file and multiple translation files method of deploying resource files for translated dialog boxes. Call this function from your application's `user_initialize()` function before any call is made to another `ProUI*` function.

---

## Syntax of Resource Files

The resource file is composed of nested statements; each statement is enclosed in parentheses, and contains either a keyword or the name of a dialog or component attribute followed by one or more values and/or other statements.

The top-level statement in a resource file for dialog must always be

```
(
Dialog dialog_name (other statements...)
)
```

where `dialog_name` is the name of the dialog itself. The dialog name is used to refer to the dialog from the source code of the application. The name of a dialog can be of any length, and contains alphanumeric characters and underscores. Case is ignored.

If the resource file contains only a layout, the top-level statement would be

```
(
Layout layout_name (other statements...)
)
```

instead. Collectively, the top statement describes the outermost container in the resource file.

The two statements that follow the name of the container are always **Components** and **Resources**.

The **Components** statement simply lists the types and names of the components that the dialog contains.

Components of type **Layout**, **MenuPane**, **CascadeButton**, **Table**, or **Tree** may have their own container-level statements following the **Dialog** statement. The formats of these statements are exactly the same as the **Dialog** statement.

If one of the components is a tab, the layouts that the tab contains are listed after the tab name in the **Components** part of the **Dialog** statement. Similarly, if one of the components is a **MenuBar** or a **CascadeButton**, the **MenuPanes** that it contains are listed after the **MenuBar** name in the **Components** part of the **Dialog** statement.

A **Resources** statement contains one or more attribute assignments. Each attribute assignment statement is of this form

```
(componentname.attributename value)
```

The **Resource** statement defines the attributes of the dialog and the components, and the **Layout** which defines the relative positions of the components, and the way in which they behave when the dialog is resized. If the component name is missing, the statement (for example, `(.attributename value)`) will be assumed to apply to an attribute of the dialog or layout itself. The attributes and their values are described in detail in the following sections of this section.

The last attribute statement in a **Resources** statement is a special one called `.Layout`. The value of a `.Layout` statement is always a single statement of type **Grid**. The **Grid** statement describes a flexible grid of rows and columns in

---

which the components are placed; this defines the neighbor-relations between components, in other words their relative positions. The absolute positions, and the sizes, of the components may change as the grid stretches and shrinks in response to the user resizing the window containing the dialog. Components of type `MenuPane` do not require a `.Layout` statement.

The `Grid` statement contains the following values:

- `Rows` statement—lists the rows in the grid.
- `Cols` statement—lists the columns in the grid.
- `Values` list—specify the contents of each grid location in turn, reading left-to-right, top-to-bottom. Each of the values can be either
  - The name of a component
  - A `Pos` statement, to specify the row and column number of the next component in the list, if it is not in the next available location. A `Pos` statement allows you to skip some locations, leaving them empty.
  - Another `Grid` statement, to show that the location contains several components on their own local grid.

The value of a `Rows` or `Cols` statement is a list of integers, one for each row or column. The value of the integer is 0 if the row or column cannot be resized when user resized the dialog. the integer value is 1 if it can be resized. (It is normal to set this to 1, so that all the components in the dialog will stretch when the dialog stretches.)

The size and position of the components within the grid is also partly determined by the values set for the `Attach` and `Offset` attributes described in more detail in the section [Master Table of Resource File Attributes on page 439](#).

### Note

Ensure that the resource file contains a new line after the last parenthesis, or else the function `ProUIDialogCreate()` will return an error.

---

## Example 8: Dialog with All Components

```
(Dialog allcomponents
 (Components
 (PushButton PushButton1)
 (PushButton PushButton2)
 (Tab Tab3
 (Layout11
 (Layout8)

## Example 9: Resource File for Dialog with Four Components on 2x2 Grid

This example shows a simple dialog which contains four components on a single 2-by-2 grid.

```

(Dialog Simple
 (Components
 (PushButton
 OK)
 (PushButton
 Cancel)
 (Label
 RadioLabel)
 (RadioGroup
 Tolgroup)
)
 (Resources
 (OK.Label
 "OK")
 (OK.TopOffset
 4)
 (OK.BottomOffset
 4)
 (OK.LeftOffset
 4)
 (OK.RightOffset
 4)
 (Cancel.Label
 "Cancel")
 (Cancel.TopOffset
 4)
 (Cancel.BottomOffset
 4)
 (Cancel.LeftOffset
 4)
 (Cancel.RightOffset
 4)
 (RadioLabel.Label
 "Value to use")
 (RadioLabel.TopOffset
 4)
 (RadioLabel.BottomOffset
 4)
 (RadioLabel.LeftOffset
 4)
 (RadioLabel.RightOffset
 4)
 (Tolgroup.Orientation
 True)
 (Tolgroup.Names
 "Top"
 "Middle"
 "Bottom")
 (Tolgroup.Labels
 "Upper limit"
 "Nominal"
 "Lower limit")
 (.Label
 "Simple Dialog")
 (.Layout
)
)

```

```

 (Grid (Rows 1 1) (Cols 1 1)
 RadioLabel
 Tolgroup
 OK
 Cancel
)
)
)
)

```

## Example 10: Resource File for Subgrid Dialog

This example shows the resource file for the preceding subgrid dialog.

```

(Dialog subgrid
 (Components
 (PushButton OK)
 (PushButton Cancel)
 (InputPanel FeatNamePanel)
 (Label FeatNameLabel)
)
 (Resources
 (OK.Label "OK")
 (OK.TopOffset 4)
 (OK.BottomOffset 4)
 (OK.LeftOffset 4)
 (OK.RightOffset 4)
 (Cancel.Label "Cancel")
 (Cancel.TopOffset 4)
 (Cancel.BottomOffset 4)
 (Cancel.LeftOffset 4)
 (Cancel.RightOffset 4)
 (FeatNamePanel.TopOffset 4)
 (FeatNamePanel.BottomOffset 4)
 (FeatNamePanel.LeftOffset 4)
 (FeatNamePanel.RightOffset 4)
 (FeatNameLabel.Label "Feature name")
 (.Label "Subgrid")
 (.Layout
 (Grid (Rows 1 1 1) (Cols 1)
 FeatNameLabel
 FeatNamePanel
 (Grid (Rows 1) (Cols 1 1)
 OK
 Cancel
)
)
)
)
)

```

## Example 11: Resource File for Subgrid Dialog with Resize

A better way to lay out the dialog in the previous example would be to place the input panel text to the left of the input panel. If this were done with a single 2-by-2 grid, the input panel label and panel itself would resize to take up the same width as the **OK** and **Cancel** buttons. To avoid this you can put the first two components in a layout of their own, which therefore has its own grid, so the columns can take up their own widths.

This example demonstrates this method.

```
(Dialog subgrid
 (Components
 (PushButton OK)
 (PushButton Cancel)
 (InputPanel FeatNamePanel)
 (Label FeatNameLabel)
)
 (Resources
 (OK.Label "OK")
 (OK.TopOffset 4)
 (OK.BottomOffset 4)
 (OK.LeftOffset 4)
 (OK.RightOffset 4)
 (Cancel.Label "Cancel")
 (Cancel.TopOffset 4)
 (Cancel.BottomOffset 4)
 (Cancel.LeftOffset 4)
 (Cancel.RightOffset 4)
 (FeatNamePanel.TopOffset 4)
 (FeatNamePanel.BottomOffset 4)
 (FeatNamePanel.LeftOffset 4)
 (FeatNamePanel.RightOffset 4)
 (FeatNameLabel.Label "Feature name")
 (.Label "Subgrid")
 (.Layout
 (Grid (Rows 1 1 1) (Cols 1)
 FeatNameLabel
 FeatNamePanel
 (Grid (Rows 1) (Cols 1 1)
 OK
 Cancel
)
)
)
)
)
```

---

## Example 12: Resource File with Offsets, Attachments, and Help Text

This example shows a section of resource file which specifies offsets, attachments, and help text is shown below. This is an extended version of the previous example.

```
(Resources
 (FeatNameLabel.Label "Feature name")
 (FeatNameLabel.AttachLeft True)
 (FeatNameLabel.TopOffset 4)
 (FeatNameLabel.BottomOffset 4)
 (FeatNameLabel.LeftOffset 4)
 (FeatNameLabel.RightOffset 4)
 (FeatNamePanel.HelpText "Enter the Feature name
here.")
 (FeatNamePanel.TopOffset 4)
 (FeatNamePanel.BottomOffset 4)
 (FeatNamePanel.LeftOffset 4)
 (FeatNamePanel.RightOffset 4)

)
```

The .Bitmap attribute is the name of a file which contains a bitmap description of an image which should be applied to the component. The file can be one of the following types:

- .GIF
- .PNG
- .PCX
- .BMP
- .ICO
- .CUR

If you supply only the root of the filename, the .bif format will be assumed.

## Example 13: Resource File with Text Question, OK and Cancel Buttons

This example shows the use of a simple dialog, which contains a text question and **OK** and **Cancel** buttons. It would be used for any kind of confirmation request.

For a programatic method of creating this dialog box refer to [Example 1: Source for Dialog with Text Question, OK and Cancel Buttons on page 371](#).

```
(Dialog confirm
 (Components
 (Label Question)
 (PushButton OK)
 (PushButton Cancel)
)
)
```

```

(Resources
 (Question.Label "Dummy label")
 (Question.TopOffset 4)
 (Question.BottomOffset 4)
 (Question.LeftOffset 4)
 (Question.RightOffset 4)
 (OK.Label "OK")
 (OK.TopOffset 4)
 (OK.BottomOffset 4)
 (OK.LeftOffset 4)
 (OK.RightOffset 4)
 (Cancel.Label "Cancel")
 (Cancel.TopOffset 4)
 (Cancel.BottomOffset 4)
 (Cancel.LeftOffset 4)
 (Cancel.RightOffset 4)
 (.Label "Confirm")
 (.Layout
 (Grid (Rows 1 1) (Cols 1)
 Question
 (Grid (Rows 1) (Cols 1 1)
 OK Cancel
)
)
)
)
)
)
)

```

## Example 14: UI List Resource File

The example below shows the resource file used to create UI List. For a programmatic method of creating the UI List refer to [Example 2: To use UI List Functions on page](#).

```

(Dialog ug_uilist
 (Components
 (SubLayout ug_uilist_layout1)
 (SubLayout ug_uilist_layout2)
)

 (Resources
 (.Label "UI List")
 (.Layout
 (Grid (Rows 1 1) (Cols 1)
 ug_uilist_layout1
 ug_uilist_layout2
)
)
)
)
)
)

```

```

(Layout ug_uilist_layout1
 (Components
 (List ug_uilist_comp)
 (Label ug_uilist_label_1)
 (TextArea ug_uilist_txtarea)
 (Label ug_uilist_lable_2)
)

 (Resources

 (Cancel.TopOffset 4)
 (Cancel.BottomOffset 4)
 (Cancel.LeftOffset 4)
 (Cancel.RightOffset 4)
 (.Layout
 (Grid (Rows 1) (Cols 1 1)
 OK Cancel
)
)
)
)
)

```

## Example 19: UG Tables Resource File

The following example shows a resource file containing a table. Components may be assigned to a table through the table layout. Components of the table layout are invisible until assigned or copied in to a table cell.

```
(Dialog ugitableexample
 (Components
 (SubLayout
 (SubLayout
 (OptionsMenu
 ToCopy)
)
)
)
 (Resources
 (ToCopy.Visible
 False)
 (ToCopy.AttachTop
 True)
 (ToCopy.AttachBottom
 True)
 (ToCopy.Names
 "ONE"
 "MANY")
 (ToCopy.Labels
 "Select One"
 "Select Many")
 (.Label
 "UG Tables")
 (.Layout
 (Grid (Rows 1 0 1) (Cols 1)
 TableLayout
 ButtonLayout
 ToCopy
)
)
)
)

(Layout TableLayout
 (Components
 (Table
 LargeTable)
)
 (Resources
 (LargeTable.Columns
 40)
 (LargeTable.MinRows
 4)
 (LargeTable.TopOffset
 4)
 (LargeTable.BottomOffset
 4)
 (LargeTable.LeftOffset
 4)
 (LargeTable.RightOffset
 4)
 (LargeTable.RowNames
 "A"
 "B"
 "C"
 "D"
 "E")
 (LargeTable.ColumnNames
 "1"
 "2"
 "3")
)
)
```

---

```

 (LargeTable.RowLabels
 "4")
 "Alpha"
 "Beta"
 "Gamma"
 "Delta"
 "Epsilon")
 (LargeTable.ColumnLabels
 "One"
 "Two"
 "Three"
 "Four")
 (LargeTable.ShowGrid
 (.AttachLeft
 True)
 (.AttachRight
 True)
 (.AttachTop
 True)
 (.AttachBottom
 True)
 (.Layout
 (Grid (Rows 1) (Cols 1)
 LargeTable
)
)
)
)

(TableLayout LargeTable
 (Components
 (PushButton
 BaseButton)
 (CheckButton
 BaseCheckButton)
 (InputPanel
 BaseInputPanel)
)

 (Resources
 (BaseButton.Label
 "Table Button")
 (BaseCheckButton.Label
 "Table Check Button")
 (BaseInputPanel.Value
 "Table Input Panel")
)
)

(Layout ButtonLayout
 (Components
 (PushButton
 CloseButton)
 (PushButton
 ModifySelectButton)
 (Label
 Label1)
)

 (Resources
 (CloseButton.Label
 "Close")
 (CloseButton.TopOffset
 4)
 (CloseButton.BottomOffset
 4)
 (CloseButton.LeftOffset
 4)
 (CloseButton.RightOffset
 4)
 (ModifySelectButton.Label
 "Toggle cells")
)
)

```

```

 (ModifySelectButton.Visible False)
 (ModifySelectButton.TopOffset 4)
 (ModifySelectButton.BottomOffset 4)
 (ModifySelectButton.LeftOffset 4)
 (ModifySelectButton.RightOffset 4)
 (.Layout
 (Grid (Rows 1 1) (Cols 1 1 1)
 (Pos 1 3)
 Label1
 ModifySelectButton
 CloseButton
)
)
)
)

```

## Example 20: UG Tables Component Resource File

The following example demonstrates different methods that can be used to assign components into table cells. The example directly assigns a stored component, copies a stored component, copies a component from elsewhere in the dialog, and copies a component from another independent dialog.

The [Example 19: UG Tables Resource File on page 478](#) is the primary resource file for the following example. The table components dialog is another dialog from which the following resource code will copy a component into the table.

For a programatic method of assigning components into table cells refer to [Example 5: To Assign Components into Table Cells on page .](#)

```

(Dialog uguitablecomponents
 (Components
 (PushButton ExternalButtonToCopy)
)

 (Resources
 (ExternalButtonToCopy.Label "From other dialog...")
 (.Layout
 (Grid (Rows 1) (Cols 1)
 ExternalButtonToCopy
)
)
)
)

```

## NakedWindow Operations

NakedWindow is an application defined area where controls can be positioned precisely by the application code.

---

It is recommended that you use the NakedWindow component:

- To contain application defined content. For example, a Win32 HWND object whose content is not being ported.
- To have precise control over child position.

### Note

Use the DrawingArea component to draw your own content.

---

### Functions Introduced

- **ProUINakedwindowShow()**
- **ProUINakedwindowHide()**
- **ProUINakedwindowIsVisible()**
- **ProUINakedwindowEnable()**
- **ProUINakedwindowDisable()**
- **ProUINakedwindowIsEnabled()**
- **ProUINakedwindowMappedSet()**
- **ProUINakedwindowMappedUnset()**
- **ProUINakedwindowIsMapped()**
- **ProUINakedwindowEnablePopupwheninsensitive()**
- **ProUINakedwindowDisablePopupwheninsensitive()**
- **ProUINakedwindowIsPopupwheninsensitiveEnabled()**
- **ProUINakedwindowEnableAlwaysontop()**
- **ProUINakedwindowDisableAlwaysontop()**
- **ProUINakedwindowIsAlwaysontopEnabled()**
- **ProUINakedwindowAttachLeft()**
- **ProUINakedwindowUnattachLeft()**
- **ProUINakedwindowIsAttachedLeft()**
- **ProUINakedwindowAttachRight()**
- **ProUINakedwindowUnattachRight()**
- **ProUINakedwindowIsAttachedRight()**
- **ProUINakedwindowAttachTop()**
- **ProUINakedwindowUnattachTop()**
- **ProUINakedwindowIsAttachedTop()**

- **ProUINakedwindowAttachBottom()**
- **ProUINakedwindowUnattachBottom()**
- **ProUINakedwindowIsAttachedBottom()**

Use the function `ProUINakedwindowShow()` to make the naked window visible.

Use the function `ProUINakedwindowHide()` to make the naked window invisible.

Use the function `ProUINakedwindowHide()` to determine if the naked window is visible or invisible.

Use the function `ProUINakedwindowEnable()` to set the naked window and all its children to be sensitive to user input.

The function `ProUINakedwindowDisable()` ignores the flag children always-on-top when arranging them.

The function `ProUINakedwindowIsEnabled()` checks if the naked window is sensitive or insensitive to the user input.

Use the function `ProUINakedwindowMappedSet()` to set the naked window to occupy space when invisible.

The function `ProUINakedwindowMappedUnset()` sets the naked window not to occupy space when invisible.

The function `ProUINakedwindowIsMapped()` checks if the naked window occupies any space when it is invisible.

The function `ProUINakedwindowEnablePopupwheninsensitive()` shows the popup menu when the naked window is insensitive.

The function `ProUINakedwindowDisablePopupwheninsensitive()` hides the popup menu when the naked window is insensitive.

The function

`ProUINakedwindowIsPopupwheninsensitiveEnabled()` checks the status (shown/hidden) of the popup menu when the naked window is insensitive. The output state is a `ProBoolean` and is `PRO_B_TRUE` when the popup menu is shown for the insensitive naked window; `PRO_B_FALSE` when the popup menu is hidden for the insensitive naked window.

Use the function `ProUINakedwindowEnableAlwaysontop()` to make children that have always-on-top enabled to be always placed above their siblings in the Z-order.

The function `ProUINakedwindowDisableAlwaysontop()` to ignore the flag children always-on-top when arranging them.

---

The function `ProUINakedwindowIsAlwaysontopEnabled()` checks if the `NakedWindow` always places children with always-on-top behavior enabled to always be above their siblings in the Z-order when arranging them. The output state is a `ProBoolean` and is `PRO_B_TRUE` if the `NakedWindow` always places children with always-on-top behavior enabled to always be above their siblings in the Z-order, `PRO_B_FALSE` otherwise

Use the function `ProUINakedwindowAttachLeft()` to attach the naked window at left side of the parent component

Use the function `ProUINakedwindowUnattachLeft()` to not attach the naked window at left side of the parent component.

The function `ProUINakedwindowIsAttachedLeft()` checks if the naked window is attached at left side of the parent component. The output state is a `ProBoolean` and is `PRO_B_TRUE` when the naked window is attached at left side of the parent component. `PRO_B_FALSE` when the naked window is not attached at left side of the parent component.

Use the function `ProUINakedwindowAttachRight()` to attach the naked window at right side of the parent component

Use the function `ProUINakedwindowUnattachRight()` to not attach the naked window at right side of the parent component.

The function `ProUINakedwindowIsAttachedRight()` checks if the naked window is attached at right side of the parent component. The output state is a `ProBoolean` and is `PRO_B_TRUE` when the naked window is attached at right side of the parent component. `PRO_B_FALSE` when the naked window is not attached at right side of the parent component.

Use the function `ProUINakedwindowAttachTop()` to attach the naked window at top side of the parent component.

Use the function `ProUINakedwindowUnattachTop()` to not attach the naked window at top side of the parent component.

The function `ProUINakedwindowIsAttachedTop()` checks if the naked window is attached at top side of the parent component. The output state is a `ProBoolean` and is `PRO_B_TRUE` when the naked window is attached at top side of the parent component. `PRO_B_FALSE` when the naked window is not attached at top side of the parent component.

Use the function `ProUINakedwindowAttachBottom()` to attach the naked window at bottom side of the parent component.

Use the function `ProUINakedwindowUnattachBottom()` to not attach the naked window at bottom side of the parent component.

The function `ProUINakedwindowIsAttachedBottom()` checks if the naked window is attached at bottom side of the parent component. The output state is a `ProBoolean` and is `PRO_B_TRUE` when the naked window is attached at bottom side of the parent component. `PRO_B_FALSE` when the naked window is not attached at bottom side of the parent component.

## User Interface: Dashboards

### User Interface: Dashboards

This section introduces the basics of dashboards and describes how Creo TOOLKIT offers the capability to create and control dashboards. Creo TOOLKIT applications can construct dashboards for any tool where they would typically require a dialog box.

The behavior of the Creo TOOLKIT dashboard is similar to the Creo Parametric dashboard. The TOOLKIT dashboards use the same commands and dismiss mechanism as the native Creo Parametric dashboard. However, individual commands may have different accessibility logic and so different dashboards can have slightly different commands available.

### Introduction to Dashboards

A dashboard is an embedded "dialog box" at the top of the Creo Parametric graphics window. A dashboard typically appears when you create or modify a feature in Creo Parametric. It offers the necessary controls, inputs, status and guidance for creating or editing of features.

## Dashboard components

- 1 Tool Icon
- 2 Dialog Bar
- 3 Slide-down Panels
- 4 Standard Buttons

A dashboard consists of the following components:

- A main dialog bar, which show the commonly used commands and entry fields. You perform most of your modeling tasks in the graphics window and the dialog bar. When you activate a tool, the dialog bar displays commonly used options and collectors.
- Standard buttons for controlling the tool.
- Slide-down panels that open to reveal less commonly-used functionality. You can use them to perform advanced modeling actions or retrieve comprehensive feature information.
- A bitmap identifies the tool (typically the same icon used on buttons that invoke the tool).

Creo Parametric uses the dashboard to create features that involve extensive interaction with user interface components and geometry manipulation. You can use dashboards in Creo TOOLKIT applications:

- Where a dialog box is too large in size or is intrusive onto the graphics window. Dashboards enable you to make a smooth-flow tool.
- To present a streamlined "simple-user" activity with more complicated actions available to "expert users".
- Where Creo TOOLKIT dashboards are not only limited to feature creation activities and solid model modes.

## Dashboard

An opaque pointer `ProUIDashboard` is a handle to the overall dashboard tool after it has been shown.

### Showing a Dashboard

Functions Introduced:

- **`ProUIDashboardShow()`**
- **`ProUIDashboardshowoptionsAlloc()`**

- **ProUIDashboardshowoptionsNotificationSet()**
- **ProUIDashboardshowoptionsTitleSet()**
- **ProUIDashboardshowoptionsIconSet()**
- **ProUIDashboardshowoptionsHelpTextSet()**
- **ProUIDashboardshowoptionsDefaultOpenSet()**
- **ProUIDashboardshowoptionsFree()**
- **ProUIDashboardDestroy()**

Use the function `ProUIDashboardShow()` to push a new dashboard User Interface into the dashboard stack mechanism. The dashboard will be shown in the message area of Creo Parametric. This function creates an event loop, and thus does not exit until the dashboard is being dismissed.

Use the function `ProUIDashboardshowoptionsAlloc()` to allocate a handle containing data used to build a dashboard. The input arguments for this function are:

- *main\_page*—Specifies the main page for the dashboard.
- *slideup\_pages*—Specifies a `ProArray` of handles representing the slide-down pages, if needed.
- *appdata*—Specifies the application data to be stored with the dashboard.

Use the function `ProUIDashboardshowoptionsNotificationSet()` to assign a callback function to be called for the indicated event occurrence in the dashboard. The input arguments for this function are:

- *options*—Specifies a handle to data used to build a dashboard.
- *notification*—Specifies the notification function to be called for the given event.
- *appdata*—Specifies the application data to be passed to the callback function when it is invoked.

You can register event notifications for the following events on the dashboard:

- `PRO_UI_DASHBOARD_CREATE`—when the dashboard is first initialized (before the pages are initialized).
- `PRO_UI_DASHBOARD_SHOW`—when the dashboard is shown or resumed.
- `PRO_UI_DASHBOARD_HIDE`—when the dashboard is paused and replaced by another tool.
- `PRO_UI_DASHBOARD_ENTER`—when you switch to a dashboard from another component in the ribbon user interface
- `PRO_UI_DASHBOARD_EXIT`—when you leave the dash board and return to a component on the ribbon user interface

- `PRO_UI_DASHBOARD_DISMISS`—upon the dashboard “close” event.
- `PRO_UI_DASHBOARD_DESTROY`—when the dashboard is finally destroyed.

The function `ProUIDashboardshowoptionsTitleSet()` sets the title of the dashboard. The input arguments of this function are:

- *dash\_options*—Specifies the handle containing data that is used to build the dashboard.
- *title*—Specifies the title of the dashboard.

Use the function `ProUIDashboardshowoptionsIconSet()` to set an icon for the specified dashboard. This is the first icon in the first group from the left on the dashboard.

The function `ProUIDashboardshowoptionsHelpTextSet()` sets the help text for the specified dashboard.

- 1. Dashboard icon
- 2. Dashboard help text

Use the function `ProUIDashboardshowoptionsDefaultOpenSet()` to set the specified dashboard as the open by default page. The input arguments follow:

- *dash\_options*—Specify the handle to the data used to build the dashboard.
- *page\_name*—Specify the page name to be opened by default.

You can use the function `ProUIDashboardshowoptionsFree()` to free a handle containing the data used to build a dashboard.

Use the function `ProUIDashboardDestroy()` to pop the dashboard from the dashboard stack mechanism. The dashboard User Interface will be destroyed.

## Accessing a Dashboard

Functions Introduced:

- **`ProUIDashboardUserdataGet()`**
- **`ProUIDashboardStdlayoutGet()`**
- **`ProUIDashboardBitmapSet()`**

Use the functions `ProUIDashboardUserdataGet()` to get the application data you attached to the dashboard items upon registration. This can be used to store the current state of the tool, and thus to control the visibility of components.

---

Creo TOOLKIT does not currently provide access to create the feature dashboard's standard buttons. However, you can use `ProUIDashboardStdlayoutGet()` to get the layout name where you can create and place the buttons in the standard button area. Typically this consists of (at least) **OK** and **Cancel** buttons.

Use the function `ProUIDashboardBitmapSet()` to assign the icon for the dashboard, which appears to the left of the slide-down panel buttons.

## Dashboard Page

Each section of content in a dashboard is called a dashboard page. The opaque handle `ProUIDashboardPage` represents an individual page, that is, either the dialog bar, or a single slide-down panel.

### Dashboard Page Options

Functions Introduced:

- **`ProUIDashboardpageoptionsAlloc()`**
- **`ProUIDashboardpageoptionsNotificationSet()`**
- **`ProUIDashboardpageoptionsFree()`**

Use the function `ProUIDashboardpageoptionsAlloc()` to allocate a handle representing a single page (or layout) that will be shown in a dashboard. The input arguments for this function are:

- *page\_name*— Specifies the page name (must be unique).
- *resource\_name*—Specifies the name of the resource file to use (whose top component must be a layout, not a dialog). If `NULL`, an empty default layout is used.
- *application\_data*—Specifies the application data stored for the page.

Use the function `ProUIDashboardpageoptionsNotificationSet()` to assign a function to be called upon a certain event occurring in the dashboard. The input arguments for this function are:

- *options*—Specifies a handle representing a dashboard page.
- *notification*—Specifies the function to be called upon the designated event occurrence.
- *appdata*—Specifies the application data passed to the callback function when it is invoked.

You can register event notifications for the following events on the dashboard page:

- `PRO_UI_DASHBOARD_PAGE_CREATE`—when the page is first created.

- `PRO_UI_DASHBOARD_PAGE_SHOW`—when the page is shown (slide-down panels only).
- `PRO_UI_DASHBOARD_PAGE_HIDE`—when the page is hidden (slide-down panels only).
- `PRO_UI_DASHBOARD_PAGE_DESTROY`—when the page is destroyed.

You can use the function `ProUIDashboardpageoptionsFree()` to free a handle representing a single page (or layout) that will be shown in a dashboard.

## Accessing a Dashboard Page

Functions Introduced:

- **`ProUIDashboardPageGet()`**
- **`ProUIDashboardpageTitleSet()`**
- **`ProUIDashboardpageForegroundcolorSet()`**
- **`ProUIDashboardStdlayoutDefaultBtnsAdd()`**
- **`ProUIDashboardStdlayoutButtonAdd()`**
- **`ProUIDashboardStdlayoutDefaultButtonNameGet()`**
- **`ProUIDashboardPauseresumeButtonStateGet()`**
- **`ProUIDashboardPauseresumeButtonStateSet()`**
- **`ProUIDashboardpageStateSet()`**
- **`ProUIDashboardpageVisibleSet()`**
- **`ProUIDashboardpageNameGet()`**
- **`ProUIDashboardpageDashboardGet()`**
- **`ProUIDashboardpageUserDataGet()`**
- **`ProUIDashboardpageClose()`**
- **`ProUIDashboardpageOpen()`**
- **`ProUIDashboardpageIsOpen()`**

Use the function `ProUIDashboardPageGet()` to obtain the handle to a given page from the dashboard. The input arguments for this function are:

- *dashboard*—Specifies the dashboard handle.
- *name*—Specifies the page name. Pass `NULL` to get the handle to the main page.

Use the function `ProUIDashboardpageTitleSet()` to assign the title string for the dashboard page. This will be shown as the button name for the slide-down panel. This should typically be called from the `CREATE` notification of the dashboard page.

---

Use the function `ProUIDashboardpageForegroundColorSet()` to set the text color for the button that invokes a slide-down panel. This technique is used in several Creo Parametric tools to notify the user that they must enter one of the panels to complete the tool.

The function `ProUIDashboardStdlayoutDefaultBtnsAdd()` adds new standard push buttons to the Creo Parametric dashboard. The input arguments follow:

- *pageHandler*—A handle to the dashboard page.
- *buttons*—The bit mask to identify the buttons to be added. This value is defined by the enumerated data type `ProUIDashboardStdLayoutButton`. The valid values are as follows:
  - `PRO_UI_DASHBOARD_BUTTON_PAUSE_RESUME`
  - `PRO_UI_DASHBOARD_BUTTON_PREVIEW`
  - `PRO_UI_DASHBOARD_BUTTON_OK`
  - `PRO_UI_DASHBOARD_BUTTON_CANCEL`

The function `ProUIDashboardStdlayoutButtonAdd()` adds a new push button to the Creo Parametric dashboard. This function is executed only once during a Creo Parametric session for each push button. Subsequent calls to this function for a previously loaded push button are ignored. The input arguments follow:

- *page\_handle*—A handle to the dashboard page.
- *button\_Name*—A unique name for the push button. The maximum size should be less than `PRO_NAME_SIZE`.
- *button\_label*—A label for the push button. The maximum size should be less than `PRO_LINE_SIZE`.
- *one\_line\_help*—A one-line help for the push button. The maximum size should be less than `PRO_LINE_SIZE`.
- *icon*—An image of the push button.
- *filename*—The name of the message file that contains the label and help string.

`PRO_NAME_SIZE` and `PRO_LINE_SIZE` are defined in the `ProSizeConst.h` header file.

The function `ProUIDashboardStdlayoutDefaultButtonNameGet()` returns the default name of the specified button id. The output argument *button\_name* is in the form of a character string. Use the function `ProStringFree()` to free this string.

---

The function `ProUIDashboardPauseresumeButtonStateGet()` returns the state of the button. The output argument `state` is defined by the enumerated data type `ProUIDashboardPauseResumeButtonState` and the valid are as values follows:

- `ProUIDashboardButtonPauseState`—Specifies that the button is in a paused state.
- `ProUIDashboardButtonResumeState`—Specifies that the button is in a resume state.

Use the function `ProUIDashboardPauseresumeButtonStateSet()` to set the pause or resume state of the button.

Use the function `ProUIDashboardpageStateSet()` to modify the visibility of the button that opens the dashboard page according to the page state. This function affects the background and foreground of the button. The input arguments follow:

- *page*—Handle to the dashboard page defined by `ProUIDashboardPage`.
- *state*—State of the page defined by the enumerated data type `ProUIDashboardPageState`. The valid values are as follows:
  - `PRO_UI_DASHBOARD_PAGE_DEFAULT_STATE`
  - `PRO_UI_DASHBOARD_PAGE_WARNING_STATE`
  - `PRO_UI_DASHBOARD_PAGE_ERROR_STATE`

Use the function `ProUIDashboardpageVisibleSet()` to modify the visibility of the button that opens the dashboard page.

Use the function `ProUIDashboardpageNameGet()` to obtain the name of the page.

Use the function `ProUIDashboardpageDashboardGet()` to obtain the dashboard that owns this page.

Use the function `ProUIDashboardpageUserdataGet()` to obtain the application stored with this dashboard page on registration.

Use the function `ProUIDashboardpageClose()` to close the dashboard slide-down page.

Use the function `ProUIDashboardpageOpen()` to open the specified dashboard page.

Use the function `ProUIDashboardpageIsOpen()` to check if the specified dashboard page is open. If the page is open, the function returns a `ProBoolean` output argument with the value `PRO_B_TRUE`. Otherwise, the function returns `PRO_B_FALSE`.argument

---

## Accessing Components in the Dashboard Pages

Components added to the dashboard are actually "owned" by the Creo Parametric dialog window. Creo Parametric automatically modifies the names of components loaded from resource files to ensure that no name collisions occur when the components are added. The functions in this section allow you to locate the names of components that you need to access.

Functions Introduced:

- **ProUIDashboardpageDevicenameGet()**
- **ProUIDashboardpageComponentnameGet()**

Use the function `ProUIDashboardpageDevicenameGet()` to obtain the device name owning the dashboard page. This name should be used in other `ProUI` functions to access the components stored in the dashboard page.

Use the function `ProUIDashboardpageComponentnameGet()` to obtain the real component name in the dashboard page, if the page contents were loaded from a layout. This name should be used in `ProUI` functions for accessing a component in the dashboard.

## User Interface: Basic Graphics

### User Interface: Basic Graphics

This section describes all the functions provided by Creo TOOLKIT that create and manipulate graphics and object displays.

Creo TOOLKIT refers to windows using integer identifiers. The base window (the big graphics window created automatically when you enter Creo Parametric) is window 0, and the text message window at the bottom is window 1.

In many of the functions in this section, you can use the identifier “-1” to refer to the current window (the one current to the Creo Parametric user).

### Manipulating Windows

This section describes how to manipulate windows using Creo TOOLKIT. It is divided into the following subsections:

- [Resizing Windows on page 495](#)
- [Manipulating the Embedded Browser in Windows on page 496](#)
- [Repainting Windows on page 496](#)
- [Controlling Which Window is Current on page 497](#)
- [Creating and Removing Windows on page 498](#)

- 
- [Retrieving the Owner of a Window on page 499](#)
  - [Visiting Windows on page 499](#)
  - [Activating Windows on page 499](#)

## Windows

Functions Introduced:

- **ProWindowNameGet()**

The function `ProWindowNameGet()` returns the window name for the specified window identifier. The input parameter *win\_id* is the identifier of the Creo Parametric window. The output parameter *win\_name* is the name of the Creo Parametric window.

## Resizing Windows

Functions Introduced:

- **ProWindowSizeGet()**
- **ProGraphicWindowSizeGet()**
- **ProWindowPixelOutlineGet()**
- **ProWindowCoordinatePixelGet()**

The function `ProWindowSizeGet()` returns the size of the Creo Parametric window including the User Interface border.

The function `ProGraphicWindowSizeGet()` returns the size of the Creo Parametric graphics window without the border. If the window occupies the whole screen, the window size is returned as 1. If the screen is 1024 pixels wide and the window is 512 pixels, the width will be returned as 0.5.

The function `ProWindowPixelOutlineGet()` returns the outline of the Creo Parametric window in pixels. The outline is the height and width of the graphic area.

The function `ProWindowCoordinatePixelGet()` converts the Windows coordinates received through the input argument *point* into Pixel coordinates. The input arguments are as follows:

- *window\_id*—Valid window identifier.
- *point*—Window space 3D coordinates given by ProArray of the Pro3dPnt object.

The output argument *pixelSpaceCoord* is the 2D pixel coordinates in integers and is returned by a ProArray of the Pro2dPnt object.

---

## Manipulating the Embedded Browser in Windows

Functions Introduced:

- **ProWindowBrowserSizeGet()**
- **ProWindowBrowserSizeSet()**
- **ProWindowURLShow()**
- **ProWindowURLGet()**

The functions `ProWindowBrowserSizeGet()` and `ProWindowBrowserSizeSet()` enable you to find and change size of the embedded browser in the Creo Parametric window. These functions refer to the browser size in terms of a percentage of the graphics window (0.0 to 100.0).

### Note

The functions `ProWindowBrowserSizeGet()` and `ProWindowBrowserSizeSet()` are not supported if the browser is open in a separate window.

---

The functions `ProWindowURLGet()` and `ProWindowURLShow()` enable you to find and change the URL displayed in the embedded browser in the Creo Parametric window.

## Repainting Windows

Functions Introduced:

- **ProWindowClear()**
- **ProWindowRepaint()**
- **ProWindowRefresh()**
- **ProWindowRefit()**
- **ProTreetoolRefresh()**

The function `ProWindowClear()` temporarily removes all graphics from the specified window. If you give the function a window identifier of `-1`, it clears the current window.

This function is not equivalent to the Creo Parametric option to quit the window. It does not break the connection between the current solid and the window. That is the purpose of the function `ProWindowDelete()`, described later in this section.

The `ProWindowRepaint()` function is equivalent to the Creo Parametric command **Repaint** in the **Graphics** toolbar, and removes highlights. The function accepts `-1` as the identifier, which indicates the current view.

---

The function `ProWindowRefresh()` is designed primarily for the purposes of animation. It updates the display very efficiently, but does not remove highlights. The function accepts `-1` as the window identifier, which indicates the current window.

The function `ProWindowRefit()` performs exactly the same action as the Creo Parametric command **View ► Refit**. (It does not accept `-1` as the current window. Use `ProWindowCurrentGet()` if you need the id of the current window.)

The function `ProTreetoolRefresh()` refreshes the display of the model tree for the specified model. This function is useful when you are modifying the model in some way, such as when you are creating patterns or features.

## Controlling Which Window is Current

Functions Introduced:

- **`ProWindowCurrentGet()`**
- **`ProWindowCurrentSet()`**
- **`ProAccessorywindowAboveactivewindowSet()`**

The functions `ProWindowCurrentGet()` and `ProWindowCurrentSet()` enable you to find out and change the current window. The window is active only for the purposes of the other Creo TOOLKIT commands that affect windows.

The function `ProWindowCurrentSet()` is not equivalent to the Creo Parametric command to activate the window and has no effect on the object returned by `ProMdlCurrentGet()`.

The function `ProAccessorywindowAboveactivewindowSet()` allows you to display the accessory window always above the active Creo Parametric window, for the current Creo TOOLKIT application. Pass the input argument `above_active_window` as `PRO_B_TRUE` to display the accessory window on top of the current window. To remove this setting, pass the input argument `above_active_window` as `PRO_B_FALSE`.

---

### Note

The configuration option `accessory_window_above` allows you to control the display of accessory window in Creo Parametric. The valid values are:

- *yes*—Always displays the accessory window above the active window.
  - *no*—Does not display the accessory window above the active window. Here, whichever is the active window is displayed on top.
-

---

## Creating and Removing Windows

Functions Introduced:

- **ProObjectwindowMdlnameCreate()**
- **ProWindowDelete()**
- **ProWindowCurrentClose()**
- **ProAccessorywindowWithTreeMdlnameCreate()**

The function `ProObjectwindowMdlnameCreate()` opens a new window containing a specified solid. The solid must already be in memory. If a window is already open on that solid, the function returns the identifier of that window. If the Main Window is empty, the function uses it instead of creating a new one. The section [Graphics Colors and Line Styles on page 504](#) shows how to use `ProObjectwindowMdlnameCreate()`.

The function `ProWindowDelete()` closes a window and breaks the object-to-window attachment. The function deletes the window, if it is not the base window. You cannot break the attachment for the currently active window. Use the function `ProWindowCurrentSet()` to make a different window be the current window before calling this function.

The function `ProWindowDelete()` is the equivalent of the Creo Parametric command to quit the window. If the window is not the Main Window, it is also deleted from the screen.

To close the current window, use the function `ProWindowCurrentClose()`. When you call this function, the control must be returned to Creo Parametric to close the current window.

This function duplicates the behavior of the **View ► Close** command in Creo Parametric. If the current window is the original window created when Creo Parametric was started, the function clears the window; otherwise, the function removes the window from the screen.

---

### Note

Any work done since the last save will be lost.

---

In Creo Parametric, when the main window is active, you can open an accessory window for operations such as edit an inserted component or a feature, preview an object, select a reference, and some other operations. The model tree associated with this Creo Parametric object is also displayed in the accessory window. For more information about the accessory window, refer the Creo Parametric help.

In Creo TOOLKIT, the function `ProAccessorywindowWithTreeMdlnameCreate()` opens an accessory window containing the specified object. If a window is already open with the

---

specified object, the function returns the identifier of that window. If an empty window exists, the function uses that window to open the object. The input argument *tree\_flag* controls the display of the model tree in the accessory window. If this flag is set to `PRO_B_TRUE` the model tree is displayed.

## Retrieving the Owner of a Window

Function Introduced:

- **ProWindowMdlGet()**

The function `ProWindowMdlGet()` retrieves the Creo Parametric model that owns the specified window. This function gives you details about the window needed to perform necessary actions on it.

### Note

If no model is associated with the specified window, Creo TOOLKIT returns `NULL` as a model pointer and `PRO_TK_NO_ERROR` as a return value.

---

## Visiting Windows

Function Introduced:

- **ProWindowsVisit()**

The function `ProWindowsVisit()` enables you to visit all the Creo Parametric windows. For a detailed explanation of visiting functions, see the section [Visit Functions in the Fundamentals on page 30](#) section.

## Activating Windows

Function Introduced:

- **ProWindowActivate()**

The function `ProWindowActivate()` activates the specified window and sets it as the current window. When you call this function, the control must be returned to Creo Parametric to activate the specified window.

You can regain control by registering callback using the function `ProUIDialogAppActionSet()`.

This functionality is equivalent to changing the active window by selecting and activating a window using the pull-down menu of **Windows** command under the **View** tab in Creo Parametric.

---

 **Note**

This function works in asynchronous graphics mode only.

---

## Flushing the Display Commands to Window

Function Introduced:

- **ProWindowDeviceFlush()**

When an application sends commands to display graphics, these calls are buffered. The buffered commands are executed whenever there is a movement of mouse in the graphics window. If the Creo TOOLKIT application modifies the current display, but does not have any interaction with the graphics window, the function `ProWindowDeviceFlush()` must be called. The function flushes the buffers and executes all the display commands on the specified window. For example, consider a link which is clicked in an embedded browser. This link alters the display in the graphics window. As there is no movement of the mouse in the graphics window, the function `ProWindowDeviceFlush()` must be called to execute the display calls.

---

 **Note**

You must not call this function often, as it causes the systems running on Windows Vista and Windows 7 to slow down. It is recommended that you call this function only after you complete all the display operations.

---

## Solid Orientation

Functions Introduced:

- **ProWindowCurrentMatrixGet()**
- **ProViewMatrixGet()**
- **ProViewMatrixSet()**
- **ProViewReset()**
- **ProViewRotate()**
- **ProWindowPanZoomMatrixSet()**
- **ProViewRefit()**

---

Each graphics window in solid (Part or Assembly) mode has two transformation matrices associated with it—the view matrix and the window matrix. The view matrix describes the transformation between solid coordinates and screen coordinates. Therefore, the view matrix describes the orientation of the solid in the window.

The window matrix is the transformation between screen coordinates and window coordinates. The window matrix describes the pan and zoom factors. The screen coordinate at which a particular point on a solid is displayed is not affected by pans and zooms—this affects window coordinates only.

The view matrix is important because the mouse input functions and some of the graphics drawing functions use screen coordinates, while all solid geometry uses solid coordinates. The view matrix enables you to transform between the two systems. The function `ProWindowCurrentMatrixGet()` provides the window matrix for the current window.

The function `ProWindowPanZoomMatrixSet()` enables you to set the pan and zoom matrix (window matrix) for the current window.

The function `ProViewRefit()` zooms and pans the view to display the specified object in the window. The input arguments are:

- *model*—Handle to the object. The supported object types are drawing, part, and assembly.
- *view*—Handle to the view, which is used to display the object. If the object is a solid model, and is displayed in the current window, you can pass the argument as `NULL`.

If the object is a drawing, pass the handle to the background view. Use the function `ProDrawingBackgroundViewGet()` to get the handle to the background view.

## Getting and Setting the View Matrix

The function `ProViewMatrixGet()` provides the view matrix for a specified window. Set the view argument to `NULL` for the current view.

The function `ProViewMatrixSet()` enables you to set the view matrix (if normalized), and therefore the orientation of the solid in the view.

### Note

Function `ProViewMatrixSet()` does not cause the view to be repainted.

---

---

A 4x4 transformation matrix describes a shift and a scaling, as well as a reorientation. You set the view matrix to define a new orientation. Creo Parametric applies its own shift and scaling to the view matrix you provide to ensure that the solid fits properly into the view. This implies the following:

- The matrix output by `ProViewMatrixGet()` is not the same as the one you previously input to the function `ProViewMatrixSet()`, although its orientation is the same.
- Each row of the matrix you provide to `ProViewMatrixSet()` must have a length of 1.0, and the bottom row must be 0, 0, 0, 1.
- The matrix you provide to `ProViewMatrixSet()` must be normalized—it cannot include scaling or shift. [Example 1: Saving Three Views on page 504](#) shows how to normalize a matrix.

## Converting a Matrix to Orthonormal

Functions Introduced:

- **`ProMatrixMakeOrthonormal()`**

The function `ProMatrixMakeOrthonormal()` converts a non-orthonormal matrix to an orthonormal matrix with the specified scaling factor.

The input arguments follow:

- *inMatrix*—The matrix to be converted to orthonormal.
- *intended\_scale*—Scale factor to be applied on the matrix.

## Storing Named Views

Functions Introduced:

- **`ProViewStore()`**
- **`ProViewRetrieve()`**
- **`ProViewNamesGet()`**
- **`ProViewFromModelitemGet()`**
- **`ProViewNameLineGet()`**
- **`ProViewIdFromNameLineGet()`**
- **`ProViewNameSet()`**
- **`ProViewDelete()`**
- **`ProViewCreate()`**

---

The `ProViewStore()` and `ProViewRetrieve()` functions enable you to save and use a named view of the solid. They are equivalent to the Creo Parametric **View ► Reorient** commands **Save**, and **Set** in the **Saved Views** tab, under the **Orientation** dialog box. You can then select the view you want from the list of view names.

The function `ProViewNamesGet()` retrieves the names of the views in the specified solid.

The function `ProViewFromModelItemGet()` retrieves the view handle from a model item handle. The model item must be of type `PRO_VIEW`.

The function `ProViewNameLineGet()` retrieves the name of the view from the view handle.

The function `ProViewIdFromNameLineGet()` retrieves the ID of the view. The input arguments are:

- *model*—Specifies the handle to the part or assembly associated with the drawing, or to the drawing that contains the view. This argument cannot be `NULL`.
- *view\_name*—Specifies the name of the view. This argument cannot be `NULL`.

The function `ProViewNameSet()` sets the name of the view in the specified solid. The inputs arguments are:

- *model*—Specifies the handle to a part, assembly, or drawing. This argument cannot be `NULL`.
- *p\_view*—Specifies the handle of the view.
- *p\_name*—Specifies the name of the view.

The function `ProViewDelete()` deletes the view from the specified solid. The input arguments are:

- *model*—Specifies the handle to a part, assembly, drawing. This argument cannot be `NULL`.
- *p\_view*—Specifies the handle of the view.

The function `ProViewCreate()` creates a new view or provides the specified name to an existing view. The input arguments are:

- *model*—The handle to a part or assembly.
- *view\_name*—The name of the view that is created in the object database.

The output argument *p\_view* is the handle to the view that is stored and is defined using the `ProView` object.

---

## Example 1: Saving Three Views

The sample code in `UgGraphViewsSave.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_graphics` shows how to set the view matrix and store a named view.

## Graphics Colors and Line Styles

Creo Parametric uses several predefined colors in its color map. The colors are represented by the values of `ProColorType()`, defined in the file `ProToolkit.h`. The names of the types generally indicate what they are used for in Creo Parametric, although many colormap entries are used for several different purposes. These also correspond to the system colors presented to the user through the user interface.

### Note

PTC reserves the right to change both the definitions of the predefined colormap and also of the assignment of entities to members of the color map as required by improvements to the user interface. PTC recommends not relying on the predefined RGB color for displaying of Creo TOOLKIT entities or graphics, and also recommends against relying on the relationship between certain colormap entries and types of entities. The following section describe how to construct your application so that it does not rely on potentially variant properties in Creo Parametric.

---

## Setting Colors to Desired Values

Functions Introduced:

- **ProTextColorModify()**
- **ProGraphicsColorModify()**

The functions `ProTextColorModify()` and `ProGraphicsColorModify()` enable you to select a different color to be used for either of the following:

- Graphics text—User custom text drawn by the `ProGraphicsTextDisplay`. Graphics text is by default displayed using `PRO_COLOR_LETTER`.
- Graphics—User custom graphics drawn by `ProGraphics` function, which is by default displayed using `PRO_COLOR_DRAWING`.

Both functions only affect the color used for new graphics, you draw using Creo TOOLKIT, not the colors used for items Creo Parametric draws.

---

Both functions take a ProColor structure as input. This structure allows you to specify color by one of the following three methods:

- **DEFAULT**—use the default Creo Parametric color entry for new graphics or text.
- **TYPE**—use a predefined ProColor type color.
- **RGB**—use a custom RGB value. This method should be used for any graphics which should not be allowed to change color (for example; if an application wants a yellow line on the screen that should always be yellow and not depend on the chosen color scheme).

Both functions output the value of the previous setting. It is good practice to return the color to its previous value after having finished drawing an object.

## Setting Colors to Match Existing Entities

Functions Introduced:

- **ProColorByTypeGet()**

The functions ProGraphicsColorModify() and ProColorTextModify() allow you to draw graphics that will change color based on changes to the Creo Parametric colormap. This allows you to draw entities in similar colors to related entities created by Creo Parametric. However, if the associations between objects and colormap entries should change in a new release of Creo Parametric, the association between the application entities and the Creo Parametric entities would be lost. The function ProColorByTypeGet() returns the standard colormap entry corresponding to a particular entity in Creo Parametric. This allows applications to draw graphics that will always match the color of a particular Creo Parametric entity.

### Example 2: Setting the Graphics Color to a Specific RGB Value

The sample code in UgGraphColorsAdjust.c located at <creo\_toolkit\_loadpoint>/protk\_appls/pt\_userguide/ptu\_graphics shows how to set the graphics color to a specific RGB value.

### Example 3: Setting The Graphics Color to Follow the Color of Creo Parametric Entity

The sample code in UgGraphColorsAdjust.c located at <creo\_toolkit\_loadpoint>/protk\_appls/pt\_userguide/ptu\_graphics shows how to set the graphics color to follow the color of Creo Parametric Entity.

---

## Modifying the Creo Parametric Color Map

Functions Introduced:

- **ProColormapGet()**
- **ProColormapSet()**

These functions enable you to find out and alter the color settings for Creo Parametric. Each color is defined in terms of the red, green, and blue values. The RGB values should be expressed in a range from 0.0 to 1.0. Note that some colors related to selection and highlighting are fixed and may not be modified.

Creo Parametric uses these colors for everything it displays.

Changes to the color map are preserved for the rest of the Creo Parametric session. If you want to have permanent changes, call `ProColormapSet()` in `user_initialize()`.

### Note

Changing the Creo Parametric color map can have unintended effects if the user has chosen an alternate color scheme. It may cause certain entries to blend into the background or to be confused with other types of entries.

---

## Example 4: Modifying the Color of the Half-Tone Display

The sample code in `UgGraphColorsAdjust.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_graphics` shows how to modify the default half-tone color (gray) to a brighter color, using the function `ProColormapSet()`. Creo Parametric uses half-tone color to display hidden lines.

## Creo Parametric Color Schemes

Functions Introduced:

- **ProColormapAlternateschemeGet()**
- **ProColormapAlternateschemeSet()**

The functions `ProColormapAlternateschemeGet()` and `ProColormapAlternateschemeSet()` enable you to change the color scheme of Creo Parametric to a predefined color scheme by turning on and off the blended background (light to dark grey) for alternate schemes. The possible alternate color schemes are as follows:

- `PRO_COLORMAP_ALT_BLACK_ON_WHITE`—Displays black entities shown on a white background.

- 
- `PRO_COLORMAP_ALT_WHITE_ON_BLACK`—Displays white entities shown on a black background.
  - `PRO_COLORMAP_ALT_WHITE_ON_GREEN`—Displays white entities shown on a dark green background.
  - `PRO_COLORMAP_OPTIONAL1`—Represents the color scheme with a dark background.
  - `PRO_COLORMAP_OPTIONAL2`—Represents the color scheme with a medium background.
  - `PRO_COLORMAP_CLASSIC_WF`—Resets the color scheme to the light to dark grey background (default upto Pro/ENGINEER Wildfire 4.0).
  - `PRO_COLORMAP_ALT_DEFAULT`—Resets the color scheme to the default color scheme of light to dark blue gradient background (from Pro/ENGINEER Wildfire 5.0 onwards).

## Setting Line Styles for Creo Toolkit Graphics

Functions Introduced:

- **`ProLineStyleSet()`**
- **`ProLineStyleDataGet()`**
- **`ProGraphicsModeSet()`**

The function `ProLineStyleSet()` enables you to set the style of graphics you draw. The function `ProLineStyleDataGet()` queries the definition of the line style.

The possible values for the line style are as follows:

- `PRO_LINestyle_SOLID`—Solid line
- `PRO_LINestyle_DOT`—Dotted line
- `PRO_LINestyle_CENTERLINE`—Alternating long and short dashes
- `PRO_LINestyle_PHANTOM`—Alternating long dashes and two dots

## Displaying the Color Selection Dialog Box

Function Introduced:

- **`ProUIColorSelectionShow()`**

The function `ProUIColorSelectionShow()` displays the dialog box used to select values for the red, green, blue (RGB) colors. The input arguments of this function are:

- `title`—Specifies the title of the selection dialog box. If this argument is `NULL`, the default value RGB will be used.

- `default_rgb_color`—Specifies the default RGB values that will be displayed when the dialog box is opened. The color black is selected, if the value specified for this argument is invalid.

To get the RGB value, you can use the following macros:

| Macro                                                      | Value                                                                                                               |
|------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>#define PRO_UI_COLOR_RGB_FLAG</code>                 | <code>(1 &lt;&lt; 24)</code>                                                                                        |
| <code>#define PRO_UI_COLOR_TRANSPARENT_RGB_FLAG</code>     | <code>(1 &lt;&lt; 25)</code>                                                                                        |
| <code>#define PRO_UI_COLOR_RGB(r, g, b)</code>             | <code>((r) &amp; 0xff)   ((g) &amp; 0xff) &lt;&lt; 8   ((b) &amp; 0xff) &lt;&lt; 16   PRO_UI_COLOR_RGB_FLAG)</code> |
| <code>#define PRO_UI_COLOR_TRANSPARENT_RGB(r, g, b)</code> | <code>(PRO_UI_COLOR_RGB(r, g, b)   PRO_UI_COLOR_TRANSPARENT_RGB_FLAG)</code>                                        |
| <code>#define PRO_UI_COLOR_IS_RGB(c)</code>                | <code>((c) &amp; PRO_UI_COLOR_RGB_FLAG ? PRO_B_TRUE : PRO_B_FALSE)</code>                                           |
| <code>#define PRO_UI_COLOR_IS_TRANSPARENT_RGB(c)</code>    | <code>((c) &amp; PRO_UI_COLOR_TRANSPARENT_RGB_FLAG ? PRO_B_TRUE : PRO_B_FALSE)</code>                               |
| <code>#define PRO_UI_COLOR_RED_VALUE(c)</code>             | <code>((c) &amp; 0xff)</code>                                                                                       |
| <code>#define PRO_UI_COLOR_GREEN_VALUE(c)</code>           | <code>((c) &gt;&gt; 8) &amp; 0xff)</code>                                                                           |
| <code>#define PRO_UI_COLOR_BLUE_VALUE(c)</code>            | <code>((c) &gt;&gt; 16) &amp; 0xff)</code>                                                                          |
| <code>#define PRO_UI_COLOR_RGB_FLAGS(c)</code>             | <code>((c) &gt;&gt; 24) &amp; 0xff)</code>                                                                          |

## Displaying Graphics

Functions Introduced:

- **ProGraphicsPenPosition()**
- **ProGraphicsLineDraw()**
- **ProGraphicsPolylineDraw()**
- **ProGraphicsMultiPolylinesDraw()**
- **ProGraphicsArcDraw()**
- **ProGraphicsCircleDraw()**

---

- **ProGraphicsPolygonDraw()**

All the functions in this section draw graphics in the current window (the Creo Parametric current window, unless redefined by a call to `ProWindowCurrentSet()`), and use the color and line style set by calls to `ProGraphicsColorSet()` and `ProLineStyleSet()`. The functions draw the graphics in the Creo Parametric graphics color. The default graphics color is white.

By default, the graphics elements are not stored in the Creo Parametric display list, so they do not get redrawn by Creo Parametric when the user selects the **Repaint** command or the orientation commands in the **Orientation** group in the **View** tab. However, if you store graphics elements in either 2-D or 3-D display lists, Creo Parametric redraws them. See the section [Display Lists on page 512](#) for more information.

The functions `ProGraphicsPenPosition()` and `ProGraphicsLineDraw()` draw three-dimensional polylines in solid mode, and take solid coordinates.

The function `ProGraphicsPenPosition()` sets the point at which you want to start drawing the line. The function `ProGraphicsLineDraw()` draws a line to the given point from the position given in the last call to either of the two functions. You call `ProGraphicsPenPosition()` for the start of the polyline, and `ProGraphicsLineDraw()` for each vertex.

If you use these functions in Drawing mode they work correctly, but use screen coordinates instead of solid coordinates.

The `ProGraphicsPolylineDraw()` and `ProGraphicsMultiPolylinesDraw()` functions also draw polylines, but you need to have the whole polyline defined in a local array before you call either function. If you are drawing many lines, use `ProGraphicsMultipolylinesDraw()` to minimize the number of function calls.

The function `ProGraphicsArcDraw()` draws an arc, in screen coordinates.

The function `ProGraphicsCircleDraw()` uses solid coordinates for the center of the circle and the radius value, but draws the circle parallel to the plane of the window. You can position the circle at a chosen solid vertex, for example, and the circle will always be clearly visible as a circle, regardless of the current solid orientation.

## Example 5: Displaying Lines and Circles

The sample code in `UgGraphLineCircleDraw.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_graphics` shows how to draw a circle at each point and draw lines between the points.

---

In this example, the user selects a series of points on a part surface.

## Displaying Text

Function Introduced:

- **ProGraphicsTextDisplay()**

The function `ProGraphicsTextDisplay()` places text, specified as a wide string, at a position specified in screen coordinates. Therefore, if you want to add text to a particular position on the solid, you must transform the solid coordinates into screen coordinates by using the view matrix.

Like the graphics polylines, arcs, and so on (added by the functions described in the section [Displaying Graphics on page 508](#)), the text items drawn by `ProGraphicsTextDisplay()` are not known to Creo Parametric, and therefore are not redrawn when you use the **Repaint** command. Use the notify or display list functions to tell Creo Parametric about the items.

### Note

These points are in the coordinate system of the current object. If the current object is a part, the points must be in the coordinate system of the part. If the current object is an assembly, the points must be in the coordinate system of the assembly.

---

See the section [Display Lists on page 512](#) for more information on the display list functions. To add permanent text to a drawing (for example, a drawing note), see the section [Drawings on page 1287](#).

## Controlling Text Attributes

Functions Introduced:

- **ProTextAttributesCurrentGet()**
- **ProTextFontIdCurrentSet()**
- **ProTextHeightCurrentSet()**
- **ProTextRotationAngleCurrentSet()**
- **ProTextSlantAngleCurrentSet()**
- **ProTextWidthFactorCurrentSet()**

These functions control the attributes of text added by calls to `ProGraphicsTextDisplay()`. You can get and set the following information:

- The font identifier

- 
- The text height, in screen coordinates
  - The ratio of the width of each character (including the gap) as a proportion of the height
  - The angle of rotation of the whole text, in counterclockwise degrees
  - The angle of slant of the text, in clockwise degrees

## Controlling Text Fonts

Functions Introduced:

- **ProTextFontDefaultIdGet()**
- **ProTextFontNameGet()**
- **ProTextFontNameToId()**
- **ProTextFontRetrieve()**
- **ProTextStyleFontGet()**
- **ProTextStyleFontSet()**

The function `ProTextFontDefaultIdGet()` returns the identifier of the default Creo Parametric text font.

The text fonts are identified in Creo Parametric by names, and in Creo TOOLKIT by integer identifiers. To move between the two types of font identifiers, use the functions `ProTextFontNameGet()` and `ProTextFontNameToId()`. Because the internal font identifiers could change between Creo Parametric sessions, it is important to call `ProTextFontNameToId()` each time you want to modify the font in Creo TOOLKIT.

The function `ProTextFontRetrieve()` loads a font with the specified name that can be used to display the text.

The functions `ProTextStyleFontGet()` and `ProTextStyleFontSet()` get and set the font used to display the text. The fonts are those available in the **Font** selector in the **Text Style** dialog in Creo Parametric.

## Validating Text Styles

Functions Introduced:

- **ProTextStyleValidate()**

The function `ProTextStyleValidate()` checks whether the properties of text style applied to the specified object type are valid. The input arguments are:

- *obj\_type*—Specifies the type of object on which the text style must be applied. The enumerated data type `ProTextStyleObjectType` defines the object type.

- 
- *r\_text\_style*—Specifies the text style that should be applied on the specified object type.

The function returns messages if it finds text styles which are not supported in the specified object type. The message is returned as array of lines. Use the function `ProWstringArrayFree()` to free memory.

#### Note

You do not need to use `ProWstringArrayFree()`, if the value of the input argument *r\_text\_style* is `NULL`.

---

## Display Lists

Functions Introduced:

- **ProDisplist2dCreate()**
- **ProDisplist2dDisplay()**
- **ProDisplist2dDelete()**
- **ProDisplist3dCreate()**
- **ProDisplist3dDisplay()**
- **ProDisplist3dDelete()**

To generate the display of a solid in a window, Creo Parametric maintains two display lists. A display list contains a set of vectors used to represent the shape of the solid in the view.

The 3-D display list contains a set of three-dimensional vectors that represent an approximation to the geometry of the edges of the solid. It gets rebuilt every time the solid is regenerated.

The 2-D display list contains the two-dimensional projections of the 3-D display list onto the current window. It is rebuilt from the 3-D display list when the orientation of the solid changes.

The functions in this section enable you to add your own vectors to the display lists, so your own graphics will be redisplayed automatically by Creo Parametric, until the display lists are rebuilt.

For example, if you just use the functions described in the section [Displaying Graphics on page 508](#), the items you draw remain on the screen only until the window is repainted. Furthermore, the objects are not plotted with the rest of the contents of the window because Creo Parametric does not know about them.

---

If, however, you add the same graphics items to the 2-D display list, they will survive each repaint (when zooming and panning, for example) and will be included in plots created by Creo Parametric.

If you add graphics to the 3-D display list, you get the further benefit that the graphics survive a change to the orientation of the solid and are displayed, even when you spin the solid dynamically.

To add graphics to a display list, you must write a function that displays the necessary vectors in three dimensions, using the graphics display functions in the usual way. For the 2-D display list, you call `ProDisplst2dCreate()` to tell Creo Parametric to use your function to create the display list vectors, then call `ProDisplst2dDisplay()` to ask it to display the new graphics those vectors represent.

#### Note

If you save the display information, you can reuse it in any session. The application should delete the display list data when it is no longer needed.

---

Using 3-D display lists is exactly analogous to using 2-D display lists.

Note that the function `ProWindowRefresh()` does not cause either of the display lists to be regenerated, but simply repaints the window using the 2-D display list.

The function `ProSolidDisplay()` regenerates both display lists, and therefore not only recenters the solid in the view and removes any highlights, but also removes any graphics you added using the 2-D display list functions.

## Getting Mouse Input

Functions Introduced:

- **`ProMousePickGet()`**
- **`ProMouseTrack()`**
- **`ProMouseBoxInput()`**

The functions `ProMousePickGet()` and `ProMouseTrack()` are used to read the position of the mouse, in screen coordinates. Each function outputs the position and an enumerated type description of which mouse buttons were pressed when the mouse was at that position. The values are defined in `ProGraphic.h`, and are as follows:

- `PRO_LEFT_BUTTON`
- `PRO_MIDDLE_BUTTON`

- `PRO_RIGHT_BUTTON`

The function `ProMousePickGet()` reports the mouse position only when you press a button. It has an input argument that is a description of the mouse buttons you want to wait for (you must have at least one). For example, you can set the *expected\_button* argument to:

```
PRO_LEFT_BUTTON | PRO_RIGHT_BUTTON
```

In this example, the function does not return until you press either the left or right button. You could also specify the value `PRO_ANY_BUTTON`.

The function `ProMouseTrack()` returns whenever the mouse is moved, regardless of whether a button is pressed. Therefore, the function can return the value `PRO_NO_BUTTON`. Its input argument enables you to control whether the reported positions are snapped to grid.

## Example 6: Drawing a Rubber-Band Line

The sample code in `UgGraphPolyLineDrawUtil.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_graphics` shows how to use the complement drawing mode. The example follows the mouse position dynamically.

## Cosmetic\_Properties

### Surface Properties

You can enhance your model using Creo TOOLKIT functions that change the surface properties, or set different light sources. The following sections describe these functions in detail.

Functions Introduced:

- **`ProSurfaceSideAppearancepropsGet()`**
- **`ProSurfaceSideAppearancepropsSet()`**
- **`ProTexturePathGet()`**
- **`ProSurfaceSideTexturereplacementpropsGet()`**
- **`ProSurfaceSideTexturereplacementpropsSet()`**
- **`ProSurfaceAppearanceDefaultPropsGet()`**
- **`ProSurfaceSideTexturepropsGet()`**
- **`ProSurfaceSideTexturepropsSet()`**
- **`ProPartTessellate()`**
- **`ProPartTessellationFree()`**

---

From Creo Parametric 5.0.0.0 onwards, the following functions have been deprecated:

- `ProSurfaceAppearancepropsGet()`
- `ProSurfaceAppearancepropsSet()`
- `ProSurfaceTexturereplacementpropsGet()`
- `ProSurfaceTexturereplacementpropsSet()`
- `ProSurfaceTexturepropsGet()`
- `ProSurfaceTexturepropsSet()`

The functions described in this section enable you to retrieve and set the surface and texture properties for the first level models in the model hierarchy.

Use the functions `ProSurfaceSideAppearancepropsGet()` and `ProSurfaceSideAppearancepropsSet()` to retrieve and set the surface properties on a specified side of the surface for the specified element using the `ProSurfaceAppearanceProps` data structure.

The data structure is defined as follows:

```
typedef struct pro_surf_appearance_props
{
 double ambient;
 double diffuse;
 double highlite;
 double shininess;
 double transparency;
 ProVector color_rgb;
 ProVector highlight_color;
 double reflection;
 ProPath name;
 ProPath label;
 ProPath description;
 ProPath keywords;
} ProSurfaceAppearanceProps;
```

The `ProSurfaceAppearanceProps` data structure contains the following fields:

- **ambient**—Specifies the indirect, scattered light the model receives from its surroundings. The valid range is 0.0 to 1.0.
- **diffuse**—Specifies the reflected light that comes from directional, point, or spot lights. The valid range is 0.0 to 1.0.
- **highlite**—Specifies the intensity of the light reflected from a highlighted surface area. The valid range is 0.0 to 1.0.
- **shininess**—Specifies the properties of a highlighted surface area. A plastic model would have a lower shininess value, while a metallic model would have a higher value. The valid range is 0.0. to 1.0.

- `transparency`—Specifies the transparency value, which is between 0 (completely opaque) and 1.0 (completely transparent).
- `color_rgb[3]`—Specifies the color, in terms of red, green, and blue. The valid range is 0.0. to 1.0.
- `highlight_color`—Specifies the highlight color, in terms of red, green, and blue. The valid range is 0.0 to 1.0.
- `reflection`—Specifies how reflective the surface is. The valid range is 0 (dull) to 100 (shiny).
- `keywords`—Mandatory field. Specifies how to set the texture on a model surface. If you do not want to set a value for this field, set a NULL string to it.

The input arguments to the function

`ProSurfaceSideAppearancepropsGet()` are:

- *item*—Specifies the `ProModelitem` object that represents the part, assembly component, subassembly, quilt, or surface.
- *surface\_side*—Specifies the direction of the side for the surface or quilt. Pass the value as 0 to specify the side which is along the surface normal. Pass 1 to specify the side opposite to the surface normal.

In cosmetic shade mode, Creo Parametric tessellates each surface by breaking it into a set of connected triangular planes. The function

`ProSurfaceTessellationGet()` invokes this algorithm on a single specified surface and provides the coordinates of the triangle corners and the normal at each vertex. This function tessellates a single surface only.

You can use the function `ProTexturePathGet()` to retrieve the full path to the texture, decal, or bump map file.

Refer to the [Tessellation on page 188](#) section of [Core: 3D Geometry on page 177](#) the section for functions `ProPartTessellate()` and `ProPartTessellationFree()`.

You can apply textures to the surfaces. Use the function

`ProSurfaceSideTexturepropsGet()` to get the texture properties for the specified side of the surface. Use the function

`ProSurfaceSideTexturepropsSet()` to set the surface texture properties for the specified side of the surface. Both these functions use the `ProSurfaceTextureProps` data structure to retrieve and set the surface texture properties.

The data structure is defined as follows:

```
typedef struct pro_surface_texture_props
{
 ProCharPath
 ProCharPath
 ProCharPath
} ProSurfaceTextureProps;
```

```
decal;
texture_map;
bump_map;
```

---

The `ProSurfaceTextureProps` data structure contains the following fields:

- `decal`—Specifies the full path to the texture map with the alpha channel (transparency). Otherwise, use `NULL`.
- `texture_map`—Specifies the full path to the texture map.
- `bump_map`—Specifies the full path to the bump map. A bump map enables you to create bumps on the surface of the texture map.

You can manipulate the placement of the surface textures. Use the function `ProSurfaceSideTexturereplacementpropsGet()` to get the properties related to the placement of surface texture for the specified side of the surface. Use the function `ProSurfaceSideTexturereplacementpropsSet()` to set the placement properties for the specified side of the surface texture. The functions `ProSurfaceSideTexturereplacementpropsGet()` and `ProSurfaceSideTexturereplacementpropsSet()` use the `ProSurfaceTexturePlacementProps` data structure.

The data structure is defined as follows:

```
typedef struct pro_surface_texture_placement_props
{
 ProTextureProjectionType
projection;
 ProTextureType
texture_type;
 ProLineEnvelope
local_csys;
 double horizontal_
offset;
 double vertical_
offset;
 double rotate;
 double horizontal_
scale;
 double vertical_
scale;
 double bump_height;
 double decal_
intensity;
 ProBoolean flip_
horizontal;
 ProBoolean flip_
vertical;
} ProSurfaceTexturePlacementProps;
```

The `ProSurfaceTexturePlacementProps` data structure contains the following fields:

- `projection`—Specifies the projection type—planar, spherical, cylindrical, or box.

- `texture_type`—Specifies the type of texture.
- `local_csys`—Specifies the direction (for planar projection), or the whole coordinate system (which defines the center for the other projection types).
- `horizontal_offset` and `vertical_offset`—Specifies the percentage of horizontal and vertical shift of the texture map on the surface.
- `rotate`—Specifies the angle to rotate the texture map on the surface.
- `horizontal_scale` and `vertical_scale`—Specifies the horizontal and vertical scaling of the texture map.
- `bump_height`—Specifies the height of the bump on the surface of the texture map.
- `decals_intensity`—Specifies the alpha or transparency mask intensity on the surface.
- `flip_horizontal` and `flip_vertical`—Specifies that the texture map on the surface should be flipped horizontally or vertically.

Use the function `ProSurfaceAppearanceDefaultPropsGet()` to get the default appearance properties of the specified type of surface. The input argument *appearance\_type* is specified by the enumerated data type `ProDefaultAppearanceType`. The output argument *appearance\_properties* is specified by the data structure `ProSurfaceAppearanceProps`.

## Setting Light Sources

Functions Introduced:

- **`ProLightSourcesGet()`**
- **`ProLightSourcesSet()`**

These functions retrieve and set the information associated with the specified window, respectively, using the *ProLightInfo* data structure. The data structure is defined as follows:

```
typedef struct pro_tk_light
{
 ProName
name;
 ProLightType
type;
 ProBoolean
status; /* active or inactive */
 double
rgb[3]; /* for all types */
 double
position[3]; /* for point and spot */
 double
direction[3]; /* for direction and spot */
}
```

```

 double
 spread_angle; /* for spot, in radian */
 ProBoolean
 cast_shadows;
} ProLightInfo;

```

The `Pro_light` structure contains the following fields:

- `name`—Specifies the name of the light source.
- `type`—Specifies the light type—ambient, direction, point, or spot.
- `status`—Specifies whether the light source is active or inactive.
- `rgb`—Specifies the red, green, and blue values, regardless of the light type.
- `position`—Specifies the position of the light, for point and spot lights only.
- `direction`—Specifies the direction of the light, for direction and spot lights only.
- `spread_angle`—Specifies the angle the light is spread, for spot lights only.
- `cast_shadows`—Specifies whether the light casts shadows. This applies to Creo Render Studio only. Refer to the Creo Render Studio Help for more information on Creo Render Studio.

## Creating 3D Shaded Data for Rendering

The functions described in this section enable you to create 3D shaded data that can be attached to a scene and rendered in Creo Parametric.

Functions Introduced:

- **`ProDispObjectCreate()`**
- **`ProDispObjectAttach()`**
- **`ProDispObjectDetach()`**
- **`ProDispObjectDelete()`**
- **`ProDispObjectSetTransform()`**
- **`ProDispObjectSetSurfaceAppearanceProps()`**

The function `ProDispObjectCreate()` creates a display object. A display object collects user specified shaded triangle data. When you render an object in Creo Parametric, rendering is done based on the triangle data using lights and materials. The display object must be attached to the scene to be rendered. The object is always displayed in shaded mode irrespective of the display mode of the current view. No HLR operations are done on display objects. The input arguments are:

- *object\_name*—Specifies the name of the display object. The name must be unique.

- *flag*—Specifies a bitmask that is used to set the property of the display object. The bitmask has the following bit flags:
  - 0x0—This is the default value. No bit flag is passed. If no bit is set, the display object behaves like a solid.
  - PRO\_DISP\_OBJECT\_TWO\_SIDED—When this bit flag is set, the display object behaves like a quilt.
  - PRO\_DISP\_OBJECT\_DYNAMIC\_PREVIEW—When this bit flag is set, the display object is considered temporary which will be deleted and recreated frequently by the user application. When this flag is set, Creo Parametric will not store the data on graphics card.
- *num\_strips*—Specifies the number of triangle strips that will contain the triangle data.
- *strip\_size*—Specifies the number of vertices in each triangle strip. It is a ProArray of size *num\_strips*.
- *strips\_array*—Specifies a ProArray of ProTriVertex structure. The structure contains information about the position and normals of the vertices for triangles.

The function `ProDispObjectAttach()` attaches the display object to a Creo Parametric scene.

After the object is attached, it will be rendered along with the Creo Parametric graphics. If the scene is regenerated, the Creo TOOLKIT application must reattach it. This API is supported only for 3D mode, that is, part, assembly, and so on and does not work in 2D mode, that is, drawings, sketch, layout, and so on. The input arguments are:

- *window*—Specifies the ID of the window in which the display object must be attached to a Creo Parametric scene.
- *obj*—Specifies the handle to the display object.
- *key\_list*—Specifies a ProArray which contains the member identifier table of the component to which the display object will be attached. Specify NULL if you want to attach the display object to the top level component.
- *new\_key*—Specifies the ID of the new node in the scene graph where the display object will be attached.
- *transform*—Specifies the position of the display object relative to its parent as a ProMatrix object.

Use the function `ProDispObjectDetach()` to detach a display object from the Creo Parametric scene. The input arguments are:

- *window*—Specifies the ID of the window from which the display object will be detached from a Creo Parametric scene.

- 
- *key\_list*—Specifies a `ProArray` which contains the member identifier table of the display object `ProDispObject` which will be detached from the scene. Pass as input *key\_list* along with *new\_key* defined in the API `ProDispObjectAttach()`.

The function `ProDispObjectDelete()` deletes the specified display object. You must detach the display object before deleting it.

The function `ProDispObjectSetTransform()` transforms a display object relative to its parent in the scene. Specify the new position using the `ProMatrix` object. It returns the original position of the display object as a `ProMatrix` object.

Use the function `ProDispObjectSetSurfaceAppearanceProps()` to set the display properties of the display object attached to a scene using the `ProSurfaceAppearanceProps` data structure. Refer to the section [Surface Properties on page 514](#) for more information on `ProSurfaceAppearanceProps`.

### Example 1: Creating a Display Object

The sample code in `TestDispObject.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_examples/pt_dispobj` shows how to create a display object and attach it to a scene. It also shows how to set the display properties for the display object.

## User Interface: Selection

### User Interface: Selection

This section contains functions that enable you to select objects in Creo Parametric from within the Graphics Window or the Model Tree using the mouse or the keyboard.

### The Selection Object

Like `ProModelitem`, the object `ProSelection` identifies a model item in the Creo Parametric database. `ProSelection`, however, contains more information than `ProModelitem`, and is therefore sometimes used instead of `ProModelitem` in situations where the extra information is needed. The most important use of `ProSelection` is as the output of the function for interactive selection, `ProSelect()` (thus the name `ProSelection`).

`ProSelection` is declared as an opaque pointer, and is, strictly speaking, a `WHandle` because, although the model item is a reference to a Creo Parametric database item, the other information is not.

Functions Introduced:

- **ProSelectionAlloc()**
- **ProSelectionSet()**
- **ProSelectionCopy()**
- **ProSelectionFree()**
- **ProSelectionAsmcomppathGet()**
- **ProSelectionModelitemGet()**
- **ProSelectionUvParamGet()**
- **ProSelectionViewGet()**
- **ProSelectionPoint3dGet()**
- **ProSelectionDepthGet()**
- **ProSelectionVerify()**
- **ProSelectionWindowIdGet()**
- **ProSelectionUvParamSet()**
- **ProSelectionViewSet()**
- **ProSelectionPoint3dSet()**
- **ProSelectionDrawingGet()**
- **ProSelectionDwgtblcellGet()**

## Unpacking a ProSelection Object

For each item of information that `ProSelection` can contain, there is a Creo TOOLKIT function that extracts that information. The following table lists these items.

| Creo TOOLKIT Function                     | Creo TOOLKIT Object         | Meaning                                                                                                                           |
|-------------------------------------------|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <code>ProSelectionAsmcomppathGet()</code> | <code>ProAsmcomppath</code> | Assembly component path                                                                                                           |
| <code>ProSelectionModelitemGet()</code>   | <code>ProModelitem</code>   | Model item                                                                                                                        |
| <code>ProSelectionPoint3dGet()</code>     | <code>ProPoint3d</code>     | 3-D point on the model item                                                                                                       |
| <code>ProSelectionUvParamSet()</code>     | <code>ProUvParam</code>     | u and v, ort, of that point                                                                                                       |
| <code>ProSelectionDepthGet()</code>       | double                      | Selection depth                                                                                                                   |
| <code>ProSelectionDistanceEval()</code>   | double                      | Distance between two selected objects. The selection objects can be surfaces, entities, surface-curves, surface-nodes, or points. |
| <code>ProSelectionViewGet()</code>        | <code>ProView</code>        | Drawing view in which the selection was made                                                                                      |
| <code>ProSelectionWindowIdGet()</code>    | int                         | Window where a selection is done                                                                                                  |

| Creo TOOLKIT Function            | Creo TOOLKIT Object | Meaning                                                         |
|----------------------------------|---------------------|-----------------------------------------------------------------|
| ProSelectionDrawing<br>Get ()    | ProDrawing          | Drawing in which the selection was made.                        |
| ProSelectionDwgtblcell<br>Get () | several integers    | Table segment, row, and column of a selected drawing table cell |

The assembly component path is the path down from the root assembly to the model that owns the database item being referenced. It is represented by the object `ProAsmcomppath` and is described fully in the [Assembly: Basic Assembly Access on page 1115](#) section.

The model item describes the database item in the context of its owning model, but does not refer to any parent assembly.

The 3-D point is the location, in solid coordinates, of a selected point on the model item, if it is a geometry object. The solid coordinates are those of the solid directly owning the model item.

If the model item is a surface, `ProUvParam` contains the *u* and *v* values that correspond to the 3-D selection point described above. If the item is an edge or curve, `ProUvParam` contains the *t* value.

The selection depth is the distance between the selected point and the point from which the selection search started. This is important only when you are using `ProSolidRayIntersectionCompute ()`, described in the section [Ray Tracing on page 201](#).

The view is used to distinguish different views of a solid in a drawing.

## Building a ProSelection Object

Some Creo TOOLKIT function require a `ProSelection` object as an input. In many cases the assembly path—`ProAsmcomppath`—and the modelitem will be all that is needed, so `ProSelectionAlloc ()` or `ProSelectionSet ()` can be used. In other cases, for example when a `ProSelection` needs to identify a specific drawing view, or a specific location on a geometry item, you may also need to call functions `ProSelectionViewSet ()`, `ProSelectionUvParamSet ()`, and `ProSelectionPoint3dSet ()`.

## ProSelection Function Examples

Examples of Creo TOOLKIT functions that use `ProSelection` are as follows:

- `ProSelect ()` uses `ProSelection` as its output to describe everything about the selected item.
- `ProGeomitemDistanceEval ()` uses `ProSelection` as its input, instead of `ProGeomitem`, so it can measure the distance between model items in different subassemblies.

- `ProSelectionHighlight()` and `ProSelectionUnhighlight()` use `ProSelection` as inputs to distinguish different instances of the same model item in different subassemblies, and also different drawing views of the same model.
- `ProFeatureCreate()` usually uses `ProSelection` objects to identify the geometry items the feature needs to reference.
- `ProDrawingDimensionCreate()` uses `ProSelection` objects to identify the entities the dimension will attach to and the drawing view in which the dimension is to be displayed.

In a case such as `ProGeomitemDistanceEval()`, which uses `ProSelection` as an input, you might need to build a `ProSelection` object out of its component data items. The function `ProSelectionAlloc()` allocates a new `ProSelection` structure, and sets the `ProAsmcomppath` and `ProModelitem` data in it. The function `ProSelectionSet()` sets that information in a `ProSelection` object that already exists. The function `ProSelectionVerify()` checks to make sure the contents of a `ProSelection` are consistent.

The function `ProSelectionCopy()` copies one `ProSelection` object to another. `ProSelectionFree()` frees the memory of a `ProSelection` created by `ProSelectionAlloc()` or as output by a Creo TOOLKIT function.

## Interactive Selection

Function Introduced:

- **ProSelect()**

`ProSelect()` is the Creo TOOLKIT function that forces the user to make an interactive graphics selection in Creo Parametric. Using this function the user can specify filters which control the items that can be selected.

Typically, the user has control over the filter options available from the `filter` menu located in the status bar at the bottom of the Creo Parametric graphics window. A call to `ProSelect()` sets application desired filters for the next expected selection.

The user interface shown when prompting for an interactive selection will be the selection dialog, with OK or Cancel buttons. Depending on the selection types permitted the user will be able to select items via:

- The graphics window
- The model tree
- The search tool
- External object

- Items external to the activated component

None of these selections or possible selections will provide guidance to the user about what to select and why. Therefore, it is important to provide detailed instructions to the user through the message window or dialog box that the application expects the user to make a selection. Use the function `ProMessageDisplay()` to explain to the user the type or purpose of the selection you want them to make.

---

### **Note**

When using this function in a UI command, make sure that the command priority for the UI command is appropriate for using `ProSelect()`. Improper priority settings can cause unpredictable results. See also [Normal priority actions on page 322](#) in the [User Interface: Menu on page 313](#) section.

---

The synopsis of `ProSelect()` is as follows:

```
ProError ProSelect (
 char option[], /* (In) The selection
filter. */
 int max_count, /* (In) The maximum number
of selections allowed.
*/
 ProSelection *p_in_sel, /* (In) An array of pointers
to selection structures
used to initialize the
array of selections. This
can be NULL. */
 ProSelFunctions *sel_func, /* (In) A pointer to a
structure of filter functions.
This can be NULL. */
 ProSelectionEnv sel_env, /* (In) Use attribute PRO_
SELECT_ACTIVE_
COMPONENT_IGNORE to also select items
external to the activate component. */
 ProSelAppAction appl_act_data, /* (In) Use NULL. */
 ProSelection **p_sel_array, /* (Out) A pointer to an
array of pointers to selected
items.
```

```

to static
the
reallocated
to this

int *p_n_sels /* (Out) The actual number of
the selections made. The
function function allocates
memory for this
and reuses it on
subsequent calls.*/
)

```

The first input argument to `ProSelect()`, *option*, is the set of item types that can be selected. This is in the form of a C string which contains the names of the types separated by commas (but no spaces). The following table lists the item types that can be selected by `ProSelect()`, the name of the type that must appear in the *option* argument, and the value of `ProType` contained in the `ProModelitem` for the selected item.

| Creo Parametric Database Item | ProSelect() Option | ProType                                         |
|-------------------------------|--------------------|-------------------------------------------------|
| Geometry Items                |                    |                                                 |
| Datum point                   | point              | PRO_POINT                                       |
| Datum axis                    | axis               | PRO_AXIS                                        |
| Datum plane                   | datum              | PRO_SURFACE                                     |
| Coordinate system datum       | csys               | PRO_CSYS                                        |
| Coordinate System Axis        | csys_axis          | PRO_CSYS_AXIS_X PRO_CSYS_AXIS_Y PRO_CSYS_AXIS_Z |
| Edge (solid or datum surface) | edge               | PRO_EDGE                                        |
| Vertex                        | edge_end           | PRO_EDGE_START, or PRO_EDGE_END                 |
| Datum curve                   | curve              | PRO_CURVE                                       |
| Datum curve end               | curve_end          | PRO_CRV_START, or PRO_CRV_END                   |
| Composite Curve               | comp_crv           | PRO_CURVE                                       |
| Edge (solid only)             | sldedge            | PRO_EDGE                                        |
| Edge (datum surface only)     | qltedge            | PRO_EDGE                                        |
| Pipe segment end              | pipeseg_end        | PRO_PSEG_START or PRO_PSEG_END                  |
| Surface (solid or quilt)      | surface            | PRO_SURFACE                                     |
| Surface (solid)               | sldface            | PRO_SURFACE                                     |

| Drawing view                                                      | dwg_view                                                                                        | PRO_VIEW                  |
| Drawing table                                                     | dwg_table                                                                                       | PRO_DRAW_TABLE            |
| Draft entity                                                      | draft_ent                                                                                       | PRO_DRAFT_ENTITY          |
| Detail symbol                                                     | dtl_symbol                                                                                      | PRO_SYMBOL_INSTANCE       |
| Detail note                                                       | any_note                                                                                        | PRO_NOTE                  |
| Table cell                                                        | table_cell                                                                                      | PRO_DRAW_TABLE            |
| Solids and Features                                               |                                                                                                 |                           |
| Feature                                                           | feature                                                                                         | PRO_FEATURE               |
| Part                                                              | part                                                                                            | PRO_PART                  |
| Component Feature                                                 | membfeat                                                                                        | PRO_FEATURE               |
| Assembly component model                                          | component                                                                                       | PRO_PART, PRO_ASSEMBLY    |
| Part or subassembly                                               | pnt_or_asm                                                                                      | PRO_PART, or PRO_ASSEMBLY |
| Miscellaneous Items                                               |                                                                                                 |                           |
| Creo Simulate Items                                               | Refer to the table in the section <a href="#">Selection of Creo Simulate Items on page 1824</a> |                           |
| External object                                                   | ext_obj                                                                                         | PRO_EXTOBJ                |
| Diagram fixed connector, fixed component, or parametric connector | dgm_obj                                                                                         | PRO_DIAGRAM_OBJECT        |
| Diagram wire (not a cable)                                        | dgm_non_cable_wire                                                                              | PRO_DIAGRAM_OBJECT        |
| Solid Body                                                        | 3d_body                                                                                         | PRO_BODY                  |
| ECAD conductor                                                    | ecad_cu                                                                                         | PRO_ECAD_CONDUCTOR        |
| MBD table                                                         | table_3d                                                                                        | PRO_TABLE                 |

The second argument specifies the maximum number of items the user can select. If there is no maximum, set this argument to -1.

The third argument to `ProSelect()` is an expandable array of `ProSelection` structures (created using `ProArrayAlloc()` and `ProSelectionAlloc()`) used to initialize the selection list. For more information refer to section [Expandable Arrays on page 63](#) in the section

---

[Fundamentals on page 30](#). This is used in situations like **Feature**, **Define** in Creo Parametric where the user has the option of removing a default selection for a feature reference.

The fourth argument is an optional structure that specifies three, user-defined filter functions. These enable you to filter the items that are selectable in a customized way. For example, you could arrange that only straight edges are selectable by writing a filter that would check the type of the edge, and return an appropriate status. This function would then be called within `ProSelect()` to prevent the user from selecting a curved edge.

The fifth argument allows the user to pass a set of attributes to `ProSelect()` using the function `ProSelectionEnvAlloc()`. The function `ProSelectionEnvAlloc()` returns the `ProSelectionEnv` handle which is given as input to `ProSelect()`. The attributes of `ProSelectionEnvAlloc()` are:

- `PRO_SELECT_DONE_REQUIRED`—Specifies that user has to click **OK** in the **Select** dialog box to get the selected items.
- `PRO_SELECT_BY_MENU_ALLOWED`—Specifies that search tool is available in the function `ProSelect()` when the attribute value is set to True, which is the default value.
- `PRO_SELECT_BY_BOX_ALLOWED`—Specifies that user must draw a bounding box to get the items selected within the box.

---

 **Note**

The attribute `PRO_SELECT_BY_BOX_ALLOWED` can be used only for the types specified under “Geometry Items” in the above table.

---

- `PRO_SELECT_ACTIVE_COMPONENT_IGNORE`—Specifies that user can select items external to the activate component.
- `PRO_SELECT_HIDE_SEL_DLG`—Specifies that the **Select** dialog box must be hidden.
- `PRO_SELECT_CANCEL_ON_CLOSE_DLG`—Specifies that the X (cancel) behaves the same as Close.

The sixth argument is not used in this release and should be set to `NULL`.

The final two arguments are the outputs, that is, an expandable array of `ProSelection` structures, and the number of items in the array. The previous section explains how to analyze the contents of a `ProSelection` object.

---

### **Note**

The array of `ProSelections` is allocated and reused on subsequent calls to `ProSelect()`.

---

Therefore, you must not free the output array. Also, if you wish to preserve any of the selections made, you should copy that selection using `ProSelectionCopy()`.

---

### **Note**

- When using the function `ProSelect()` from within a loop, if you encounter the error `PRO_TK_PICK_ABOVE (-14)`, then you must handle this error by returning control back to Creo Parametric.
  - The function `ProSelect()` returns `PRO_TK_NO_ERROR` when you end the command without making any selection in Creo Parametric. The function returns the output argument `p_n_sels` as zero and the array `p_sel_array` as `NULL`.
- 

## Highlighting

Functions Introduced:

- **`ProSelectionHighlight()`**
- **`ProSelectionDisplay()`**
- **`ProSelectionUnhighlight()`**

The function `ProSelectionHighlight()` highlights an item specified by a `ProSelection` object in a color chosen from the enumerated type `ProColorType`. This highlight is the same as the one used by Creo Parametric (and `ProSelect()`) when selecting an item—it just repaints the wire-frame display in the new color. The highlight is removed if you use the View Repaint command or `ProWindowRepaint()`; it is not removed if you use `ProWindowRefresh()`.

The function `ProSelectionUnhighlight()` removes the highlight.

`ProSelectionHighlight()` will not change the highlight color of an item already highlighted. If you need to do this, call `ProSelectionUnhighlight()` on the first item.

---

The function `ProSelectionDisplay()` does the same highlight as `ProSelectionHighlight()` but uses the standard highlight color used by Creo Parametric.

---

 **Note**

For performance reasons, calls to `ProSelectionHighlight()` are cached and executed after a short delay or after a window repaint.

---

## Selection\_Buffer

### Introduction to Selection Buffers

Selection is the process of choosing items on which you want to perform an operation. In Creo Parametric, before a feature tool is invoked, the user can select items to be used in a given tool's collectors. Collectors are like storage bins of the references of selected items. The location where preselected items are stored is called the selection buffer.

Depending on the situation, different selection buffers may be active at any one time. In Part and Assembly mode, Creo Parametric offers the default selection buffer, the Edit selection buffer, and other more specialized buffers. Other Creo Parametric modes offer different selection buffers.

In the default Part and Assembly buffer there are two levels at which selection is done:

- First Level Selection

Provides access to higher-level objects such as features or components. You can make a second level selection only after you select the higher-level object.

- Second Level Selection

Provides access to geometric objects such as edges and faces.

---

 **Note**

First-level and second-level objects are usually incompatible in the selection buffer.

---

Creo TOOLKIT allows access to the contents of the currently active selection buffer. The available functions allow your application to:

- Get the contents of the active selection buffer.

- 
- Remove the contents of the active selection buffer.
  - Add to the contents of the active selection buffer.

## Reading the Contents of the Selection Buffer

Functions Introduced:

- **ProSelbufferSelectionsGet()**
- **ProSelectionCollectionGet()**
- **ProSelbufferChangePostAction()**

Use the function `ProSelbufferSelectionsGet()` to access the contents of the current selection buffer. The function returns independent copies of the selections in the selection buffer (if the buffer is cleared, this array is still valid).

If there is no active selection buffer this function returns an error.

Use the standard Creo TOOLKIT functions to parse the contents of the `ProSelection` array.

However, the selection buffer stores chain and surface collections using a special mechanism. The function `ProSelectionCollectionGet()` can be used to extract the `ProCollection` object from a `ProSelection`.

### Note

As per the manner of storage of the collection in the selection buffer, once the collection has been cleared from the buffer the `ProSelection` referring to the collection is no longer valid. Therefore, it is recommended to extract the `ProCollection` object from the `ProSelection` before there is a possibility that it may be cleared from the selection buffer.

---

Creo Parametric will execute the callback function `ProSelbufferChangePostAction()` defined by the application, when there is a change in the selection buffer. This function is available by calling the function `ProNotificationSet()` with the value of the notify type as `PRO_SELBUFFER_CHANGE_POST`.

The function `ProSelbufferChangePostAction()` is applicable for selection buffer change in drawing mode and solid mode.

## Removing the Items from the Selection Buffer

Functions Introduced:

- **ProSelbufferClear()**
- **ProSelbufferSelectionRemove()**

---

Use the function `ProSelbufferClear()` to clear the currently active selection buffer of all contents. After the buffer is cleared, all contents are lost.

Use the function `ProSelbufferSelectionRemove()` to remove a specific selection from the selection buffer. The input argument is the index of the item (the index where the item was found in the call to `ProSelbufferSelectionsGet()`).

---

 **Note**

Because of the specialized nature of the Edit buffer in Creo Parametric, modification of the contents of the Edit buffer is not supported.

---

## Adding Items to the Selection Buffer

Functions Introduced:

- **`ProSelbufferSelectionAdd()`**
- **`ProSelbufferCollectionAdd()`**

Use the function `ProSelbufferSelectionAdd()` to add an item to the active selection buffer.

---

 **Note**

The selected item must refer to an item that is in the current model such as its owner, component path or drawing view.

---

This function may fail due to any of the following reasons:

- There is no current selection buffer active.
- The selection does not refer to the current model.
- The item is not currently displayed and so cannot be added to the buffer.
- The selection cannot be added to the buffer in combination with one or more objects that are already in the buffer. For example: geometry and features cannot be selected in the default buffer at the same time.

Use the function `ProSelbufferCollectionAdd()` to add a chain or surface collection to the active selection buffer. It has similar restrictions as `ProSelbufferSelectionAdd()`.

### Note

because of the specialized nature of the Edit buffer in Creo Parametric, modification of the contents of the Edit buffer is not supported.

Refer to the sample code [Example 3: Assigning Creo Parametric command to popup menus on page 339](#). This example demonstrates the use of the selection buffer to determine the context for a popup menu button.

## User Interface: Curve and Surface Collection

### User Interface: Curve and Surface Collection

This section describes the Creo TOOLKIT functions to access the details of curve and surface collections for query and modification. Curve and surface collections are required inputs to a variety of Creo Parametric tools such as Round, Chamfer, and Draft.

### Introduction to Curve and Surface Collection

A curve collection or chain is a group of separate edges or curves that are related, for example, by a common vertex, or tangency. Once selected, these separate entities are identified as a chain so they can be modified as one unit.

The different chain types are as follows:

- One-by-one—a chain of edges, curves or composite curves, each adjacent pair of which has a coincident endpoint. Some applications may place other conditions on the resulting chain.
- Tangent—a chain defined by the selected item and the extent to which adjacent entities are tangent.
- Curve—an entire composite curve or some portion of it that is defined by two component curves of the curve.
- Boundary—an entire loop of one-sided edges that bound a quilt or some portion thereof defined by two edges of the boundary loop.
- Surf Chain—an entire loop of edges that bound a face (solid or surface) or some portion of it that is defined by two edges of the loop.
- Intent Chain—an intent chain entity, usually created as the result of two intersecting features.

- 
- From/To—a chain that begins at a start-point, follows an edge line, and ends at the end-point.

Surface sets are one or more sets of surfaces either for use within a tool, or before entering a tool.

The definition of a surface set may not be independent in all respects from that of any other. In other words, the ability to construct some types of surface sets may depend on the presence of or on the content of others. On this account, we have different surface sets as follows:

- One-by-One Surface Set—Represents a single or a set of single selected surfaces, which belong to solid or surface geometry.
- Intent Surface Set—Represents a single or set of intent surfaces, which are used for the construction of the geometry of features. This instruction facilitates the reuse of the feature construction surface geometry as "intent" reference. This is also known as "logical object surface set".
- All Solid or Quilt Surface Set—Represents all the solid or quilt surfaces in the model.
- Loop Surface Set—Represents all the surfaces in the loop in relation with the selected surface and the edge. This is also known as "neighboring surface set".
- Seed and Boundary Surface Set—Represents all the surfaces between the seed surface and the boundary surface, excluding the boundary surface itself.

Surface set collection can be identified as a gathering a parametric set of surfaces in the context of a tool that specifically requests surface sets and is nearly identical to selection of a surface set.

Chain collection can be identified as a gathering a chain in the context of a tool that specifically requests chain objects and is nearly identical to chain selection.

Collection is related to Selection as follows:

Selection is the default method of interaction with Creo Parametric system. Selection is performed without the context of any tool. In other words, the system does not know what to do with selected items until the user tells the system what to do. Collection is essentially Selection within the context of a tool. Items are gathered for a specific use or purpose as defined by the tool, which forms the Collection. It is possible to convert the collections into the sets of selections using the collection APIs.

## The ProCollection object

A `ProCollection` object is an opaque pointer to a structure in which a surface or curve collection is stored. It represents a chain or surface set and extracts the details from an appropriate structure from Creo Parametric.

## Interactive Collection

Functions Introduced:

- **ProCurvesCollect()**
- **ProSurfacesCollect()**

Use the function `ProCurvesCollect()` to interactively create a collection of curves by invoking a chain collection user interface.

### Chain collection User Interface

Use the function `ProSurfacesCollect()` to interactively create a collection of surfaces by invoking a surface sets dialog.

## Surface Sets dialog box

For the functions `ProCurvesCollect()` and `ProSurfacesCollect()` the input arguments are as follows:

- *types*—Specifies an array defining the permitted instruction types. The following instruction types are supported:
  - `PRO_CHAINCOLLUI_ONE_BY_ONE`—for creating "One by One" chain.
  - `PRO_CHAINCOLLUI_TAN_CHAIN`—for creating "Tangent" chain.
  - `PRO_CHAINCOLLUI_CURVE_CHAIN`—for creating "Curve" chain.
  - `PRO_CHAINCOLLUI_BNDRY_CHAIN`—for creating "Boundary Loop" chain.
  - `PRO_CHAINCOLLUI_FROM_TO`—for creating "From-To" chain.

- `PRO_CHAINCOLLUI_ALLOW_LENGTH_ADJUSTMENT`—for allowing length adjustment in curves.
- `PRO_CHAINCOLLUI_ALLOW_ALL`—for allowing all the supported instruction types.
- `PRO_CHAINCOLLUI_ALLOW_EXCLUDED`—for excluding chain.
- `PRO_CHAINCOLLUI_ALLOW_APPENDED`—for appending chain.
- *n\_types*—Specifies the size of the types array.
- *filter\_func*—Specifies the filter function. The filter function is called before each selection is accepted. If your application wishes to reject a certain selection, it can return an error status from this filter. You may pass `NULL` to skip the filter.
- *app\_data*—Specifies the application data that will be passed to *filter\_func*. You may pass `NULL` when this is not required.
- *collection*—Specifies the collection object where the results will be stored. This should be preallocated using `ProCollectionAlloc()` (for `ProCurvesCollect()`) and `ProSrfcollectionAlloc()` (for `ProSurfacesCollect()`) respectively. The collection properties and instructions will be stored in this handle after the call to the functions `ProCurvesCollect()` and `ProSurfacesCollect()`. Use the functions for programmatic access to curve and surface collections and to extract the required information.

The output arguments are as follows:

- *sel\_list*—Specifies a pointer to an array of `ProSelection` objects describing the current resulting curves and edges or surfaces resulting from the collection. You may pass `NULL` if you are not currently interested in the results of the collection.
- *n\_sel*—Specifies the number of entries in *sel\_list*.

## Accessing Collection object from Selection Buffer

Function Introduced:

### • **ProSelectionCollectionGet()**

The selection buffer stores chain and surface collections using a special mechanism. The function `ProSelectionCollectionGet()` can be used to extract the `ProCollection` object from a `ProSelection`. The function `ProSelectionCollectionGet()` may fail due to the following conditions:

- `PRO_TK_INVALID_TYPE`—The selection object does not contain a collection.

- 
- `PRO_TK_INVALID_PTR`—The selection object contains a chain, but this chain reference is no longer valid. Chain references contained in `ProSelections` are only valid for as long as the chain is selected in the selection buffer.

---

 **Note**

It is recommended to extract the `ProCollection` object from the `ProSelection` before it can be cleared from the selection buffer.

---

## Adding a Collection Object to the Selection Buffer

Function Introduced:

- **`ProSelbufferCollectionAdd()`**

Use the function `ProSelbufferCollectionAdd()` to add a chain or surface collection to the active selection buffer. The function

`ProSelbufferCollectionAdd()` may fail due to the following conditions:

- `PRO_TK_INVALID_ITEM`—The collection does not correctly reference the current model.
- `PRO_TK_NOT_DISPLAYED`—The collection contains one or more items that are not currently displayed (for example, due to inactive geometry) and so cannot be added to the buffer.
- `PRO_TK_BAD_CONTEXT`—The selection cannot be added to the buffer in combination with one or more objects that are already in the buffer (for example geometry and features selected at the same time).

For further information on related functions, refer to the section [Selection Buffer on page 530](#) of section [User Interface: Selection on page 521](#).

## Programmatic Access to Collections

A `ProCollection` object may be returned from some indeterminate contexts or functions, however it can only be one of the following types:

- `PRO_COLLECTION_LEGACY`—legacy curve collection type (generated by `ProCurvesCollect()` or a superseded function like `ProCollectionAlloc()`).
- `PRO_COLLECTION_SRFCOLL`—surface collection type.
- `PRO_COLLECTION_CRV_COLL`—curve collection type.

Function Introduced:

- **`ProCollectionTypeGet()`**

---

Use the function `ProCollectionTypeGet()` `ProCollectionType`

## Contents of Curve Collection

Functions Introduced:

- **ProCrvcollectionInstructionsGet()**
- **ProCrvcollinstrTypeGet()**
- **ProCrvcollinstrAttributeIsSet()**
- **ProCrvcollinstrReferencesGet()**
- **ProCrvcollinstrValueGet()**
- **ProCrvcollinstrFree()**
- **ProCrvcollinstrArrayFree()**

Use the function `ProCrvcollectionInstructionsGet()` to get the instructions from the curve collection.

Use the function `ProCrvcollinstrTypeGet()` to get the curve collection instruction type.

Curve collection instructions can be of the following types:

- `PRO_CURVCOLL_EMPTY_INSTR`—to be used when you do not want to pass any other instruction.
- `PRO_CURVCOLL_ADD_ONE_INSTR`—for creating "One by One" chain.
- `PRO_CURVCOLL_TAN_INSTR`—for creating "Tangent" chain.
- `PRO_CURVCOLL_CURVE_INSTR`—for creating "Curve" chain.
- `PRO_CURVCOLL_SURF_INSTR`—for creating "Surface Loop" chain.
- `PRO_CURVCOLL_BNDRY_INSTR`—for creating "Boundary Loop" chain.
- `PRO_CURVCOLL_LOG_OBJ_INSTR`—for creating "Logical Object" chain.
- `PRO_CURVCOLL_PART_INSTR`—for creating chain on all possible references, or to choose from convex or concave only.
- `PRO_CURVCOLL_FEATURE_INSTR`—for creating chain from feature curves.
- `PRO_CURVCOLL_FROM_TO_INSTR`—for creating "From-To" chain.
- `PRO_CURVCOLL_EXCLUDE_ONE_INSTR`—for excluding the entity from the chain.
- `PRO_CURVCOLL_TRIM_INSTR`—to trim chain.
- `PRO_CURVCOLL_EXTEND_INSTR`—to extend chain.
- `PRO_CURVCOLL_START_PNT_INSTR`—to set the chain start point.

- `PRO_CURVCOLL_ADD_TANGENT_INSTR`—to add all edges tangent to the ends of the chain.
- `PRO_CURVCOLL_ADD_POINT_INSTR`—to add selected point or points to the collection.
- `PRO_CURVCOLL_OPEN_CLOSE_LOOP_INSTR`—to add a closed chain that is considered as open.
- `PRO_CURVCOLL_QUERY_INSTR`—for creating “Query” chain.
- `PRO_CURVCOLL_CNTR_INSTR`—to add contours to the collection.
- `PRO_CURVCOLL_SRFS_BNDRY_INSTR`—to collect boundary of the given set of surfaces.
- `PRO_CURVCOLL_SRFS_BNDRY_ADJ_INSTR`—to collect edges adjacent to the boundary of the given surfaces.
- `PRO_CURVCOLL_SKET_ADD_ONE_INSTR`—for creating “One by One” in sketcher.
- `PRO_CURVCOLL_SKET_FROM_TO_INSTR`—for creating “From-to” sketcher chain.
- `PRO_CURVCOLL_RESERVED_INSTR`—to determine the number of instructions defined in the curve instruction.

Use the function `ProCrvcollinstrAttributeIsSet()` to check whether a special attribute is set for the curve collection instruction.

The curve collection instruction attributes can be of the following types:

- `PRO_CURVCOLL_NO_ATTR`—applicable when there are no attributes present.
- `PRO_CURVCOLL_ALL`—applicable for all edges.
- `PRO_CURVCOLL_CONVEX`—applicable for convex edges only.
- `PRO_CURVCOLL_CONCAVE`—applicable for concave edges only.

Use the function `ProCrvcollinstrReferencesGet()` to get the references contained in a curve collection instruction.

Use the function `ProCrvcollinstrValueGet()` to get the value of a curve collection instruction. This is valid for instructions of `PRO_CURVCOLL_TRIM_INSTR` and `PRO_CURVCOLL_EXTEND_INSTR` type.

Use the function `ProCrvcollinstrFree()` to release a curve collection instruction.

Use the function `ProCrvcollinstrArrayFree()` to release the `ProArray` of curve collection instructions.

---

## Creation and Modification of Curve Collections

Functions Introduced:

- **ProCrvcollectionAlloc()**
- **ProCrvcollectionCopy()**
- **ProCrvcollectionInstructionAdd()**
- **ProCrvcollectionInstructionRemove()**
- **ProCrvcollinstrAlloc()**
- **ProCrvcollinstrAttributeSet()**
- **ProCrvcollinstrAttributeUnset()**
- **ProCrvcollinstrReferenceAdd()**
- **ProCrvcollinstrReferenceRemove()**
- **ProCrvcollinstrValueSet()**
- **ProCrvcollectionRegenerate()**

Use the function `ProCrvcollectionAlloc()` to allocate a curve collection.

Use the function `ProCrvcollectionCopy()` to copy a curve collection which is a newly allocated collection object internally and can be freed from memory using the function `ProCollectionFree()`.

### Note

`ProCrvcollectionCopy()` function should be used to convert the collection object returned by `ProCurvesCollect()` to a `PRO_COLLECTION_CRV_COLL` type of collection so that it can be used by the curve collection access functions.

---

Use the function `ProCrvcollectionInstructionAdd()` to add an instruction to a curve collection.

Use the function `ProCrvcollectionInstructionRemove()` to remove an instruction from a curve collection.

Use the function `ProCrvcollinstrAlloc()` to allocate a curve collection instruction.

Use the function `CrvcollinstrAttributeSet()` to add an attribute to the curve collection instruction.

Use the function `ProCrvcollinstrAttributeUnset()` to remove an attribute of a curve collection instruction.

Use the function `ProCrvcollinstrReferenceAdd()` to add a reference to curve collection instruction references.

---

Use the function `ProCrvcollinstrReferenceRemove()` to remove a reference to curve collection instruction.

Use the function `ProCrvcollinstrValueSet()` to set value of the curve collection instruction.

Use the function `ProCrvcollectionRegenerate()` to generate an array of objects based on the rules and information in the collection.

## Contents of Surface Collection

Functions Introduced:

- **ProSrffcollectionInstructionsGet()**
- **ProSrffcollinstrTypeGet()**
- **ProSrffcollinstrIncludeGet()**
- **ProSrffCollinstrInfoGet()**
- **ProSrffcollinstrReferencesGet()**
- **ProSrffcollinstrArrayFree()**
- **ProSrffcollinstrFree()**
- **ProSrffcollrefTypeGet()**
- **ProSrffcollrefItemGet()**
- **ProSrffcollrefArrayFree()**
- **ProSrffcollrefFree()**

Use the function `ProSrffcollectionInstructionsGet()` to get an array of instructions assigned to the surface collection.

Use the function `ProSrffcollinstrTypeGet()` to get the type of surface collection instruction.

Surface collection instructions can be of the following types:

- `PRO_SURFCOLL_SINGLE_SURF`—Instruction specifying a set of single surfaces.
- `PRO_SURFCOLL_SEED_N_BND`—Instruction specifying a combination of Seed and Boundary type of surfaces.
- `PRO_SURFCOLL_SEED_N_BND_INC_BND`—Instruction specifying a combination of Seed and Boundary type of surfaces and also includes the seed surfaces.
- `PRO_SURFCOLL_QUILT_SRFS`—Instruction specifying quilt type of surfaces.
- `PRO_SURFCOLL_ALL_SOLID_SRFS`—Instruction specifying all solid surfaces in the model.

- 
- `PRO_SURFCOLL_NEIGHBOR`—Instruction specifying neighbor type of surfaces (boundary loop).
  - `PRO_SURFCOLL_NEIGHBOR_INC`—Instruction specifying neighbor type of surfaces (boundary loop) and also includes the seed surfaces.
  - `PRO_SURFCOLL_LOGOBJ_SRFS`—Instruction specifying intent surfaces. Intent surfaces are also known as "logical objects".
  - `PRO_SURFCOLL_GEOM_RULE`—Instruction specifying collection of surfaces using geometry rules.
  - `PRO_SURFCOLL_SHAPE_BASED`—Instruction specifying collection of shape based surfaces.
  - `PRO_SURFCOLL_TANG_SRF`—Instruction specifying collection of tangent surfaces.

The following flags are used as an input to `ProSurfacesCollect` and drive its behavior of the interactive collection.

- `PRO_SURFCOLL_DISALLOW_QLT`—Do not allow selections from quilts.
- `PRO_SURFCOLL_DISALLOW_SLD`—Do not allow selections from solid geometry.
- `PRO_SURFCOLL_DONT_MIX`—Allow selections from only solid or only quilt but no mixing.
- `PRO_SURFCOLL_SAME_SRF_LST`—Allow selections from same solid or same quilt.
- `PRO_SURFCOLL_USE_BACKUP`—Prompts Creo Parametric to regenerate using backups.
- `PRO_SURFCOLL_DONT_BACKUP`—Do not back up copy of references.
- `PRO_SURFCOLL_DISALLOW_LOBJ`—Do not allow selections from intent surfaces or logical objects.
- `PRO_SURFCOLL_ALLOW_DTM_PLN`—Allows datum plane selection. It is not supported in Pro/ENGINEER Wildfire 2.0.

Use the function `ProSrfcollinstrIncludeGet()` to check whether the include flag of the surface collection instruction is set. If the include flag is `PRO_B_TRUE`, the surfaces generated by this instruction add surfaces to the overall set. If the include flag is `PRO_B_FALSE`, the surfaces generated by this instruction are removed from in the overall set.

Use the function `ProSrfCollinstrInfoGet()` to get the information about the bit flags from the surface collection instruction. For more information on bit flags, see the function `ProSrfCollinstrInfoSet()` in the section [Creation and Modification of Surface Collections on page 545](#).

---

Use the function `ProSrfcollinstrReferencesGet()` to get the references contained in a surface collection instruction.

Use the function `ProSrfcollinstrArrayFree()` to free a `ProArray` of surface collection reference handles.

Use the function `ProSrfcollinstrFree()` to release the surface collection instructions.

Use the function `ProSrfcollrefTypeGet()` to get the type of reference contained in the surface collection reference.

Surface collection references can be of the following types:

- `PRO_SURFCOLL_REF_SINGLE`—Specifying the collection reference belonging to the "single surface set" type of instruction. This type of reference can belong to single surface type of instruction.
- `PRO_SURFCOLL_REF_SINGLE_EDGE`—Specifying the collection reference belonging to the an "single surface set" edge type of instruction.
- `PRO_SURFCOLL_REF_SEED`—Specifying the collection reference to be the seed surface. This type of reference can belong to seed and boundary type of instruction.
- `PRO_SURFCOLL_REF_SEED_EDGE`—Specifying the collection reference of seed edge type. This type of reference can belong to seed and boundary type of instruction.
- `PRO_SURFCOLL_REF_BND`—Specifying the collection reference to be a boundary surface. This type of reference can belong to seed and boundary type of instruction.

A single seed and boundary type of instruction will have at least one of each seed and boundary type of reference.

- `PRO_SURFCOLL_REF_NEIGHBOR`—Specifying the collection reference to be of neighbor type. This type of reference belongs neighbor type of instruction.
- `PRO_SURFCOLL_REF_NEIGHBOR_EDGE`—Specifying the collection reference of neighbor edge type. This type of reference belongs to neighbor type of instruction.

A neighbor type of instruction will have one neighbor and one neighbor edge type of reference.

- `PRO_SURFCOLL_REF_GENERIC`—Specifying the collection reference to be of generic type. This type of reference can belong to intent surfaces , quilt and all-solid type of instructions.

Use the function `ProSrfcollrefArrayFree()` to free a `ProArray` of surface collection reference handles.

---

Use the function `ProSrfcollrefFree()` to free a surface collection reference handle.

Use the function `ProSrfcollrefItemGet()` to get the geometry item contained in the surface collection reference.

## Creation and Modification of Surface Collections

Functions Introduced:

- **`ProSrfcollectionAlloc()`**
- **`ProSrfcollectionCopy()`**
- **`ProSrfcollectionInstructionAdd()`**
- **`ProSrfcollectionInstructionRemove()`**
- **`ProSrfcollinstrAlloc()`**
- **`ProSrfcollinstrIncludeSet()`**
- **`ProSrfCollinstrInfoSet()`**
- **`ProSrfcollinstrReferenceAdd()`**
- **`ProSrfcollinstrReferenceRemove()`**
- **`ProSrfcollrefAlloc()`**
- **`ProSrfcollectionRegenerate()`**

Use the function `ProSrfcollectionAlloc()` to allocate a surface collection.

Use the function `ProSrfcollectionCopy()` to copy a surface collection into a newly allocated `ProCollection` handle.

Use the function `ProSrfcollectionInstructionAdd()` to add an instruction to surface collection.

Use the function `ProSrfcollectionInstructionRemove()` to remove the instructions from surface collections.

The function `ProSrfcollectionInstructionRemove()` may fail due to invalid index specifications for the instruction or if the collection contains instruction for curves.

Use the function `ProSrfcollinstrAlloc()` to allocate a surface collection instruction.

Use the function `ProSrfcollinstrIncludeSet()` to set the include flag for a surface collection instruction.

---

### Note

In the functions `ProSrfcollinstrAlloc()` and `ProSrfcollinstrIncludeSet()` to exclude the surfaces generated in the collection instruction pass the input arguments as follows:

- Specify the surface collection instruction as `PRO_SURFCOLL_SINGLE_SURF`.
- Specify the *include* argument as `PRO_B_FALSE`.

---

Use the function `ProSrfCollinstrInfoSet()` to set the information about the bit flags in the surface collection instruction. You can pass the bit maps information as bitmask containing one or more bit flags.

The following bit flags can be passed as input argument:

- `PRO_SURFCOLL_ALL_GEOM_RULE`—Specifies that when this flag is included with other rule flags, all the rules are applied. Otherwise, any applicable geometry rule is applied.
- `PRO_SURFCOLL_CO_PLANNAR_GEOM_RULE`—Specifies that the surfaces coplanar to the seed surface should be collected.
- `PRO_SURFCOLL_PARALLEL_GEOM_RULE`—Specifies that the surfaces parallel to the seed surface should be collected.
- `PPRO_SURFCOLL_CO_AXIAL_GEOM_RULE`—Specifies that the surfaces coaxial with the seed surface should be collected.
- `PRO_SURFCOLL_EQ_RADIUS_GEOM_RULE`—Specifies that the surfaces with the same radius and type as the seed surface should be collected.
- `PRO_SURFCOLL_SAME_CONVEXITY_GEOM_RULE`—Specifies that the surfaces that have the same convexity and type as the seed surface should be collected.

---

### Note

The bit flags `PRO_SURFCOLL_ALL_GEOM_RULE`, `PRO_SURFCOLL_CO_PLANNAR_GEOM_RULE`, `PRO_SURFCOLL_PARALLEL_GEOM_RULE`, `PRO_SURFCOLL_CO_AXIAL_GEOM_RULE`, `PRO_SURFCOLL_EQ_RADIUS_GEOM_RULE`, and `PRO_SURFCOLL_SAME_CONVEXITY_GEOM_RULE` are related to `PRO_SURFCOLL_GEOM_RULE`, that is, the geometry rule surface set.

---

- 
- `PRO_SURFCOLL_SHAPE_CHAMFER`—Collects surfaces with chamfered edges. If used alone then only primary chamfer shapes are added to the collection set.
  - `PRO_SURFCOLL_SHAPE_ROUND`—Collects surfaces with round shape. If used alone then only the primary round shapes are added to the collection set.
  - `PRO_SURFCOLL_SHAPE_PROTR_BOSS`—Collects surfaces of the type boss. The protrusion surfaces with the secondary shapes are also added to the set.
  - `PRO_SURFCOLL_SHAPE_PROTR_RIB`—Collects surfaces of the type rib. The protrusion surfaces without the secondary shapes are added to set.
  - `PRO_SURFCOLL_SHAPE_CUT_POCKET`—Collects cut surfaces with the secondary shapes.
  - `PRO_SURFCOLL_SHAPE_CUT_SLOT`—Collects cut surfaces without the secondary shapes being added to set.
  - `PRO_SURFCOLL_SHAPE_MORE_SHAPES`—Use this flag only with `PRO_SURFCOLL_SHAPE_CHAMFER` and `PRO_SURFCOLL_SHAPE_ROUND` to add the secondary chamfer and round shapes to the surface set.

---

 **Note**

The bit flags `PRO_SURFCOLL_SHAPE_ROUND`, `PRO_SURFCOLL_SHAPE_PROTR_BOSS`, `PRO_SURFCOLL_SHAPE_PROTR_RIB`, `PRO_SURFCOLL_SHAPE_CUT_POCKET`, `PRO_SURFCOLL_SHAPE_CUT_SLOT`, `PRO_SURFCOLL_SHAPE_MORE_SHAPES` and `PRO_SURFCOLL_SHAPE_CHAMFER` are related to `PRO_SURFCOLL_SHAPE_BASED`, that is, the shape surface set.

---

- `PRO_SURFCOLL_TANGENT_NEIGHBOURS_ONLY`—Specifies that the surfaces that have at least one tangent edge with another surface in the tangent surface set, starting from the seed surface should be collected.

---

 **Note**

The bit flag `PRO_SURFCOLL_TANGENT_NEIGHBOURS_ONLY` is related to `PRO_SURFCOLL_TANG_SRF`, that is, the tangent surface set.

---

- `PRO_SURFCOLL_SEEDNBOUND_STRONG_REFS`—Specifies that the boundary surfaces are considered as strong surfaces. This bit flag is related to `PRO_SURFCOLL_SEED_N_BND` and `PRO_SURFCOLL_SEED_N_BND_INC_BND`. If the selected references is missing, the feature will fail.

---

## Note

- Before you call `ProSrfCollinstrInfoSet()` function, you must set the include flag (`PRO_B_TRUE / PRO_B_FALSE`) for the surface collection instruction using the `ProSrfcollinstrIncludeSet()`.
- For the geometry based, the shape based, and the tangent based surface collections, the surface collection reference type (first input argument to the function `ProSrfcollrefAlloc()`) must be `PRO_SURFCOLL_REF_SEED`.
- If you want to apply all the geometry rule flags included in the info argument of the function `ProSrfCollinstrInfoSet()`, the flag `PRO_SURFCOLL_ALL_GEOM_RULE` must be included in info argument. If you do not include the `PRO_SURFCOLL_ALL_GEOM_RULE` flag, any of the geometry rule flags will be applied.

Use the function `ProSrfcollinstrReferenceAdd()` to add a reference to the surface collection instruction.

Use the function `ProSrfcollinstrReferenceRemove()` to remove a reference from the surface collection instruction.

Use the function `ProSrfcollectionRegenerate()` to generate an array of objects based on the rules and information in the collection.

## Access of Collection Object from Feature Element Trees

Functions Introduced:

- **`ProElementCollectionGet()`**
- **`ProElementCollectionSet()`**
- **`ProElementCollectionProcess()`**

Use the function `ProElementCollectionGet()` to extract a collection object from an element of a feature element tree of the following types:

- `PRO_E_STD_CURVE_COLLECTION_APPL`
- `PRO_E_STD_SURF_COLLECTION_APPL`

Use the function `ProElementCollectionSet()` to assign a collection object into the appropriate elements of the above mentioned types.

---

 **Note**

Point collections (`PRO_E_POINT_COLLECTION_APPL`) are accessed from the element as normal `ProReference` object—by using `ProElementReferenceGet()` and `ProElementReferenceSet()` APIs.

---

Use the function `ProElementCollectionProcess()` to generate a list of geometric items in the form of array of `ProReference` object constituting the collection. It returns a `ProArray` of the selected curves, edges, or surfaces that exist in the collection owned by the element. This function differs from `ProCrvcollectionRegenerate()` and `ProSrfcollectionRegenerate()` because those functions generate a list of collected entities based on standard rules. The function `ProElementCollectionProcess()`, if applied to a collection element from a given feature, will use the feature's rules to process the collection and return the exact geometric entities used by the feature.

---

 **Note**

If this element is extracted from an existing feature tree using `ProFeatureElementtreeExtract()`, the returned `reference_array` will be on the basis of the feature rules. On the other hand, if this element is newly created and not yet assigned to a feature, then the returned `reference_array` will be as per the default rules.

---

## Programmatic Access to Legacy Collections

Functions Introduced:

- **`ProCollectionAlloc()`**
- **`ProCollectionrefAlloc()`**
- **`ProCollectionrefSelectionSet()`**
- **`ProCollectionrefTypeSet()`**
- **`ProCollectioninstrAlloc()`**
- **`ProCollectioninstrTypeSet()`**
- **`ProCollectioninstrRefAdd()`**
- **`ProCollectionInstrAdd()`**
- **`ProCollectionInstrVisit()`**

- 
- **ProCollectioninstrTypeGet()**
  - **ProCollectioninstrRefVisit()**
  - **ProCollectionrefSelectionGet()**
  - **ProCollectionrefTypeGet()**
  - **ProCollectionFree()**
  - **ProCollectioninstrFree()**
  - **ProCollectionrefFree()**
  - **ProCollectionInstrRemove()**
  - **ProCollectioninstrRefRemove()**
  - **ProCrvcollectionInstrRegen()**

The functions listed in this section have been superseded. PTC recommends using the `ProCrvcollection*` and `ProSrfcollection*` functions instead of these; documentation for these functions is provided for maintenance of existing applications.

## **Example 1: Interactive Curve Collection using Creo TOOLKIT**

The sample code in the file `UgGeomCurveLength.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_geometry` demonstrates the interactive curves collection and computes the total curve length - consisting of addition of lengths of individual curves in resulting selection set. The collection filter function is set to allow only edge type of selections.

## **Example 2: Interactive Surface Collection using Creo TOOLKIT**

The sample code in the file `UgGeomSurfArea.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_geometry` demonstrates the interactive surface collection and computes the total area - consisting of addition of areas of individual surfaces in resulting selection set. It also creates parameter of double type on the individual surfaces and assigns it with the value of the individual surface area.

---

# User Interface: Animation

## Introduction

This section describes the Creo TOOLKIT functions that enable you to create animation frames and movies.

Creo TOOLKIT provides the functions that enable you to animate parts and assemblies. Creo TOOLKIT handles lower-level considerations, such as hardware-dependent graphics and the user interface.

Two animation techniques are available:

- Batch animation—You create an animation movie (`ProAnimMovie` object) and users control the movie using an interface similar to a VCR. Users can perform such operations as “Play”, “Fast-Forward”, “Rewind”, and so on. The following figure shows the animation dialog box.

### Animation Dialog Box

- Frame-by-frame (single) animation—You create a single animation (`ProSingleAnim` object) and code the control loop into your application. The batch animation interface does not appear. To replay the movie, you must reexecute the control loop of your application.

For both batch and single animation, you must build the animation from two important elements. These elements are:

- Animation object (`ProAnimObj` object)—Contains the object to be animated and its transformation, with respect to its immediate parent. In constructing the animation, you can show motion by creating a series of `ProAnimObj` objects, each with a different transformation.

- 
- Animation frame (`ProAnimFrame` object)—Captures the image of the animation objects at one instance of the animation. Your final animation is a series of animation frames shown in succession.

## Animation Objects

Functions Introduced:

- **`ProAnimobjectCreate()`**
- **`ProAnimobjectDelete()`**

An animation object can be a part or an assembly. To create an animation object, call the function `ProAnimobjectCreate()` and pass as input the component path of the object to be animated. You must also supply the location of the animation object with respect to its immediate parent—not with respect to the top-level assembly. This distinction is important when the depth of the assembly hierarchy is greater than 1.

To delete an animation object, use the function `ProAnimobjectDelete()`.

## Animation Frames

Functions Introduced:

- **`ProAnimframeCreate()`**
- **`ProAnimframeObjAdd()`**
- **`ProAnimframeObjRemove()`**
- **`ProAnimframeDelete()`**
- **`ProAnimframeObjVisit()`**

After you have created animation objects, you must create an animation frame in which to store the objects. To create an animation frame, call the function `ProAnimframeCreate()` and supply a frame view matrix. The frame view matrix is a transformation from the top model coordinate system that allows you to alter the view of the top-level model in your animation. This functionality could be used, for example, to change the view of an assembly while the assembly components (animation objects) move as specified in the call to `ProAnimobjectCreate()`.

### Note

The frame view matrix is specified as a transformation from the root assembly.

---

Creating an animation frame does not cause the animation objects to be contained in the frame. To add animation objects to a frame, you must call the function `ProAnimframeObjAdd()`.

To remove an object from a frame, call the function `ProAnimframeObjRemove()`. To delete a frame, call `ProAnimframeDelete()`.

The function `ProAnimframeObjVisit()` enables you to visit each animation object in an animation frame. The input arguments of the function specify the action and filtration functions, which are of type `ProAnimObjAct`.

## Playing\_Animations

### Single Animation

This section describes how to use your animation frames to construct and play the animation. As previously mentioned, there are two types of animation—single and batch.

Functions Introduced:

- **ProSingleAnimationInit()**
- **ProSingleAnimationPlay()**
- **ProSingleAnimationClear()**

If you want to use single animation, your Creo TOOLKIT application must include a control loop that displays one animation frame after another. Before executing your control loop, initialize the single animation by calling `ProSingleAnimationInit()`. Within the loop, display each frame in turn using the function `ProSingleAnimationPlay()`.

---

#### Note

Single animation does not involve the batch animation user interface. The control over a single animation is contained entirely within your application.

---

The function `ProSingleAnimationClear()` clears the specified single animation.

### Batch Animation

Batch animation implements the user interface shown in the [Introduction on page 551](#) section. The interface enables users to control the playing of your animation movie.

---

## Animation Movies

Functions Introduced:

- **ProAnimmovieCreate()**
- **ProAnimmovieFrameAdd()**
- **ProAnimmovieFrameRemove()**
- **ProAnimmovieDelete()**
- **ProAnimmovieFrameVisit()**

The function `ProAnimmovieCreate()` creates an animation movie. At its creation, a movie does not contain any frames. To add frames to the animation movie, call the function `ProAnimmovieFrameAdd()`.

To remove a frame from an animation movie, call the function `ProAnimmovieFrameRemove()`. Note that this action does not cause the frame to be deleted; use `ProAnimmovieDelete()` to release the memory of the animation frame.

The function `ProAnimmovieFrameVisit()` enables you to visit each of the frames in an animation movie. The input arguments to the function specify the action and filtration functions, which are of type `ProAnimFrameAct`.

## Playing a Batch Animation

Function Introduced:

- **ProBatchAnimationStart()**
- **ProAnimmovieSpinflagSet()**

Batch animation manages the display of animation frames inside Creo Parametric. When you call `ProBatchAnimationStart()`, the system displays the VCR-like user interface. This interface enables users to control the speed and direction of the animation.

The function `ProBatchAnimationStart()` requires as input the animation movie to be started (animated). In addition, you can supply a callback function to be invoked before each animation frame is displayed. The callback function is of type `ProBatchAnimAct`.

Use the function `ProAnimmovieSpinflagSet()` to set the `ProBoolean` flag that allows spin in a batch animation process. If the animation includes view modifications, this flag should be set to false, otherwise it can be true.

---

## Example 1: Creating a Batch Animation

The sample code in the file `UgAnimAsmcompAnim.c` located at `<creo_toolkit_loadpoint>\protk_appls\pt_userguide\ptu_anim`, shows how to animate an assembly component. The selected component rotates about the x-axis.

# Annotations: Annotation Features

## Overview of Annotation Features

This section describes how to access annotation features for special customizations. It provides specific functions for creation, access, and modification of annotation features and elements.

An annotation feature is a new feature available in Pro/ENGINEER Wildfire 2.0. It is composed of one or more "annotation elements". Each annotation element is composed of references, parameters and annotations (notes, symbols, geometric tolerances, surface finishes, reference dimensions, driven dimensions, and manufacturing template annotations). The annotation feature allows annotation information to have the same benefits as geometry in Creo Parametric models, that is, parameters can be assigned to these annotation elements, and missing geometric references can cause features to fail in some situations.

The feature type `PRO_FEAT_ANNOTATION` represents an annotation feature. Functions referring to annotation features use the structure `ProAnnotationFeat`, which is identical to `ProFeature`.

Functions referring to annotation elements use the structure `ProAnnotationElem` which is identical to the structure `ProModelItem` and is defined as

```
typedef struct pro_model_item
{
 ProType type;
 int id;
 ProMdl owner;
}ProAnnotationElem
```

Like other `ProModelItem` derivatives, each annotation element has a unique id assigned to it in the model.

Annotation elements may belong to annotation features, or may also be found in data-sharing features (features like Copy Geometry, Publish Geometry, Merge, Cutout, and Shrinkwrap features).

Creo TOOLKIT does not expose the feature element tree for annotation features because some elements in the tree are used for non-standard purposes. Instead, Creo TOOLKIT provides specific functions for creating, redefining, and reading the properties of annotation features and annotation elements.

---

## Creating Annotation Features

Functions Introduced:

- **ProAnnotationfeatCreate()**
- **ProDatumtargetAnnotationfeatureCreate()**

The function `ProAnnotationfeatCreate()` creates a new annotation feature in the model. Specify the following as the input parameters for this function:

- *model*—Specify the solid model on which the feature will be created. Specify the component path if the feature is created in an assembly context.
- *use\_ui*—Specifies a boolean flag that determines how the annotation features will be created. It can have the following values:
  - `FALSE`—Indicates that the feature will be a new empty annotation feature with one general annotation element in it. Modify the new annotation element and add others using subsequent steps.
  - `TRUE`—Indicates that Creo Parametric will invoke the annotation feature creation user interface.

The function `ProDatumtargetAnnotationfeatureCreate()` creates a new Datum Target Annotation Feature (DTAF) in the model. This function takes the same input arguments as the earlier function `ProAnnotationfeatCreate()`.

## Redefining Annotation Features

Redefining an annotation feature involves creation of new annotation elements, deletion of elements that are not required and modification of the feature properties.

---

### Note

The functions in this section are shortcuts to redefining the feature containing the annotation elements. Because of this, Creo Parametric must regenerate the model after making the required changes to the annotation element. The functions include a flag to optionally allow the **Fix Model** User Interface to appear upon a regeneration failure.

---

Functions Introduced:

- **ProAnnotationfeatElementAdd()**
- **ProAnnotationfeatElementArrayAdd()**

- 
- **ProAnnotationfeatElementDelete()**
  - **ProAnnotationfeatElementCopy()**

The function `ProAnnotationfeatElementAdd()` adds a new non-graphical annotation element to the feature.

The function `ProAnnotationfeatElementArrayAdd()` adds a series of new annotation elements to the feature. Each element may be created as non-graphical or may be assigned a pre-existing annotation.

---

 **Note**

In case of Datum Target Annotation Features (DTAFs), you can add only one set datum tag annotation element using the function `ProAnnotationfeatElementArrayAdd()`.

---

The function `ProAnnotationfeatElementDelete()` deletes an annotation element from the feature. The function deletes the annotation element, its annotations, parameters, references, and application data from the feature.

---

 **Note**

In case of Datum Target Annotation Features (DTAFs), `ProAnnotationfeatElementDelete()` allows you to delete only a Datum Target Annotation Element (DTAE) from a DTAF. This function does not allow deletion of a set datum tag annotation element from the DTAF.

---

The function `ProAnnotationfeatElementCopy()` copies and adds an existing annotation element to the specified annotation feature.

## Redefining Annotation Features Interactively

- **ProFeatureRedefineUI()**

The function `ProFeatureRedefineUI()` invokes the user interface for a feature, allowing the user to redefine the feature interactively. For Pro/ENGINEER Wildfire 2.0, this function supports annotation features only.

## Visiting Annotation Features

Functions Introduced:

- **ProSolidFeatVisit()**
- **ProModelitemNameGet()**

---

Use the function `ProSolidFeatVisit()` to visit the annotation features in the specified model.

The function `ProModelitemNameGet()` returns the name of the annotation feature.

## Creating Datum Targets

Functions Introduced:

- **ProMdlDatumTargetCreate()**

The function `ProMdlDatumTargetCreate()` creates a new datum target.

The input arguments are:

- *p\_owner\_mdl*—Specifies the model in which the datum target will be created.
- *type*—Specifies the type of target area using the enumerated data type `ProDatumTargetType`. The valid values are:
  - `PRO_DATUM_TARGET_NONE`
  - `PRO_DATUM_TARGET_POINT`
  - `PRO_DATUM_TARGET_CIRCLE`
  - `PRO_DATUM_TARGET_RECTANGLE`
- *annot\_plane*—Specifies the annotation plane.
- *attach\_sels*—Specifies the reference to which the datum target will be attached. To specify a single reference, pass `ProSelection` for index 0 and `NULL` for index 1.

For a pair of references, pass `ProSelection` for both indexes. In this case, the datum target is attached to the solid at the intersection point of the two references.

- *text\_pnt*—Specifies the location of the text in the datum target.

## Visiting Annotation Elements

The functions described in this section enable you to visit all the annotation elements in a solid model.

Functions Introduced:

- **ProFeatureAnnotationelemsVisit()**
- **ProSolidAnnotationelemsVisit()**

The function `ProFeatureAnnotationelemsVisit()` visits the annotation elements in the specified feature.

The function `ProSolidAnnotationelemsVisit()` visits the annotation elements in a solid model.

---

The filter function `ProAnnotationelemFilterAction()` and the visit function `ProAnnotationelemVisitAction()` are specified as input arguments for the above functions.

The function `ProAnnotationelemFilterAction()` is a generic function for filtering an annotation element. It returns the filter status of the specified annotation element. The filter status is passed as the input argument to the function `ProAnnotationelemVisitAction()` which is a generic function for visiting annotation elements.

## Accessing Annotation Elements

The following functions provide access to the properties of an annotation element.

Functions Introduced:

- **`ProAnnotationelemAnnotationGet()`**
- **`ProAnnotationelemCopyGet()`**
- **`ProAnnotationelemFeatureGet()`**
- **`ProAnnotationelemIsDependent()`**
- **`ProAnnotationelemIsIncomplete()`**
- **`ProAnnotationelemReferencesCollect()`**
- **`ProAnnotationelemQuiltreferenceSurfacesCollect()`**
- **`ProAnnotationelemTypeGet()`**
- **`ProAnnotationelemReferenceDescriptionGet()`**
- **`ProAnnotationelemReferenceIsStrong()`**
- **`ProAnnotationelemReferenceAutopropagateGet()`**
- **`ProAnnotationelemHasMissingrefs()`**

The function `ProAnnotationelemAnnotationGet()` returns the annotation contained in an annotation element.

The function `ProAnnotationelemCopyGet()` returns the copy flag of the annotation elements. This property is not supported for elements in data sharing features.

The function `ProAnnotationelemFeatureGet()` returns the feature that owns the annotation element.

The function `ProAnnotationelemIsDependent()` returns the value of the dependency flag for the annotation element. This property is supported only for the elements in data sharing features.

The function `ProAnnotationelemIsIncomplete()` returns a true value if the annotation element has missing strong references.

---

The function `ProAnnotationelemReferencesCollect()` returns an array of references contained in the specified annotation element. The input arguments for this function are:

- *element*—Specifies the annotation element.
- *ref\_type*—Specifies the type of references and can have one of the following values:
  - `PRO_ANNOTATION_REF_ALL`—All references
  - `PRO_ANNOTATION_REF_WEAK`—Weak references
  - `PRO_ANNOTATION_REF_STRONG`—Strong references
- *source*—Specifies the source of the references and can have one of the following values:
  - `PRO_ANNOTATION_REF_ALL`—From both user and annotation.
  - `PRO_ANNOTATION_REF_FROM_ANNOTATION`—From the annotation (or custom data) only.
  - `PRE_ANNOTATION_REF_FROM_USER`—From the user only.

Annotation elements have special default behavior for propagation of datum points to features in other models. The flag that controls this behavior can automatically propagate datum points or any other applicable items to data sharing features after the user has selected all other strong references of the annotation elements.

Here, applicable items are items that are designated to auto-propagate, using a checkbox in the references collector, for specific annotation elements.

The function

`ProAnnotationelemQuiltreferenceSurfacesCollect()` returns the surfaces which make up a quilt surface collection reference for the annotation element.

---

 **Note**

All the surfaces made inactive by features occurring after the annotation element in the model regeneration are also returned.

---

The function `ProAnnotationelemReferenceAutopropagateGet()` gets the autopropagate flag of the specified annotation element reference.

The function `ProAnnotationelemTypeGet()` returns the type of the annotation contained in the annotation element. It can have one of the following values:

- `PRO_ANNOT_TYPE_NONE`—Specifies a non-graphical annotation.

- 
- `PRO_ANNOT_TYPE_NOTE`—Specifies a note. Refer to the section [Notes on page 611](#) for details.
  - `PRO_ANNOT_TYPE_GTOL`—Specifies a geometric tolerance. Refer to the section [Geometric Tolerances on page 620](#) for details.
  - `PRO_ANNOT_TYPE_SRFFIN`—Specifies a surface finish. Refer to the section [Surface Finish Annotations on page 626](#) for details.
  - `PRO_ANNOT_TYPE_SYMBOL`—Specifies a symbol. Refer to the section [Symbol Annotations on page 629](#) for details.
  - `PRO_ANNOT_TYPE_DRVDIM`—Specifies a driven dimension. Refer to the section [Accessing Reference and Driven Dimensions on page 604](#) for details.
  - `PRO_ANNOT_TYPE_REFDIM`—Specifies a reference dimension. Refer to the section [Accessing Reference and Driven Dimensions on page 604](#) for details.
  - `PRO_ANNOT_TYPE_CUSTOM`—Specifies a manufacturing template annotation.
  - `PRO_ANNOT_TYPE_SET_DATUM_TAG`—Specifies a set datum tag. Refer to the section [Accessing Set Datum Tags on page 620](#) for details.
  - `PRO_ANNOT_TYPE_DRIVINGDIM`—Specifies a driving dimension annotation element. Refer to the section [Driving Dimension Annotation Elements on page 604](#) for details.

The function `ProAnnotationelemReferenceDescriptionGet()` gets the description property for a given annotation element reference.

### Note

The description string is same as that of the tooltip text for the reference name in the Annotation Feature UI.

---

The function `ProAnnotationelemReferenceIsStrong()` identifies if a reference is weak or strong in a given annotation element.

The function `ProAnnotationelemHasMissingrefs()` enables you to identify if an annotation element has missing references. The input parameters of this function allow you to investigate specific types and sources of references, or check all references simultaneously.

## Modification of Annotation Elements

The functions described in this section allow you to modify the properties of an annotation element.

---

 **Note**

The functions in this section are shortcuts to redefining the feature containing the annotation elements. Because of this, Creo Parametric must regenerate the model after making the indicated changes to the annotation element. The functions include a flag to optionally allow the **Fix Model** User Interface to appear upon a regeneration failure.

---

Functions Introduced:

- **ProAnnotationelemAnnotationSet()**
- **ProAnnotationelemCopySet()**
- **ProAnnotationelemDependencySet()**
- **ProAnnotationelemReferenceAdd()**
- **ProAnnotationelemReferenceRemove()**
- **ProAnnotationelemReferenceStrengthen()**
- **ProAnnotationelemReferenceWeaken()**
- **ProAnnotationelemReferenceDescriptionSet()**
- **ProAnnotationelemReferenceAutopropagateSet()**
- **ProAnnotationelemReferencesSet()**
- **ProAnnotationelemArrayReferencesSet()**
- **ProAnnotationreferencesetAlloc()**
- **ProAnnotationreferencesetReferenceAdd()**
- **ProAnnotationelemReferencesInheritGet()**
- **ProAnnotationelemReferencesInheritSet()**
- **ProAnnotationreferencesetFree()**
- **ProAnnotationreferencesetProarrayFree()**

The function `ProAnnotationelemAnnotationSet()` allows you to modify the annotation contained in an annotation element. Specify the value for the input argument *annotation* as `NULL` to modify the annotation element to be a non-graphical annotation.

---

 **Note**

The above function does not support Datum Target Annotation Elements (DTAEs).

---

---

If you modify the annotation contained in the annotation element, the original annotation is automatically removed from the element and is owned by the model.

The function `ProAnnotationelemCopySet()` provides write access to the copy flag of the annotation element. This property is not supported for annotations in data sharing features.

The function `ProAnnotationelemDependencySet()` sets the value for the dependency flag. This property is supported only for annotations in data sharing features.

The function `ProAnnotationelemReferenceAdd()` adds a strong user-defined reference to the annotation element.

The function `ProAnnotationelemReferenceRemove()` removes the user defined reference from the annotation element.

The function `ProAnnotationelemReferenceStrengthen()` converts a weak reference to a strong reference.

The function `ProAnnotationelemReferenceWeaken()` converts a strong reference to a weak reference.

The function `ProAnnotationelemReferenceDescriptionSet()` sets the description property for a given annotation element reference.

The function `ProAnnotationelemReferenceAutopropagateSet()` sets the autopropagate flag of the specified annotation element reference.

The function `ProAnnotationelemReferencesSet()` replaces all the user-defined references in the annotation element with a `ProArray` of references specified as the input argument.

The function `ProAnnotationelemArrayReferencesSet()` replaces all the user-defined references for a `ProArray` of annotation elements with the `ProArray` of reference sets specified as the input argument.

---

 **Note**

All the annotation elements must belong to the same feature. The number of reference sets should match the number of annotation elements to be modified.

---

The function `ProAnnotationreferencesetAlloc()` allocates a set of user-defined references to be assigned to an annotation element.

The function `ProAnnotationreferencesetReferenceAdd()` adds a new reference to an existing set of user-defined annotation references.

---

The function `ProAnnotationelemReferencesInheritGet()` checks if a child annotation element inherits references from its parent. The input argument *elem* specifies the annotation element using a `ProAnnotationElem` object. The output argument *inherit* returns `PRO_B_TRUE` if the element inherits references from the parent.

The function `ProAnnotationelemReferencesInheritSet()` sets the semantic inherit references flag in a child annotation element to inherit references from its parent. The input arguments are:

- *elem*—Specifies the annotation element using a `ProAnnotationElem` object.
- *inherit*—Specifies `PRO_B_FALSE` to disable inheritance of references from the parent if enabled and removes the parent-inherited references from the child annotation element.

The function `ProAnnotationreferencesetFree()` releases the set of user-defined references to be assigned to an annotation element.

The function `ProAnnotationreferencesetProarrayFree()` releases an array of reference sets to be assigned to an annotation element.

### Example 1: Creating/ Adding Annotation Element Array Reference Set

The sample code in the file

`CreoTkAnnotationElemArrayReferencesSet.c` located at `<creo_toolkit_loadpoint>\protk_appls\pt_userguide\creotk_examples\creotk_annotations`, shows how to add single or multiple references to an Annotation Element or Annotation Feature prior to single regeneration using `ProAnnotationelemReferenceAdd()`.

## Parameters Assigned to Annotation Elements

The functions described in this section allow you to access parameters assigned to the annotation element. Specify the annotation element as the parameter owner for these functions.

Functions Introduced:

- **ProParameterIsEnumerated()**
- **ProParameterRangeGet()**

The function `ProParameterIsEnumerated()` identifies an enumerated parameter and returns the available values assigned to it. The output of the function is `PRO_B_TRUE` if the parameter is enumerated and `PRO_B_FALSE` if it is not. The output argument also presents `ProArray` of values that can be assigned to the enumerated parameter.

---

The function `ProParameterRangeGet()` identifies whether a parameter is restricted to a range of values. It optionally provides the boundary conditions for the range.

For more information on functions that allow you to view, create, delete, and modify parameters, refer to [Core: Parameters on page 216](#).

## Automatic Propagation of Annotation Elements

Automatic local propagation of annotation elements can be done based on some specified conditions, using a Creo TOOLKIT application. A Creo TOOLKIT application can register the following notification event types (`ProNotifyType`):

- `PRO_FEATURE_CREATE_POST`
- `PRO_FEATURE_REDEFINE_POST`

When an appropriate event occurs during a Creo Parametric session, the associated notification function can invoke a local propagation.

Functions Introduced:

- **`ProAnnotationelemAutopropagate()`**

The function `ProAnnotationelemAutopropagate()` causes the local and automatic propagation of annotation elements to the currently selected feature within the same model, after a supported feature has either been created or modified. The propagation behavior is dependant on the standard Creo Parametric algorithm and on the current contents of the selection buffer.

Following are the list of supported features:

- Draft
  - Surface
  - Solid
- Offset
  - Surface
  - With Draft
  - Expand
- Mirror Surface
- Copy Surface
- Move Surface

The Creo TOOLKIT application can be written so as to specify the condition for the automatic propagation, based on created feature-type, subtype or any other required properties.

---

The function propagates based on the current contents of the selection buffer.

For notification of type `PRO_FEATURE_REDEFINE_POST`, Creo Parametric does not automatically populate the selection buffer with the feature that was redefined. The Creo TOOLKIT application would be then required to populate the selection buffer with the feature using the appropriate functions. Refer to the section Introduction to [Selection Buffers on page 530](#) in the section [User Interface: Selection on page 521](#) for more information on selection buffer.

### Note

The function `ProAnnotationelemAutopropagate()` works regardless of the current value for the configuration option, `auto_propagate_ae`. PTC advises that the Creo TOOLKIT application respect the current value of this configuration option; otherwise, duplicate versions of the propagated annotations can result.

---

## Detail Tree

Creo Parametric 1.0 onwards, when the **3D Annotation** tab is active, you can view the active combination state of a model and the annotations assigned to it. This representation is called a Detail Tree. For more information on Detail Tree, see the Creo Parametric help. Use the following functions to refresh, expand, and collapse the detail tree:

Functions Introduced:

- **ProDetailtreeRefresh()**
- **ProDetailtreeExpand()**
- **ProDetailtreeCollapse()**

Use the function `ProDetailtreeRefresh()` to rebuild the detail tree in the Creo Parametric window that contains the model.

Use the function `ProDetailtreeExpand()` to expand the detail tree in the Creo Parametric window.

Use the function `ProDetailtreeCollapse()` to collapse all nodes of the detail tree in the Creo Parametric window and make its child nodes invisible.

The input arguments to these functions are:

- *solid*—Handle to the model that contains the detail tree.
- *window\_id*—ID of the Creo Parametric window in which you want to refresh, expand, or collapse the detail tree.

---

### Note

Use `PRO_VALUE_UNUSED` to refresh, expand, or collapse the detail tree in the active window.

---

## Access to Annotations

The structure for the annotations is similar to the structure `ProModelItem` and is defined as

```
typedef struct pro_model_item
{
 ProType type;
 int id;
 ProMdl owner;
}ProAnnotation
```

The value of *type* for different annotations is as follows:

- `PRO_NOTE`—Specifies a note. Functions specific to notes use the object type `ProNote`.
- `PRO_SYMBOL_INSTANCE`—Specifies a symbol instance. Functions specific to symbols use the object `ProDtlsyminst`.
- `PRO_GTOL`—Specifies a geometric tolerance. Functions specific to Gtols use the object `ProGtol`.
- `PRO_SURF_FIN`—Specifies a surface finish. Functions specific to surface finish use the object `ProSurfFinish`.
- `PRO_REF_DIMENSION`—Specifies a reference dimension.
- `PRO_DIMENSION`—Specifies a driving or driven dimension. Reference, driven and driving dimension functions may use the object type `ProDimension`.
- `PRO_SET_DATUM_TAG`—Specifies a set datum tag annotation. Functions specific to set datum tag use the object type `ProSetdatumtag`.
- `PRO_CUSTOM_ANNOTATION`—Specifies a custom annotation type. Currently, used only for manufacturing template annotations.

Functions Introduced:

- **`ProAnnotationElementGet()`**
- **`ProAnnotationByViewShow()`**
- **`ProAnnotationByFeatureShow()`**
- **`ProAnnotationByComponentShow()`**

- **ProCombstateAnnotationErase()**
- **ProDrawingAnnotationErase()**
- **ProAnnotationShow()**
- **ProAnnotationIsShown()**
- **ProAnnotationIsInactive()**
- **ProAnnotationDisplay()**
- **ProAnnotationUndisplay()**
- **ProAnnotationUpdate()**
- **ProFeatureParamsDisplay()**

The function `ProAnnotationElementGet()` returns the annotation element that contains the annotation.

The function `ProAnnotationByViewShow()` displays the annotation of the specified type in the selected view.

The function `ProAnnotationByFeatureShow()` displays the annotation of the specified type for the selected feature.

The function `ProAnnotationByComponentShow()` displays the annotation of the specified type for the selected component.

From Creo Parametric 2.0 M060 onward, you can specify the view in which the annotations for the selected feature and component must be displayed. For the functions `ProAnnotationByFeatureShow()` and `ProAnnotationByComponentShow()`, specify the view where the annotations must be displayed. If you pass the input argument *view* as `NULL`, the annotations are displayed in all the views.

The following types of annotations are displayed for the functions `ProAnnotationByViewShow()`, `ProAnnotationByFeatureShow()`, and `ProAnnotationByComponentShow()`:

- `PRO_DIMENSION`
- `PRO_REF_DIMENSION`
- `PRO_NOTE`
- `PRO_GTOL`
- `PRO_SURF_FIN`
- `PRO_AXIS`
- `PRO_SET_DATUM_TAG`
- `PRO_SYMBOL_INSTANCE`
- `PRO_DATUM_TARGET`

---

If you want to display an annotation which is dependent on another annotation for its display in the drawing, then the Creo TOOLKIT application must first display the parent annotation. Only after the parent annotation is displayed, the application can display its dependent annotations. For example, if a geometric tolerance is placed on a dimension, then the application must call the function `ProAnnotationByViewShow()` for `PRO_DIMENSION` type. The dimension is displayed. To display the geometric tolerance, call the function `ProAnnotationByViewShow()` for `PRO_GTOL`. The same logic applies for the functions `ProAnnotationByFeatureShow()`, and `ProAnnotationByComponentShow()`.

The function `ProCombstateAnnotationErase()` removes an annotation from the display for the specified combined state.

The function `ProDrawingAnnotationErase()` removes an annotation from the display for the specified drawing. The annotation is not shown in the specified drawing.

---

 **Note**

The annotation which was removed from the display using the functions `ProCombstateAnnotationErase()` and `ProDrawingAnnotationErase()` will become visible again, only if the function `ProAnnotationShow()` is called to explicitly display the annotation.

---

The function `ProAnnotationShow()` shows the annotation in the current combined state. The annotation will be visible until it is explicitly erased from the combined state. The function also adds the specified annotation to the current combined state, if not added. If the specified annotation has been erased, then the function changes the display status of the erased annotation and makes it visible in the combined state, that is, it unerases the annotation.

This function is also capable of showing an annotation in a drawing view similar to the Creo Parametric command `Show` and `Erase`. This function supersedes the functions `ProDimensionShow()` and `ProNoteDisplay()`.

The function `ProAnnotationIsShown()` returns the display status of the annotation in the current combined state or drawing.

---

 **Note**

To get the display status of set datum tags in a drawing, use the function `ProDrawingSetDatumTagIsShown()`.

---

---

The function `ProAnnotationIsInactive()` indicates whether the annotation can be shown or not. An annotation becomes inactive if all the weak references it points to have been lost or consumed.

The functions `ProAnnotationDisplay()` and `ProAnnotationUndisplay()` temporarily display and remove an annotation from the display for the specified combined state or drawing. The functions `ProAnnotationDisplay()` and `ProAnnotationUndisplay()` should be used together. To edit a shown annotation, it must be first removed temporarily from display using the function `ProAnnotationUndisplay()` followed by the editing function calls, and finally must be redisplayed using the function `ProAnnotationDisplay()`, so that the updated annotation is correctly visible to the user.

The function `ProAnnotationUpdate()` updates the display of an annotation, but does not actually display it. If the annotation is not currently displayed (because it is hidden by layer status or inactive geometry), the text extracted from the annotation with the mode `PRODISPMODE_NUMERIC` may include callout symbols, instead of the text shown to the user. `ProAnnotationUpdate()` informs Creo Parametric to update the contents of the annotation in order to cross-reference these callout values. This function supports 3D model notes of the type `ProNote` and detail notes of the type `ProDtlNote`.

When you want to force the display of dimensions or parameters, geometric tolerances (gtols), and so on on a single feature, use the function `ProFeatureParamsDisplay()`.

---

#### **Note**

- The function `ProAnnotationDisplay()` supersedes the functions `ProDimensionShow()` and `ProGtolShow()`.
  - The function `ProAnnotationUndisplay()` supersedes the functions `ProDimensionErase()` and `ProGtolErase()`.
  - The function `ProDimensionDisplayUpdate()` is superseded by a combination of `ProAnnotationDisplay()` and `ProAnnotationUndisplay()`.
- 

## Converting Annotations to Latest Version

Functions Introduced:

- **`ProAnnotationNeedsConversion()`**
- **`ProAnnotationLegacyConvert()`**

---

The function `ProAnnotationNeedsConversion()` returns true in the following cases:

- Annotations created in releases earlier than Creo Parametric 4.0 F000
- Annotations created using the deprecated functions `ProGtolCreate()` or `ProSetdatumtagCreate()`

The input argument *annotation* can be a gtol, reference dimension, driven dimension, set datum tag, or datum tag which needs to be converted.

The function returns the following values for the output argument *needs\_conversion*:

- `PRO_B_TRUE`—When the annotation needs conversion.
- `PRO_B_FALSE`—When the annotation is already converted.

The function `ProAnnotationLegacyConvert()` converts annotations to the latest Creo Parametric version.

You can call the function `ProAnnotationLegacyConvert()` only if the function `ProAnnotationNeedsConversion()` returns true.

## Annotation Text Styles

Functions Introduced:

- **`ProAnnotationTextstyleGet()`**
- **`ProAnnotationTextstyleSet()`**
- **`ProTextStyleFree()`**

The function `ProAnnotationTextstyleGet()` retrieves the text style for the specified annotation. The input arguments are:

- *annotation*—Specifies the annotation.
- *drawing*—Specifies a drawing only when the annotation is owned by the solid, but is displayed in the drawing.
- *comp\_path*—Specifies the component path to the solid that owns the annotation.

Use the function `ProTextStyleFree()` to free the allocated data structure.

The method `ProAnnotationTextstyleSet()` sets the text style for the specified annotation.

## Annotation Orientation

An Annotation Orientation refers to the annotation plane or the parallel plane in which the annotation lies, the viewing direction, and the text rotation. You can define the annotation orientation using a datum plane or flat surface, a named

---

view, or as flat to screen. If the orientation is defined by a datum plane, you can set its reference to `frozen` or `driven`; where `frozen` indicates that the reference to the datum plane or named view has been removed.

Functions Introduced:

- **ProAnnotationplaneCreate()**
- **ProAnnotationplaneFromViewCreate()**
- **ProAnnotationplaneFlatToScreenCreate()**
- **ProAnnotationplaneTypeGet()**
- **ProAnnotationplaneReferenceGet()**
- **ProAnnotationplanePlaneGet()**
- **ProAnnotationplaneVectorGet()**
- **ProAnnotationplaneFrozenGet()**
- **ProAnnotationplaneFrozenSet()**
- **ProAnnotationplaneForcetoplaneflagGet()**
- **ProAnnotationplaneForcetoplaneflagSet()**
- **ProAnnotationplaneViewnameGet()**
- **ProAnnotationplaneAngleGet()**
- **ProAnnotationplaneActiveGet()**
- **ProMdlAnnotplanesFromGalleryCollect()**
- **ProMdlAnnotationplanesCollect()**
- **ProAnnotationplaneNamesGet()**
- **ProAnnotationplaneByNameInit()**
- **ProAnnotationplaneNameAssign()**
- **ProAnnotationplaneAddToGallery()**
- **ProAnnotationplaneRemoveFromGallery()**
- **ProAnnotationplaneRotate()**

The function `ProAnnotationplaneCreate()` creates a new annotation plane from either a datum plane, a flat surface, or an existing annotation that already contains an annotation plane.

The function `ProAnnotationplaneFromViewCreate()` creates a new annotation plane from a saved model view.

The function `ProAnnotationplaneFlatToScreenCreate()` returns the annotation plane item representing a flat-to-screen annotation in the model. This function takes a `ProBoolean` input argument *by\_screen\_point*, which identifies whether the annotations on this plane are located by screen points, or by model units.

---

## Note

You can only place notes, surface finishes, and symbols as flat to screen. Dimensions, geometric tolerances and set datum tags are not supported as flat-to-screen annotations.

---

Use the function `ProAnnotationplaneTypeGet()` to obtain the annotation plane type. It can have one of the following values:

- `PRO_ANNOTATIONPLANE_REFERENCE`—The annotation plane is created from a datum plane or a flat surface, and can be frozen or be associative to the reference.
- `PRO_ANNOTATIONPLANE_NAMED_VIEW`—The annotation plane is created from a named view or a view in the drawing.
- `PRO_ANNOTATIONPLANE_FLATTOSCREEN_BY_MODEL_PNT`—The annotation plane is flat-to-screen and annotations are located by model units.
- `PRO_ANNOTATIONPLANE_FLATTOSCREEN_BY_SCREEN_PNT`—The annotation plane is flat-to-screen and annotations are located by screen points.
- `PRO_ANNOTATIONPLANE_FLATTOSCREEN_LEGACY`—The annotation uses a legacy flat-to-screen format (located in model space).

The function `ProAnnotationplaneReferenceGet()` returns the planar surface used as the annotation plane.

The function `ProAnnotationplanePlaneGet()` returns the geometry of the annotation plane in terms of the `ProPlanedata` object containing the origin and orientation of the annotation plane.

The functions `ProAnnotationplaneFrozenGet()` and `ProAnnotationplaneFrozenSet()` determine and assign, respectively, whether the annotation orientation is frozen or driven by reference to the plane geometry. These functions are applicable only for annotation planes governed by references.

The functions `ProAnnotationplaneForcetoplaneflagGet()` and `ProAnnotationplaneForcetoplaneflagSet()` return and assign, respectively, the value of the `ProBoolean` argument *force\_to\_plane* for an annotation plane. If this argument is set to `PRO_B_TRUE`, then the annotations that reference the annotation plane are placed on that plane. If the annotation orientation is not frozen, that is, driven by the reference plane, and if the reference plane is moved, then the annotations also move along with the plane.

The function `ProAnnotationplaneViewnameGet()` obtains the name of the view that was originally used to determine the orientation of the annotation plane.

## Note

If the named view orientation has been changed after the annotation plane was created, the orientation of the plane will not match the current orientation of the view.

The function `ProAnnotationplaneVectorGet()` returns the normal vector that determines the viewing direction of the annotation plane.

The function `ProAnnotationplaneAngleGet()` returns the current rotation angle in degrees for a given annotation plane and the text orientation of all annotations on that plane.

The function `ProAnnotationplaneActiveGet()` returns the active annotation plane in the specified model.

The function `ProMdlAnnotplanesFromGalleryCollect()` collects the names of all the annotation planes in the gallery. The output argument `names` is a `ProArray` of names in the gallery. Use the function `ProWstringArrayFree()` to free the allocated memory. The function returns the error `PRO_TK_EMPTY` if there are no annotation planes in the gallery.

The function `ProMdlAnnotationplanesCollect()` collects the names of all the named annotation planes in the specified model. The function returns the error `PRO_TK_EMPTY` if there are no annotation planes in the model.

The function `ProAnnotationplaneNamesGet()` returns the names of the specified annotation plane.

The function `ProAnnotationplaneByNameInit()` finds and returns the annotation plane with the specified name. The function returns the error `PRO_TK_E_NOT_FOUND` if the annotation plane with the specified name does not exist.

The function `ProAnnotationplaneNameAssign()` assigns a name to the specified annotation plane. The function returns the error `PRO_TK_E_NOT_FOUND` if the specified annotation plane does not exist in the model. The function returns the error `PRO_TK_E_FOUND` if an annotation plane with the specified name already exists in the model.

Use the function `ProAnnotationplaneAddToGallery()` to add an annotation plane with the specified name to the gallery.

Use the function `ProAnnotationplaneRemoveFromGallery()` to remove the annotation plane with the specified name from the gallery.

The function `ProAnnotationRotate()` rotates a given annotation by the specified angle. This moves the annotation to a new annotation plane with the appropriate rotation assigned. Other annotations on the annotation's current plane are unaffected by this function.

---

 **Note**

You can only rotate annotations that belong to annotation elements using the above function.

---

## Annotation Associativity

The functions described in this section allow you to ensure associativity between shown annotations in drawings and 3D models. You can independently control the position associativity and attachment associativity of a drawing annotation.

---

 **Note**

- Drawing annotations can have only uni-directional associativity, that is, changes to the position and attachment of the annotation in the 3D model are reflected for the annotation in the drawing view, but not vice-versa.
  - You cannot modify the position associativity and attachment associativity of a drawing annotation from the 3D model.
  - You cannot make free, flat-to-screen annotations in a drawing view associative to the annotations in the 3D model.
  - Annotation properties such as text, jogs, breaks, skew, witness line clippings, and flip arrow states are not associative.
- 

Functions Introduced:

- **ProAnnotationIsAssociative()**
- **ProAnnotationPositionUpdate()**
- **ProAnnotationAttachmentUpdate()**

The function `ProAnnotationIsAssociative()` identifies if a given annotation in a drawing view is associative to the annotation in the 3D model. It has the following output arguments:

- *assoc\_position*—Specifies if the position of the annotation is associative.
- *assoc\_attach*—Specifies the attachment associativity. It takes one of the following values:
  - `PRO_ANNOTATTACH_ASSOCIATIVITY_PARTIAL`—Specifies that the drawing annotation is partially associative.

- 
- `PRO_ANNOTATTACH_ASSOCIATIVITY_FULL`—Specifies that the drawing annotation is fully associative.
  - *future\_use*—This argument is for future use.

The function `ProAnnotationPositionUpdate()` updates the position of the drawing annotation, and makes it associative to the position of the annotation in the 3D model.

---

 **Note**

You can update the associative position only for drawing annotations that have their placement based on model coordinates.

---

The function `ProAnnotationAttachmentUpdate()` updates the attachment of the drawing annotation, and makes it associative to the attachment of the annotation in the 3D model. Associative attachment of an annotation refers to both – its references and its attachment point on its references.

---

 **Note**

You can update the associative attachment only for drawing annotations that are attached to the geometry.

---

## Annotation Security

The functions described in this section allow you to manage whether an annotation is designated as a security marking. You can independently control the security marking option of a drawing annotation. You cannot copy such annotations. Annotations designated as security markings have the following characteristics:

- Always visible whenever the model is viewed in a product that supports the security markings.
- Listed at the top of the detail tree in an active combined state.
- Shown by an icon in the Detail Tree and Model Tree.

Functions Introduced:

- **`ProAnnotationSecuritymarkingSet()`**
- **`ProAnnotationSecuritymarkingGet()`**

---

Use the function `ProAnnotationSecuritymarkingSet()` to set the security marking option for notes and symbols. The input arguments follow:

- `a`
- *annotation*—Annotation must be flat to screen, unattached, and standalone note or symbol.
- *is\_secure*—Pass a `ProBoolean` value `PRO_B_TRUE` to designate security marking.

Use the function `ProAnnotationSecuritymarkingGet()` to retrieve the security marking option for notes and symbols.

## Interactive Selection

Annotation features, annotation elements, and annotations can be selected interactively using `ProSelect()` or can be obtained from the selection buffer using the function `ProSelbufferSelectionsGet()`.

For more information on interactive selection refer to section [User Interface: Selection on page 521](#).

## Display Modes

Functions Introduced:

- **`ProDisplaymodeGet()`**
- **`ProDisplaymodeSet()`**

These functions specify whether the display of dimensions shows symbols or values, and enables you to switch the mode. This is the equivalent to the Creo Parametric command **Switch Dimensions** in the **Relations** dialog box.

## Designating Dimensions and Symbols

Function Introduced:

- **`ProSymbolDesignate()`**
- **`ProSymbolUndesignate()`**
- **`ProSymbolDesignationVerify()`**

The function `ProSymbolDesignate()` designates a dimension, dimension tolerance, geometric tolerance or surface finish symbol to the specified model.

The function `ProSymbolUndesignate()` undesignates the dimension, dimension tolerance, geometric tolerance or surface finish symbol from the specified model.

---

The function `ProSymbolDesignationVerify()` determines if a dimension, dimension tolerance, geometric tolerance or surface finish symbol has been designated to a model.

## Designate an Annotation

Functions introduced:

- **ProAnnotationDesignateSet()**
- **ProAnnotationDesignateGet()**
- **ProDrawingViewAnnotDispStatusGet()**
- **ProAnnotationReferencesInheritGet()**
- **ProAnnotationReferencesInheritSet()**
- **ProAnnotationReferenceIsInherit()**

Use the function `ProAnnotationDesignateSet()` to set the annotation designate type.

The input arguments for the function `ProAnnotationDesignateSet()` are:

- *annotation*— Specify an annotation
- *designate*— Specify the designate type

Use the function `ProAnnotationDesignateGet()` to get the annotation designate type.

The input argument for this function is:

- *annotation*— Specify an annotation

The function returns the value for the output argument *designate* that gets the designate type.

Use the function `ProDrawingViewAnnotDispStatusGet()` to get the display status of all annotations of a drawing view. The input arguments are:

- *draw*—The drawing from which to fetch the annotations status using the `ProDrawing` object.
- *view*—The view for which annotations display status should be fetched using the `ProView` object.

The output arguments are:

- *p\_annot\_array*—Specifies the `ProArray` using the `ProAnnotation` object. Use the function `ProAnnotationreferencearrayFree()` to free the allocated memory.
- *p\_annot\_display\_status\_array*—Specifies the `ProArray` of annotation display statuses as `TRUE` or `FALSE`, where `TRUE` indicates a displayed annotation and `FALSE` indicates an erased annotation.

---

The function `ProAnnotationReferencesInheritGet()` checks whether a child annotation inherits references from its parent. The input argument *annotation* specifies the annotation by using the `ProAnnotation` object.

The output argument *inherit* returns `PRO_B_TRUE` if the child annotation inherits references.

The function `ProAnnotationReferencesInheritSet()` sets a child annotation to inherit references from the parent. The input arguments are:

- *annotation*—Specify the annotation by using the `ProAnnotation` object.
- *inherit*—`PRO_B_TRUE` to inherit references from the parent.

The function `ProAnnotationReferenceIsInherit()` checks whether the specified reference is an inherited annotation reference. The input arguments are:

- *annotation*—Specify the annotation by using the `ProAnnotation` object.
- *ref*—Specify the annotation reference by using the `ProAnnotationReference` object.

The output argument *inherit* returns `PRO_B_TRUE` if the child annotation inherits references.

## Dimensions

### The ProDimension Object

The `ProDimension` object handle is a `DHandle` that is equivalent to `ProModelitem`. The owner field can be a solid or a drawing, depending upon where the dimension is stored. Dimensions created in drawing mode may be stored in the drawing or in the solid depending upon the setting of the `config.pro` option `CREATE_DRAWING_DIMS_ONLY`. The `type` field is either `PRO_DIMENSION` or `PRO_REF_DIMENSION`. The `ID` is the integer used to identify the dimension inside Creo Parametric. It corresponds to the numerical part of the default symbol assigned to the dimension when it is created.

The `ProDimension` object also inherits from `ProModelitem`, which means that functions such as `ProModelitemInit()` and `ProSelectionModelitemGet()` can be used for it (`ProDimensionSymbolGet()` and `ProDimensionSymbolSet()` are recommended for this purpose, instead of `ProModelitemNameGet()` and `ProModelitemNameSet()`).

### Visiting Dimensions

Functions Introduced:

- **ProSolidDimensionVisit()**
- **ProDrawingDimensionVisit()**

- 
- **ProDimensionSymbolGet()**
  - **ProDimensionValueGet()**
  - **ProDimensionParentGet()**
  - **ProDimensionTypeGet()**
  - **ProDimensionNomvalueGet()**
  - **ProDimensionIsDisplayRoundedValue()**
  - **ProDimensionDisplayRoundedValueSet()**
  - **ProDimensionDisplayedValueGet()**
  - **ProDimensionOverridevalueGet()**
  - **ProDimensionValuedisplayGet()**
  - **ProDimensionIsFractional()**
  - **ProDimensionDecimalsGet()**
  - **ProDimensionDenominatorGet()**
  - **ProDimensionIsReldriven()**
  - **ProDimensionIsRegenednegative()**
  - **ProDimensionBoundGet()**
  - **ProDimensionOwnerfeatureGet()**
  - **ProDimensionIsAccessibleInModel()**
  - **ProDimensionIsSignDriven()**
  - **ProDimensionDisplayFormatGet()**
  - **ProDimensionOriginSideGet()**
  - **ProSelectionDimWitnessLineGet()**
  - **ProSelectionDimArrowGet()**
  - **ProSelectionDimArrowSet()**

The two visit functions `ProSolidDimensionVisit()` and `ProDrawingDimensionVisit()` conform to the usual style of visit functions. (Refer to section [Visit Functions on page 67](#) in the section [Fundamentals on page 30](#).) A dimension is stored in a solid if it is a “shown” dimension, that is, if it was created automatically by Creo Parametric as part of the feature definition. A dimension will also be stored in a solid if it was created in drawing mode while the `config.pro` option `CREATE_DRAWING_DIMS_ONLY` was set to `NO`.

The function `ProDimensionSymbolGet()` returns the symbol (the name) of the specified dimension.

The function `ProDimensionValueGet()` returns the value of the dimension.

---

Some feature dimensions are dependent on dimensions of other features. To modify the dependent dimension, you must get the parent dimension and modify it. Use the function `ProDimensionParentGet()` to get the parent dimension of the specified dependent dimension. For example, consider a sketch feature, which is used to create an extrude feature. In this case, the section dimensions of the extrude feature depend on the dimensions of the sketch feature. To modify the section dimensions of extrude feature, the dimensions of the sketch feature must be retrieved and modified.

---

 **Note**

Multiple dimensions may depend on a single parent dimension.

---

The function `ProDimensionTypeGet()` returns the type of the dimension in terms of the following values:

- `PRODIMTYPE_LINEAR`
- `PRODIMTYPE_RADIUS`
- `PRODIMTYPE_DIAMETER`
- `PRODIMTYPE_ANGLE`
- `PRODIMTYPE_ARC_LENGTH`
- `PRODIMTYPE_IPAR_INT`

The function `ProDimensionNomvalueGet()` returns the nominal value of a dimension. The function returns the nominal value even if the dimension is set to the upper or lower bound. The nominal value is returned in degrees for an angular dimension and in the system of units for other types of dimensions.

Use the function `ProDimensionIsDisplayRoundedValue()` to determine whether the specified dimension is set to display its rounded off value.

In Creo TOOLKIT, a rounded off value is a decimal value that contains only the desired number of digits after the decimal point. For example, if a dimension has the stored value 10.34132 and you want to display only two digits after the decimal point, you must round off the stored value to two decimal places. Thus, rounding off converts 10.34132 to 10.34.

Use the function `ProDimensionDisplayRoundedValueSet()` to set the attribute of the given dimension to display either the rounded off value or the stored value. You can use this function for all dimensions, except angular dimensions created prior to Pro/ENGINEER Wildfire 4.0, ordinate baseline dimensions, and dimensions of type `DIM_IPAR_INT`. For these dimensions, the functions returns an error status `PRO_TK_NOT_VALID`.

---

If you choose to display the rounded off value, the function `ProDimensionDisplayedValueGet()` retrieves the displayed rounded value of the specified dimension. Otherwise, it retrieves the stored value.

The function `ProDimensionOverridevalueGet()` returns the override value for a dimension. The default override value is zero.

---

 **Note**

The override value is available only for driven dimensions.

---

Use the function `ProDimensionValuedisplayGet()` to obtain the type of value displayed for a dimension. The valid types are:

- `PRO_DIMVALUEDISPLAY_NOMINAL`—Displays the actual value of the dimension along with the tolerance value.
- `PRO_DIMVALUEDISPLAY_OVERRIDE`—Displays the override value for the dimension along with the tolerance value.
- `PRO_DIMVALUEDISPLAY_HIDE`—Displays only the tolerance value for the dimension.

The function `ProDimensionIsFractional()` returns whether the dimension is expressed in terms of a fraction rather than a decimal. If the dimension is decimal, the function `ProDimensionDecimalsGet()` outputs the number of decimals digits that are significant; if the dimension is fractional, the function `ProDimensionDenominatorGet()` returns the value of the largest possible denominator used to define the fractional value.

The function `ProDimensionIsRelDriven()` returns whether the dimension is driven by a relation.

The function `ProDimensionIsRegenednegative()` returns whether the dimension really has a negative value in relation to its original definition. Dimensions are always displayed in Creo Parametric with positive values, and `ProDimensionValueGet()` will always return a positive value, so this function is needed to show whether a dimension has been “flipped” as a result of being assigned a negative value during the last regeneration.

The function `ProDimensionBoundGet()` returns the bound status of a dimension.

The function `ProDimensionFeatureGet()` has been deprecated. Use the function `ProDimensionOwnerfeatureGet()` instead.

---

The function `ProDimensionOwnerfeatureGet()` returns the feature that owns the specified dimension.

---

 **Note**

For dimensions or reference dimensions in annotation elements, the function `ProDimensionOwnerfeatureGet()` returns the annotation feature that directly owns the annotation element.

---

The function `ProDimensionIsAccessibleInModel()` identifies if a specified dimension is owned by the model. By default, the dimension is accessible in the model.

When you set a negative value to a dimension, it will either change the dimension to this negative value, or flip the direction around its reference and show a positive value dimension instead. Use the function `ProDimensionIsSignDriven()` to check this. The function returns the following values for the output argument *is\_sign\_driven*:

- `PRO_B_TRUE`—When the negative sign in the dimension value is used to flip the direction.
- `PRO_B_FALSE`—When the negative sign is used to indicate a negative value, that is, the dimension is negative.

The configuration option `show_dim_sign` when set to *yes* allows you to display negative dimensions in the Creo Parametric user interface.

When the option is set *no*, the dimensions always show positive value. However, in this case, if you set a negative value for the dimension, the direction is flipped.

---

 **Note**

Some feature types, such as, dimensions for coordinate systems and datum point offsets, always show negative or positive values, even if the option is set to *no*. These features do not depend on the configuration option.

---

The function `ProDimensionDisplayFormatGet()` retrieves the format in which the specified dimension is displayed. The enumerated data type `ProDimensionDisplayFormat` returns the following values:

- `PRO_DIM_DISPLAY_DECIMAL`—Specifies that the dimension is displayed in decimal format.
- `PRO_DIM_DISPLAY_FRACTIONAL`—Specifies that the dimension is displayed in fractional format.

---

For dimensions, sometimes it may be required to indicate the origin or start of measurement. The origin is indicated by placing the dimension origin symbol on the witness line. The function `ProDimensionOriginSideGet()` retrieves the witness line which is set as the origin for a dimension. The output argument *dim\_side* returns the index of witness line. If dimension origin has not been set for the specified dimension, the argument returns -1.

You can place annotations such as, geometric tolerances and datum feature symbol, on the witness lines of dimensions. The function `ProSelectionDimWitnessLineGet()` gets information about the dimension which has an annotation attached to its witness line. You must get the input object `ProSelection` from the annotation which is attached to the witness line. For example, if the leader of a geometric tolerance is attached to the witness line of a dimension, the `ProSelection` object is returned by the function `ProGtolAttachLeadersGet()`. The output arguments are:

- *dimension*—Specifies a pointer to the dimension which is associated with the selected witness line.
- *wline\_side*—Specifies the index of the witness line to which the annotation is attached.
- *location*—Specifies the location on the witness line where the annotation is attached.

The function `ProSelectionDimArrowGet()` receives information from a selection of a dimension arrow. The input argument *selection* selects the dimension arrow. The output arguments are:

- *dimension*—Specifies an arrow for the selected dimension.
- *wline\_side*—Specifies the side of the selected dimension.
- *location*—Specifies the `ProPoint3d` location of the attached dimension, which may be offset from the dimension arrow.

The function `ProSelectionDimArrowSet()` fills the selection if the dimension arrow has an offset. The input arguments are as follows:

- *dimension*—Specifies an arrow for the selected dimension.
- *wline\_side*—Specifies the side of the selected dimension.
- *location*—Specifies the `ProPoint3d` location of the attached dimension, which may be offset from the dimension arrow.

The output argument *selection* selects the dimension arrow.

## **Example 2: Changing the Displayed Value of Selected Model Dimension to Rounded or Non-Rounded**

The sample code in the file `UgDimDisplayRounded.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_dims`, shows the displayed value of a selected model dimension to rounded/non-rounded.

---

## Modifying Dimensions

Functions Introduced:

- **ProDimensionSymbolSet()**
- **ProDimensionValueSet()**
- **ProDimensionOverridevalueSet()**
- **ProDimensionValuedisplaySet()**
- **ProDimensionDecimalsSet()**
- **ProDimensionDenominatorSet()**
- **ProDimensionBoundSet()**
- **ProDimensionDimensionReset()**
- **ProDimensionBasicSet()**
- **ProDimensionInspectionSet()**
- **ProDimensionElbowSet()**
- **ProDimensionArrowtypeSet()**
- **ProDimensionSimpleBreakCreate()**
- **ProDimensionJogCreate()**
- **ProDimensionWitnesslineErase()**
- **ProDimensionWitnesslineShow()**
- **ProDimensionDisplayFormatSet()**
- **ProDimensionOriginSideSet()**
- **ProDimensionEnvelopeGet()**
- **ProDimensionTangentAttachUpdate()**

The function `ProDimensionSymbolSet()` allows you to change the symbol (the name) of a dimension. You can use this function only with solid dimensions.

---

### **Note**

The function will return the error `PRO_TK_NO_CHANGE` if the specified symbol already exists for another dimension in the model.

---

The function `ProDimensionValueSet()` changes the value of a dimension. It does not allow you to change the value of any dimension whose value is driven in some other way, for example, a driven or reference dimension or a dimension that is driven by a relation.

---

The function `ProDimensionOverridevalueSet()` assigns the override value for a dimension. This value is restricted to real numbers. The default override value is zero.

---

 **Note**

You can set the override value only for driven dimensions.

---

The function `ProDimensionValuedisplaySet()` sets the type of value to be displayed for a dimension.

The function `ProDimensionDecimalsSet()` sets the number of decimal places for a decimal dimension.

When you call the function `ProDimensionDecimalsSet()` for a driving dimension:

- If the number of decimal places required to display the stored value of the dimension is greater than the number of decimal places specified in the function `ProDimensionDecimalsSet()` and the Round Displayed Value attribute of the dimension is ON, the stored value is unchanged. Only the displayed number of decimal places is changed and the displayed value is updated accordingly.

For example, consider a dimension with its stored value as 12.12323 and the Round Displayed Value attribute of the dimension is set to ON. If the function `ProDimensionDecimalsSet()` sets the number of decimal places to 3, the stored value of the dimension is unchanged, that is, the stored value will be 12.12323. The displayed value of the dimension is rounded to 3 decimal places, that is, 12.123. The Round Displayed Value attribute is not changed.

- If the number of decimal places required to display the stored value of the dimension is greater than the number of decimal places specified in the function `ProDimensionDecimalsSet()` and the Round Displayed Value attribute of the dimension is OFF, the number of decimal places of the dimension is modified and the stored value is rounded to the specified number of decimal places.

For example, consider a dimension with its stored value as 12.12323 and the Round Displayed Value attribute of the dimension is OFF. If the function `ProDimensionDecimalsSet()` sets the dimension to 3 decimal places, then the stored value of the dimension is rounded to 3 decimal places and is modified to 12.123. The dimension is displayed as 12.123.

- If the number of decimal places required to display the stored value of the dimension is less than the number of decimal places specified in the function `ProDimensionDecimalsSet()`, the number of decimal places is set to

---

the specified value. The status of the Round Displayed Value attribute is not considered, as no change or an increase to the number of decimal places will have no effect on the stored value.

For example, consider a dimension with its stored value as 12.12323. If the function `ProDimensionDecimalsSet()` sets the dimension to 8 decimal places and if trailing zeros are displayed, then the dimension is displayed as 12.12323000.

For a driven dimension:

- If the number of decimal places set by the function is greater than or equal to the number of decimal places required to display the stored value of the dimension, the decimal places value is changed and no change to the Round Displayed Value attribute is made.
- If the number of decimal places of the dimension is less than the number required to display the stored value of the dimension, the Round Displayed Value attribute is AUTOMATICALLY set to ON as it is not possible to change the stored value of a driven dimension.

---

 **Note**

The value given for the input argument decimals of the function `ProDimensionDecimalsSet()` should be a non-negative number. It should be such that when you apply either the upper or the lower values of the tolerance to the given dimension, the total number of digits before and after the decimal point in the resulting values does not exceed 13.

---

The function `ProDimensionDenominatorSet()` sets the denominator for the fractional dimensions. When you call the function `ProDimensionDenominatorSet()`:

- The stored value remains unchanged if,
  - it can be expressed as an exact fraction with the given denominator, regardless of whether the round-off attribute is set or not.
  - the stored value cannot be expressed as an exact fraction, but the round-off attribute is set. In this case, the fraction is the approximate representation of the stored value.
- The stored value changes to the nearest fraction and triggers a regeneration of the model, if it cannot be expressed as an exact fraction with the given denominator and the round-off attribute is not set.

The functions `ProDimensionBoundSet()` sets the bound status of the dimension.

---

The function `ProDimensionDimensionReset()` sets the dimension to the value it had at the end of the last successful regeneration. You can use this function to recover from a failed regeneration.

The function `ProDimensionBasicSet()` and the function `ProDimensionInspectionSet()` set the basic and inspection notations of the dimension. These functions are applicable to both driven and driving dimensions.

---

 **Note**

The basic and inspection notations of the dimension are not available when only the tolerance value for a dimension is displayed.

---

The function `ProDimensionElbowSet()` sets the length of the elbow for the specified dimension in a solid. The function can also be used to set the length of the elbow for a dimension in a drawing, where the dimension is created in a solid and is displayed in a drawing. To work with dimensions shown in a drawing, pass the name of the drawing in the input argument *drawing*.

The function `ProDimensionSimpleBreakCreate()` creates a simple break on an existing dimension witness line. The input arguments are:

- `dimension`—Specifies a pointer to the dimension whose witness line is to be broken.
- `drawing`—Specifies the drawing in which the dimension is present. You can specify a NULL value.
- `index`—Specifies the index of the witness line. Depending on which side of the dimension the witness line lies, specify the value as 1 or 2. Use the method `ProDimlocationWitnesslinesGet` to get the location of the witness line end points for a dimension.

---

 **Note**

This argument is not applicable for ordinate, radius, and diameter dimensions.

---

- `break_start`—Specifies the start point of the break.
- `break_end`—Specifies the end point of the break.

The function `ProDimensionJogCreate()` creates a jog on an existing dimension witness line. The input arguments are:

- `dimension`—Specifies a pointer to the dimension where the jog will be created.

- 
- *drawing*—Specifies the drawing in which the dimension is present. You can specify a NULL value.
  - *index*—Specifies the index of the witness line. Depending on which side of the dimension the witness line lies, specify the value as 1 or 2. Use the method `ProDimlocationWitnesslinesGet` to get the location of the witness line end points for a dimension.

---

 **Note**

This argument is not applicable for ordinate, radius, and diameter dimensions.

---

- *jog\_points*—Specifies an array of points to position the jog. If the specified witness line has no jog added to it, then you must specify minimum two points that is, the start point and end point of the jog.

---

 **Note**

The functions `ProDimensionSimpleBreakCreate()` and `ProDimensionJogCreate()` return the error type `PRO_TK_INVALID_TYPE` when breaks and jogs are not supported for the specified dimension type, for example, diameter dimension.

The functions return the error type `PRO_TK_ABORT` when it is not possible to create breaks or jogs for the specified dimension witness line. For example, if you add a jog that is duplicate to an existing jog on the dimension witness line.

---

The function `ProDimensionArrowtypeSet()` sets the arrow type for the specified arrow in a dimension. The input arguments are:

- *dimension*—Specifies the dimension.
- *drawing*—Specifies the drawing in which the dimension is displayed. To set the arrow type in the owner model, specify the argument value as NULL.
- *arrow\_index*—Specifies the index of the witness line. Depending on which side of the dimension the witness line lies, specify the value as 1 or 2.

---

 **Note**

The value of *arrow\_index* is ignored for ordinate and radius dimensions.

---

- 
- *arrow\_type*—Specifies the type of arrow and is defined using the enumerated data type `ProLeaderType`. The valid values are:
    - `PROLEADERTYPE_ARROWHEAD`
    - `PROLEADERTYPE_DOT`
    - `PROLEADERTYPE_FILLEDDOT`
    - `PROLEADERTYPE_NOARROW`
    - `PROLEADERTYPE_CROSS`
    - `PROLEADERTYPE_SLASH`
    - `PROLEADERTYPE_INTEGRAL`
    - `PROLEADERTYPE_BOX`
    - `PROLEADERTYPE_FILLEDBOX`
    - `PROLEADERTYPE_DOUBLEARROW`
    - `PROLEADERTYPE_CROSS_N_ARROW`
    - `PROLEADERTYPE_TARGET`
    - `PROLEADERTYPE_LEFTHALF`
    - `PROLEADERTYPE_RIGHTHALF`
    - `PROLEADERTYPE_TRIANGLE`
    - `PROLEADERTYPE_AUTOMATIC`

The function `ProDimensionWitnesslineErase()` erases a specified witness line from the dimension. The input arguments are:

- *dimension*—Specifies the dimension whose witness line must be erased. This argument cannot be `NULL`.
- *drawing*—Specifies the drawing in which the dimension is displayed. To erase a witness line from a solid, specify this argument as `NULL`.
- *WitnesslineIndex*—Specifies the index of the witness line. Specify the value as 1 or 2 depending on which side of the dimension the witness line lies. Use the method `ProDimlocationWitnesslinesGet()` to get the location of the witness line end points for a dimension.

Use the function `ProDimensionWitnesslineShow()` to show the erased witness line for the specified dimension.

---

#### **Note**

The functions `ProDimensionWitnesslineErase()` and `ProDimensionWitnesslineShow()` erase and show the witness lines of dimensions and reference dimensions, respectively. These functions work with both drawings and solids.

---

---

The function `ProDimensionDisplayFormatSet()` sets the format in which the specified dimension must be displayed.

Use the function `ProDimensionOriginSideSet()` to set a witness line as the origin or start of measurement for the specified dimension. Specify the index of the witness line in the input argument *dim\_side*. If a witness line is already set as origin, pass *dim\_side* as -1 to remove the origin.

The function `ProDimensionEnvelopeGet()` returns the envelope of a line in the specified dimension. While retrieving coordinates of the dimension in a specified solid, if the dimension is displayed in the solid as well as in the drawing, the drawing must not be active. The input arguments follow:

- *dimension*—Dimension
- *drawing*—Drawing. The value for this input argument must be passed only if the solid dimension is shown in the drawing. Else, pass it as NULL.
- *line\_number*—The line number of the dimension. To get a full dimension envelope, pass this value as `PRO_VALUE_UNUSED`.

The output argument *envelope* is the envelope surrounding the text line in the model coordinate system. For drawing, the envelope surrounding the dimension is in the screen coordinates.

The function `ProDimensionTangentAttachUpdate()` sets the dimension to take the minimum, maximum, or center distance between the tangent lines of the arcs. The input arguments are:

- *dimension*—Handle to input dimension.
- *tangent*—First or second tangent specified using the enumerated data type `ProDimArcTangent`. The valid values are:
  - `PRO_DIM_TANGENT_FIRST`
  - `PRO_DIM_TANGENT_SECOND`
- *type*—Type of tangent specified using the enumerated data type `ProDimArcAttachType`. The valid values are:
  - `PRO_DIM_TANGENT_MIN`—Sets the dimension line at the minimum distance on the arc.
  - `PRO_DIM_TANGENT_MAX`—Sets the dimension line at the maximum distance on the arc.
  - `PRO_DIM_TANGENT_CENTER`—Sets the dimension line at the center of the arc.

### Example 3: Modifying a Dimension

The sample code in the file `UgDimsChange.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_dims` demonstrates how to modify a dimension. The dimensions belonging to a given feature are displayed. You can choose the dimension you wish to modify.

---

## Dimension References

The functions explained in this section enable you to work with semantic dimension references.

Function Introduced:

- **ProDimensionAdditionalRefsAdd()**
- **ProDimensionAdditionalRefsGet()**
- **ProDimensionAdditionalRefDelete()**

The function `ProDimensionAdditionalRefsAdd()` adds additional semantic references in the specified dimension. The input arguments are:

- *dim*—Specifies a dimension.
- *type*—Specifies the type of reference using the enumerated data type `ProDimensionReferenceType`. The type is classified based on the list to which the references are added. The valid values are:
  - `PRO_DIM_REF_FIRST`—Adds the semantic references to the first list of references.
  - `PRO_DIM_REF_SECOND`—Adds the semantic references to the second list of references.
  - `PRO_DIM_SRF_COLL`—Adds the semantic references to the collection of surfaces.

---

### Note

When a reference includes more than one collection, the function `ProDimensionAdditionalRefsAdd()` returns the error `PRO_TK_MAX_LIMIT_REACHED` and no reference is added.

---

- *refs* —Specifies a `ProArray` of references that will be added to the specified dimension.

---

### Note

Currently, the reference types `PRO_ANNOT_REF_SINGLE` and `PRO_ANNOT_REF_SRF_COLLECTION` are supported.

---

The function `ProDimensionAdditionalRefsGet()` returns a `ProArray` of references of the specified type for a dimension. In the input argument *type*, specify the type of reference using the enumerated data type

---

`ProDimensionReferenceType`. Use the function `ProAnnotationreferencearrayFree()` to release the memory assigned to the `ProArray` of references.

Use the function `ProDimensionAdditionalRefDelete()` to delete the specified reference. The references are specified by their index number which start from 0. You can get existing references from `ProDimensionAdditionalRefsGet()`. The index is ignored if the type of reference is surface collection, as only one reference of the type `PRO_DIM_SRF_COLL` can exist.

The input argument for both the functions `ProDimensionAdditionalRefsGet()` and `ProDimensionAdditionalRefDelete()` specifies the type of reference using the enumerated data type `ProDimensionReferenceType`. The type is classified based on the list to which the references are added. The valid values are:

- `PRO_DIM_REF_FIRST`—Adds the semantic references to the first list of references.
- `PRO_DIM_REF_SECOND`—Adds the semantic references to the second list of references.
- `PRO_DIM_SRF_COLL`—Adds the semantic references to the collection of surfaces.

## Clean Up Dimensions

You can clean up the placement of dimensions in a drawing to meet the industry standards, and enable easier reading of your model detailing. You can adjust the location and display of dimensions by setting controls on the placement of a dimension. You can also set the cosmetic attributes, like flip the direction of arrow when the arrows do not fit between the witness lines and center the dimension text between two witness lines.

Function Introduced:

### • **ProDrawingDimensionsCleanup()**

Use the function `ProDrawingDimensionsCleanup()` to clean up the dimensions in a drawing. The input arguments are:

- *draw*—Specifies the drawing.
- *view*—Specifies the view in which the dimensions must be cleaned. If you pass the value as `NULL`, the dimensions are cleaned for all the views in the specified drawing.

The dimensions are cleaned using the default values set in the **Clean Dimensions** dialog box in Creo Parametric user interface.

---

## Dimension Tolerances

Functions Introduced:

- **ProToleranceDefaultGet()**
- **ProDimensionDisplayedToleranceGet()**
- **ProSolidToleranceGet()**
- **ProSolidToleranceSet()**
- **ProDimensionIsToleranceDisplayed()**
- **ProDimensionToltypeGet()**
- **ProDimensionToltypeSet()**
- **ProDimensionToleranceGet()**
- **ProDimensionToleranceSet()**
- **ProDimensionTolerancedecimalsGet()**
- **ProDimensionTolerancedecimalsSet()**
- **ProDimensionTolerancedenominatorGet()**
- **ProDimensionTolerancedenominatorSet()**

The function `ProToleranceDefaultGet()` tells you the current default value for a given tolerance, that is, the value set in the configuration file to be used for new models. There is a separate tolerance for linear and angular dimensions (`PROTOLERANCE_LINEAR` and `PROTOLERANCE_ANGULAR`) and for each number of decimal places in the range 1 to 6 (12 tolerance settings in all).

If the round off attribute for the given dimension is set, the function `ProDimensionDisplayedToleranceGet()` retrieves the displayed rounded values of the upper and lower limits of the specified dimension. Otherwise, it retrieves the stored values of the tolerances as done by the function `ProSolidToleranceGet()`. For example, consider a dimension that is set to round off to two decimal places and has the upper and lower tolerances 0.123456. By default, the tolerance values displayed are also rounded off to two decimal places. In this case, the function `ProDimensionDisplayedToleranceGet()` retrieves the upper and lower values as 0.12.

The input argument of the function `ProDimensionDisplayedToleranceGet()` is a dimension handle. The output arguments of this function are pointers to the rounded values of the upper and lower limits of the specified dimension. You must allocate a memory location for each of the output arguments. Pass a `NULL` pointer if you do not want to use an output argument. You cannot pass a null for both the output arguments.

The functions `ProSolidToleranceGet()` and `ProSolidToleranceSet()` let you find and set the current value of the specified dimensional tolerance. The function

---

`ProDimensionIsToleranceDisplayed()` tells you whether the tolerances of the specified dimension are currently being displayed. Refer to the *Creo Parametric Detailed Drawings Help* for more information.

The function `ProDimensionToltypeGet()` returns the display format for the specified dimension tolerance using the enumerated data type `ProDimToleranceType`. The valid values are:

- `PRO_TOL_DEFAULT`—Displays dimensions without tolerances. Similar to the nominal option in *Creo Parametric*.
- `PRO_TOL_LIMITS`—Displays dimension tolerances as upper and lower limits.

---

 **Note**

This format is not available when only the tolerance value for a dimension is displayed.

---

- `PRO_TOL_PLUS_MINUS`—Displays dimensions as nominal with plus-minus tolerances. The positive and negative values are independent.
- `PRO_TOL_PLUS_MINUS_SYM`—Displays dimensions as nominal with a single value for both the positive and the negative tolerance.
- `PRO_DIM_TOL_SYM_SUPERSCRIPT`—Displays dimensions as nominal with a single value for positive and negative tolerance. The text of the tolerance is displayed in a superscript format with respect to the dimension text.
- `PRO_DIM_TOL_BASIC`—Displays dimensions as basic dimensions. Basic dimensions are displayed in an enclosed feature control frame. Tolerances are not displayed in basic dimensions, only the numerical part of the dimension value and its symbol are enclosed in the rectangular box. Any additional text in the dimension value is not included in the box.

Use the function `ProDimensionToltypeSet()` to set the display format for the specified dimension tolerance.

The function `ProDimensionToleranceGet()` reports the deviation of the upper and lower tolerances from the nominal value. The values are always reported as independent upper and lower tolerance values; the actual display of the tolerance is determined by `ProDimensionToltypeGet()`. Tolerances are not applicable for reference dimensions.

---

 **Note**

If the upper tolerance value is negative, it will be displayed with a ‘-’ sign. But if the lower tolerance value is negative, it will be displayed with a ‘+’ sign.

---

The function `ProDimensionToleranceSet()` sets the upper and lower tolerance limits. The values are always accepted as independent upper and lower tolerance values; the actual display of the tolerance is determined by `ProDimensionToltypeSet()`. It is not applicable to reference dimensions.

The functions `ProDimensionTolerancedecimalsGet()` and `ProDimensionTolerancedecimalsSet()` obtain and assign the number of decimal places shown for the upper and lower values of the dimension tolerance. Thus, the decimals of the dimension tolerance can be set independent of the number of dimension decimals. By default, the number of decimal places for tolerance values is calculated based upon the “linear\_tol” settings of the model.

---

 **Note**

The input *tolerance\_decimals* to the `ProDimensionTolerancedecimalsSet()` function should be a non-negative number and it should be such that when you apply either the upper or the lower values of the tolerance to the given dimension, the total number of digits before and after the decimal point in the resulting values does not exceed 13.

---

If the dimension tolerance value is a fraction, the functions `ProDimensionTolerancedenominatorGet()` and `ProDimensiondenominatorSet()` obtain and assign the value for the largest possible denominator for the upper and lower tolerance values. By default, this value is defined by the `config.pro` option, `dim_fraction_denominator`.

## ISO/DIN Tolerance Table Use

Functions Introduced:

- **ProSolidModelclassGet()**
- **ProSolidModelclassSet()**
- **ProSolidTolclassLoad()**
- **ProDimensionTollabelGet()**
- **ProDimensionTollabelSet()**

---

Creo TOOLKIT provides functions that programmatically set and return ISO/DIN tolerance table data. These functions allow changes to values before the label is set. For all other labels, use the `ProDimensionTollabelSet()` command.

The functions `ProSolidModelclassGet()` and `ProSolidModelclassSet()` respectively return or set the type of tolerance to use for a particular model. Valid settings are:

- COARSE
- FINE
- MEDIUM
- VERY\_COARSE

The function `ProSolidTolclassLoad()` loads a hole or shaft ISO/DIN tolerance table into the current session memory.

The functions `ProDimensionTollabelGet()` and `ProDimensionTollabelSet()` respectively get or set the ISO/DIN tolerance table assigned to the specified dimension.

## Dimension Text

Functions Introduced:

- **`ProDimensionTextWstringsGet()`**
- **`ProDimensionTextWstringsSet()`**

Superseded Functions:

- **`ProDimensionTextGet()`**
- **`ProDimensionTextSet()`**

The functions `ProDimensionTextGet()` and `ProDimensionTextSet()` have been deprecated. Use the functions `ProDimensionTextWstringsGet()` and `ProDimensionTextWstringsSet()` instead.

The function `ProDimensionTextWstringsGet()` retrieves the text of the specified dimension as a `ProArray` of wide character strings. Use the function `ProWstringproarrayFree()` to release the memory allocated for the `ProArray`.

The function `ProDimensionTextWstringsSet()` sets the text of the specified dimension using a `ProArray` of wide character strings. This is equivalent to editing dimensions in Creo Parametric.

---

### **Note**

From Creo Parametric 2.0 onward, the functions `ProDimensionTextWstringsGet()` and `ProDimensionTextGet()` will always include the dimension value @D that appears in the **Dimension Properties** dialog box.

---

## Dimension Text Style

Functions Introduced:

- **ProDimensionTextstyleGet()**
- **ProDimensionTextstyleSet()**

The function `ProDimensionTextstyleGet()` returns the text style assigned to a specified dimension or reference dimension.

The function `ProDimensionTextstyleSet()` sets the text style assigned to a specified dimension or reference dimension.

---

### **Note**

Only some of the text style properties may be assigned to dimensions.

---

## Dimension Prefix and Suffix

Functions Introduced:

- **ProDimensionPrefixGet()**
- **ProDimensionPrefixSet()**
- **ProDimensionSuffixGet()**
- **ProDimensionSuffixSet()**

The function `ProDimensionPrefixGet()` retrieves the prefix assigned to a specified dimension. Use the function `ProDimensionPrefixSet()` to set the prefix of the type `ProLine` for a dimension.

The function `ProDimensionSuffixGet()` retrieves the suffix assigned to a specified dimension. Use the function `ProDimensionSuffixSet()` to set the suffix of the type `ProLine` for a dimension.

---

## Dimension Location

The functions described in this section extract the dimension location and geometry in 3D space for solid model dimensions.

Functions Introduced:

- **ProDimensionLocationGet()**
- **ProDimlocationFree()**
- **ProDimensionMove()**

The function `ProDimensionLocationGet()` returns the location of the elements that make up a solid dimension or reference dimension.

This function optionally takes a view used to determine the orientation of the model when calculating the dimension locations. The orientation often determines the text location, presence or absence of elbows, and other dimension location properties.

Use the function `ProDimlocationFree()` to free the structure containing the dimension location data.

The function `ProDimensionMove()` enables you to move the specified dimension to the given location within its owner model.

## Dimension Entity Location

The following functions extract the locations of geometric endpoints for the dimension. You can calculate the dimension location plane, witness line, and dimension orientation vectors from these points. The location of the points is specified in the same coordinate system as the solid model.

Functions Introduced:

- **ProDimlocationTextGet()**
- **ProDimlocationArrowsGet()**
- **ProDimlocationWitnesslinesGet()**
- **ProDimlocationArrowtypesGet()**
- **ProDimlocationCenterleadertypeGet()**
- **ProDimlocationZExtensionlinesGet()**
- **ProDimlocationNormalGet()**

The function `ProDimlocationTextGet()` returns the location of the dimension text in model coordinates. If the dimension contains an elbow, the function returns the location of the elbow joint and the length of the elbow in model coordinates.

The function `ProDimlocationArrowsGet()` returns the location of the arrow heads for the dimension.

---

The function `ProDimlocationWitnesslinesGet()` returns the location of the witness line ends for the dimension.

The function `ProDimlocationArrowtypesGet()` returns the type of arrows used for the leader of a specified 3D dimension. The dimension location obtained using the function `ProDimensionLocationGet()` serves as an input argument for this function.

---

 **Note**

In case of radial dimensions where the arrow head type cannot be changed, the function `ProDimlocationArrowtypesGet()` always returns the “Arrow head” leader type.

---

The function `ProDimlocationCenterleadertypeGet()` obtains the type of center leader used for the dimension, if the dimension uses a center leader. The type of center leader is determined by the orientation of the dimension text. This function also returns the length and direction of the elbow used by the center leader and the leader end symbol.

- `PRO_DIM_CLEADER_CENTERED_ELLOW`—Specifies that the dimension text is placed next to and centered about the elbow of the center leader.
- `PRO_DIM_CLEADER_ABOVE_ELLOW`—Specifies that the dimension text is placed next to and above the elbow of the center leader.
- `PRO_DIM_CLEADER_ABOVE_EXT_ELLOW`—Specifies that the dimension text is placed above the extended elbow of the center leader.
- `PRO_DIM_PARALLEL_ABOVE`—Specifies that the dimension text is placed parallel to and above the center leader.
- `PRO_DIM_PARALLEL_BELOW`—Specifies that the dimension text is placed parallel to and below the center leader.

---

 **Note**

- A center leader type is available only for linear and diameter dimensions.
  - The elbow length and direction is not available for `PRO_DIM_PARALLEL_ABOVE` and `PRO_DIM_PARALLEL_BELOW` center leader types.
-

---

The function `ProDimlocationZExtensionlinesGet()` obtains the endpoints of the Z-extension line created for a specified dimension. Z-extension lines are automatically created whenever the dimension's attachment does not intersect its reference in the Z-Direction. The Z-extension line is attached at the edge of the surface at the closest distance from the dimension witness line.

The function `ProDimlocationNormalGet()` returns the vector normal to the dimensioning plane for a radial or diameter dimension. This normal vector should correspond to the axis normal to the arc being measured by the radial or diameter dimension.

The following figures illustrate the potential location of the arrow heads and witness lines for different dimension types.

### Linear and psuedo-linear dimensions

For a linear type of dimension, there are typically two arrow locations A1 and A2 as shown in the above figure. w1 and w2 indicate the two witness line locations.

If the dimension type has an elbow joint indicated by E, the elbow length is the distance between the text and E. If the dimension does not have an elbow, the text occurs on the line between A1 and A2, and its position is returned by the function `ProDimensionTextGet()`. Pattern parameter dimensions and length-of-arc dimensions also typically return this dimension structure.

## Angular dimensions

For an angular type of dimension, there are two arrow locations A1 and A2 as shown in the above figure. w1 and w2 indicate the two witness line locations. For some angular dimensions the two witness line endpoints are coincident, but they are returned as independent locations. This dimension type does not have an elbow joint.

## Diameter dimensions

For a diameter type of dimension, there are two arrow locations A1 and A2 as shown in the above figure. The elbow joint for this dimension is indicated by E. The elbow length is the distance between the text and the elbow joint. This dimension type does not have any witness line locations.

## Radius dimensions

For a radius type dimension, there is one arrow location indicated by A1 and an elbow joint indicated by E. The elbow length is the distance between the text and the elbow joint.

The function `ProDimlocationArrowsGet()` returns a NULL value for the second arrow location. This dimension type does not have any witness line locations.

## Example 4: Dimension Location Properties

The sample code in the file `UgDimLocationUtils.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_dims` demonstrates use of the dimension location properties. It finds linear dimensions that are oriented parallel to a specified direction vector. It shows these dimensions in the Creo Parametric user interface. The orientation of the dimension is determined from the coordinates of the two dimension arrowheads.

## Dimension Orientation

Functions Introduced:

- **`ProDimensionPlaneSet()`**
- **`ProDimensionPlaneGet()`**

The function `ProDimensionPlaneSet()` assigns an annotation plane as the orientation of a specified dimension stored in an annotation element.

The function `ProDimensionPlaneGet()` obtains the orientation of a specified dimension stored in an annotation element.

### Note

For dimensions that are not assigned a specific orientation, the orientation obtained includes `PRO_ID_NO_ANNOTATION_PLANE` as its ID.

---

## Driving Dimension Annotation Elements

You can convert driving dimensions created by features into annotation elements and place them on annotation planes. However, you can create the driving dimension annotation elements only in the features that own the dimensions. These annotation elements cannot have any user defined or system references.

In Creo TOOLKIT, a driving dimension annotation element uses the `ProModelItem` handle with the type field `PRO_DIMENSION` and the appropriate dimension ID.

Functions such as `ProSolidDimensionVisit()` and `ProFeatureDimensionVisit()` can be used to find both edit dimensions and driving dimension annotation elements.

Functions Introduced:

- **`ProDimensionAnnotationelemCreate()`**
- **`ProDimensionAnnotationelemDelete()`**

The function `ProDimensionAnnotationelemCreate()` creates an annotation element for a specified driving dimension, based on the desired annotation orientation.

The function `ProDimensionAnnotationelemDelete()` removes the annotation element containing the driving dimension. It deletes all the parameters and relations associated with the annotation element.

## Accessing Reference and Driven Dimensions

The functions described in this section provide additional access to reference and driven dimension annotations.

Many functions listed in the previous sections that are applicable for driving dimensions are also applicable for reference and driven dimensions.

Functions Introduced:

- **`ProDimensionIsDriving()`**
- **`ProDimensionCreate()`**
- **`ProDimensionAttachmentsGet()`**
- **`ProDimensionAttachmentsSet()`**

- 
- **ProDimensionDelete()**
  - **ProDimensionCanRegenerate()**

The function `ProDimensionIsDriving()` determines if a dimension is driving geometry or is driven by it. If a dimension drives geometry, its value can be modified and the model regenerated with the given change. If a dimension is driven by geometry, its value is fixed but it can be deleted and redefined as necessary. A driven dimension may also be included in an annotation element.

The function `ProDimensionCreate()` creates a new driven or reference dimension. Specify the geometric references and parameters required to construct the required dimension as the input parameters for this function. Once the reference dimension is created, use the function `ProAnnotationShow()` to display it. The input arguments of this function are as follows:

- *model*—Specifies the solid model.
- *dimension\_type*—Specifies the type of dimension. This parameter can have the following values:
  - `PRO_REF_DIMENSION`—Specifies a reference dimension.
  - `PRO_DIMENSION`—Specifies a driven dimension.
- *annotation\_plane*—Specifies the annotation plane for the dimensions.
- *attachments\_arr*—Specifies the points on the model where you want to attach the dimension.

---

 **Note**

The attachments structure is an array of two `ProSelection` entities. It is provided to support options such as intersect where two entities must be passed as input. From Creo Parametric 3.0 onward, you can create dimensions that have intersection type of reference. The intersection type of reference is a reference that is derived from the intersection of two entities. Refer to the Creo Parametric Detailed Drawings Help for more information on intersection type of reference.

---

- *dsense\_arr*—Specifies more information about how the dimension attaches to each attachment point of the model, that is, to what part of the entity
- *orient\_hint*—Specifies the orientation of the dimension and has one of the following values:
  - `PRO_DIM_ORNT_HORIZ`—Specifies a horizontal dimension.
  - `PRO_DIM_ORNT_VERT`—Specifies a vertical dimension.

- `PRO_DIM_ORNT_SLANTED`—Specifies the shortest distance between two attachment points (available only when the dimension is attached to points).
- `PRO_DIM_ORNT_ELPS_RAD1`—Specifies the start radius for a dimension on an ellipse.
- `PRO_DIM_ORNT_ELPS_RAD2`—Specifies the end radius for a dimension on an ellipse.
- `PRO_DIM_ORNT_ARC_ANG`—Specifies the angle of the arc for a dimension of an arc.
- `PRO_DIM_ORNT_ARC_LENGTH`—Specifies the length of the arc for a dimension of an arc.
- `PRO_DIM_ORNT_LIN_TANCRV_ANG`—Specifies the value to dimension the angle between the line and the tangent at a curve point (the point on the curve must be an endpoint).
- `PRO_DIM_ORNT_RAD_DIFF`—Specifies the linear dimension of the radial distance between two concentric arcs or circles.
- `PRO_DIM_ORNT_NORMAL`—Specifies the linear dimension between two points to be placed normal to the selected reference.
- `PRO_DIM_ORNT_PARALLEL`—Specifies the linear dimension between two points to be placed parallel to the selected reference.
- *location*—Specifies the initial location of the dimension text.

The function `ProDimensionAttachmentsGet()` and `ProDimensionAttachmentSet()` provide access to the geometric references and parameters of the driven or reference dimension. These functions support dimensions that are created with intersection type of reference.

The function `ProDimensionDelete()` deletes the driven or reference dimension. Dimensions stored in annotation elements should be deleted using `ProAnnotationFeatElementDelete()`.

The function `ProDimensionCanRegenerate()` checks if a driven dimension can be regenerated. For driven dimensions created in drawing mode and owned by a solid, which can be displayed only in the context of that drawing, specify the name of the drawing in the input argument *drawing*.

## 45-degree Chamfer Dimensions

You can create 45-degree chamfer dimensions by referencing one of the following items:

- Edges, including solid or surface edges, silhouette edges, curves, and sketches.
- Surfaces

- 
- Revolve surfaces

The functions described in this section provide access to the display style of 45-degree chamfer dimensions in a solid. These functions can also be used to access the display style of the chamfer dimension in a drawing, where the dimension is created in a solid and is displayed in a drawing. To work with dimensions shown in a drawing, pass the name of the drawing in the input argument *drawing* in the functions.

#### Note

The default display of a 45-degree chamfer dimension depends upon the setting of the `config.pro` option, `default_chamfer_text`.

---

Functions Introduced:

- **ProDimensionChamferLeaderGet()**
- **ProDimensionChamferLeaderSet()**
- **ProDimensionChamferTextGet()**
- **ProDimensionChamferTextSet()**
- **ProDimensionConfigGet()**
- **ProDimensionConfigSet()**

The functions `ProDimensionChamferLeaderGet()` and `ProDimensionChamferLeaderSet()` retrieve and set the style of the leader for the specified 45-degree chamfer dimension. The valid values are as follows:

- `PRO_DIM_CHMFR_LEADER_STYLE_NORMAL`—Specifies that the leader of a chamfer dimension is normal to the chamfer edge (ASME, ANSI, JIS, ISO Standard).
- `PRO_DIM_CHMFR_LEADER_STYLE_LINEAR`—Specifies that the leader of a chamfer dimension has linear style of display.
- `PRO_DIM_CHMFR_LEADER_STYLE_DEFAULT`—Specifies that the chamfer dimension leader style should be displayed using the default value set in the detail option `default_chamfer_leader_style`.

The functions `ProDimensionChamferTextGet()` and `ProDimensionChamferTextSet()` retrieve and set the dimension scheme for the specified 45-degree chamfer dimension. The valid values are as follows:

- `PRO_DIM_CHMFRSTYLE_CD = 0`—Specifies that the chamfer dimension text should be displayed in the C(Dimension value) format (JIS/GB Standard).

- `PRO_DIM_CHMFRSTYLE_D_X_45 = 1`—Specifies that the chamfer dimension text should be displayed in the (Dimension value) x45 format (ISO/DIN Standards).
- `PRO_DIM_CHMFRSTYLE_CUSTOM = 3`— Specifies that the chamfer dimension text should be displayed in a customized format.
- `PRO_DIM_CHMFRSTYLE_DEFAULT = 4`—Specifies that the chamfer dimension text should be displayed using the default value set in the drawing detail option `default_chamfer_text`.
- `PRO_DIM_CHMFRSTYLE_45_X_D = 6`—Specifies that the chamfer dimension text should be displayed in the 45 X (Dimension value) format (ASME/ANSI Standards).
- `PRO_DIM_CHMFRSTYLE_D = 9`— Specifies that the chamfer dimension text should be displayed in the (Dimension value) format.
- `PRO_DIM_CHMFRSTYLE_D_X_45_ASME = 10`— Specifies that the chamfer dimension text should be displayed in the (Dimension value) X 45 format.

The functions `ProDimensionConfigGet()` and `ProDimensionConfigSet()` retrieve and set the dimension configuration for chamfer dimensions. The dimension configuration defines the style in which the dimension must be displayed. The valid values are as follows:

- `PRO_DIMCONFIG_LEADER`—Creates the dimension with a leader.
- `PRO_DIMCONFIG_LINEAR`—Creates a linear dimension.
- `PRO_DIMCONFIG_CENTER_LEADER`—Creates the dimension with the leader note attached to the center of the dimension leader line.

## Accessing Ordinate and Baseline Dimensions

The functions described in this section enable you to create 3D ordinate driven dimensions in 3D models as model annotations or as annotation elements. They also provide the ability to define a baseline annotation element, and then define model ordinate dimension annotations and ordinate dimension annotation elements that reference the baseline annotation element.

### Baseline Dimensions

Functions Introduced:

- **`ProAnnotationfeatBaselineCreate()`**
- **`ProDimensionIsBaseline()`**
- **`ProDimensionBaselinedirectionGet()`**
- **`ProDimensionTangentAttachGet()`**

---

The function `ProAnnotationfeatBaselineCreate()` creates an ordinate baseline annotation element and corresponding dimension. Specify the feature reference geometry, text location, direction and annotation plane as input arguments for this function.

The function `ProDimensionIsBaseline()` identifies whether a dimension is a baseline dimension.

This function `ProDimensionBaselinedirectionGet()` retrieves the direction of an ordinate baseline dimension when it is not implied from the attachment reference returned by `ProDimensionAttachmentsGet()`. The input argument *dimension* specifies the ordinate baseline dimension using the object `ProDimension`.

The output argument *dir\_vec* is a `ProVector` and it gives the direction of the baseline ordinate dimension.

The function `ProDimensionTangentAttachGet()` retrieves the attachment of dimension to the arc or circle for the input tangent. The input arguments are:

- *dimension*—The handle for the input dimension using the object `ProDimension`.
- *tangent*—Specify the first or second tangent using the object `ProDimArcTangent`.

The output argument *type*—Specifies the type of attachment type to the arc as minimum, maximum, or center using the object `ProDimArcAttachType`.

## Ordinate Dimensions

Function Introduced:

- **`ProDimensionOrdinateCreate()`**
- **`ProDimensionOrdinatestandardGet()`**
- **`ProDimensionOrdinatestandardSet()`**
- **`ProDimensionOrdinatereferencesSet()`**
- **`ProDimensionMove()`**
- **`ProDimensionIsOrdinate()`**
- **`ProDimensionAutoOrdinateCreate()`**

The function `ProDimensionOrdinateCreate()` creates a new model ordinate driven dimension or a model ordinate reference dimension in a solid model. It requires the input of a reference baseline annotation as well as a geometry reference. The annotation plane for the new dimension will be inherited from the baseline. Once the reference dimension is created, use the function `ProAnnotationShow()` to display it.

---

To create an ordinate driven dimension element or a model ordinate reference dimension pass the ordinate dimensions created by `ProDimensionOrdinateCreate()` to the function `ProAnnotationelemAnnotationSet()`.

The function `ProDimensionOrdinatestandardGet()` returns the display standard for the ordinate dimensions in the drawing. The style of the ordinate dimension may be as follows:

- `PRO_DIM_ORDSTD_DEFAULT`—Specifies the default style for the ordinate dimensions.
- `PRO_DIM_ORDSTD_ANSI`—Specifies the American National Standard style for the ordinate dimension. It places the related ordinate dimensions without a connecting line.
- `PRO_DIM_ORDSTD_JIS`—Specifies the Japanese Industrial Standard style for the ordinate dimension. It places the ordinate dimensions along a connecting line that is perpendicular to the baseline and starts with an open circle.
- `PRO_DIM_ORDSTD_ISO`—Specifies the International Standard of Organization style for the ordinate dimension.
- `PRO_DIM_ORDSTD_DIN`—Specifies the German Institute for Standardization style for the ordinate dimension.
- `PRO_DIM_ORDSTD_SAME_AS_3D`—Specifies the ordinate dimension style for 2D drawings. Not used in 3D ordinate dimensions.

The function `ProDimensionOrdinatestandardSet()` sets the style for the specified ordinate dimension or a set of ordinate dimensions.

The function `ProDimensionAttachmentsGet()` returns the attachment geometry for the dimension.

In order to change the dimension's attachments you must use the function `ProDimensionOrdinatereferencesSet()`.

The function `ProDimensionMove()` enables you to move the specified 3D ordinate dimension to the specified location within its owner model. For ordinate dimensions in the JIS or ISO/DIN style, all dimensions stay aligned during movement. For ordinate dimensions in the ANSI style, each dimension can be adjusted independent of the other dimensions. If the style is changed back to JIS or ISO/DIN, all the dimensions become aligned with the baseline.

The function `ProDimensionIsOrdinate()` identifies if a dimension is ordinate.

---

The function `ProDimensionAutoOrdinateCreate()` creates ordinate dimensions automatically for the selected surfaces. The function returns a `ProArray` of dimensions. The input arguments are:

- `drawing`—Specifies the drawing where the ordinate dimensions must be automatically created.
- `surface_array`—Specifies a set of parallel surfaces for which the ordinate dimensions must be created. This is a `ProArray` of selection handles. You can free this array using the function `ProSelectionarrayFree()`.
- `baseline`—Specifies a reference element used to create the baseline dimension. The reference element can be an edge, a curve, or a datum plane.

## Notes

The functions in this section enable you to access the notes created in Creo Parametric .

### Note

These functions are applicable to solids (parts and assemblies) only. However, when notes on a solid are viewed from Drawing mode, they can also be accessed using the `ProDtlnote()` functions described in the section [Drawings on page 1287](#).

---

A note is modeled in Creo TOOLKIT as an instance of `ProModelitem` with the type `PRO_NOTE`. You can select a note by supplying the selection option `note_3d` to `ProSelect()`. You can access the name of a note using the functions `ProModelitemNameGet()` and `ProModelitemNameSet()`.

## Creating and Deleting Notes

Functions Introduced:

- **`ProSolidNoteCreate()`**
- **`ProNoteDelete()`**

The function `ProSolidNoteCreate()` takes as input a `ProMdl` for the solid (either a part or an assembly), a `ProModelitem` for the owner of the note, and an expandable array `ProLineList` for the note text. The function outputs a `ProNote` object for the created note. Once the note is created, use the function `ProAnnotationShow()` to display it.

The function `ProNoteDelete()` deletes the note specified by its `ProNote` object. Notes stored in annotation elements should be deleted using `ProAnnotationfeatElementDelete()`.

---

## Note Properties

Functions Introduced:

- **ProNoteTextGet()**
- **ProNoteTextSet()**
- **ProNoteURLGet()**
- **ProNoteURLSet()**
- **ProNoteURLWstringGet()**
- **ProNoteURLWstringSet()**
- **ProNoteURLExtraInfoGet()**
- **ProNoteURLExtraInfoSet()**
- **ProNoteOwnerGet()**
- **ProNoteLeaderstyleGet()**
- **ProNoteLeaderstyleSet()**
- **ProNoteElbowlengthGet()**
- **ProNoteElbowlengthSet()**
- **ProNoteLineEnvelopeGet()**
- **ProNoteAttachNormtanleaderGet()**
- **ProNoteAttachScreenSet()**
- **ProNoteWrapTextGet()**
- **ProNoteWrapTextSet()**
- **ProNoteReferencesAdd()**
- **ProNoteReferencesGet()**
- **ProNoteReferenceDelete()**

The function `ProNoteTextGet()` returns the text of a 3D model note. The function `ProNoteTextSet()` modifies the text of an existing 3D model note. You can also make symbols to be called out in the 3D notes using the function `ProNoteTextSet()`.

Use the function `ProNoteUndisplay()` followed by `ProNoteDisplay()` to update the display status of the note.

The function `ProNoteURLGet()` retrieves the Uniform Resource Locator (URL) associated with the specified note, whereas `ProNoteURLSet()` sets the associated URL for the specified note. Specify the note and the URL wide string or the name of the valid combined state as input arguments to the function `ProNoteURLWstringSet`.

---

### **Note**

The functions `ProNoteURLGet()` and `ProNoteURLSet()` have been deprecated. Instead, use the functions `ProNoteURLWstringGet()` and `ProNoteURLWstringSet()` that return and set, respectively, the Uniform Resource Locator (URL) associated with the specified note as a wistring.

---

The function `ProNoteURLExtraInfoGet()` retrieves the information of whether opening the URL for a specified note appends the extra information `"?<model name>+<note id>"`.

The function `ProNoteURLExtraInfoSet()` sets whether opening the URL for a specified note should append the extra info `"?<model name>+<note id>"`.

The input argument *p\_note\_item* to both the functions is the note for which the extra information needs to be appended.

The function `ProNoteOwnerGet()` retrieves the owner of the specified note. The owner can be the solid model, a user-chosen feature, or the feature that contains the note's annotation element.

The function `ProNoteLeaderstyleGet()` returns the leader style used for the note. It can be either standard or ISO. The function `ProNoteLeaderstyleSet()` sets the leader style of the note.

The function `ProNoteElbowlengthGet()` returns the elbow properties for the specified note.

The function `ProNoteElbowlengthSet()` sets the elbow properties of the note. This is equivalent to **Move Text** option in the **Dimension Properties** dialog box in Creo Parametric.

---

### **Note**

The elbow properties can be retrieved and set for the flat-to-screen notes and the drawing notes.

---

The function `ProNoteLineEnvelopeGet()` returns the envelope of a line for a specified note.

The function `ProNoteAttachNormtanleaderGet()` returns the properties of a leadered note which is normal/tangent to specified note.

---

### **Note**

Creo Parametric adds hard line breaks to the multiple lines drawing notes created in Creo Elements/Pro during retrieval. The hard line breaks display the text of the note on separate lines in the **Note Properties** dialog box as they actually appear in the drawing note.

---

The function `ProNoteAttachScreenSet()` sets the location of the note text at the screen location. The input arguments follow:

- *note\_attach*—Specifies the handle for `ProNoteAttach`.
- *p1*—The parameter in the X direction.
- *p2*—The parameter in the Y direction.
- *p3*—The parameter in the Z direction.

The functions `ProNoteWrapTextGet()` and `ProNoteWrapTextSet()` get and set the wrap status of the text for a specified note in a solid. The function `ProDtlNoteWrapTextSet()` sets the text wrapping status to ON or OFF.

The input arguments are listed below:

- *note*—Specifies the note for which the wrap status is to be set.
- *wrap*—Specifies if the text is wrapped. To wrap the text specify the value as `Pro_B_True`.
- *wrapwidth*—Specifies the width of the wrapped text line, if the input argument *wrap* is set to `Pro_B_True`.

The function `ProNoteReferencesAdd()` adds semantic references to a specified note in a solid. The input arguments are as follows:

- *note*—Specifies the note to which the additional semantic references are to be added.
- *refs*—Specifies the array of additional semantic references using the enumerated data type `ProAnnotationReference`.

---

### **Note**

When a reference includes more than one collection, the function `ProNoteReferencesAdd()` returns the error `PRO_TK_MAX_LIMIT_REACHED` and no reference is added.

---

The function `ProNoteReferencesGet()` returns a `ProArray` of additional semantic references for a note.

---

The function `ProNoteReferenceDelete()` deletes the additional semantic references. The input arguments are as follows:

- *note*—Specifies the note from which the additional semantic references are to be deleted.
- *index\_ref*—Specifies the index references. Indices start from 0.

## Visiting Notes

Function introduced:

- **ProMdlNoteVisit()**

The function `ProMdlNoteVisit()` enables you to visit all the notes in the specified model. The input arguments are:

- *mdl\_handle*—Specify the model (`PRO_PART` or `PRO_ASSEMBLY`) using the `ProMdl` object.
- *visit\_action*—Specify the action to perform on each note. See `ProMdlNoteVisitAction` for the prototype and return values.
- *filter\_action*—Specify the filter function. If `NULL`, all notes are visited using the action function. See `ProMdlNoteFilterAction` for the prototype and return values.
- *app\_data*—Specify the application data that is passed to the visiting and filter functions using the `ProAppData` object.

The function returns the following errors:

- `PRO_TK_NO_ERROR`—The function successfully visited all the notes.
- `PRO_TK_GENERAL_ERROR`—The function stopped visiting the notes due to the filter function or visit action returning `PRO_TK_GENERAL_ERROR`.
- `PRO_TK_BAD_INPUTS`—One or more inputs were invalid.
- `PRO_TK_E_NOT_FOUND`—The model does not contain any valid notes.

## Note Text Styles

Functions Introduced:

- **ProTextStyleAlloc()**
- **ProTextStyleFree()**
- **ProNoteTextStyleGet()**
- **ProNoteTextStyleSet()**

The function `ProTextStyleAlloc()` allocates the opaque handle for a `ProTextStyle` data structure. The function `ProTextStyleFree()` frees the allocated data structure.

---

The function `ProNoteTextStyleGet()` enables you to retrieve the text style of a specified note, whereas `ProNoteTextStyleSet()` enables you to set the text style of the note.

## Text Style Properties

Functions introduced

- **`ProTextStyleHeightGet()`**
- **`ProTextStyleHeightSet()`**
- **`ProTextStyleWidthGet()`**
- **`ProTextStyleWidthSet()`**
- **`ProTextStyleAngleGet()`**
- **`ProTextStyleAngleSet()`**
- **`ProTextStyleSlantAngleGet()`**
- **`ProTextStyleSlantAngleSet()`**
- **`ProTextStyleThicknessGet()`**
- **`ProTextStyleThicknessSet()`**
- **`ProTextStyleUnderlineGet()`**
- **`ProTextStyleUnderlineSet()`**
- **`ProTextStyleMirrorGet()`**
- **`ProTextStyleMirrorSet()`**
- **`ProTextStyleJustificationGet()`**
- **`ProTextStyleJustificationSet()`**
- **`ProTextStyleVertJustificationGet()`**
- **`ProTextStyleVertJustificationSet()`**
- **`ProTextStyleColorGetWithDef()`**
- **`ProTextStyleColorSetWithDef()`**
- **`ProTextStyleIsHeightInModelUnits()`**
- **`ProTextStyleHeightInModelUnitsSet()`**
- **`ProSolidDefaulttextheightGet()`**

These functions enable you to retrieve and set the properties of the specified text style. You can retrieve and set text properties such as the height, width factor, angle, slant angle, thickness, underline, mirror.

---

 **Note**

The system uses the value `-1.0` for properties that use default values, or that have not been set yet.

---

The function `ProTextStyleJustificationGet()` returns the horizontal justification for the text style object.

The function `ProTextStyleJustificationSet()` sets the horizontal justification for the text style object using the enumerated data type `ProTextHrzJustification`. The values defined by the enumerated type are as follows:

- `PRO_TEXT_HRZJUST_DEFAULT`—Aligns the text using the default justification. The justification selected for the first note becomes the default for all successive notes added during the current session.
- `PRO_TEXT_HRZJUST_LEFT`—Aligns the text style object to the left.
- `PRO_TEXT_HRZJUST_CENTER`—Aligns the text style object in the centre.
- `PRO_TEXT_HRZJUST_RIGHT`—Aligns the text style object to the right.

The function `ProTextStyleVertJustificationGet()` returns the vertical justification for the text style object.

The function `ProTextStyleVertJustificationSet()` sets the vertical justification for the text style object using the enumerated data type `ProVerticalJustification`. The values defined by the enumerated type are as follows:

- `PRO_VERTJUST_DEFAULT`—Aligns the text using the default justification. The justification selected for the first note becomes the default for all successive notes added during the current session.
- `PRO_VERTJUST_TOP`—Aligns the text style object to the top.
- `PRO_VERTJUST_MIDDLE`—Aligns the text style object to the middle.
- `PRO_VERTJUST_BOTTOM`—Aligns the text style object to the bottom.

The function `ProTextStyleColorGetWithDef()` also supports default color. If the specified text style object is of default color, `PRO_COLOR_METHOD_DEFAULT` will be returned.

The function `ProTextStyleColorSetWithDef()` also supports default color and enables you to set the text style object to the default color.

The functions `ProTextStyleIsHeightInModelUnits()` and `ProTextStyleHeightInModelUnitsSet()` obtain and assign whether the text height is in relation to the model units, or a fraction of the screen size. These functions are applicable only for flat-to-screen annotations.

---

The function `ProSolidDefaulttextheightGet()` returns the default text height for annotations and dimensions for a given solid model.

## Accessing the Note Placement

The functions described in this section provide access to the properties of a 3D note.

Functions Introduced:

- **ProNotePlacementGet()**
- **ProNoteAttachFreeGet()**
- **ProSolidDispoutlineGet()**
- **ProNoteAttachLeadersGet()**
- **ProNoteAttachOnitemGet()**
- **ProNoteAttachPlaneGet()**
- **ProNoteAttachRelease()**

The function `ProNotePlacementGet()` retrieves the a `ProNoteAttach` structure for the given note. The `ProNoteAttach` object is an opaque handle that describes the location of a note and the leaders attached to it. The functions in this section enable you to set up a `ProNoteAttach` object and assign it to a note, and to read the `ProNoteAttach` information on a note.

The function `ProNoteAttachFreeGet()` retrieves the location of the note text. The note text is stored in relative model coordinates, where  $\{0.5, 0.5, 0.5\}$  indicates the exact center of the model's display bounding box obtained from `ProSolidDispoutlineGet()`, and  $\{0.0, 0.0, 0.0\}$  and  $\{1.0, 1.0, 1.0\}$  represent the corners of the box.

The function `ProSolidDispoutlineGet()` provides you with the maximum and minimum values of X, Y, and Z occupied by the display outline of the solid, with respect to the default provided coordinate system.

The function `ProNoteAttachLeadersGet()` returns the attachment points and properties for the leaders stored in the specified note attachment data.

---

### Note

The function `ProNoteAttachLeadersGet()` requires the owner of the note to be displayed.

---

The functions `ProNoteAttachOnitemGet()` provides the location of an "On Item" note attachment data.

---

The function `ProNoteAttachPlaneGet()` returns the annotation plane assigned to the note attachment data.

The function `ProNoteAttachRelease()` releases the allocated opaque handle.

## Modifying 3D Note Attachments

The actual note created in Creo Parametric will not be modified by the access functions until the note attachment is assigned to the note using the modification function `ProNotePlacementSet()`.

Functions Introduced:

- **`ProNoteAttachAlloc()`**
- **`ProNoteAttachFreeSet()`**
- **`ProNoteAttachAddend()`**
- **`ProNoteAttachLeaderAdd()`**
- **`ProNoteAttachLeaderRemove()`**
- **`ProNoteAttachOnitemSet()`**
- **`ProNoteAttachPlaneSet()`**
- **`ProNotePlacementSet()`**

The function `ProNoteAttachAlloc()` allocates a `ProNoteAttach` object for a note attachment.

To set the location of an attachment point, call the function `ProNoteAttachFreeSet()`. See the description of `ProNoteAttachFreeGet()` for an explanation of the coordinates used by this function.

The function `ProNoteAttachAddend()` adds a leader to the specified attachment. The leader points to a location on the parent model specified by an argument of type `ProSelection`.

The attachment types are specified in `ProNoteAttachAttr`. The possible values are as follows:

- `PRO_NOTE_ATT_NONE`
- `PRO_NOTE_ATT_NORMAL`
- `PRO_NOTE_ATT_TANGENT`

Use the function `ProNoteAttachLeaderAdd()` to specify the type of arrowhead for the leader. This function supersedes the function `ProNoteAttachAddend()`.

---

The function `ProNoteAttachLeaderAdd()` adds a leader to the specified attachment. The leader points to a location on the parent model specified by an argument of type `ProSelection`. The selection UV parameters determine the precise attachment point for the note leader. The attachment types are specified by the parameter *attr* and can have one of the following values:

- `PRO_NOTE_ATT_NORMAL`—Specifies a normal attachment.
- `PRO_NOTE_ATT_TANGENT`—Specifies a tangent attachment.

The function `ProNoteAttachLeaderRemove()` removes a leader from the note attachment data.

The function `ProNoteAttachOnitemSet()` sets the location of an "On Item" note placement. Using this function removes any leaders currently assigned to the note attachment.

The function `ProNoteAttachPlaneSet()` sets the annotation plane of the notes. The annotation plane of a note in an annotation element may not be removed.

The function `ProNotePlacementSet()` assigns the a `ProNoteAttach` structure for the given note, thus defining or redefining the placement for the note.

---

 **Note**

If modifying an existing note, the functions `ProNoteAttach*Set()` do not modify the note until the note attachment is reassigned to the note using the modification function `ProNotePlacementSet()`.

---

## Geometric Tolerances

For more information on Geometric Tolerances refer to the section [Annotations: Geometric Tolerances on page 631](#).

## Accessing Set Datum Tags

The functions described in this section provide the ability to access and display set datum tag annotations in 3D models.

Functions Introduced:

- **`ProSolidSetdatumtagVisit()`**
- **`ProSetdatumtagReferenceGet()`**
- **`ProGeomitemSetdatumtagGet()`**
- **`ProSetdatumtagAttachmentGet()`**

- 
- **ProSetdatumtagAttachmentSet()**
  - **ProSetdatumtagPlacementGet()**
  - **ProSetdatumtagPlaneGet()**
  - **ProSetdatumtagPlaneSet()**
  - **ProSetdatumtagTextstyleGet()**
  - **ProSetdatumtagTextstyleSet()**
  - **ProMdlSetdatumtagCreate()**
  - **ProMdlSetdatumtagDelete()**
  - **ProSetdatumtagLabelGet()**
  - **ProSetdatumtagLabelSet()**
  - **ProSetdatumtagAdditionalTextGet()**
  - **ProSetdatumtagAdditionalTextSet()**
  - **ProSetdatumtagElbowGet()**
  - **ProSetdatumtagElbowSet()**
  - **ProSetdatumtagASMEDisplayGet()**
  - **ProSetdatumtagASMEDisplaySet()**
  - **ProSetdatumtagReferencesAdd()**
  - **ProSetdatumtagReferencesGet()**
  - **ProSetdatumtagReferenceDelete()**
  - **ProSetdatumtagTextPointGet()**
  - **ProSetdatumtagAdditionalTextLocationGet()**
  - **ProDrawingSetDatumTagIsShown()**
  - **ProDrawingSetdatumtagErase()**
  - **ProDrawingSetdatumtagVisit()**
  - **ProDrawingLegacySetdatumtagErase()**
  - **ProDrawingLegacySetdatumtagIsShown()**

The function `ProSolidSetdatumtagVisit()` enables you to visit the set datum tag annotations in a solid model.

Use the function `ProMdlSetdatumtagCreate()`. The function `ProMdlSetdatumtagCreate()` creates a new set datum tag annotation. The input arguments are as follows:

- *reference*—Specify a datum reference (plane or axis) from the model as the geometric reference for the set datum tag. If you want to make this tag reference model geometry, use Creo TOOLKIT to create a datum plane or axis referencing the geometry first, and then use that datum in this argument.

- 
- *annotation\_plane*—Specify an Annotation Plane for the annotation.
  - *attachment*—Optionally, specify the location for placement of the set datum tag. The argument can contain:
    - A dimension
    - A gtol.
    - A geometry selection to which the set datum will be attached.

---

 **Note**

Once the set datum tag annotation is created, use the function `ProAnnotationShow()` to display it.

---

The function `ProSetdatumtagAttachmentGet()` returns the item on which the datum tag is placed.

The function `ProSetdatumtagAttachmentSet()` specifies the item on which the datum tag is placed.

---

 **Note**

From Creo Parametric 2.0 M090 onward, to specify the datum plane or datum axis as the attachment option, pass the input argument *attachment* as *NULL* in the function `ProSetdatumtagAttachmentSet()`. The datum tag is attached to the datum axis at the default location.

---

The function `ProSetdatumtagPlacementGet()` returns the item type, id, and owner on which the set datum tag is placed. Use this function in cases where it is not possible to construct the selection. For example, when the solid owned datum feature symbol is attached to a solid owned dimension that is created in a drawing. The function returns the attachment item contained in the `ProModelitem` structure.

The function `ProSetdatumtagPlaneGet()` returns the annotation plane for the specified set datum tag.

The function `ProSetdatumtagPlaneSet()` sets the annotation plane for the set datum tag.

The function `ProGeomitemSetdatumtagGet()` returns the set datum tag that uses the specified geometric item as the reference, if available.

---

The function `ProSetdatumtagReferenceGet()` returns the datum specified as a reference for the set datum tag.

---

 **Note**

The functions `ProGeomitemSetdatumtagGet()` and `ProSetdatumtagReferenceGet()` return information only for datum tags created in releases prior to Creo Parametric 4.0 F000.

---

The function `ProSetdatumtagTextstyleGet()` returns the text style details for the set datum tag. The function `ProSetdatumtagTextstyleGet()` is deprecated. Use the function `ProAnnotationTextstyleGet()` instead.

The function `ProSetdatumtagTextstyleSet()` sets the text style details for the set datum tag. The function `ProSetdatumtagTextstyleSet()` is deprecated. Use the function `ProAnnotationTextstyleSet()` instead.

The function `ProMdlSetdatumtagCreate()` creates a datum feature symbol in the specified drawing or solid. After creating a datum feature symbol, to display it, call the function `ProAnnotationShow()`. The input arguments are as follows:

- *p\_mdl*—Specifies a drawing or solid.
- *attachment*—Specifies the location of the datum feature symbol on the geometry. The argument can contain:
  - A dimension
  - A gtol
  - A geometry selection to which the set datum will be attached
- *annotation\_plane*—Specifies an annotation plane for the annotation. If the datum feature symbol is attached to a dimension or gtol, the argument can be NULL. However, for a drawing, the argument must be passed as NULL.
- *label*—Specifies the label for the datum feature symbol.

Use the function `ProMdlSetdatumtagDelete()` to delete the specified datum feature.

You can specify a string identifier as a label that will appear within the datum feature symbol frame. The functions `ProSetdatumtagLabelGet()` and `ProSetdatumtagLabelSet()` get and set the label for the specified datum feature symbol.

You can also specify additional text that appears along with the datum feature symbol instance. The label for the datum feature symbol and the additional text appear horizontally aligned to the screen. The functions

---

`ProSetdatumtagAdditionalTextGet()` and `ProSetdatumtagAdditionalTextSet()` get and set the additional text for the specified datum feature symbol. The functions also enable you to get and set the position of the additional text around the frame of the datum feature symbol using the enumerated data type `ProDtmFeatAddlTextPos`. The valid values are:

- `PRO_DTM_FEAT_ADDL_TEXT_RIGHT`
- `PRO_DTM_FEAT_ADDL_TEXT_BOTTOM`
- `PRO_DTM_FEAT_ADDL_TEXT_LEFT`
- `PRO_DTM_FEAT_ADDL_TEXT_TOP`
- `PRO_DTM_FEAT_ADDL_TEXT_DEFAULT`

It is possible to set the display style of the leader which attaches the datum feature symbol to the geometry. You can set the appearance of the leader as straight or have an elbow. The function `ProSetdatumtagElbowSet()` enables you set the display of the leader. Pass the input argument *elbow* as `PRO_B_TRUE` to set the leader with an elbow. The function `ProSetdatumtagElbowGet()` checks if the leader of the specified datum feature symbol has an elbow.

The function `ProSetdatumtagASMEDisplaySet` displays the datum feature symbol according to the ASME standard. Use the function `ProSetdatumtagASMEDisplayGet()` to check if the specified datum feature symbol is displayed as per ASME standard.

The function `ProSetdatumtagReferencesAdd()` adds semantic references to the specified datum feature symbol.

---

 **Note**

When a reference includes more than one collection, the function `ProSetdatumtagReferencesAdd()` returns the error `PRO_TK_MAX_LIMIT_REACHED` and no reference is added.

---

The function `ProSetdatumtagReferencesGet()` returns a `ProArray` of semantic references that were used to place the specified datum feature symbol. Use the function `ProAnnotationreferencearrayFree` to free the allocated memory. Use the function `ProSetdatumtagReferenceDelete()` to delete semantic references in the specified datum feature symbol. The references are specified by their index number.

In Creo Parametric 7.0.0.0 and later, the function `ProSetdatumtagTextLocationGet()` is deprecated.

Use the function `ProSetdatumtagTextPointGet()` instead. The function `ProSetdatumtagTextPointGet()` retrieves the text point for the specified datum feature symbol.

---

The function `ProSetdatumtagAdditionalTextLocationGet()` retrieves the location of additional text for the specified datum feature symbol.

The function `ProDrawingSetDatumTagIsShown()` returns the display status of the set datum tag in the specified view of a drawing. The input arguments are:

- *set\_datum\_tag*—Specifies the set datum tag.
- *drawing*—Specifies the drawing that shows the annotation.
- *view*—Specifies the drawing view.

The function returns `PRO_B_TRUE` if the set datum tag is shown in the specified drawing view, and `PRO_B_FALSE` if it is not shown in the drawing view.

The function `ProDrawingSetDatumTagIsShown()` returns the error `PRO_TK_BAD_CONTEXT` if the datum feature symbol cannot be shown in the specified drawing view.

Use the function `ProDrawingSetdatumtagErase()` to set a set datum tag to be erased from the specified view of a drawing. The annotation is not displayed until it is explicitly displayed using the function `ProAnnotationShow()`.

The function `ProDrawingSetdatumtagVisit()` enables you to visit the set datum tag annotations in the specified drawing.

The function `ProDrawingLegacySetdatumtagErase()` sets the legacy set datum tag to be erased from drawing view. As a result, the drawing database does not show the annotation until it is explicitly

Use the function `ProDrawingLegacySetdatumtagIsShown()` to check if the legacy set datum tag is shown.

---

 **Note**

The functions `ProDrawingLegacySetdatumtagErase()` and `ProDrawingLegacySetdatumtagIsShown()` are applicable for legacy set datum tags only.

---

The input arguments for both the functions `ProDrawingLegacySetdatumtagErase()` and `ProDrawingLegacySetdatumtagIsShown()` are:

- *drawing*—The drawing where legacy set datum tag needs to be shown. or is already present.
- *view*—Drawing view. The value should not be `NULL`.
- *path*—Component path.
- *tag*—Legacy set datum tag.

---

If the legacy set datum tag is shown, the function

`ProDrawingLegacySetdatumtagIsShown()` returns a `ProBoolean` output argument with the value as `PRO_B_TRUE`, else it returns `PRO_B_FALSE`.

## Accessing Set Datums for Datum Axes or Planes

The functions described in this section provide access to the “Set Datum” status of a datum axis or plane.

### Note

These function support the “Set Datum” capability which existed before Set Datum Tag annotations.

---

Functions Introduced:

- **`ProGeomitemSetdatumGet()`**
- **`ProGeomitemSetdatumSet()`**
- **`ProGeomitemSetdatumClear()`**

The function `ProGeomitemSetdatumGet()` specifies whether the datum plane or axis is a “Set Datum”. This function supersedes the function `ProGeomitemIsGtolref()`.

The function `ProGeomitemSetdatumSet()` sets the datum plane or axis to be a “Set Datum”. This function supersedes the function `ProGeomitemGtolrefSet()`.

The function `ProGeomitemSetdatumClear()` removes the “Set Datum” status of a datum plane or axis. This function supersedes the function `ProGeomitemGtolrefClear()`.

## Surface Finish Annotations

The functions described in this section provide read access to the properties of the surface finish object. They also allow you to create and modify surface finishes.

The style of surface finishes for releases previous to Pro/ENGINEER Wildfire 2.0 was a flat-to-screen symbol attached to a single surface. From Pro/ENGINEER Wildfire 2.0 onwards, the method for construction of surface finishes has been modified. The new style of surface finish is a symbol instance that may be attached on a surface or with a leader or offset to another surface finish, symbol, note, or gtol. The following functions support both the old and new surface finish annotations, except where specified.

Functions Introduced:

- 
- **ProSolidSurffinishVisit()**
  - **ProSurffinishCreate()**
  - **ProSurffinishReferencesGet()**
  - **ProSurffinishSrfcollectionGet()**
  - **ProSurffinishSrfcollectionSet()**
  - **ProSurffinishAdditionalReferencesAdd()**
  - **ProSurffinishAdditionalReferencesGet()**
  - **ProSurffinishAdditionalReferenceDelete()**
  - **ProSurffinishDataGet()**
  - **ProSurffinishModify()**
  - **ProSurffinishValueGet()**
  - **ProSurffinishValueSet()**
  - **ProSurffinishDelete()**

The function `ProSolidSurffinishVisit()` visits the surface finishes stored in the specified solid model. This function accepts a visit function `ProSurfaceVisitAction()` and a filter function `ProSurfaceFilterAction()` as the input arguments.

The function `ProSurffinishCreate()` creates a new symbol-based surface finish annotation. The function requires a symbol instance data structure for creation. Once the surface finish annotation is created, use the function `ProAnnotationShow()` to display it.

#### **Note**

The data must conform to the requirements for surface finishes, that is, attachment must be via leader to or on one or more surfaces.

---

You can use the standard surface finish symbol definitions from the symbol instance data structure. Use the function `ProSolidDtlsymdefRetrieve()` to retrieve the surface finish symbol definitions from the location `PRO_DTLSYMDEF_SRC_SURF_FINISH_DIR`. The surface finish value should be set using the variant text options for symbol instances.

The function `ProSurffinishReferencesGet()` returns the surface or surfaces referenced by the surface finish.

The function `ProSurffinishSrfcollectionGet()` obtains a surface collection which contains the references of the surface finish.

---

The function `ProSurffinishSrfcollectionSet()` assigns a surface collection to be the references of the surface finish. This overwrites all current surface finish references. The following types of surface collections are supported:

- One by one surface set
- Intent surface set
- Excluded surface set
- Seed and Boundary surface set
- Loop surface set
- Solid surface set
- Quilt surface set

---

 **Note**

Only those surface finishes that are contained within annotation elements may use a collection of references instead of a single surface reference.

---

The function `ProSurffinishAdditionalReferencesAdd()` adds references to the specified surface finish. The input arguments follow:

- *surf\_finish*—Surface finish to which the references are to be added.
- *refs*—Array of references specified using the `ProAnnotationReference` structure. You can add only one reference if you select `PRO_ANNOT_REF_SRF_COLLECTION`.

---

 **Note**

The function `ProSurffinishAdditionalReferencesAdd()` returns the error `PRO_TK_MAX_LIMIT_REACHED` when more than one reference from the type `PRO_ANNOT_REF_SRF_COLLECTION` is added

---

The function `ProSurffinishAdditionalReferencesGet()` returns a `ProArray` of references for a specified surface finish.

Use the function `ProAnnotationreferencearrayFree()` to release the memory assigned to the `ProArray` of references.

The function `ProSurffinishAdditionalReferenceDelete()` deletes the specified surface finish references. The input arguments follow:

- *surf\_finish*—Surface finish from which the references are to be deleted.

- 
- `index_ref`—Index of the references that must be deleted. Indices start from 0. Get existing references from the function `ProDtlsyminstReferencesGet()`.

The function `ProSurffinishDataGet()` returns the symbol instance data for the surface finish. This function supports only new symbol-based surface finishes.

The function `ProSurffinishModify()` modifies the symbol instance data for the specified surface finish. This function supports only new symbol-based surface finishes.

The function `ProSurffinishValueGet()` retrieves the value of a surface finish annotation.

The function `ProSurffinishValueSet()` sets the value of a surface finish annotation.

The function `ProSurffinishDelete()` deletes the specified surface finish.

The functions described above supersede the Pro/Develop functions `pro_surf_finish_number()`, `pro_get_surf_finish()`, `pro_delete_surface_finish()` and `pro_set_surface_finish()`.

## Symbol Annotations

The functions described in this section provide support for 3D mode symbols. Creo TOOLKIT functions for symbol instances are used in both 2D and 3D modes. Symbols for a particular mode must conform to the requirements for that mode. Some `ProDtlsyminst` functions have been modified to accept a `ProMdl` object as the input instead of `ProDrawing` object to support 3D mode operations.

### Creating, Reading and Modifying 3D Symbols

Functions Introduced:

- **`ProDtlsyminstCreate()`**
- **`ProDtlsyminstDataGet()`**
- **`ProDtlsyminstModify()`**
- **`ProDtlsyminstdataPlaneGet()`**
- **`ProDtlsyminstdataPlaneSet()`**

The function `ProDtlsyminstCreate()` creates a symbol instance in the specified model. Once the symbol instance is created, use the function `ProAnnotationShow()` to display it. In Creo Parametric 10.0.0.0 and later, you can use the function `ProDtlsyminstCreate()` to place 3D symbols as offset to other symbol, dimension, note or a datum target.

The function `ProDtlsyminstDataGet()` returns the symbol instance data.

---

The function `ProDtlSymInstModify()` modifies the symbol instance.

For more information about creating, accessing and modifying symbols via the `ProDtlSymInst` and `ProDtlSymInstData` structures, refer to the [Drawings on page 1287](#) section.

The functions `ProDtlSymInstDataPlaneGet()` and `ProDtlSymInstDataPlaneSet()` provide access to the symbol annotation plane. Annotation planes are required for 3D symbol instances but are not applicable for 2D symbol instances.

## Locating and Collecting 3D Symbols and Symbol Definitions

Functions Introduced:

- **`ProSolidDtlSymDefVisit()`**
- **`ProSolidDtlSymInstVisit()`**
- **`ProSolidDtlSymDefEntityVisit()`**
- **`ProSolidDtlSymDefNoteVisit()`**
- **`ProSolidDtlSymDefRetrieve()`**
- **`ProSolidDtlSymInstsCollect()`**
- **`ProSolidDtlSymDefsCollect()`**

The functions `ProSolidDtlSymDefVisit()` and `ProSolidDtlSymInstVisit()` allow traversal of symbol definitions and instances in a solid model.

The functions `ProSolidDtlSymDefEntityVisit()` and `ProSolidDtlSymDefNoteVisit()` allow traversal of items contained in a symbol definition stored in a solid model.

The function `ProSolidDtlSymDefRetrieve()` allows retrieval of a symbol definition into a given solid model. The input arguments for this function are as follows:

- *solid*—Specifies a handle to the solid model.
- *location*—Specifies the location of the symbol definition file. It can one of the following values:
  - `PRO_DTL_SYMDEF_SRC_SYSTEM`—Specifies the system symbol definition directory.
  - `PRO_DTL_SYMDEF_SRC_SYMBOL_DIR`—Specifies the system surface finish symbol definition directory.
  - `PRO_DTL_SYMDEF_SRC_SYMBOL_DIR`—Specifies the location controlled by the configuration option `pro_symbol_dir`.

- 
- `PRO_DTLSYMDEF_SRC_PATH`—Specifies the absolute path to a directory containing the symbol definition.
  - *filepath*—Specifies the path to the file with a symbol definition. The path is relative to the location specified in the argument *location*.
  - *filename*—Specifies the name of the symbol definition file.
  - *version*—Specifies the version of the symbol definition file.
  - *update*—Specifies the update flag. If `TRUE`, the definition will be loaded even if a definition of that name already exists in the model. If `FALSE`, the retrieval will not take place if the definition exists in the model.

You can use symbol instances from different symbol definitions in a solid. The function `ProSolidDtlsyminstsCollect()` collects all the symbol instances used in the specified solid as a `ProArray`. The function `ProSolidDtlsymdefsCollect()` returns a `ProArray` of all the symbol definitions used in the specified solid. The function returns symbol definitions only for the symbol instances used in the solid. Use the function `ProArrayFree()` to release the memory assigned to the `ProArray` of symbol definitions and symbol instances.

## Annotations: Geometric Tolerances

### Annotations: Geometric Tolerances

The functions in this section allow a Creo TOOLKIT application to read, modify, and create geometric tolerances (gtols) in a solid or drawing. We recommend that you study the Creo Parametric documentation on geometric tolerances, and develop experience with manipulating geometric tolerances using the Creo Parametric commands before attempting to use these functions.

## Geometric\_Tolerance\_Objects

### Overview

The geometric tolerance objects enable you to access internal data structure of geometric tolerances (gtol). The object also references and gets attachment details for gtols.

---

From Creo Parametric 4.0 F000 onward, the object `Gtoldata` has been deprecated. All the `ProGtolData*` functions have also been deprecated. Use the new `ProGtol*` functions instead. The new functions are defined in the header files `ProGtol.h` and `ProGtolAttach.h`.

---

 **Note**

Geometric tolerance functions deprecated in Creo Parametric 4.0 F000 must not be used with the new geometric tolerance functions available from Creo Parametric 4.0 F000 in a Creo TOOLKIT application. If the functions are used together in an application, the results may be unpredictable.

---

## ProGtol

Geometric tolerances in a Creo Parametric model are referenced by the data handle, `ProGtol`. This handle is identical to `ProModelitem`, in which the type field is set to `PRO_GTOL`. You can use `ProSelect()` with the option `gtol` to select a `gtol`, after which you can extract the `ProGtol` handle using `ProSelectionModelitemGet()`.

## ProGtolAttach

This is an opaque handle object that references an internal data structure which provides complete attachment details for a `gtol`. The structure contains attachment information such as, type of placement, annotation plane, location and references and so on for a `gtol`.

## Visiting Geometric Tolerances

Function Introduced:

- **ProMdlGtolVisit()**

The function `ProMdlGtolVisit()` visits geometric tolerances stored in a part, assembly, or drawing. The forms of the visit and filter functions are similar to those of most other visit functions—they receive a `ProGtol` pointer as input argument to identify the `gtol`.

## Reading Geometric Tolerances

The functions explained in this section enable you to access and read the properties of a geometric tolerance.

Function Introduced:

- **ProGtolNameGet()**

- 
- **ProGtolTypeGet()**
  - **ProGtolTopModelGet()**
  - **ProGtolReferencesGet()**
  - **ProGtolDatumReferencesGet()**
  - **ProGtolValueStringGet()**
  - **ProGtolCompositeGet()**
  - **ProGtolCompositeShareRefGet()**
  - **ProGtolSymbolStringGet()**
  - **ProGtolIndicatorsGet()**
  - **ProGtolAllAroundGet()**
  - **ProGtolAllOverGet()**
  - **ProGtolAddlTextBoxedGet()**
  - **ProGtolBoundaryDisplayGet()**
  - **ProGtolUnilateralGet()**

The function `ProGtolNameGet()` returns the name of the geometric tolerance (gtol) as a `wchar_t*` string. Use the function `ProWstringFree()` to free the string.

The function `ProGtolTypeGet()` returns the type of the gtol using the enumerated data type `ProGtolType`. The various types of gtol, are straightness, flatness, and so on.

The function `ProGtolTopModelGet()` returns the model that defines the origin of `ProSelection` structures used to define references inside the gtol. This will usually be the model that contains the gtol; but if the gtol was created in drawing mode and added to a solid in a drawing view, the owner will be the drawing, while the model is the solid.

`ProGtolReferencesGet()` returns a `ProArray` of the geometric entities referenced by the specified gtol. The entities are additional references used to create the gtol.

Use the function `ProAnnotationreferencearrayFree()` to free the `ProArray`.

The function `ProGtolDatumReferencesGet()` returns the primary, secondary, and tertiary datum references for a gtol as `wchar_t*` strings. Use the function `ProWstringFree()` to free the strings.

The function `ProGtolCompositeGet()` retrieves the value and the datum references, that is, the primary, secondary, and tertiary references for the specified composite gtol.

---

The function `ProGtolCompositeGet()` returns an array of values in which the first value is the primary value of the gtol and the rest are secondary, tertiary, and so on.

The function `ProGtolValueStringGet()` retrieves the value specified in the gtol as a `wchar_t*` string. Use the function `ProWstringFree()` to free the string.

The function `ProGtolValueStringGet()` returns a value string which is the primary value of the gtol and is displayed in the first box of the **Composite Frame** in the gtol ribbon.

For more information about gtols and the ribbon tab, refer to the Creo Parametric online help.

Use the function `ProGtolSymbolStringGet()` to retrieve the string value in the specified font for the gtol symbol. The input arguments are:

- *symbol*—Specifies the type of symbol using the enumerated data type `ProGtolSymbol`. The valid values are:
  - `PRO_GTOL_SYMBOL_DIAMETER`—Specifies the diameter for the feature.
  - `PRO_GTOL_SYMBOL_FREE_STATE`—Specifies that the model is not subjected to any force, except the gravitational force.
  - `PRO_GTOL_SYMBOL_STAT_TOL`—Specifies statistical tolerance.
  - `PRO_GTOL_SYMBOL_TANGENT_PLANE`—Specifies the tangent plane.
  - **Material Symbols**—The material conditions are represented using the following values:
    - `PRO_GTOL_SYMBOL_LMC`—Specifies least material condition and is displayed by the symbol .
    - `PRO_GTOL_SYMBOL_MMC`—Specifies maximum material condition and is displayed by the symbol .
    - `PRO_GTOL_SYMBOL_RFS`—Specifies the material condition regardless of the feature size and is displayed by the symbol .
    - `PRO_GTOL_SYMBOL_DEFAULT_RFS`—Specifies the material condition regardless of the feature size, but does not show a symbol in the frame.
    - `PRO_GTOL_SYMBOL_LMC_R`—Specifies least material condition with reciprocity. The reciprocity is displayed on drawings with the symbol ® after the symbol .

- `PRO_GTOL_SYMBOL_MMC_R`—Specifies maximum material condition with reciprocity. The reciprocity is displayed on drawings with the symbol

Ⓜ after the symbol.

---

### Note

You can use the reciprocity condition together with the maximum material condition or the minimum material condition to use the maximum tolerance allowed for a feature. The material conditions with reciprocity are applicable only for the ISO standard.

---

- **Indicator Symbols**—Indicators are displayed after the gtol symbol according to the standard. The Indicator symbols are represented using the following values:

`PRO_INDICATOR_SYMBOL_ANGULARITY`—Specifies the angular position of a feature to a reference.

- `PRO_INDICATOR_SYMBOL_PERPENDICULARITY`—Specifies that the two features must be perpendicular to each other. It is also used to indicate perpendicularity for features such as axis to a reference.
- `PRO_INDICATOR_SYMBOL_PARALLELISM`—Specifies that the two features must be parallel to each other. It is also used to indicate parallelism for features such as axis to a reference.
- `PRO_INDICATOR_SYMBOL_SYMMETRY`—Specifies that the two features must be symmetric about a center.
- `PRO_INDICATOR_SYMBOL_RUNOUT`—Applicable only for direction feature. Specifies that the direction of the width of the tolerance zone is equal to run-out, that is perpendicular to the surface of the tolerance feature.
- `PRO_GTOL_SYMBOL_TRANSLATION`—Specifies the translation symbol.
- *font*—Specifies the tolerancing font used for symbols. The valid values are defined in the enumerated data `ProSymbolFont`:
  - `PRO_FONT_LEGACY`—Specifies that symbols use the legacy font.
  - `PRO_FONT_ASME`—Specifies that symbols use ASME font.
  - `PRO_FONT_ISO`—Specifies that symbols use ISO font.
  - `PRO_FONT_STROKED_ASME`—Specifies that symbols use stroked ASME fonts that are native to Creo.
  - `PRO_FONT_STROKED_ISO`—Specifies that symbols use stroked ISO fonts that are native to Creo.

---

The function `ProGtolIndicatorsGet()` retrieves all the indicators assigned to the specified gtol. It returns `ProArray` of indicator types, symbols, and datum feature symbols.

The function `ProGtolCompositeShareRefGet()` checks if the datum references are shared between all the rows defined in the composite gtol.

The functions `ProGtolSymbolStringGet()` and `ProGtolValueStringGet()`, provide information on the different symbolic modifiers available to the gtol.

The function `ProGtolAllOverGet()` returns a boolean value that indicates if the **All Over** symbol has been set in the specified gtol. The function `ProGtolAllAroundGet()` checks if the **All Around** symbol has been set for the specified gtol. The **All Over** symbol and **All Around** symbol specifies that the profile tolerance must be applied to all the three dimensional profile of the part. The symbol is available only for surface profile gtol, that is, of type `PROGTOLTYPE_SURFACE`.

The function `ProGtolAddlTextBoxedGet()` checks if a box has been created around the specified additional text in a geometric tolerance.

The function `ProGtolBoundaryDisplayGet()` checks if the boundary modifier has been set for the specified gtol. Use the function `ProGtolUnilateralGet()` to check if the profile boundary has been set to unilateral in the specified gtol. If set to unilateral, the function also checks if the tolerance disposition is in the outward direction of the profile.

---

#### Note

When the new `ProGtol*Get()` functions, except `ProGtolTopModelGet()`, `ProGtolReferencesGet()`, `ProGtolReferenceDelete()`, and `ProGtolValidate()` are called on geometric tolerances created in releases prior to Creo Parametric 4.0 F000, these legacy geometric tolerances are converted to the new Creo Parametric 4.0 geometric tolerances. In this case, the revision number of the model is also incremented.

---

## Creating a Geometric Tolerance

Functions Introduced:

- `ProGtolTypeSet()`
- `ProGtolReferencesAdd()`
- `ProGtolReferenceDelete()`

- **ProGtolDatumReferencesSet()**
- **ProGtolValueStringSet()**
- **ProGtolCompositeSet()**
- **ProGtolCompositeShareRefSet()**
- **ProGtolAllAroundSet()**
- **ProGtolAllOverSet()**
- **ProGtolAddlTextBoxedSet()**
- **ProGtolElbowlengthSet()**
- **ProGtolBoundaryDisplaySet()**
- **ProGtolUnilateralSet()**
- **ProMdlGtolCreate()**
- **ProGtolDtlnotesCollect()**

The basic steps in creating a gtol are:

1. Allocate a `ProGtolAttach` structure using `ProGtolAttachAlloc()`.
2. Set the attachment properties using the `ProGtolAttach*Set()` functions.
3. Set tolerance properties using the `ProGtol*Set()` functions.
4. Create the tolerance using `ProMdlGtolCreate()`. Once the tolerance is created, you must use the function `ProAnnotationShow()` to display it.
5. Free `ProGtolAttach` using `ProGtolAttachFree()`.

The function `ProGtolTypeSet()` sets the type of geometric tolerance using the enumerated data type `ProGtolType`.

Use the function `ProGtolReferencesAdd()` to add datum references to the specified gtol.

#### **Note**

When a reference includes more than one collection, the function `ProGtolReferencesAdd()` returns the error `PRO_TK_MAX_LIMIT_REACHED` and no reference is added.

---

Use the function `ProGtolReferenceDelete()` to delete the datum references from the specified gtol.

The function `ProGtolIndicatorsSet()` sets the indicators for the specified gtol. The input arguments are:

- *gtol*—Specifies the gtol.

- *types*—Specifies a ProArray of indicator types using the enumerated data type ProGtolIndicatorType. Use the function ProArrayFree() to free the array.
- *symbols*—Specifies a ProArray of strings for indicator symbols. Free the array using the function ProWstringproarrayFree().
- *dfs*—Specifies a ProArray of strings for datum feature symbols. Free the array using the function ProWstringproarrayFree().

The function ProGtolCompositeSet() sets the value and datum references, primary, secondary, and tertiary for the specified composite gtol.

Use the function ProGtolCompositeShareRefSet() to specify if datum references in a composite gtol must be shared between all the defined rows. Pass the input argument *share* as PRO\_B\_TRUE to share the references.

The function ProGtolValueStringSet() sets the specified value for a gtol.

Use the function ProGtolDatumReferencesSet() to set the datum references for the specified gtol. The datum references are set as wchar\_t\* strings. Use the function ProWstringFree() to free the strings.

The datum references are given to ProGtolDatumReferencesSet() in the form of wchar\_t\* strings. Use the function ProWstringFree() to free the strings.

The function ProGtolElbowlengthSet() sets the elbow along with its properties for a leader type of gtol. The function is supported for leader type gtol which are placed on the annotation plane. The input arguments are:

- *gtol*—Specifies a gtol.
- *elbow\_length*—Specifies the length of the elbow in model coordinates.
- *elbow\_direction*—Specifies the direction of the elbow in model coordinates. The gtol text also moves in this direction.

The function ProGtolBoundaryDisplaySet() sets the boundary modifier for the specified gtol. Use the function ProGtolUnilateralSet() to set the profile boundary as unilateral in the specified gtol. The function also sets the tolerance disposition to the outward direction of the profile.

The function ProGtolAllAroundSet() sets the **All Over** symbol for the specified geometric tolerance.

The function ProGtolAllAroundSet() sets the **All Around** symbol for the specified geometric tolerance.

The function ProGtolAddlTextBoxedSet() creates a box around the specified additional text in a geometric tolerance. Boxes can be created around additional text added above and below the frame of the geometric tolerance.

---

From Creo Parametric 4.0 F000 onward, stacked geometric tolerance creates separate notes for each tolerance. For a stacked geometric tolerance, the functions `ProGtolDtlnoteGet()`, `ProDtlnoteDataGet()`, and `ProDtlnotedataLinesCollect()` will return information about individual notes for each geometric tolerance.

The function `ProGtolDtlnotesCollect()` returns the detail notes that represent a geometric tolerance in the specified drawing. The input arguments follow:

- *solid\_model\_gtol*—The handle to the geometric tolerance.
- *drawing* —The drawing where the note is displayed.

The function returns an array of drawing notes that represents the geometric tolerance.

## Attaching the Geometric Tolerances

The functions explained in this section enable you to access and set attachment options for the geometric tolerance.

Function Introduced:

- **ProGtolAttachGet()**
- **ProGtolAttachSuppressedLeadersGet()**
- **ProGtolAttachSet()**
- **ProGtolAttachTypeGet()**
- **ProGtolAttachLeadersGet()**
- **ProGtolAttachLeadersSet()**
- **ProGtolleaderGet()**
- **ProGtolleaderZExtensionlineGet()**
- **ProGtolEnvelopeGetWithFlags()**
- **ProGtolEnvelopeGet()**
- **ProGtolleadersFree()**
- **ProGtolAttachOffsetItemGet()**
- **ProGtolAttachOffsetItemSet()**
- **ProGtolAttachFreeGet()**
- **ProGtolAttachFreeSet()**
- **ProGtolleaderFree()**
- **ProGtolAttachOnDatumGet()**
- **ProGtolAttachOnDatumSet()**
- **ProGtolAttachOnAnnotationGet()**
- **ProGtolAttachOnAnnotationSet()**

- **ProGtolAttachMakeDimGet()**
- **ProGtolAttachMakeDimSet()**
- **ProGtolMakeDimensionGet()**

The function `ProGtolAttachGet()` retrieves all the attachment related information for a gtol as a `ProGtolAttach` structure. Use the function `ProGtolAttachSet()` to set the attachment options. If the function `ProGtolAttachSet()` specifies one or more leaders, the leaders are described by a separate opaque object called `ProGtolleader`. This object is allocated by call to the function `ProGtolleaderAlloc()`. Use the function `ProGtolleaderFree()` to free the allocated memory.

The function `ProGtolAttachTypeGet()` retrieves the type of attachment for a gtol. It uses the enumerated data type `ProGtolAttachType` to provide information about the placement of the gtol. The valid values are:

- `PRO_GTOL_ATTACH_DATUM`—Specifies that the gtol is placed on its reference datum.
- `PRO_GTOL_ATTACH_ANNOTATION`—Specifies that the gtol is attached to an annotation.
- `PRO_GTOL_ATTACH_ANNOTATION_ELBOW`—Specifies that the gtol is attached to the elbow of an annotation.
- `PRO_GTOL_ATTACH_FREE`—Specifies that the gtol is placed as a free. It is unattached to the model or drawing.
- `PRO_GTOL_ATTACH_LEADERS`—Specifies that the gtol is attached with one or more leader to geometry such as, edge, dimension witness line, coordinate system, axis center, axis lines, curves, or surface points, vertices, section entities, draft entities, and so on. The leaders are represented using an opaque handle, `ProGtolleader`.
- `PRO_GTOL_ATTACH_OFFSET`—Specifies that the gtol frame can be placed at an offset from the following drawing objects: dimension, dimension arrow, gtol, note, and symbol.
- `PRO_GTOL_ATTACH_MAKE_DIM`—Specifies that the gtol frame is attached to a dimension line.

Use the function `ProGtolAttachLeadersGet()` to get attachment details for leader type of gtol. The output arguments are:

- *plane*—Specifies the annotation plane. For gtols defined in drawing, it returns `NULL`.
- *type*—Specifies the attachment type for the leader using the enumerated data type `ProGtolLeaderAttachType`.
- *leaders*—Specifies a `ProArray` of gtol leaders.
- *location*—Specifies the location of gtol text in model coordinates.

---

Use the function `ProGtolAttachSuppressedLeadersGet()` to get the number of leaders that are suppressed due to missing references.

Use the function `ProGtolAttachLeadersSet()` to set the attachment options for leader type of gtol.

To unpack the information in the `ProGtolLeader` handle, use the function `ProGtolLeaderGet()`. After reading the leaders, free the leader array by calling `ProGtolLeadersFree()`.

The function `ProGtolLeaderZExtensionlineGet()` retrieves the Z-Extension line of the gtol leader. The leader location coordinates are required when the gtol is moved to a different annotation plane.

The function `ProGtolEnvelopeGetWithFlags()` gets the envelope of the gtol. To retrieve coordinates of the gtol in a specified solid, if the gtol is displayed in the solid as well as in the drawing, the drawing must not be active. The input arguments are:

- *gtol*—The handle to the gtol using the object `ProGtol`.
- *drawing*—Specify the drawing using the object `ProDrawing`. Pass the value only for solid gtol shown in a drawing; otherwise, pass it as `NULL`.
- *flags*—Specify the gtol envelope flag using the enumerated data type `ProGtolEnvelopeFlag`. The value `PRO_GTOL_ENVELOPE_SKIP_OUTSIDE_TEXT` must be passed to get an envelope without an additional text; otherwise, pass it as `PRO_GTOL_ENVELOPE_DEFAULT`.

The output argument *envelope* is the envelope surrounding the gtol in the model coordinate system. For flat-to-screen gtol, the envelope is in screen coordinates. For a drawing, it is in the screen coordinates. For additional texts, there is no padding.

The function `ProGtolEnvelopeGet()` returns the envelope of the gtol. The output argument *envelope* is the envelope surrounding the gtol in the coordinate system of the model. For drawing, the envelope of the gtol is in the screen coordinates. While retrieving coordinates of the gtol in a specified solid, if the gtol is displayed in the solid as well as in the drawing, the drawing must not be active.

The function `ProGtolAttachOffsetItemGet()` returns the offset references for the specified `ProGtolAttach` structure. The function returns the following output arguments:

- *offset\_ref*—Specifies the offset reference as a `ProSelection` object. The reference can be a dimension, arrow of a dimension, another geometric tolerance, note, or a symbol instance. If there are no offset references, the output argument returns `NULL`.
- *offset*—Specifies the position of the offset reference as model coordinates.

Use the function `ProGtolAttachOffsetItemSet()` to set the offset references for the specified `ProGtolAttach` structure.

---

The function `ProGtolAttachFreeGet()` gets the details for free type of gtol. It retrieves information about the annotation plane and location of the gtol text in model coordinates. For gtols defined in drawing, the function returns NULL for annotation plane. Use the function `ProGtolAttachFreeSet()` to set the options for free type gtol.

The functions `ProGtolAttachOnDatumGet()` and `ProGtolAttachOnDatumSet()` get and set datum symbol for the geometric tolerance. From Creo Parametric 4.0 F000 onward, datum symbols are defined using datum feature symbol. The functions work with the new datum feature symbol along with the legacy datum tag annotations.

The function `ProGtolAttachOnAnnotationGet()` retrieves the annotation for the specified `ProGtolAttach` structure. The function `ProGtolAttachOnAnnotationSet()` sets the specified annotation to the attachment structure. The input arguments are:

- *gtol\_attach*—Specifies the attachment structure `ProGtolAttach` for a geometric tolerance.
- *p\_annot*—Specifies the annotation. For gtols in the solid you can set `PRO_DIMENSION`, `PRO_GTOL`, and `PRO_NOTE` type of annotations. For drawing gtols, you can set `PRO_DIMENSION`, `PRO_GTOL`, and `PRO_NOTE` type of annotations.
- *elbow*—Specifies that the annotation must be placed on the elbow of the leader instead of the gtol text. If the annotation type is set as `PRO_NOTE`, then you must set *elbow* as `PRO_B_TRUE`.

The function `ProGtolAttachMakeDimGet()` gets all the information for a geometric tolerance created with **Make Dim** type of reference. **Make Dim** type of reference mode enables you to create a dimension line and place the gtol frame attached to it. The geometric tolerance appears in standard dimension format, but with the geometric tolerance instead of a dimension value. The output arguments are:

- *plane*—Specifies the annotation plane for the gtol.
- *attachments\_arr*—Specifies the points on the model or drawing where the gtol is attached.
- *dsense\_arr*—Specifies more information about how the gtol attaches to each attachment point of the model or drawing.
- *orient\_hint*—Specifies the orientation of the gtol using the enumerated data type `ProDimOrient`. The valid values are
  - `PRO_DIM_ORNT_HORIZ`—Specifies a horizontal dimension.
  - `PRO_DIM_ORNT_VERT`—Specifies a vertical dimension.
  - `PRO_DIM_ORNT_SLANTED`—Specifies the shortest distance between two attachment points. This value is available only when the dimension is attached to points.

- `PRO_DIM_ORNT_ELPS_RAD1`—Specifies the start radius for a dimension on an ellipse.
- `PRO_DIM_ORNT_ELPS_RAD2`—Specifies the end radius for a dimension on an ellipse.
- `PRO_DIM_ORNT_ARC_ANG`—Specifies the angle of the arc for a dimension of an arc.
- `PRO_DIM_ORNT_ARC_LENGTH`—Specifies the length of the arc for a dimension of an arc.
- `PRO_DIM_ORNT_LIN_TANCRV_ANG`—If the dimension is attached to a line and an end point of a curve, the default dimension will be a linear dimension showing the distance between the line and the curve point. Set this value if you want the dimension to show instead the angle between the line and the tangent at the curve point.
- `PRO_DIM_ORNT_RAD_DIFF`—Specifies the linear dimension of the radial distance between two concentric arcs or circles.
- `PRO_DIM_ORNT_NORMAL`—Specifies the linear dimension between two points to be placed normal to the selected reference.
- `PRO_DIM_ORNT_PARALLEL`—Specifies the linear dimension between two points to be placed parallel to the selected reference.
- *location*—Specifies the location of gtol text as model coordinates.

The function `ProGtolAttachMakeDimSet()` sets all the options to create a geometric tolerance with **Make Dim** type of reference.

The function `ProGtolMakeDimensionGet()` gets the dimension of the **Make Dim** type of reference using a gtol object. The input argument is *gtol* specifies the valid geometric tolerance.

The output argument *dim* returns `ProDimension of Make Dim gtol`.

## Deleting a Geometric Tolerance

Function Introduced:

- **ProGtolDelete()**

The function `ProGtolDelete` permanently removes a gtol.

## Validating a Geometric Tolerance

Function Introduced:

- **ProGtolValidate()**

---

The function `ProGtolValidate` checks if the specified geometric tolerance is syntactically correct. For example, when a string is specified instead of a number for a tolerance value, it is considered as syntactically incorrect. The input arguments are:

- *gtol*—Specifies the geometric tolerance to be checked.
- *ProGtolValidityCheckType*—Specifies the type of check. Currently, the tolerance is checked for correct syntax.

## Geometric Tolerance Layout

The functions described in this section provide access to the layout for the text and symbols in a geometric tolerance.

Functions Introduced:

- **ProGtolElbowlengthGet()**
- **ProGtolLineEnvelopeGet()**
- **ProGtolRightTextEnvelopeGet()**

The function `ProGtolElbowlengthGet()` returns the length and direction of the geometric tolerance leader elbow.

The function `ProGtolLineEnvelopeGet()` returns the bounding box coordinates for one line from the geometric tolerance.

The function `ProGtolRightTextEnvelopeGet()` returns the bounding box coordinates for the right text in a specified geometric tolerance.

---

### Note

The functions `ProGtolLineEnvelopeGet()` and `ProGtolRightTextEnvelopeGet()` support the geometric tolerances placed on annotation planes.

---

## Additional Text for Geometric Tolerances

You can place multi-line additional text to the right, left, bottom, and above a geometric tolerance control frame while creating and editing a gtol in both drawing and model modes.

Functions Introduced:

- **ProGtolRightTextGet()**
- **ProGtolRightTextSet()**
- **ProGtolLeftTextGet()**

- 
- **ProGtolLeftTextSet()**
  - **ProGtolTopTextGet()**
  - **ProGtolTopTextSet()**
  - **ProGtolBottomTextGet()**
  - **ProGtolBottomTextSet()**

The function `ProGtolRightTextGet()` retrieves the text added to the right of the specified geometric tolerance.

Use the function `ProGtolRightTextSet()` to set the text to be added to the right of the specified geometric tolerance.

The function `ProGtolLeftTextGet()` retrieves the text added to the left of the specified geometric tolerance.

Use the function `ProGtolLeftTextSet()` to set the text to be added to the left of the specified geometric tolerance.

The function `ProGtolTopTextGet()` retrieves the text added to the top of the specified geometric tolerance.

Use the function `ProGtolTopTextSet()` to set the text to be added to the top of the specified geometric tolerance.

The function `ProGtolBottomTextGet()` retrieves the text added to the bottom of the specified geometric tolerance.

Use the function `ProGtolBottomTextSet()` to set the text to be added to the bottom of the specified geometric tolerance.

---

#### **Note**

If the additional text extends over multiple lines, the input string must contain `\n` characters to indicate line breaks. The output string also contains `\n` characters indicating line breaks. The text added to the top of a gtol cannot extend beyond the length of the geometric tolerance control frame.

---

## Geometric Tolerance Text Style

The functions described in this section access the text style properties of a geometric tolerance.

Functions Introduced:

- **ProGtolTextstyleGet()**
- **ProGtolTextstyleSet()**
- **ProGtoltextTextstyleGet()**

- 
- **ProGtolTextstyleSet()**
  - **ProGtolTopTextHorizJustificationSet()**
  - **ProGtolTopTextHorizJustificationGet()**
  - **ProGtolBottomTextHorizJustificationSet()**
  - **ProGtolBottomTextHorizJustificationGet()**

The function `ProGtolTextstyleGet()` returns the text style assigned of a specified geometric tolerance.

The function `ProGtolTextstyleSet()` assigns the text style of a specified geometric tolerance.

The function `ProGtolTextstyleGet()` retrieves the text style of the additional text applied to the specified geometric tolerance.

The function `ProGtolTextstyleSet()` assigns the text style of the additional text applied to the specified geometric tolerance. Specify the instance of the additional text to be accessed using the enumerated data type `ProGtolTextType`.

The function `ProGtolTopTextHorizJustificationSet()` sets the horizontal justification for the additional text applied to the specified geometric tolerance at the top.

The function `ProGtolTopTextHorizJustificationGet()` retrieves the horizontal justification for the additional text applied to the specified geometric tolerance at the top.

The function `ProGtolBottomTextHorizJustificationSet()` sets the horizontal justification for the additional text applied to the specified geometric tolerance at the bottom.

The function `ProGtolBottomTextHorizJustificationGet()` retrieves the horizontal justification for the additional text applied to the specified geometric tolerance at the bottom.

## Prefix and Suffix for Geometric Tolerances

You can easily add a prefix and suffix to a geometric tolerance in both drawing and model modes. They have the same text style as the geometric tolerance text.

A prefix will be placed before the tolerance value; a suffix will be placed after the material condition, if one exists.

Functions Introduced:

- **ProGtolPrefixGet()**
- **ProGtolPrefixSet()**
- **ProGtolSuffixGet()**

- **ProGtolSuffixSet()**

The function `ProGtolPrefixGet()` obtains the prefix text for the specified geometric tolerance.

The function `ProGtolPrefixSet()` assigns the prefix set for the specified geometric tolerance.

The function `ProGtolSuffixGet()` obtains the suffix text for the specified geometric tolerance.

The function `ProGtolSuffixSet()` assigns the suffix text for the specified geometric tolerance.

## Parameters for Geometric Tolerance Attributes

System parameters are automatically generated for the attributes of a geometric tolerance upon the creation of the geometric tolerance. These parameters are used for downstream processes such as Coordinate Measuring Machine (CMM) operations, and in driving other annotation and feature relationships.

---

### Note

Parameters are generated only for geometric tolerances created within annotation features because 2D or 3D geometric tolerances created outside annotation elements do not have a placeholder for parameters.

---

The following table lists the various system parameters and the gtol attributes for which the parameters are generated:

| Parameter                      | Gtol Attribute                                                                                                           |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| PTC_GTOL_PRIMAY_TOL            | Primary tolerance value                                                                                                  |
| PTC_GTOL_TYPE                  | Geometric tolerance type                                                                                                 |
| PTC_GTOL_MATERIAL_CONDITION    | Material condition for the primary tolerance value                                                                       |
| PTC_GTOL_COMPOSITE_TOL         | Composite tolerance value; available only if the gtol type is Surface or Position                                        |
| PTC_GTOL_PERUNIT_TOL           | Pre-unit tolerance value; available only if the gtol type is Straightness, Perpendicular, Surface, Parallel, or Flatness |
| PTC_GTOL_UNITLENGTH_TOL        | Unit length value; available only if the gtol type is Straightness, Perpendicular, Surface, or Parallel                  |
| PTC_GTOL_UNITAREA_TOL          | Unit area value; available only if the gtol type is Flatness                                                             |
| PTC_GTOL_PROJECTEDTOLZONE_TOL  | Projected tolerance zone value; available only if the gtol type is Angular, Perpendicular, Parallel, or Position         |
| PTC_GTOL_UNEQUALLYDISPOSED_TOL | Unequally disposed tolerance value; available only if the gtol type is Surface                                           |

---

You can access the parameters of gtol attributes by using the Creo TOOLKIT parameter functions `ProParameter*Get()` and `ProParameter*Set()`, and the UDF placement functions related to variable parameters `ProUdfvarparam*()` and `ProUdfdataVarparamAdd()`. Refer to the section [Core: Parameters on page 216](#) for more information on parameters.

## Annotations: Designated Area Feature

### Introduction to Designated Area Feature

This section describes how to access designated area features through Creo TOOLKIT.

A Designated Area is a “cosmetic surface” that can be referenced by annotations (including driven dimensions), and propagates as you add geometry to the model. It is used to indicate an area that needs to be closely examined or treated differently.

The designated area is made up of sets of chains constructed by a selection of edges or curves. The curves might lie on a solid (by default), a quilt, or on a plane. If the chains lie on multiple object types, then you must decide on one object type to place the target area.

You can attach an annotation to the created surface or to its boundaries. You can also include the designated area as a reference in a data sharing feature, if its parent surface is included. Geometry of this feature can be accessed using standard Creo TOOLKIT functions such as `ProFeatureGeomitemVisit()` and `ProSolidQuiltVisit()`.

### Feature Element Tree for the Designated Area

The element tree for the Designated Area feature is documented in the header file `ProDesignatedArea.h`. The following figure demonstrates the feature element tree structure:

## Feature Element Tree for a Designated Area

| |--PRO_E_DSGNTAREA_CREATION_FLIP
| |
|-- PRO_E_DSGNTAREA_SETS
| |
| |--PRO_E_DSGNTAREA_SET
```

The following list details special information about the elements in this tree:

- **PRO\_E\_FEATURE\_TYPE**—Specifies the feature type, should always have the value **PRO\_FEAT\_DSGNT\_AREA**.
- **PRO\_E\_STD\_FEATURE\_NAME**—Specifies the name of the designated area feature.
- **PRO\_E\_DSGNTAREA\_CREATION**—Specifies the data used for creation of the designated area. It consists of the following elements:
  - **PRO\_E\_DSGNTAREA\_CREATION\_TYPE**—Specifies whether the designated area lies on a solid, a quilt, or on a plane, where the new surface will be constructed from a chain not related to existing surfaces. It can have one of the following values:
    - **PRO\_DSGNTA\_CR\_SOLID**—Specifies that the feature is created on a solid model.
    - **PRO\_DSGNTA\_CR\_QUILT**—Specifies that the feature is created on a selected quilt
    - **PRO\_DSGNTA\_CR\_AIR**—Specifies that the feature is created on a plane from a chain of curves not lying on any model surface
  - **PRO\_E\_DSGNTAREA\_LIE\_ON**—Specifies the placement reference of the feature. If the type is **PRO\_DSGNTA\_CR\_QUILT**, the feature must include the placement quilt. If the type is **PRO\_DSGNTA\_CR\_SOLID**, it can optionally include a single surface of the solid, which will be the only surface of the solid used in constructing the feature. If you do not specify a

- single surface, all solid surfaces will be included in the designated area feature references.
- PRO\_E\_DSGNTAREA\_CREATION\_FLIP—Specifies the flip option to switch between inside and outside the boundary chains, and can be set to either TRUE or FALSE.
  - PRO\_E\_DSGNTAREA\_SETS—Specifies an array of compound elements of the type PRO\_E\_DSGNTAREA\_SET that contain the designated area boundaries.

## Element Details of PRO\_E\_DSGNTAREA\_SET

### PRO\_E\_DSGNTAREA\_SETS

```

|-- PRO_E_DSGNTAREA_SETS
|
|--PRO_E_DSGNTAREA_SET
|
|--PRO_E_DSGNTAREA_SET_REFS
|
|--PRO_E_STD_CHAIN HOLDER
|
|--PRO_E_STD_CURVE_COLLECTION_APPL

```

Each PRO\_E\_DSGNTAREA\_SET contains the following element:

PRO\_E\_DSGNTAREA\_SET\_REFS — Specifies the set of references to be used for creation of the designated area and consists of the following element:

- PRO\_E\_STD\_CHAIN HOLDER — Specifies the set of chains and can consists of one or more of the following element:
  - PRO\_E\_STD\_CURVE\_COLLECTION\_APPL — Specifies the collection of curves to be used as reference. Each curve set must consist of a closed loop. For more information about curve collections, refer to the section, User Interface: Curve and Surface Collection.

## Accessing Designated Area Properties

The following functions determine the appearance of the designated area by controlling its boundary properties such as the line style and the appearance of the surface.

Functions Introduced:

- **ProDesignatedareaStatusGet()**
- **ProDesignatedareaLinestyleGet()**

- **ProDesignatedareaLineStyleSet()**
- **ProDesignatedareaColorGet()**
- **ProDesignatedareaColorSet()**

The function `ProDesignatedareaStatusGet()` identifies the current status of the geometry of the created designated area. The input value to this function is a quilt from the designated area, or from a data sharing feature referencing the designated area.

The output geometry can have one of the following values:

- `PRO_DSGNTAREA_STATUS_ACTIVE`—Specifies that the geometry is active in the indicated model.
- `PRO_DSGNTAREA_STATUS_INACTIVE`—Specifies that the geometry is inactive due to geometry features occurring after the designated area feature in the regeneration order.
- `PRO_DSGNTAREA_STATUS_OUT_OF_COPIED_GEOM`—Specifies that the parent geometry used from the trimming was cut out from the model.

The function `ProDesignatedareaLineStyleGet()` returns the line style used for the boundary of the designated area. Use the function `ProDesignatedareaLineStyleSet()` to set the line style.

The function `ProDesignatedareaColorGet()` returns the color used for the boundary of the designated area. Use the function `ProDesignatedareaColorSet()` to set the color.

## Data Management: Windchill Operations

### Data Management: Windchill Operations

Creo Parametric has the capability to be directly connected to Windchill solutions, including Windchill ProjectLink, Pro/INTRALINK and PDMLink servers. This access allows users to manage and control the product data seamlessly from within Creo Parametric.

This section lists Creo TOOLKIT APIs that support Windchill servers and server operations in a connected Creo Parametric session.

### Introduction

The functions introduced in this section provide support for the basic Windchill server operations from within Creo Parametric. Refer to the compatibility matrix on PTC.com for information on the versions of Windchill compatible with Creo Parametric.

---

With these functions, operations such as registering a Windchill server, managing workspaces, and check in or check out of objects will be possible via Creo TOOLKIT.

The capabilities of the APIs described in this section are similar to the operations available from within the Creo Parametric client, with some restrictions. Some of the APIs specified in this section are supported in non-interactive mode, that is, batch mode application or asynchronous application.

### Note

When Creo Parametric applications are running in asynchronous non-graphical mode, they require login credentials before execution. If you want to override the requirement of specifying login credentials for Creo Parametric applications, set the environment variable `PROWT__AUTH__MODE` to `PROWT__AUTH__UNATTENDED`.

---

For more information about batch mode refer to the section [Using Creo Parametric TOOLKIT to Make a Batch Creo Parametric Session on page 58](#) and for asynchronous mode refer to the section [Core: Asynchronous Mode on page 277](#).

## Accessing a Windchill Server from a Creo Parametric Session

Creo Parametric allows you to register Windchill servers as a connection between the Windchill database and Creo Parametric. Although the represented Windchill database can be from ProjectLink, Pro/INTRALINK or PDMLink, all types of databases are represented in the same way.

You can use the following identifiers when referring to Windchill servers in Creo TOOLKIT:

- **Codebase URL**—This is the root portion of the URL that is used to connect to a Windchill server. For example, `http://wcserver.company.com/Windchill`.
- **Server Alias**—A server alias is used to refer to the server after it has been registered. The alias is also used to construct paths to files in the server workspaces and commonspaces. The server alias is chosen by the user or application and it need not have any direct relationship to the codebase URL. An alias can be any normal name, such as `my_alias`.

---

## Accessing Information Before Registering a Server

To start working with a Windchill server, you must establish a connection by registering the server in Creo Parametric. The functions described in this section enable you to connect to a Windchill server and access information related to the server.

Functions Introduced:

- **ProBrowserAuthenticate()**
- **ProServerClassGet()**
- **ProServerVersionGet()**
- **ProServerContextsCollect()**
- **ProServerWorkspacesCollect()**

Use the function `ProBrowserAuthenticate()` to set the authentication context using a valid username and password. A successful call to this function allows the Creo Parametric session to register with any server accepting the username and password combination. A successful call to this function also ensures that an authentication dialog box does not appear during the registration process. You can call this function any number of times to set the authentication context for any number of Windchill servers, provided that you register the appropriate servers or servers immediately after setting the context.

The function `ProServerClassGet()` returns the class of the server. The values are:

- `Windchill`—Denotes a `WindchillPDMLink` server.
- `ProjectLink`—Denotes `WindchillProjectLink` type of servers.

This function accepts the server codebase URL as the input.

The function `ProServerVersionGet()` returns the version of Windchill that is configured on the server, for example, 9.0 or 10.0. This function accepts the server codebase URL as the input.

### Note

`ProServerVersionGet()` works only for Windchill servers and returns the `PRO_TK_UNSUPPORTED` error, if the server is not a Windchill server.

---

The function `ProServerContextsCollect()` gives a list of all the available contexts for a specified server. A context is used to associate a workspace with a product, project, or library. This function accepts the server codebase URL as the input.

---

The function `ProServerWorkspacesCollect()` returns the list of available workspaces for the specified server. The workspace data returned contains the name of the workspace and its context. This function accepts the server codebase URL as the input.

## Registering and Activating a Server

From Creo Parametric 2.0 onward, the Creo TOOLKIT APIs call the same underlying API as Creo Parametric to register and unregister servers. Hence, registering the servers using Creo TOOLKIT APIs is similar to registering the servers using the Creo Parametric user interface. Therefore, the servers registered by Creo TOOLKIT are available in the Creo Parametric Server Registry. The servers are also available in other locations in the Creo Parametric user interface such as, the **Folder Navigator** and the embedded browser.

Functions Introduced:

- **ProServerRegister()**
- **ProServerActivate()**
- **ProServerUnregister()**

The function `ProServerRegister()` registers the specified server with the codebase URL. You can automate the registration of servers in interactive mode. To preregister the servers use the standard `config.fld` setup. If you do not want the servers to be preregistered in batch mode, set the environment variable `PTC_WF_ROOT` to an empty directory before starting Creo Parametric.

A successful call to `ProBrowserAuthenticate()` with a valid username and password is essential for `ProServerRegister()` to register the server without launching the authentication dialog box. Registration of the server establishes the server alias.

The function `ProServerActivate()` sets the specified server as the active server in the Creo Parametric session.

The function `ProServerUnregister()` unregisters the specified server. This is similar to **Server Registry ► Delete** through the user interface.

## Accessing Information From a Registered Server

Functions Introduced:

- **ProServerActiveGet()**
- **ProServerContextGet()**
- **ProServerAliasGet()**
- **ProServersCollect()**
- **ProServerLocationGet()**

---

- **ProServerIsOnline()**

The function `ProServerActiveGet()` returns the primary server.

The function `ProServerContextGet()` returns the active context of the active server.

The function `ProServerAliasGet()` returns the alias of a server if you specify the codebase URL.

The function `ProServersCollect()` returns a list of the aliases of all the registered servers.

The function `ProServerLocationGet()` returns the codebase URL for the server if you specify the alias.

The function `ProServerIsOnline()` checks if the specified server is online or offline. It returns `PRO_B_TRUE` if the server is online.

## Accessing the Workspace

For every workspace, a new distinct storage location is maintained in the user's personal folder on the server (server-side workspace) and on the client (client-side workspace cache). Together, the server-side workspace and the client-side workspace cache make up the workspace.

### Workspace Data

Functions Introduced:

- **ProServerworkspacedataAlloc()**
- **ProServerworkspacedataNameGet()**
- **ProServerworkspacedataContextGet()**
- **ProServerworkspacedataFree()**
- **ProServerworkspacedataProarrayFree()**

The workspace data is an opaque handle that contains the name and context of the workspace. The function `ProServerWorkspacesCollect()` returns an array of workspace data. Workspace data is also required for the function `ProServerWorkspaceCreate()` to create a workspace with a given name and a specific context.

The function `ProServerworkspacedataAlloc()` creates a workspace data structure to describe a workspace. The workspace contains the name of the workspace and the context in which the workspace is stored.

The function `ProServerworkspacedataNameGet()` retrieves the name of the workspace from the workspace data.

The function `ProServerworkspacedataContextGet()` retrieves the context of the workspace from the workspace data.

---

Use the function `ProServerworkspacedataFree()` to free the workspace data structure from memory.

Use the function `ProServerworkspacedataProarrayFree()` to free the workspace data array from the memory.

## Creating and Modifying the Workspace

Functions Introduced

- **ProServerWorkspaceCreate()**
- **ProServerWorkspaceGet()**
- **ProServerWorkspaceSet()**
- **ProServerWorkspaceDelete()**

The function `ProServerWorkspaceCreate()` creates and activates a new workspace.

The function `ProServerWorkspaceGet()` retrieves the name of the active workspace.

The function `ProServerWorkspaceSet()` sets a specified workspace as an active workspace.

The function `ProServerWorkspaceDelete()` deletes the specified workspace. The function deletes the workspace only if the following conditions are met:

- The workspace is not the active workspace.
- The workspace does not contain any checked out objects.

Use one of the following techniques to delete an active workspace:

- Make the required workspace inactive using `ProServerWorkspaceSet()` with the name of some other workspace and then call `ProServerWorkspaceDelete()`.
- Unregister the server using `ProServerUnregister()` and delete the workspace using the codebase URL instead of the alias.

## Workflow\_to\_Register\_a\_Server

### To Register a Server with an Existing Workspace

Perform the following steps to register a Windchill server with an existing workspace:

1. Set the appropriate authentication context using the function `ProBrowserAuthenticate()` with a valid username and password.

- 
2. Look up the list of workspaces using the function `ProServerWorkspacesCollect()`. If you already know the name of the workspace on the server, then ignore this step.
  3. Register the workspace using the function `ProServerRegister()` with an existing workspace name on the server.
  4. Activate the server using the function `ProServerActivate()`.

## To Register a Server with a New Workspace

Perform the following steps to register a Windchill server with a new workspace:

1. Perform steps 1 to 4 in the preceding section to register the Windchill server with an existing workspace.
2. Use the function `ProServerContextsCollect()` to choose the required context for the server.
3. Create a new workspace with the required context using the function `ProServerWorkspaceCreate()`. This function automatically makes the created workspace active.

### Note

You can create a workspace only after the server is registered.

---

## Aliased URL

An aliased URL serves as a handle to the server objects. You can access the server objects in the commonspace (shared folders) and the workspace using the aliased URL. An aliased URL is a unique identifier for the server object and the format is as follows:

- Object in workspace has a prefix `wtws`

```
wtws://<server_alias>/<workspace_name>/<object_
server_name>
```

where `<object_server_name>` includes `<object_`  
`name>.<object_extension>`

For example, `wtws://my_server/my_workspace/abcd.prt`,  
`wtws://my_server/my_workspace/intf_file.igs`

where

`<server_alias>` is `my_server`

---

<workspace\_name> is my\_workspace

- Object in commonspace has a prefix wtpub

wtpub://<server\_alias>/<folder\_location>/<object\_server\_name>

For example, wtpub://my\_server/path/to/cs\_folder/abcd.prt

where

<server\_alias> = my\_server

<folder\_location> = path/to/cs\_folder

---

 **Note**

- <object\_server\_name> must be in lowercase.
  - The APIs are case-sensitive to the aliased URL.
  - <object\_extension> should not contain Creo Parametric versions, for example, .1 or .2, and so on.
- 

## Server Operations

After registering the Windchill server with Creo Parametric, you can start accessing the data on the Windchill servers. The Creo Parametric interaction with Windchill servers leverages the following locations:

- Commonsplace (Shared folders)
- Workspace (Server-side workspace)
- Workspace local cache (Client-side workspace)
- Creo Parametric session
- Local disk

The functions described in this section enable you to perform the basic server operations. The following diagram illustrates how data is transferred among these locations.

## Save

Functions Introduced:

- **ProMdlSave()**

The function `ProMdlSave()` stores the object from the session in the local workspace cache, when a server is active.

## Upload

An upload transfers Creo Parametric files and any other dependencies from the local workspace cache to the server-side workspace.

Function Introduced:

- **ProServerObjectsUpload()**

---

The function `ProServerObjectsUpload()` uploads the specified object to the workspace. The object to be uploaded must be present in the current Creo Parametric session. Additionally, ensure that you save the object using the function `ProMdlSave()` before you upload it.

---

 **Note**

To upload all the objects to the workspace without retrieving them in the current Creo Parametric session, use the function `ProServerObjectsCheckin()` with the checkin option *upload\_only* set to `PRO_B_TRUE`.

---

## Checkin

After you have finished working on objects in your workspace, you can share the design changes with other users. The checkin operation copies the information and files associated with all changed objects from the workspace to the Windchill database.

### Functions Introduced

- **`ProServerObjectsCheckin()`**
- **`ProServercheckinoptsAlloc()`**
- **`ProServercheckinoptsDeflocationSet()`**
- **`ProServercheckinoptsLocationAdd()`**
- **`ProServercheckinoptsBaselineSet()`**
- **`ProServercheckinoptsKeepcheckedoutSet()`**
- **`ProServercheckinoptsCommentSet()`**
- **`ProServercheckinoptsAutoresolveSet()`**
- **`ProServercheckinoptsUploadonlySet()`**
- **`ProServercheckinoptsFree()`**

The function `ProServerObjectsCheckin()` checks in or uploads an object to the database. The object to be checked in or uploaded must be present in the current Creo Parametric session. Changes made to the object are not included unless you save the object to the workspace using the function `ProMdlSave()` before it is checked in or uploaded.

---

 **Note**

`ProServerObjectsCheckin()` checks in the target object by default. To only upload the object, set the checkin option *upload\_only* to `PRO_B_TRUE`.

---

If you pass `NULL` as the value of the input argument *options*, the checkin operation is similar to the **Auto Check In** option in Creo Parametric. For more details on **Auto Check In**, refer to the online help for Creo Parametric.

By using an appropriately constructed *options* argument, you can control the checkin or upload operation. The APIs described in this section help in constructing the *options* argument.

The function `ProServercheckinoptsAlloc()` allocates a set of checkin or upload options for the object. These options are as follows:

- **Default location**—Specifies the default *folder\_location* on the server for the automatic checkin operation. Use the function `ProServercheckinoptsDeflocationSet()` to set this location.
- **Server location**—Specifies the *folder\_location* on the server in which an object will be checked in or uploaded. Use the function `ProServercheckinoptsLocationAdd()` to set this location.
- **Baseline**—Specifies the baseline information for the objects upon checkin. This information does not apply to upload operations. Use the function `ProServercheckinoptsBaselineSet()` to create a new baseline. The baseline information for a checkin operation is as follows:

- *baseline\_name*—Specifies the name of the baseline.
- *baseline\_number*—Specifies the number of the baseline.

The default format for the baseline name and baseline number is `Username + time (GMT) in milliseconds`.

- *baseline\_location*—Specifies the location of the baseline.
- *baseline\_lifecycle*—Specifies the name of the lifecycle.
- **keep\_checked\_out**—If this option is set to `PRO_B_TRUE`, then the contents of the selected object are checked in to the Windchill server and automatically checked out again for further modification. The default value is `PRO_B_FALSE`. This option does not apply to upload operations. Use the function `ProServercheckinoptsKeepcheckedoutSet()` to set the *keep\_checked\_out* flag.
- **autoresolve**—Specifies the option used to automatically resolve objects that have not been completely checked in or uploaded to the database. The

---

autoresolve options specified by the enumerated type `ProServerAutoresolveOption` are as follows:

- `PRO_SERVER_DONT_AUTORESOLVE`—Model references missing from the workspace are not automatically resolved. This may result in a conflict upon checkin. This option is used by default.
- `PRO_SERVER_AUTORESOLVE_IGNORE`—Missing references are automatically resolved by ignoring them.
- `SERVER_AUTORESOLVE_UPDATE_IGNORE`—Missing references are automatically resolved by updating them in the database and ignoring them if not found.

Use the function `ProServercheckinoptsCommentSet()` to set the history comment for checkin operations. These checkin comments are visible in the Windchill **History** tab.

Use the function `ProServercheckinoptsAutoresolveSet()` to assign the appropriate *autoresolve* option.

- *upload\_only*—Specifies the option to fully check in the target object or only upload the object to the server. Set this option to `PRO_B_TRUE` to only upload and not check in the target objects and to `PRO_B_FALSE` to upload and check in the objects. By default, this option is `PRO_B_FALSE`, if not explicitly set, to cause a checkin. Use the function `ProServercheckinoptsUploadonlySet()` to set the *upload\_only* flag.

Use the function `ProServercheckinoptsFree()` to free the memory of the checkin options.

## Notification Functions

A Creo TOOLKIT notification is called before you attempt to check in a model through the Creo Parametric user interface. The notification functions are established in a session using the function `ProNotificationSet()`.

Function Introduced:

- **ProCheckinUIPreAction()**

The notification function `ProCheckinUIPreAction()` is called when you select **File>Auto Check In**, **File>Custom Check In**, or the corresponding options on the **Model Tree** menu in the Creo Parametric user interface. It is called before any action is performed by the corresponding menu commands. This function is available by calling `ProNotificationSet()` with the value of the notify type as `PRO_CHECKIN_UI_PRE`.

---

## Retrieval

Standard Creo TOOLKIT provides several functions that are capable of retrieving models. When using these functions with Windchill servers, remember that these functions do not check out the object to allow modifications.

Functions Introduced:

- **ProMdlnameRetrieve()**
- **ProMdlFiletypeLoad()**

The function `ProMdlnameRetrieve()` loads an object into a session given its name and type. This function searches for the object in the active workspace, the local directory, and any other paths specified by the configuration option `search_path`.

The function `ProMdlFiletypeLoad()` loads an object into session given its path. The path can be a disk path, a workspace path, or a commonspace path. Refer to the section [Aliased URL on page 657](#) for examples of these types of paths.

## Checkout and Download

To modify an object from the commonspace, you must check out the object. The process of checking out communicates your intention to modify a design to the Windchill server. The object in the database is locked, so that other users can obtain read-only copies of the object, and are prevented from modifying the object while you have it checked out.

Checkout is often accompanied by a download action, where the objects are brought from the server-side workspace to the local workspace cache. In Creo TOOLKIT, both operations are covered by the same set of functions.

Functions Introduced:

- **ProServerObjectsCheckout()**
- **ProServerMultiobjectsCheckout()**
- **ProServercheckoutoptsAlloc()**
- **ProServercheckoutoptsFree()**
- **ProServercheckoutoptsDependencySet()**
- **ProServercheckoutoptsIncludeinstancesSet()**
- **ProServercheckoutoptsVersionSet()**
- **ProServercheckoutoptsDownloadSet()**
- **ProServercheckoutoptsReadonlySet()**

---

The function `ProServerObjectsCheckout()` checks out and optionally downloads the object to the workspace based on the configuration specifications of the workspace. It takes the following two potential identifiers for the model to checkout:

- `ProMdl handle`—Specifies the object to be checked out. This is applicable if the model has already been retrieved without checking out.
- `Aliased URL`—Specifies the commonspace path of the object.

Use the function `ProServerMultiobjectsCheckout()` to check out and download a `ProArray` of objects to the workspace based on the configuration specifications of the workspace.

#### Note

Creo TOOLKIT functions do not support the `AS_STORED` configuration.

---

If you specify the value of the input argument *checkout* as `PRO_B_TRUE` in the above functions, the selected object is checked out. Otherwise, the object is downloaded without being checked out. The download action enables you to bring read-only copies of objects into your workspace. This allows you to examine the object without placing a lock on it.

If you pass `NULL` as the value of the input argument *options* in the above functions, then the default Creo Parametric checkout rules apply.

The function `ProServercheckoutoptsAlloc()` allocates a set of checkout options for the object. These options are as follows:

- *dependency*—Specifies the dependency rule used while checking out dependents of the object selected for checkout. The function `ProServercheckoutoptsDependencySet()` sets the dependency rule for checkout. The types of dependencies specified by the enumerated type `ProServerDependency` are as follows:
  - `PRO_SERVER_DEPENDENCY_ALL`—All the objects that are dependent on the selected object are downloaded, that is, they are added to the workspace.
  - `PRO_SERVER_DEPENDENCY_REQUIRED`—All the objects that are required to successfully retrieve the selected object in the CAD application are downloaded, that is, they are added to workspace.
  - `PRO_SERVER_DEPENDENCY_NONE`—None of the dependent objects from the selected object are downloaded, that is, they are not added to workspace.

- *include\_option*—Specifies the rule for including instances from the family table during checkout. The function `ProServercheckoutoptsIncludeinstancesSet()` sets the flag to include instances during checkout. The type of instances specified by the enumerated type `ProServerInclude` are as follows:
  - `PRO_SERVER_INCLUDE_ALL`—All the instances of the selected object are checked out.
  - `PRO_SERVER_INCLUDE_SELECTED`—The application selects the instance members from the family table to be included during checkout.
  - `PRO_SERVER_INCLUDE_NONE`—No additional instances from the family table are added to the object list.
- *version*—Specifies the version of the object that is checked out or downloaded to the workspace. If *version* is not set, the object is checked out according to the current workspace configuration. The function `ProServercheckoutoptsVersionSet()` sets the version of the object.
- *download*—Specifies the checkout type as `download` or `link`. The value `download` specifies that the object content is downloaded and checked out, while `link` specifies that only the metadata is downloaded and checked out. Use the function `ProServercheckoutoptsDownloadSet()` to set this option.
- *readonly*—Downloads the file without checking out the file. To use this option you must set the *checkout* argument of the function `ProServerObjectsCheckout()` as `PRO_B_FALSE`. Use the function `ProServercheckoutoptsReadonlySet()` to set the *readonly* flag to `PRO_B_TRUE`.

Use the function `ProServercheckoutoptsFree()` to free the memory of the checkout options.

The following truth table explains the dependencies of the different control factors in `ProServerObjectsCheckout()` and the effect of different combinations on the end result.

| Argument <i>checkout</i> in <code>ProServerObjectsCheckout()</code> | <code>ProServercheckoutoptsDownloadSet()</code> | <code>ProServercheckoutoptsReadonlySet()</code> | Result                                               |
|---------------------------------------------------------------------|-------------------------------------------------|-------------------------------------------------|------------------------------------------------------|
| <code>PRO_B_TRUE</code>                                             | <code>PRO_B_TRUE</code>                         | NA                                              | Object is checked out and its content is downloaded. |
| <code>PRO_B_TRUE</code>                                             | <code>PRO_B_FALSE</code>                        | NA                                              | Object is checked out but content is not downloaded. |

| Argument <i>checkout</i> in ProServerObjectsCheckout() | ProServercheck-<br>outoptsDown-<br>loadSet() | ProServercheck-<br>outoptsReadonly-<br>Set() | Result                                                  |
|--------------------------------------------------------|----------------------------------------------|----------------------------------------------|---------------------------------------------------------|
| PRO_B_FALSE                                            | NA                                           | PRO_B_TRUE                                   | Object is downloaded without checkout and as read-only. |
| PRO_B_FALSE                                            | NA                                           | PRO_B_FALSE                                  | This combination is invalid and is not supported.       |

The function ProServercheckoutoptsReadonlySet () can be used to download objects without checking them out. To download objects, you must set the *checkout* argument of the function ProServerObjectsCheckout () as PRO\_B\_FALSE before using ProServercheckoutoptsReadonlySet () .

The following table describes the different values that can be specified for the check out options for the functions ProServercheckoutoptsReadonlySet () and ProServerObjectsCheckout () . It also describes the actions that can be performed on the downloaded or checked out object from the Creo Parametric user interface or using the Creo TOOLKIT applications.

The following table explains the dependencies of the different control factors on ProServercheckoutoptsReadonlySet () :

| Argument <i>readonly</i> in ProServercheckoutoptsReadonlySet() | Argument <i>checkout</i> in ProServerObjectsCheckout() | State of Object Content        | Options Available in the Creo Parametric User Interface                                                                                                                                                                                                                                | Actions that can be Performed Using Creo TOOLKIT Applications |
|----------------------------------------------------------------|--------------------------------------------------------|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------|
| PRO_B_TRUE                                                     | PRO_B_FALSE                                            | Downloaded but not checked out | The <b>Conflicts</b> dialog box allows you to perform one of the following operations on the object: check out, revise and check out, continue with modifications, or make the object read only.<br><br>Refer to the Creo Parametric Help for more information on resolving conflicts. | Check out the object and modify it                            |
| PRO_B_FALSE                                                    | PRO_B_FALSE                                            | Checked out                    | The object can be modified.                                                                                                                                                                                                                                                            | The object can be modified.                                   |

| Argument<br><i>readonly</i> in<br>ProServer-<br>checkoutopts-<br>ReadOnlySet() | Argument<br><i>checkout</i> in<br>ProServerOb-<br>jectsCheck-<br>out() | State of Object<br>Content     | Options<br>Available in<br>the Creo<br>Parametric<br>User Interface                                                                                                                              | Actions that can be<br>Performed Using Creo<br>TOOLKIT Applications |
|--------------------------------------------------------------------------------|------------------------------------------------------------------------|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|
| PRO_B_TRUE                                                                     | PRO_B_TRUE                                                             | Checked out                    | The object can be modified.                                                                                                                                                                      | The object can be modified.                                         |
| No option set                                                                  | PRO_B_FALSE                                                            | Downloaded but not checked out | The <b>Conflicts</b> dialog box allows you to perform one of the following operations on the object: check out, revise and check out, continue with modifications, or make the object read only. | Check out the object and modify it                                  |

## Undo Checkout

Function Introduced:

- **ProServerObjectsUndocheckout()**

Use the function `ProServerObjectsUndocheckout()` to undo a checkout of the specified object. When you undo a checkout, the changes that you have made to the content and metadata of the object are discarded and the content, as stored in the server, is downloaded to the workspace. This function is applicable only for the model in the active Creo Parametric session.

## Import and Export

Creo TOOLKIT provides you with the capability of transferring specified objects to and from a workspace. Import and export operations must take place in a session with no models.

Functions Introduced:

- **ProCurrentWorkspaceImport()**
- **ProCurrentWorkspaceExport()**
- **ProCurrentWorkspaceImpexMessagesGet()**
- **ProWsimpexmessageDataGet()**
- **ProWsimpexmessageArrayFree()**
- **ProWsexportSecondarycontentoptionSet()**

The function `ProCurrentWorkspaceImport()` imports specified objects from disk to the current workspace in a linked session of Creo Parametric.

---

The function `ProCurrentWorkspaceExport()` exports the specified objects from the current workspace to a location on disk in a linked session of Creo Parametric.

Both `ProCurrentWorkspaceImport()` and `ProCurrentWorkspaceExport()` allow you to specify a dependency criterion to process the following items:

- All external dependencies
- Only required dependencies
- No external dependencies

All warnings, conflicts, or errors generated during import or export operations are logged in the `proimpex.errors` file created in the Creo Parametric working directory. Alternatively, you can obtain this information using the function `ProCurrentWorkspaceImpexMessagesGet()`. This function returns a `ProArray` of messages generated by the last call to `ProCurrentWorkspaceImport()` or `ProCurrentWorkspaceExport()`.

The function `ProWsimpexmessageDataGet()` extracts the contents of the message generated by `ProCurrentWorkspaceImport()` or `ProCurrentWorkspaceExport()`. The message contains the following items:

- *type*—Specifies the severity of the message in the form of the enumerated type `ProWsimpexMessageType`. The severity is one of the following types:
  - `PRO_WSIMPEX_MSG_INFO`—Specifies an informational type of message.
  - `PRO_WSIMPEX_MSG_WARNING`—Specifies a low severity problem that can be resolved according to the configured rules.
  - `PRO_WSIMPEX_MSG_CONFLICT`—Specifies a conflict that can be overridden.
  - `PRO_WSIMPEX_MSG_ERROR`—Specifies a conflict that cannot be overridden or a serious problem that prevents processing of an object.
- *object*—Specifies the object name or the name of the object path described in the message.
- *description*—Specifies the description of the problem or the message information.
- *resolution*—Specifies the resolution applied to resolve a conflict that can be overridden. This is applicable when the message is of the type `PRO_WSIMPEX_MSG_CONFLICT`.

- 
- *succeeded*—Determines whether the resolution succeeded or not. This is applicable when the message is of the type `PRO_WSIMPEX_MSG_CONFLICT`.

Use the function `ProWsimpexmessageArrayFree()` to free the memory allocated to the array of messages returned by `ProCurrentWorkspaceImpexMessagesGet()`.

The function `ProWsexportSecondarycontentoptionSet()` sets the `ProBoolean` option that controls the export of secondary contents. If this option is set to `PRO_B_TRUE`, secondary contents are exported along with the primary Creo Parametric model files. By default, it is `PRO_B_TRUE`.

## File Copy

Creo TOOLKIT provides you with the capability of copying a file from the workspace or target folder to a location on the disk and vice-versa.

Functions Introduced:

- **ProFileCopyToWS()**
- **ProFileCopyFromWS()**
- **ProFileCopyFromWSDocument()**
- **ProFileselectionDocNameGet()**
- **ProDocumentFileContentsRead()**

Use the function `ProFileCopyToWS()` to copy a file from disk to the workspace. The file can optionally be added as secondary content to a given workspace file. If the viewable file is added as secondary content, a dependency is created between the Creo Parametric model and the viewable file.

Use the function `ProFileCopyFromWS()` to copy a file from the workspace to a location on disk.

---

## Note

When importing or exporting Creo Parametric models, PTC recommends that you use `ProCurrentWorkspaceImport()` and `ProCurrentWorkspaceExport()`, respectively, to perform the operation. Functions that copy individual files do not traverse Creo Parametric model dependencies, and therefore do not copy a fully retrievable set of models at the same time.

Additionally, only the functions `ProCurrentWorkspaceImport()` and `ProCurrentWorkspaceExport()` provide full metadata exchange and support. That means `ProCurrentWorkspaceImport()` can communicate all the Creo Parametric designated parameters, dependencies, and family table information to a PDM system while `ProCurrentWorkspaceExport()` can update exported Creo Parametric data with PDM system changes to designated and system parameters, dependencies, and family table information. Hence PTC recommends the use of `ProFileCopyToWS()` and `ProFileCopyFromWS()` to process only non-Creo Parametric files.

---

The function `ProFileCopyFromWSDocument()` copies a primary or secondary file from the workspace to the specified location on disk. The input arguments are:

- *source\_file*—Specifies the path to the primary or secondary file. The path must be specified as `wtws://<path to the file>`.  
  
Use the functions such as, `ProFileMdlnameOpen()` and `ProFileMdlfiletypeOpen()`, to get the path to the files.
- *document\_name*—Specifies the name of the primary file, which is associated with the secondary file specified in the argument *source\_file*. Use the function `ProFileselectionDocNameGet()` to get the name of the primary file for a secondary file.  
  
In the argument *source\_file*, if a primary file is specified, then pass the argument *document\_name* as `NULL`.
- *target\_directory*—Specifies a path on the local disk where the file must be copied.

The function `ProFileselectionDocNameGet()` returns the name of the primary file for the selected secondary file. The secondary files are selected in the file open functions. The functions such as, `ProFileMdlnameOpen()`, `ProFileMdlfiletypeOpen()` and so on, are used to open the dialog box where you can browse and select a secondary file. The function `ProFileselectionDocNameGet()` returns the name of the primary file for

---

the last selected secondary file in the file open functions. If you select a primary file in these file open functions, then the function `ProFileselectionDocNameGet()` returns the error `PRO_TK_E_NOT_FOUND`.

The function `ProDocumentFileContentsRead()` reads the contents of the specified file. The file can be located on the local disk or Windchill. The function returns a `ProArray` of characters. Declare the output variable as `char*` and typecast it as `ProArray*` when you pass it to the API. Use the function `ProArrayFree()` to free the `ProArray`.

---

 **Note**

The function `ProDocumentFileContentsRead()` is not supported for CAD models.

---

## Server Object Status

Function Introduced:

- **`ProServerObjectIsModified()`**

The function `ProServerObjectIsModified()` verifies the current status of the object in the workspace as well as in the local workspace cache. The status of the object is as follows:

- *checkout\_status*—Specifies whether the object is checked out for modification. The value `PRO_B_TRUE` indicates that the specified object is checked out to the active workspace.

The value `PRO_B_FALSE` indicates one of the following statuses:

- The specified object is not checked out
  - The specified object is only uploaded to the workspace, but was never checked in
  - The specified object is only saved to the local workspace cache, but was never uploaded
- *modifiedInWS*—Specifies whether the object has been modified in the workspace since checkout. The value of this argument is `PRO_B_FALSE` if the newly created object has not been uploaded.
  - *modifiedLocally*—Specifies whether the object has been modified in the local workspace cache. The value of this argument is `PRO_B_TRUE` if the object has been saved in the local workspace cache. The argument returns `PRO_B_FALSE` if the object has not been saved after modifying it in the local workspace cache.

## Note

The function `ProServerObjectStatusGet ()` is deprecated. Use the function `ProServerObjectIsModified ()` instead.

## Delete Objects

Function Introduced:

- **ProServerObjectsRemove()**

The function `ProServerObjectsRemove ()` deletes the array of objects from the workspace. When passed with the *mode\_names* array as NULL, this function removes all the objects in the active workspace.

## Conflicts During Server Operations

Functions Introduced:

- **ProServerconflictsDescriptionGet()**
- **ProServerconflictsFree()**

Conflict objects are provided to capture the error condition while performing the following server operations using the specified APIs:

| Operation                      | API                                                                                   | Error Object                                |
|--------------------------------|---------------------------------------------------------------------------------------|---------------------------------------------|
| Checkin an object or workspace | <code>ProServerObjectsCheckin ()</code>                                               | <code>ProServerCheckinConflicts</code>      |
| Checkout an object             | <code>ProServerObjectsCheckout ()</code>                                              | <code>ProServerCheckoutConflicts</code>     |
| Undo checkout of an object     | <code>ProServerObjectsUndocheckout ()</code>                                          | <code>ProServerUndoCheckoutConflicts</code> |
| Upload object                  | <code>ProServerObjectsUpload ()</code>                                                | <code>ProServerUploadConflicts</code>       |
| Download object                | <code>ProServerObjectsCheckout ()</code> (with download as <code>PRO_TB_TRUE</code> ) | <code>ProServerCheckoutConflicts</code>     |
| Delete workspace               | <code>ProServerWorkspaceDelete ()</code>                                              | <code>ProServerDeleteConflicts</code>       |
| Remove object                  | <code>ProServerObjectsRemove ()</code>                                                | <code>ProServerRemoveConflicts</code>       |

These APIs return a common status `PRO_TB_CHECKOUT_CONFLICT` and a conflict object `ProServerConflicts`. The conflict object is used to get more details about the error condition.

---

Use the function `ProServerConflictsDescriptionGet()` to extract details of the error condition. This description is similar to the description displayed by the Creo Parametric HTML User Interface in the conflict report.

The function `ProServerconflictsFree()` frees the memory of the conflict structure returned by the functions.

## Utility APIs

The functions specified in this section enable you to obtain the handle to the server objects to access them. The handle may be the Aliased URL or the model name of the http URL. These utilities enable the conversion of one type of handle to the other type.

Functions Introduced:

- **`ProServerModelNameToAliasedURL()`**
- **`ProServerAliasedURLToModelName()`**
- **`ProServerAliasedURLToURL()`**

The function `ProServerModelNameToAliasedURL()` enables you to search for a server object by its name. Specify the complete file name of the object as the input, for example, `test_part.prt`. The function returns the aliased URL for a model on the server. For more information regarding the aliased URL, refer to the section [Aliased URL on page 657](#). During the search operation, the workspace takes precedence over the shared space.

You can also use this function to search for files that are not in the Creo Parametric format. For example, `my_text.txt`, `prodev.dat`, `intf_file.stp`, and so on.

The function `ProServerAliasedURLToModelName()` returns the name of the object from the given aliased URL on the server.

The function `ProServerAliaseURLToURL()` converts an aliased URL to a standard URL to the objects on the server.

For example, `wtps://my_alias/Wildfire/abcd.prt` is converted to an appropriate URL on the server as `<server.mycompany.com>/Windchill`.

## Sample Batch Workflow

A typical workflow using the Windchill APIs for an asynchronous non-graphical application is as follows:

1. Start a Creo Parametric session using the function `ProEngineerConnectionStart()`.
2. Authenticate the browser using the function `ProBrowserAuthenticate()`.

3. Register the server with the new workspace using the function `ProServerRegister()`.
4. Activate the server using the function `ProServerActivate()`.
5. Check out and retrieve the model from the vault URL using the function `ProServerObjectsCheckout()` followed by `ProMdlnameRetrieve()`.
6. Modify the model according to the application logic.
7. Save the model to the workspace using the function `ProMdlSave()`.
8. Check in the modified model back to the server using the function `ProServerObjectsCheckin()`.
9. After processing all models, unregister from the server using the function `ProServerUnregister()`.
10. Delete the workspace using `ProServerWorkspaceDelete()`.
11. Stop Creo Parametric using the function `ProEngineerEnd()`.

## Interface: Data Exchange

### Exporting Information Files

This section describes various methods of importing and exporting files in Creo TOOLKIT.

Functions Introduced:

- **ProOutputFileMdlnameWrite()**

The function `ProOutputFileMdlnameWrite()` is used to create files of several types from data in Creo Parametric. This function operates only on the current object. The file types are declared in `ProUtil.h`. The export formats and their type constants are as listed in the following table.

| Export Format                               | Creo TOOLKIT function                    | Type Constant                                           |
|---------------------------------------------|------------------------------------------|---------------------------------------------------------|
| Bills of material                           | <code>ProOutputFileMdlnameWrite()</code> | <code>PRO_BOM_FILE</code>                               |
| Drawing setup file                          |                                          | <code>PRO_DWG_SETUP_FILE</code>                         |
| Feature identifier                          |                                          | <code>PRO_FEAT_INFO</code> , <code>PRO_FEAT_INFO</code> |
| Material file (currently assigned material) |                                          | <code>PRO_MATERIAL_FILE</code>                          |
| CL Data output, NC Sequence file            |                                          | <code>PRO_MFG_FEAT_CL</code>                            |
| CL Data operation file                      |                                          | <code>PRO_MFG_OPER_CL</code>                            |
| Information on Creo Parametric Objects      |                                          | <code>PRO_MODEL_INFO</code>                             |
| Program file                                |                                          | <code>PRO_PROGRAM_FILE</code>                           |

| Export Format             | Creo TOOLKIT function | Type Constant             |
|---------------------------|-----------------------|---------------------------|
| Cable Parameters file     |                       | PRO_CABLE_PARAMS_FILE     |
| Connector Parameters file |                       | PRO_CONNECTOR_PARAMS_FILE |
| Spool file                |                       | PRO_SPOOL_FILE            |
| Difference Report file    |                       | PRO_DIFF_REPORT_FILE      |
| IGES file                 |                       | PRO_IGES_FILE             |
| DXF file                  |                       | PRO_DXF_FILE              |
| DWG file                  |                       | PRO_DWG_FILE              |
| Render file               |                       | PRO_RENDER_FILE           |
| SLA ASCII file            |                       | PRO_SLA_ASCII_FILE        |
| SLA Binary file           |                       | PRO_SLA_BINARY_FILE       |
| INVENTOR file             |                       | PRO_INVENTOR_FILE         |
| CATIA facets file         |                       | PRO_CATIAFACETS_FILE      |
| IGES 3D file              |                       | PRO_IGES_3D_FILE          |
| STEP file                 |                       | PRO_STEP_FILE             |
| VDA file                  |                       | PRO_VDA_FILE              |
| FIAT file                 |                       | PRO_FIAT_FILE             |
| CATIA DIRECT file         |                       | PRO_CATIA_DIRECT_FILE     |
| ACIS file                 |                       | PRO_ACIS_FILE             |
| CGM file                  |                       | PRO_CGM_FILE              |

The option `PRO_RELATION_FILE` creates a file that contains a list of all the model relations and parameters.

To access parameters on the connector entry ports, you must call the function `ProOutputFileMdlnameWrite()` with the option `PRO_CONNECTOR_PARAMS_FILE`. The function writes a text file to disk. This text file is in the same format as the file that you edit when using the Creo Parametric command **Connector ► Modify Parameters ► Mod Param**.

To generate and export a difference report to text or CSV format, call the function `ProOutputFileMdlnameWrite()` with the option `PRO_DIFF_REPORT_FILE`.

#### Note

As this report is generated and exported from the Creo Parametric embedded browser, using this output type will cause Creo Parametric to show the difference report in the browser.

For some of the options used with `ProOutputFileMdlnameWrite()`, you must provide some more information, using the last four arguments. The following list shows the arguments to be set and when:

- 
- For `PRO_RENDER_FILE`, `PRO_INVENTOR_FILE`, `PRO_CATIAFACETS_FILE`, `PRO_SLA_ASCII_FILE`, and `PRO_SLA_BINARY_FILE`, set the following argument:
    - *arg1*—The name of the coordinate system. If this is NULL, the function uses the default coordinate system.
  - For `PRO_SPOOL_FILE`, set *arg1* to the spool name.
  - For `PRO_FEAT_INFO`, `PRO_MFG_FEAT_CL`, and `PRO_MFG_OPER_CL`, set the following argument:
    - *arg2*—The integer identifier of the feature.
  - For `PRO_IGES_3D_FILE`, `PRO_STEP_FILE`, `PRO_VDA_FILE`, `PRO_FIAT_FILE`, `PRO_CATIA_DIRECT_FILE`, or `PRO_ACIS_FILE`, set the following argument:
    - *arg2*—The integer pointer to an odd or even number.
  - For `PRO_CGM_FILE`, set the following arguments:
    - *arg2*—Represents the integer pointer to the export type `PRO_EXPORT_CGM_CLEAR_TEXT` or `PRO_EXPORT_CGM_MIL_SPEC`.
    - *arg3*—Represents the integer pointer to the scalar type `PRO_EXPORT_CGM_ABSTRACT` or `PRO_EXPORT_CGM_METRIC`.
  - For `PRO_CONNECTOR_PARAMS`, set the following arguments:
    - *arg1*—Represents the integer pointer to `ProIdTable`. `ProIdTable` is an integer array of component identifiers.
    - *arg2*—Represents the integer pointer to the number of component identifiers.
  - For `PRO_CABLE_PARAMS_FILE`, set the following arguments:
    - *arg1*—Represents a `ProSolid` (part pointer).
    - *arg2*—Represents the cable name.
  - For `PRO_DIFF_REPORT_FILE`, set the following argument:
    - *arg4*—Represents the model to which the input model is compared to generate the difference report.
  - For `PRO_RELATION_FILE`, set the following argument:
    - *arg2*—Represents the individual feature relations. It is an integer pointer to the feature identifier that gets the relations contained in a feature. If this is NULL you get the relations contained in the model.

## Exporting 2D Models

Functions Introduced:

- **Pro2dExport()**
- **Pro2dExportdataAlloc()**
- **Pro2dExportdataFree()**
- **Pro2dExportdataSheetoptionSet()**
- **Pro2dExportdataSheetsSet()**
- **Pro2dExportdataModelspacesheetSet()**
- **ProProductviewexportoptsAlloc()**
- **ProProductviewexportoptsFree()**
- **ProProductviewexportoptsFormatSet()**
- **ProProductviewFormattedMdlnameExport()**
- **ProPrintPrinterOptionsGet()**
- **ProPrintMdlOptionsGet()**
- **ProPrintPlacementOptionsGet()**
- **ProPrintPCFOptionsGet()**
- **ProPrintExecute()**

| Export Format       | Creo TOOLKIT Functions           | Type Constant      |
|---------------------|----------------------------------|--------------------|
| STEP                | Pro2dExport ()                   | PRO_STEP_FILE      |
| IGES                |                                  | PRO_IGES_FILE      |
| MEDUSA              |                                  | PRO_MEDUSA_FILE    |
| DXF                 |                                  | PRO_DXF_FILE       |
| DWG                 |                                  | PRO_DWG_FILE       |
| CGM                 |                                  | PRO_CGM_FILE       |

| DXF                 | ProOutputFileMdlnameWrite ()     | PRO_DXF_FILE       |
| DWG                 |                                  | PRO_DWG_FILE       |
| CGM file            |                                  | PRO_CGM_FILE       |
| PVS file, Plot file |                                  | PRO_PV_FORMAT_PVS  |
| ED file, Plot file  | ProProductviewFormattedExport () | PRO_PV_FORMAT_ED   |
| EDZ file            |                                  | PRO_PV_FORMAT_EDZ  |
| PVZ file            |                                  | PRO_PV_FORMAT_PVZ  |
| Plot file           | ProPrintExecute ()               | N/A                |

The function `Pro2dExport ()` exports existing two-dimensional models into a single object file. The exported model can be a single drawing, notebook or diagram, or multiple sheets of a drawing. It supports the STEP, SET, IGES, Medusa, DXF, CGM, TIFF, Stheno, and DWG formats. The interface file obtained

---

using the function `Pro2dExport()` is controlled by one of its input argument *data*, an instance of the `Pro2dExportdata` object. Note that the *data* argument is optional; you do not have to specify it when exporting only the current sheet of the 2D model. Additionally, several Creo Parametric configuration options related to entity type export options can affect the results of the export operation. Refer to the Creo Parametric Online Help for details on the configuration options.

## Example 1 Publishing a Drawing

The sample code in `UgDwgPublishContext.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_dwg` shows how to publish a drawing in the given context.

The functions `Pro2dExportdataAlloc()` and `Pro2dExportdataFree()` allocate and free the memory for the `Pro2dExportdata` object containing the 2D export options and flags.

The function `Pro2dExportdataSheetoptionSet()` assigns the sheet export option for export to the specified 2D format. The sheet export option can take one of the following values:

- `PRO2DEXPORT_CURRENT_TO_MODEL_SPACE`—Specifies that only the drawing's current sheet will be exported as model space into the specified 2D format. This is the default value.
- `PRO2DEXPORT_CURRENT_TO_PAPER_SPACE`—Specifies that only the drawing's current sheet will be exported as paper space into the specified 2D format. This value is only available for formats that support the concept of model space and paper space, for example, DXF and DWG.
- `PRO2DEXPORT_ALL`—Specifies that all the sheets in a drawing will be exported into the specified 2D format as paper space, if applicable to the format type.
- `PRO2DEXPORT_SELECTED`—Specifies that selected sheets in a drawing will be exported as paper space and one sheet will be exported as model space.

The function `Pro2dExportdataSheetsSet()` assigns the sheet numbers to be exported as paper space to the specified 2D export format file. Use this function only if the sheet export option is set to `PRO2DEXPORT_SELECTED`.

The function `Pro2dExportdataModelspacesheetSet()` assigns the sheet number to be exported as model space. Use this function only if the export format supports the concept of model space and paper space, and if the sheet export option is set to `PRO2DEXPORT_SELECTED`.

The functions `ProProductviewexportoptsAlloc()` and `ProProductviewexportoptsFree()` allocate and free the memory assigned to the `ProProductviewExportOptions` object containing the Creo View export formats.

---

The function `ProProductviewexportoptsFormatSet()` assigns the flag specifying the Creo View export format.

The function `ProProductviewFormattedMdlnameExport()` exports a drawing to one of the following user-defined Creo View formats:

- `PRO_PV_FORMAT_PVS`
- `PRO_PV_FORMAT_ED`
- `PRO_PV_FORMAT_EDZ`
- `PRO_PV_FORMAT_PVZ`

Use the function `ProPrintPrinterOptionsGet()` to get the options for a specified printer. Specify the printer type as the input argument for this function. The supported printer types are:

- `POSTSCRIPT`—Generic Postscript
- `COLORPOSTSC`—Color Postscript
- `MS_PRINT_MGR`—MS Print Manager

---

 **Note**

For a list of all supported printers, please refer to the **Add Printer Type** list in the **Printer Configuration** dialog box of Creo Parametric.

---

The function gets the initialized printer options. The options include the file related options, print command options and printer specific options as follows:

- File Related:
  - `save_to_file`—Saves a plot to a file.
  - `save_method`—Specifies if the plot is to be appended to a file, saved to a single file, or saved to multiple files.
  - `filename`—Specifies the name of the file to which the plot is saved.
  - `delete_after`—Deletes the plot file after printing.
- Print Command:
  - `send_to_printer`—Sends the plot directly to the printer.
  - `print_command`—Specifies the complete command that you want to use for printing.
  - `pen_table`—Specifies the complete path to the file containing the pen table.
  - `paper_size`—Specifies the size of the paper to be printed.
  - `quantity`—Specifies the number of copies to be printed.

- 
- **Printer Specific:**
    - `sw_handshake`—Specifies the type of the handshake initialization sequence. Specify the value as `True` to set the initialization sequence to Software and as `False` to set it to Hardware.

---

 **Note**

Consult your system administrator for more information on handshaking.

- `roll_media`—Specifies whether to use roll-media or cut-sheet.
  - `use_ttf`—Specifies whether to use TrueType font or stroked text.
  - `slew`—Specifies the speed of the pen in centimeters per second in X and Y direction.
  - `rotate_plot`—Specifies that the plot is to be rotated by 90 degrees.
- 

Use the function `ProPrintMdlOptionsGet()` to get the initialized model options for the model to be printed. The available model options are:

- `mdl`—Specifies the model to be printed.
- `quality`—Determines the quality of the model to be printed. It checks for no line, no overlap, simple overlap, and complex overlap.

The model options specific to drawing objects are:

- `use_drawing_size`—Overrides the size of the paper specified in the Printer options.
- `draw_format`—Prints the drawing format used.
- `segmented`—If true, that is the value is set to a boolean of 1, the printer prints drawing full size, but in segments that are compatible with the selected paper size. This option is available only if you are plotting a single page.
- `layer_only`—Prints the specified layer only.
- `layer_name`—Prints the name of the layer.
- `sheets`—Prints the current sheet, all sheets, or selected sheets.
- `range`—An array of two integers specifying the start and end sheet numbers.

The model option specific to solid objects is:

- `use_solid_scale`—Prints using the scale used in the solid model.

Use the function `ProPrintPlacementOptionsGet()` to get the current print placement options such as print scale, offset, zoom, and so on. The options available for the object placement are:

- 
- Placement Options:
    - `scale`—Specifies the scale used for the selected plot.
    - `offset`—An array of two doubles representing the offset from the lower-left corner of the plot.
    - `keep_panzoom`—Maintains the pan and zoom values of a window.
  - Clipping Options:
    - `clip_plot`—Specifies whether you want to clip the plot.
    - `shift_to_ll_corner`—Shifts the clip area to the lower-left corner of the plot
    - `clip_area`—Two dimensional array of four double representing the area that is clipped. The range of the values of this option is 0.0 through 1.0.
  - Label Options:
    - `place_label`—Specifies whether you want to place the label on the plot.
    - `label_height`—Height of the label in inches.

Use the function `ProPrintPCOptionsGet()` to get the print options from a specified Plotter Configuration File. Specify the name of the plotter configuration file and the name of the model to be printed. The function gets the printer options, model options and placement options.

Use the function `ProPrintExecute()` to print a Creo Parametric window using the specified printer options, model options and placement options. The drawing must be displayed in a window to be successfully printed.

## Automatic Printing of 3D Models

Creo TOOLKIT provides the capability of automatically creating and plotting a drawing of a solid model. The Creo TOOLKIT application needs only to supply instructions for the print activity, and Creo Parametric will automatically create the drawing, print it, and then discard it.

The methods listed here are analogous to the command **File ► Print ► Quick Drawing** in Creo Parametric's user interface.

Functions Introduced:

- **`ProQuickprintoptionsAlloc()`**
- **`ProQuickprintoptionsFree()`**
- **`ProQuickprintoptionsLayouttypeSet()`**
- **`ProQuickprintoptionsOrientationSet()`**
- **`ProQuickprintoptionsSizeSet()`**
- **`ProQuickprintoptionsViewAdd()`**

- **ProQuickprintoptionsThreeviewlayoutSet()**
- **ProQuickprintoptionsProjectionsSet()**
- **ProQuickprintoptionsTemplateSet()**
- **ProQuickprintoptionsPrintFlatToScreenAnnotsSet()**
- **ProQuickprintExecute()**

The function `ProQuickprintoptionsAlloc()` allocates a quick drawing options handle.

Use the function `ProQuickprintoptionsFree()` to free a quick drawing options handle.

Use the function `ProQuickprintoptionsLayouttypeSet()` to assign the layout type for the quick drawing operation. You can either specify a drawing layout using the instructions or use a template to define the drawing. The following are the available layout types:

- `PRO_QPRINT_LAYOUT_PROJ`—Use a projected view-type layout.
- `PRO_QPRINT_LAYOUT_MANUAL`—Use a manually arranged layout.
- `PRO_QPRINT_LAYOUT_TEMPLATE`—Use a drawing template to define the layout. If this option is used, only the template name is needed to define the print; other options are not used.

Use the function `ProQuickprintoptionsOrientationSet()` to assign the sheet orientation for the quick drawing operation. The following are the available sheet orientation types:

- `PRODEV_ORIENTATION_PORTRAIT`
- `PRODEV_ORIENTATION_LANDSCAPE`

Use the function `ProQuickprintoptionsSizeSet()` to assign the size of the print for the quick drawing operation. `ProPlotPaperSize` specifies the paper size and can be any of the following types:

- `A_SIZE_PLOT`
- `B_SIZE_PLOT`
- `C_SIZE_PLOT`
- `D_SIZE_PLOT`
- `E_SIZE_PLOT`
- `A4_SIZE_PLOT`
- `A3_SIZE_PLOT`
- `A2_SIZE_PLOT`
- `A1_SIZE_PLOT`
- `A0_SIZE_PLOT`

- `F_SIZE_PLOT`

---

 **Note**

Variable size plots are not supported by this utility.

---

Use the function `ProQuickprintoptionsViewAdd()` to add a new general view. The input arguments of this function are:

- *options*—Specifies the options handle.
- *location*—Specifies the location of the view being added for projected view layout. This option is ignored for a manual view layout. It can be of the following types:
  - `PRO_QPRINTPROJ_GENVIEW_MAIN`
  - `PRO_QPRINTPROJ_GENVIEW_NW`
  - `PRO_QPRINTPROJ_GENVIEW_SW`
  - `PRO_QPRINTPROJ_GENVIEW_SE`
  - `PRO_QPRINTPROJ_GENVIEW_NE`

The general view location options are analogous to the locations in the quick drawing user interface:

---

### **Note**

For manual view layouts, the order in which the views are added determine their final location in the drawing. For this configuration, PTC does not support using more than four views.

- *view\_name*—Specifies the name of the saved model view.
- *scale*—Specifies the view scale.
- *display\_style*—Specifies the view display style to use and is of the following types:
  - `PRO_DISPSTYLE_DEFAULT`
  - `PRO_DISPSTYLE_WIREFRAME`
  - `PRO_DISPSTYLE_HIDDEN_LINE`
  - `PRO_DISPSTYLE_NO_HIDDEN`
  - `PRO_DISPSTYLE_SHADED`
  - `PRO_DISPSTYLE_FOLLOW_ENVIRONMENT`
  - `PRO_DISPSTYLE_SHADED_WITH_EDGES`

---

Use the function `ProQuickprintoptionsThreeviewlayoutSet()` to assign the layout type when three views are being used in a manual layout (`PRO_QPRINT_LAYOUT_MANUAL`). The layout can be either of the following types:

- `PRO_QPRINTMANUAL_3VIEW_1_23VERT`
- `PRO_QPRINTMANUAL_3VIEW_23_VERT1`
- `PRO_QPRINTMANUAL_3VIEW_123_HORIZ`

These options correspond to the diagrams in the user interface:

Use the function `ProQuickprintoptionsProjectionsSet()` assign the projected views to be included in the quick drawing operation. The function applies only to `PRO_QPRINT_LAYOUT_PROJ`. The projections are of the following types:

- `PRO_QPRINTPROJ_TOP_VIEW`
- `PRO_QPRINTPROJ_RIGHT_VIEW`
- `PRO_QPRINTPROJ_LEFT_VIEW`
- `PRO_QPRINTPROJ_BOTTOM_VIEW`
- `PRO_QPRINTPROJ_BACK_NORTH`
- `PRO_QPRINTPROJ_BACK_EAST`
- `PRO_QPRINTPROJ_BACK_SOUTH`
- `PRO_QPRINTPROJ_BACK_WEST`

---

 **Note**

Projection views takes the same view scale and display style as the main view.

---

The options correspond to the projected members of the diagram in the user interface:

Use the function `ProQuickprintoptionsTemplateSet()` to assign the path to the drawing template file to be used for the quick drawing operation. The function applies only to layout type `PRO_QPRINT_LAYOUT_TEMPLATE`.

#### **Note**

The quick drawing operation shows the exact image of the model as is shown on-screen. Therefore, if the drawing template has drawing views set with display options such as view clipping, simplified representations, or layers, these settings are ignored while plotting. The resulting plot reflects whatever is seen on-screen.

Use the function

`ProQuickprintoptionsPrintFlatToScreenAnnotsSet()` to set the `ProBoolean` flag to print flat-to-screen annotations. The flat-to-screen annotations created at screen locations in the Creo Parametric graphics window are printed at their relative locations in the drawing. You can print flat-to-screen annotations such as notes, symbols, and surface finish symbols.

Once the instructions have been prepared, use the function

`ProQuickprintExecute()` to execute a print operation for a given solid model. It has the following input arguments:

- *solid*—Specifies the solid model to be printed.

- *pcf\_path*—Specifies the path to the plotter configuration file to use. If no path is specified, then the path will have the value of the configuration option `quick_print_plotter_config_file`.
- *options*—Specifies the details of the quick drawing operation given by the `ProQuickprintOptions` handle.

## Exporting 3D Models

Creo TOOLKIT provides export capabilities for three dimensional geometry to various formats.

Functions Introduced:

- **ProIntf3DFileWrite()**
- **ProIntf3DFileWriteWithDefaultProfile()**
- **ProIntf3DLayerSetupFileSet()**
- **ProIntf3DLayerSetupFileIsIgnored()**
- **ProIntf3DCsysSet()**
- **ProIntf3DCsysIsIgnored()**
- **ProIntf3DModelDataClear()**
- **ProOutputBrepRepresentationAlloc()**
- **ProOutputBrepRepresentationFlagsSet()**
- **ProIntfExportProfileLoad()**
- **ProOutputBrepRepresentationIsSupported()**
- **ProOutputBrepRepresentationFree()**
- **ProOutputInclusionAlloc()**
- **ProOutputInclusionFacetparamsSet()**
- **ProOutputInclusionWithOptionsSet()**
- **ProOutputInclusionFlagsSet()**
- **ProOutputInclusionFree()**
- **ProOutputLayerOptionsAlloc()**
- **ProOutputLayerOptionsAutoidSet()**
- **ProOutputLayerOptionsSetupfileSet()**
- **ProOutputLayerOptionsFree()**
- **ProOutputAssemblyConfigurationIsSupported()**
- **ProRasterFileWrite()**
- **ProIntfSliceFileWithOptionsMdlnameExport()**

- **ProExportVRML()**
- **ProProductviewexportoptsAlloc()**
- **ProProductviewexportoptsFree()**
- **ProProductviewexportoptsFormatSet()**
- **ProProductviewFormattedMdlnameExport()**

| Export Format                                               | Creo TOOLKIT Functions                                         | Type Constant                 |

| PVZ file                                                                         |                                | PRO_PV_FORMAT_PVZ |
| VRML                                                                             | ProExportVRML()                | N/A               |
| Shrinkwrap                                                                       | ProSolidShrinkwrap<br>Create() | N/A               |

The following data is included during the export of Creo Parametric models to other formats:

- 3D Manufacturing Format (3MF)—From Creo Parametric 5.0.1.0 onward, you can export Creo Parametric models to the 3MF format. The export includes part-level colors, top-assembly parameters, facet geometry, and hidden entities.
- JT—Creo Parametric models are exported to JT with their color overrides. Components with color overrides at any level in an assembly structure are supported.

From Creo Parametric 3.0 onward, the Product Manufacturing Information (PMI) of the annotations is exported as semantic representation from Creo Parametric to JT models. The semantic export is supported only for 3D notes and basic dimensions. All the other types of annotations are exported as graphical entities. You can export planar and zonal cross-sections attached to combined states from Creo Parametric files to JT.

#### Note

From Creo Parametric 2.0 M200 onward the license `INTF_for_JT` is required to export a Creo Parametric model to JT. If the license is not available the functions return the error `PRO_TK_NO_LICENSE`.

- Creo View—You can export colors assigned to the components of assemblies and their sub-assembly models, including the colors of the sub-level entities such as parts, quilts, and faces from Creo Parametric to Creo View.

Creo Parametric models are exported to Creo View with their color overrides. Components with color overrides at any level in an assembly structure are supported. Along with components, color overrides are also supported for component model items, such as, face and quilts.

- 
- SolidWorks—From Creo Parametric 3.0 onward, you can export Creo Parametric models to SolidWorks. The export includes basic geometry such as datum features, colors, attributes, and layers, part models, assembly structures, boundary representation geometry, and non-geometric data.
  - Unigraphics—The export of Creo Parametric models to Unigraphics includes the export of basic geometry such as datum features, colors, attributes, and layers.

---

 **Note**

Refer to the Creo Parametric Data Exchange Help for more information on exporting geometry from Creo Parametric to other formats. Refer to the compatibility matrix on PTC.com for the supported software versions.

---

The following functions will be deprecated in a future release of Creo Parametric . Use the function `ProIntf3DFileWriteWithDefaultProfile()` instead to export Creo Parametric models to other file formats. All the options that can be set with these functions, can also be set using the export profile option in Creo Parametric. Refer to the Creo Parametric Data Exchange Online Help for more information.

- `ProIntf3DFileWrite()`
- `ProOutputInclusionAlloc()`
- `ProOutputInclusionFree()`
- `ProOutputInclusionFlagsSet()`
- `ProOutputLayerOptionsAlloc()`
- `ProOutputLayerOptionsAutoidSet()`
- `ProOutputLayerOptionsSetupfileSet()`
- `ProOutputLayerOptionsFree()`
- `ProOutputInclusionWithOptionsSet()`

The function `ProIntf3DFileWriteWithDefaultProfile()` exports a Creo Parametric model to the specified output format using the default export profile.

The function `ProIntf3DFileWrite()` will be deprecated in a future release of Creo Parametric. Use the function `ProIntf3DFileWriteWithDefaultProfile()` instead. The function `ProIntf3DFileWrite()` exports a Creo Parametric model to the specified output format. The following types of output formats are supported:

- STEP
- VDA

- 
- IGES
  - CATIA MODEL
  - SAT (ACIS format in Creo Parametric)
  - NEUTRAL
  - CADD5
  - CATIA SESSION
  - PARASOLID
  - UG
  - CATIA V5
  - JT Open
  - CATIA Graphical Representation
  - DWG
  - DXF

While exporting the model, you can specify the structure and contents of the output files as:

- Flat File—Exports all of the geometry of the assembly to a single file as if it were a part. This is similar to the Single File format in Creo Parametric for STEP output.
- Single File—Exports an assembly structure to a file with external references to component files. This file contains only top-level geometry. This is similar to the Dittos format in Creo Parametric for CATIA, Separate Parts Only for STEP and One Level for IGES outputs. A part or an assembly is exported as a single file for the DXF and the DWG formats.
- Multi Files—Exports an assembly structure to a single file and the components to component files. It creates component parts and subassemblies with their respective geometry and external references. This option supports all levels of hierarchy. This is similar to All Levels format for IGES and Separate All Parts for STEP in Creo Parametric.
- Parts—Exports an assembly as multiple files containing geometry information of its components and assembly features. This is similar to All Parts format for IGES in Creo Parametric.

Some output formats support only certain types of assembly configurations. The default assembly configuration is a flat file.

## Note

Using the Creo TOOLKIT function `ProIntf3DFileWrite()` you can export a Creo Parametric 3D model to a JT file format.

From Creo Parametric 2.0 M200 onward, the function `ProIntf3DFileWrite()` exports a Creo Parametric 3D model to JT file format only if the license `INTF_for_JT` is available. If the license is not available the function returns the error `PRO_TK_NO_LICENSE`.

Starting with Creo Parametric 1.0, XT-brep data format is supported along with the JT-brep format for storing the 3D model data to export. Use the new configuration option `intf3d_out_jt_brep` to export the Creo Parametric model using the function `ProIntf3DFileWrite()`. This configuration option takes the following values:

- **NO**—This is the default value. When you set the configuration option `intf3d_out_jt_brep` as **NO**, the function `ProIntf3DFileWrite()` exports the Creo Parametric model to JT format as facet representation only.
- **JT\_BREP**—When you set the configuration option `intf3d_out_jt_brep` to **JT\_BREP**, the exported Creo Parametric model has both the JT-brep format and the faceted representation.
- **XT\_BREP**—When you set the configuration option `intf3d_out_jt_brep` to **XT\_BREP**, the exported Creo Parametric model has both the XT-brep format and the faceted representation.
- The export of a Creo Parametric 3D model to a JT file format using the function `ProIntf3DFileWrite()` is also impacted by the following configuration options:

- 
- `intf3d_out_jt_auto_lods`—It takes the values `yes` or `no*`. If you set the configuration option `intf3d_out_jt_auto_lods` to `yes`, you can export up to three Levels of Detail (LODs) to the JT format.
  - `intf3d_out_jt_config_name`—Name of the JT configuration file. You can define a configuration file `jt.config`. You can define parameters and export options in this file. You can also control the export of the LODs to the JT format via Creo TOOLKIT using this file. The options set in this file override the setting of the configuration option `intf3d_out_jt_auto_lods`. Refer to the section [Export Options in the JT Configuration File on page 701](#) for more information about the options that can be set in the `jt.config` file.
  - `intf3d_out_jt_config_path`—Path of the JT configuration file.
  - The configuration option `intf3d_out_export_as_facets` is now obsolete.
- 

The function `ProIntf3DLayerSetupFileSet()` sets the layer setup file for the export. The input arguments follow:

- *model*—The model used for export.
- *layer\_setup\_file*—The full path of the input layer setup file. Pass the value as `NULL` to set default layer setup settings for input `file_type`. Layer setup file is not supported for `PRO_INTF_EXPORT_CADDS` and `PRO_INTF_EXPORT_NEUTRAL` file types.

The function `ProIntf3DLayerSetupFileIsIgnored()` checks if layer setup file is ignored or not during export. This function returns if the layer setup file is used for the last export, using the function `ProIntf3DFileWriteWithDefaultProfile()`.

For reliable results, call the function

`ProIntf3DFileWriteWithDefaultProfile()` before calling `ProIntf3DLayerSetupFileIsIgnored()`.

The output argument `is_ignored` returns `PRO_B_TRUE` if the layer setup file is ignored and returns `PRO_B_FALSE` if layer setup file is not ignored.

The function `ProIntf3DCsysSet()` sets the reference coordinate system `Csys` for the export. The input arguments follow:

- *pro\_model*—The model used for export.
- *csys\_sel*—The reference coordinate system. Pass the value as `NULL` to set default coordinate system. Reference `Csys` is not supported for `PRO_INTF_EXPORT_CADDS` and `PRO_INTF_EXPORT_NEUTRAL` file types.

---

The function `ProIntf3DCsysIsIgnored()` checks if the reference coordinate system is ignored or not during export. The function returns if the reference Csys is used for the last export, using the function `ProIntf3DFileWriteWithDefaultProfile()`.

For reliable results, call the function `ProIntf3DFileWriteWithDefaultProfile()` before calling `ProIntf3DLayerSetupFileIsIgnored()`.

The output argument `is_ignored` returns `PRO_B_TRUE` if the reference Csys is ignored and returns `PRO_B_FALSE` if the reference Csys is not ignored.

The function `ProIntf3DModelDataClear()` clears the model data set by the functions `ProIntf3DLayerSetupFileSet()` and `ProIntf3DCsysSet()`.

Use the function `ProOutputAssemblyConfigurationIsSupported()` to check if the specified assembly configuration is valid for the particular model and the specified export format. This function must be called before exporting the model to the specified output format using the function `ProIntf3DFileWrite()` except for the CADDs and STEP2D formats.

The function `ProOutputBrepRepresentationAlloc()` allocates memory for the geometric representation data structure. This data structure represents the types of geometry supported by the export operation. The types of geometric representations are:

- Wireframe
- Surfaces
- Solid
- Quilts (Shell in Creo Parametric)

These correspond to the options shown in the Creo Parametric dialog box for export. Note that some formats allow a combination of types to be input.

The function `ProOutputBrepRepresentationFlagsSet()` sets the flags for the geometric representation data structure. It specifies the type of geometry to be exported.

The function `ProIntfExportProfileLoad()` loads the specified profile for export. You can use this function when you want to use the export profile of your choice instead of the default export profile in a particular Creo Parametric session. The input argument *profile* is the full path to the profile along with the profile name and extension.

---

 **Note**

Once the export profile file is loaded in a Creo Parametric session, it will be active in the interactive mode as well.

---

The function `ProOutputBrepRepresentationIsSupported()` checks if the specified geometric representation is valid for a particular export format. This function should be called before exporting the model to the specified output format using the function `ProIntf3DFileWrite()`, to check if the planned configuration is supported by the Creo Parametric interface options.

The function `ProOutputBrepRepresentationFree()` frees the memory allocated for the geometry data structure.

The function `ProOutputInclusionAlloc()` will be deprecated in a future release of Creo Parametric. The function `ProOutputInclusionAlloc()` allocates memory for the inclusion structure to be used while exporting the model.

The function `ProOutputInclusionFlagsSet()` will be deprecated in a future release of Creo Parametric. It is recommended that you set this option in export profile file in Creo Parametric. The function `ProOutputInclusionFlagsSet()` determines whether to include certain entities during export. The types of entities are:

- **Datums**—Determines whether datum curves are included when exporting files. If the flag is set to true the datum curve and point information is included during export. The default value is false.
- **Blanked**—Determines whether entities on blanked layers are exported. If the flag is set to true, entities on blanked layers are exported. The default value is false.
- **Facets**—Determines whether faceted geometry is included when exporting the models. The default value of the flag is false.

The function `ProOutputInclusionFacetparamsSet()` assigns the parameters to use while exporting the model to a faceted format such as `PRO_INTF_EXPORT_CATIA_CGR`. These parameters are as follows:

- *chord\_height*—The chord height to use for the exported facets.
- *angle\_control*—The angle control to use for the exported facets.

---

 **Note**

The function `ProOutputInclusionFacetparamsSet()` has been deprecated. Use the function `ProOutputInclusionWithOptionsSet()` instead.

---

The function `ProOutputInclusionWithOptionsSet()` will be deprecated in a future release of Creo Parametric. It is recommended that you set this option in export profile file in Creo Parametric. Use the function `ProOutputInclusionWithOptionsSet()` to set the parameters and configuration flags used while exporting the model to a faceted format such as `PRO_INTF_EXPORT_CATIA_CGR`. The input arguments are as follows:

- *parameters*—Specifies a `ProArray` of parameters that consists of the following three elements:
  - *chord\_height*—The chord height of the exported facets.
  - *angle\_control*—The angle control of the exported facets. Specify a value between 0.0 to 1.0. If the angle control is out of bounds, Creo Parametric changes it to the closest limit without returning an error.
  - *step\_size*—The step size of the exported facets. If the step size is less or equal to 0, it is ignored.

---

 **Note**

If the chord height or step size are too small or too big, then Creo Parametric resets it to the smallest or biggest acceptable value, respectively, without returning an error.

---

- *config\_flags*—Specifies the configuration flags that control the export operation. They are as follows:
  - `PRO_FACET_STEP_SIZE_OFF`—Switches off the step size control.
  - `PRO_FACET_FORCE_INTO_RANGE`—Forces the out-of-range parameters into range. If any of the `PRO_FACET_*_DEFAULT` option is set, then the option `PRO_FACET_FORCE_INTO_RANGE` is not applied on that parameter.
  - `PRO_FACET_STEP_SIZE_ADJUST`—Adjusts the step size according to the component size.
  - `PRO_FACET_CHORD_HEIGHT_ADJUST`—Adjusts the chord height according to the component size.

- `PRO_FACET_USE_CONFIG`—If this flag is set, values of the flags `PRO_FACET_STEP_SIZE_OFF`, `PRO_FACET_STEP_SIZE_ADJUST`, and `PRO_FACET_CHORD_HEIGHT_ADJUST` are ignored and the configuration settings from the Creo Parametric user interface are used during the export operation
- `PRO_FACET_CHORD_HEIGHT_DEFAULT`—Uses the default value set in the Creo Parametric user interface for the chord height.
- `PRO_FACET_ANGLE_CONTROL_DEFAULT`—Uses the default value set in the Creo Parametric user interface for the angle control.
- `PRO_FACET_STEP_SIZE_DEFAULT`—Uses the default value set in the Creo Parametric user interface for the step size.
- `PRO_FACET_INCLUDE_QUILTS`—Includes quilts in the export of Creo Parametric model to the specified format.
- `PRO_EXPORT_INCLUDE_ANNOTATIONS`—Includes annotations in the export of Creo Parametric model to the specified format.

---

 **Note**

To include annotations, during the export of Creo Parametric model, you must call the function `ProMdlDisplay()` before calling `ProIntf3DFileWrite()`.

---

- `PRO_FACET_VISIBLE_MODELS`—Exports models which have their visibility status set to **Show** in Creo Parametric. Models that are hidden are not exported.

---

 **Note**

The behavior of the function

`ProOutputInclusionWithOptionsSet()` is similar to the function `ProOutputInclusionFacetparamsSet()` if the configuration flag `PRO_FACET_STEP_SIZE_OFF` is set.

---

The function `ProOutputInclusionFree()` will be deprecated in a future release of Creo Parametric. The function `ProOutputInclusionFree()` frees the memory allocated for the inclusion structure.

The function `ProOutputLayerOptionsAlloc()` will be deprecated in a future release of Creo Parametric. The function `ProOutputLayerOptionsAlloc()` allocates memory for the layer options data structure. The layer options are:

- **AutoId**—A flag indicating whether layers should be automatically assigned numerical ids when exporting.
- **LayerSetupFile**—The layer setup file contains the name of the layer, its display status, the interface ID and number of sub layers.

Specify the name and complete path of the layer setup file. This file contains the layer assignment information.

The function `ProOutputLayerOptionsAutoidSet()` will be deprecated in a future release of Creo Parametric. It is recommended that you set this option in export profile file in Creo Parametric. The function `ProOutputLayerOptionsAutoidSet()` enables you to set or remove an interface layer ID. If true, automatically assigns interface ids to layers not assigned ids and exports them. The default value is false.

The function `ProOutputLayerOptionsSetupfileSet()` will be deprecated in a future release of Creo Parametric. It is recommended that you set this option in export profile file in Creo Parametric. Use the function `ProOutputLayerOptionsSetupfileSet()` to specify the name and complete path of the layer setup file.

The function `ProOutputLayerOptionsFree()` will be deprecated in a future release of Creo Parametric. The function `ProOutputLayerOptionsFree()` frees the memory allocated for the layer options structure.

Use function `ProRasterFileWrite()` to create a standard Creo Parametric raster output file. Note that this function does not support output of drawings (2-dimensional objects) in Drawing mode.

The `PRO_SPOOL_FILE` option reads in a Diagram spool file.

The function `ProIntfSliceFileWithOptionsMdlnameExport()` exports to tessellated formats such as STL, Render, AMF, Inventor, CatiaFacets, 3MF, and Optegra Visualizer based on the values of a `ProArray` of parameters and two configuration flags. These formats require the maximum chord height, angle control, and transformation to be specified for the model being exported. If the specified model is an assembly, the last input argument of the function is the component path; if the model is a part, this argument is `NULL`. The inputs arguments are as follows:

- *model*—Specify the pointer to the model to be exported and is specified using the object `ProMdl`.
- *output\_file\_name*—Specify the output file name.
- *file\_type*—Specify the file type to be exported and is defined using the enumerated data type `ProImportExportFile`.
- *parameters*—Specify a `ProArray` of parameters that consists of the following three elements:
  - *chord\_height*—The chord height of the exported facets.

- *angle\_control*—The angle control of the exported facets. Specify a value between 0.0 to 1.0. If the angle control is out of bounds, Creo Parametric changes it to the closest limit without returning an error.
- *step\_size*—The step size of the exported facets. If the step size is less or equal to 0, it is ignored.

---

 **Note**

If the chord height or step size are too small or too big, then Creo Parametric resets it to the smallest or biggest acceptable value, respectively, without returning an error.

---

- *config\_flags*—Specify the configuration flags that control the export operation. They are as follows:
  - `PRO_FACET_STEP_SIZE_OFF`—Switches off the step size control.
  - `PRO_FACET_FORCE_INTO_RANGE`—Forces the out-of-range parameters into range. If any of the `PRO_FACET_*_DEFAULT` option is set, then the option `PRO_FACET_FORCE_INTO_RANGE` is not applied on that parameter.
  - `PRO_FACET_STEP_SIZE_ADJUST`—Adjusts the step size according to the component size.
  - `PRO_FACET_CHORD_HEIGHT_ADJUST`—Adjusts the chord height according to the component size.
  - `PRO_FACET_USE_CONFIG`—If this flag is set, values of the flags `PRO_FACET_STEP_SIZE_OFF`, `PRO_FACET_STEP_SIZE_ADJUST`, and `PRO_FACET_CHORD_HEIGHT_ADJUST` are ignored and the configuration settings from the Creo Parametric user interface are used during the export operation
  - `PRO_FACET_CHORD_HEIGHT_DEFAULT`—Uses the default value set in the Creo Parametric user interface for the chord height.
  - `PRO_FACET_ANGLE_CONTROL_DEFAULT`—Uses the default value set in the Creo Parametric user interface for the angle control.
  - `PRO_FACET_STEP_SIZE_DEFAULT`—Uses the default value set in the Creo Parametric user interface for the step size.
  - `PRO_FACET_INCLUDE_QUILTS`—Includes quilts in the export of Creo Parametric model to the specified format.

- 
- `PRO_EXPORT_INCLUDE_ANNOTATIONS`—Includes annotations in the export of Creo Parametric model to the specified format.

---

 **Note**

To include annotations, during the export of Creo Parametric model, you must call the function `ProMdlDisplay()` before calling `ProIntf3DFileWrite()`.

---

- `PRO_FACET_VISIBLE_MODELS`—Exports models which have their visibility status set to **Show** in Creo Parametric. Models that are hidden are not exported.
- *transf*—Specify the transformation matrix. This is the transformation from the result in the Assembly (top model) coordinates to the desired result (at selected coordinate system, if any). If the value is set to `NULL`, no matrix is applied.
- *comp\_path*—Specify the component path, in the case of an assembly component. This is used to compute selected model's transformation in current assembly. If the model is a part, set this to `NULL`.

The function `ProExportVRML()` exports a solid from a Creo Parametric session, or a Creo Parametric solid stored in a file, into a directory of VRML files. This output directory contains assembly structure data, part and assembly names, and geometrical data representing the parts. This function accepts as input only Creo Parametric assemblies or parts.

`ProExportVRML()` supports creation of multiple output files from either parts or assemblies. If you export an assembly, the function creates an output file for each member of the assembly and one for the assembly itself. Default file names are:

`asm1_a.wrl, asm2_a.wrl, ... asmN_a.wrl`

where `asm` is the assembly name.

If you export parts, `ProExportVRML()` creates an output file for each part. Default names are `part_p.wrl`, where `part` is the part name. For more information on `ProExportVRML()`, refer to “Exporting Files to VRML” or “Batch Utilities” in the “Interface” section of Creo Parametric help.

The functions `ProProductviewexportoptsAlloc()` and `ProProductviewexportoptsFree()` allocate and free the memory assigned to the `ProProductviewExportOptions` object containing the Creo View export formats.

The function `ProProductviewexportoptsFormatSet()` assigns the flag specifying the Creo View export format.

---

The function `ProProductviewFormattedMdlnameExport()` exports a part or an assembly to one of the following user-defined Creo View formats.

- `PRO_PV_FORMAT_PVS`
- `PRO_PV_FORMAT_ED`
- `PRO_PV_FORMAT_EDZ`
- `PRO_PV_FORMAT_PVZ`

### Example 2: To Export a Model File to IGES Format

The sample code in `UgInterfaceExport.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_interface` shows how to export a model file to IGES format using options similar to those seen in the UI.

## Export Options in the JT Configuration File

You can export up to three levels of detail (LODs) from Creo Parametric files to the JT format. An LOD is a graphical representation of details such as the chord height, angle control, and step size for faceted surfaces. Each faceted surface is made up of a specific number of triangles. These shaded triangles represent the object. The more triangles that describe the object, the more details you can view.

You can create and use a configuration file, `jt.config`, to control the export of the LODs from Creo Parametric files to the JT format. The `jt.config` file is located in the `<creo_loadpoint>\<datecode>\Common Files\text\jt\` directory. The options set in this file override the configuration options in the `config.pro` configuration file.

You can include the following parameters or export options in the `jt.config` file:

- `EAITranslator`—Specifies the setting for the export of control parameters.
  - `chordalOption`—Specifies whether to apply the chordal value as an absolute value in model units or as a relative value that is a percentage of the part size. The valid values are:
    - ◆ `RELATIVE`—Tessellates all the parts in a model relative to their size equally. The chordal value is applied as a fractional percentage.
    - ◆ `ABSOLUTE`—Tessellates all the parts in a model regardless of their size. The chordal value is applied as an absolute value.

- 
- `structureOption`—Specifies the mapping of the JT product structure to the JT file structure in the JT files after export. The supported product structures are:
    - ◆ `JtkPER_PART`—Specifies that the assembly is exported as a single JT file. The parts in the assembly are exported and saved as individual JT files in a sub-directory of the same name as the top-level assembly file.
    - ◆ `JtkFULL_SHATTER`—Specifies that each component of the assembly is exported as a separate JT file.
    - ◆ `JtkMONOLITHIC`—Specifies that the assembly is exported as a single JT file.
  - `writeWhichFiles`—Specifies which components must be exported to JT format.
    - ◆ `ALL`—This is the default option. Specifies that the entire assembly along with its parts must be exported.
    - ◆ `ASSEMBLY_ONLY`—Specifies that only the product structure must be exported.
    - ◆ `PARTS_ONLY`—Specifies that only the parts in the assembly must be exported without the assembly structure.
  - `JtFileFormat`—Specifies the version of the JT format in which the files must be exported. Refer to the Creo Parametric Data Exchange Help, for more information on `AUTO` option.
  - `includeBrep`—Specifies a boolean value to include the geometry boundary representation definition, that is, JT-brep or XT-brep, in the files exported to JT format. It controls the export of annotations as semantic representations. You cannot include the JT-brep and the XT-brep data structures in the same file. The valid values are `true` or `false`.
  - `autoXtBrep`—Specifies a boolean value to automatically convert the boundary representation geometry to parasolid format during the export. When you set the option to `true`, the boundary representation data is converted to the parasolid format. When set to `false`, the boundary representation data is stored in the proprietary JT format.

You can use the `autoXtBrep` option with the `includeBrep` option to switch between the JT-brep and the XT-brep structures.
  - `numLODs`—Specifies the number of LOD definitions. PTC recommends creating up to three LODs.
  - `LOD`—Specifies a group of parameters that control tessellation for a specific LOD. It also specifies the number of the current LOD.
    - `Level`—Specifies the current LOD number.

- 
- **Chordal**—Specifies the maximum distance that a tessellated line segment deviates from the actual curve it approximates. It takes the value as a floating number from [0.0,1.0]. The value specified is as determined by the `chordalOption` option. If the chordal value exceeds the model size, you can consider the model size as the chordal value.

---

 **Note**

For best results, use chordal values in conjunction with the `Angular` parameter. Chordal values primarily affect the larger features of the model while the angular values affect the smaller features of the model.

---

- **Length**—Specifies the maximum absolute length of the tessellated line segments in a curve approximation. If the `Length` value exceeds the model size, consider the default value as `(model_size/30)`.
- **Label**—Specifies the user-defined name for the LOD.
- **Angular**—Specifies the angle control value for LOD definitions and triangulation export to JT format. This parameter sets the absolute maximum angle between two adjacent line segments in a curve approximation. The angle has its value between 0 and 90 degrees. The maximum angle value indicates coarse tessellation while the lowest value indicates fine tessellation and high quality LOD.
- **proeConfig**—Specifies the options that are specific to Creo Parametric.
  - **autoLODgeneration**—Specifies a boolean value to automatically generate three LODs from Creo Parametric. The valid values are `true` or `false`.

---

 **Note**

When `autoLODgeneration` is set to `true`, the LOD options set in the `jt.config` file are ignored.

---

- 
- `autoLODStepSize`—Specifies a boolean value to use the step size parameter during the automatic generation of LODs using the options set in Creo Parametric. This option is available only when `autoLODgeneration` is set to `true`.

---

 **Note**

When `autoLODStepSize` is set to `true`, the step size set in the `jt.config` file is ignored.

---

- `LOD[n]angle`—Regulates the amount of additional improvement along curves with small radii for LOD1, LOD2, and LOD3. It takes the value as a floating number from [0.0,1.0]. This option is available only when `autoLODgeneration` is set to `false`.
- `UseJTAngularControl`—Specifies the type of angle control to be used. Angles can be controlled using the Creo Parametric angle control values or the JT angle control values. Set this parameter to `true` to use the JT angle control values. Specify the angle control values in the `Angular` option.

By default, this parameter is set to `false`. In this case, the Creo Parametric angle control options, `LOD1angle`, `LOD2angle`, `LOD3angle`, and so on, are used to define the LOD generation.

You must set the configuration options `intf3d_out_jt_config_name` and `intf3d_out_jt_config_path` to specify the name and location of the `jt.config` file.

## Shrinkwrap Export

To improve performance in large assembly design, you can export lightweight representations of models called Shrinkwrap models. A shrinkwrap model is based on the external surfaces of the source part or assembly model and captures the outer shape of the source model.

You can create the following types of non associative exported Shrinkwrap models:

- **Surface Subset**—This type consists of a subset of the original model's surfaces.
- **Faceted Solid**—This type is a faceted solid representing the original solid.
- **Merged Solid**—The external components from the reference assembly model are merged into a single part representing the solid geometry in all collected components.

| Export Format | Creo TOOLKIT Functions     | Type Constant |
|---------------|----------------------------|---------------|
| Shrinkwrap    | ProSolidShrinkwrapCreate() | N/A           |

Function Introduced:

- **ProSolidShrinkwrapMdlnameCreate()**

You can export the specified solid model as a Shrinkwrap model using the function `ProSolidShrinkwrapMdlnameCreate()`. This function requires:

- The model to be exported as Shrinkwrap
- The template model where the Shrinkwrap geometry will be created.
- The name of the exported file if the export format is VRML or STL.

## Setting Shrinkwrap Options

Functions Introduced:

- **ProShrinkwrapoptionsAlloc()**
- **ProShrinkwrapoptionsFree()**
- **ProShrinkwrapoptionsQualitySet()**
- **ProShrinkwrapoptionsAutoholefillingSet()**
- **ProShrinkwrapoptionsIgnoreskeletonsSet()**
- **ProShrinkwrapoptionsIgnorequiltsSet()**
- **ProShrinkwrapoptionsIgnoreconstrbodiesSet()**
- **ProShrinkwrapoptionsAssignmasspropsSet()**
- **ProShrinkwrapoptionsDatumrefsSet()**

The function `ProShrinkwrapoptionsAlloc()` allocates memory for the structure defining the shrinkwrap options. The types of shrinkwrap methods are:

- `PRO_SWCREATE_SURF_SUBSET`—Surface Subset
- `PRO_SWCREATE_FACETED_SOLID`—Faceted Solid
- `PRO_SWCREATE_MERGED_SOLID`—Merged Solid

The function returns the options handle which is used to set the members of the structure defining the shrinkwrap options.

The function `ProShrinkwrapoptionsFree()` frees the memory allocated by the function `ProShrinkwrapoptionsAlloc()`.

---

The function `ProShrinkwrapoptionsQualitySet()` specifies the quality level for the system to use when identifying surfaces or components that will contribute to the Shrinkwrap model. Quality ranges from 1 which produces the coarsest representation of the model in the fastest time, to 10 which produces the most exact representation. The default value is true.

The function `ProShrinkwrapoptionsAutoholefillingSet()` sets a flag that forces Creo Parametric to identify all holes and surfaces that intersect a single surface and fills those holes during shrinkwrap. The default value is true.

The function `ProShrinkwrapoptionsIgnoreskeletonsSet()` determines whether the skeleton model geometry must be included in the Shrinkwrap model.

`ProShrinkwrapoptionsIgnorequiltsSet()` determines whether external quilts will be included in the Shrinkwrap model.

`ProShrinkwrapoptionsIgnoreconstrbodiesSet()` determines whether construction bodies are included in the Shrinkwrap model.

`ProShrinkwrapoptionsAssignmasspropsSet()` assigns mass properties to the Shrinkwrap model. The default value is false and the mass properties of the original model is assigned to the Shrinkwrap model. If the value is set to true, the user will have to assign a value for the mass properties.

`ProShrinkwrapoptionsDatumrefsSet()` selects the datum planes, points, curves, axes, and coordinate system references to be included from the Shrinkwrap model.

## Surface Subset Options

Functions Introduced:

- **`ProShrinkwrapoptionsIgnoresmallsurfsSet()`**
- **`ProShrinkwrapoptionsAdditionalssurfacesSet()`**

The function `ProShrinkwrapoptionsIgnoresmallsurfsSet()` sets a flag that forces Creo Parametric to skip surfaces smaller than a certain size. The default value of this argument is false. The size of the surface is specified as a percentage of the model's size.

Use `ProShrinkwrapoptionsAdditionalssurfacesSet()` to select individual surfaces to be included in the Shrinkwrap model.

## Faceted Solid Options

Functions Introduced:

- **`ProShrinkwrapoptionsFacetedformatSet()`**
- **`ProShrinkwrapoptionsFramesFileSet()`**

---

Use the function `ProShrinkwrapoptionsFacetedformatSet()` to specify the output file format of the Shrinkwrap model. The types of output format are:

- `PRO_SWFACETED_PART`—Creo Parametric part with normal geometry. This is the default format type.
- `PRO_SWFACETED_LIGHTWEIGHT_PART`—Lightweight Creo Parametric part with lightweight, faceted geometry.
- `PRO_SWFACETED_STL`—An STL file
- `PRO_SWFACETED_VRML`—A VRML file

The function `ProShrinkwrapoptionsFramesFileSet()` enables you to select a frame file to create a faceted solid motion envelope model that represents the full motion of the mechanism captured in the frame file. Specify the name and complete path of the frame file.

## Merged Solid Options

Function Introduced:

- **`ProShrinkwrapoptionsAdditionalcomponentsSet()`**

Use the function

`ProShrinkwrapoptionsAdditionalcomponentsSet()` to select individual components of the assembly to be merged into the Shrinkwrap model.

## Example 3: To Export a Model to VRML Format

The sample code in `UgInterfaceExport.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_interface` shows how to create a faceted shrinkwrap model in VRML format

## Example 4: To Create a Shrinkwrap Part Model as a Merged Solid

The sample code in `UgInterfaceExport.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_interface` shows how to create a new empty model and copy the merged solid shrinkwrap information into it.

## Exporting to PDF and U3D

The functions described in this section support the export of Creo Parametric drawings and solid models to Portable Document Format (PDF) and U3D format. You can export a drawing or a 2D model as a 2D raster image embedded in a PDF file. You can export Creo Parametric solid models in the following ways:

- As a U3D model embedded in a one-page PDF file

- As 2D raster images embedded in the pages of a PDF file representing saved views
- As a standalone U3D file

While exporting multiple sheets of a Creo Parametric drawing to a PDF file, you can choose to export all sheets, the current sheet, or selected sheets.

These functions also allow you to insert a variety of non-geometric information to improve document content, navigation, and search.

Functions Introduced:

- **ProPDFOptionsAlloc()**
- **ProPDFOptionsIntpropertySet()**
- **ProPDFOptionsBoolpropertySet()**
- **ProPDFOptionsStringpropertySet()**
- **ProPDFOptionsDoublepropertySet()**
- **ProPDFExport()**
- **ProPDFWithProfileExport()**
- **ProPDFOptionsFree()**

The function `ProPDFOptionsAlloc()` allocates memory for the PDF options structure.

The function `ProPDFOptionsIntpropertySet()` sets the value for an integer or enum property of the PDF options structure. The types of export options are as follows:

- `PRO_PDFOPT_EXPORT_MODE`—Enables you to select the object to be exported to PDF and the export format. The values are:
  - `PRO_PDF_2D_DRAWING`—Specifies that only 2D drawings will be exported to PDF. This is the default.
  - `PRO_PDF_3D_AS_NAMED_VIEWS`—Specifies that Creo Parametric models will be exported as 2D raster images embedded in PDF files.
  - `PRO_PDF_3D_AS_U3D_PDF`—Specifies that Creo Parametric models will be exported as U3D models embedded in one-page PDF files.
  - `PRO_PDF_3D_AS_U3D`—Specifies that a Creo Parametric model will be exported as a U3D (\*.u3d) file. This value ignores the options available for the PDF options structure.
- `PRO_PDFOPT_PDF_SAVE`—Enables you to specify the PDF format while exporting 2D drawings and solid models. The values are:

- 
- `PRO_PDF_ARCHIVE_1`—Exports the 2D drawing to the PDF/A format. This type is applicable only for 2D drawings, that is, when you set the option `PRO_PDFOPT_EXPORT_MODE` to `PRO_PDF_2D_DRAWING`.  
If you set the option `PRO_PDFOPT_PDF_SAVE` to `PRO_PDF_ARCHIVE_1`, the following options are set as shown below:
    - ◆ `PRO_PDFOPT_LAYER_MODE` is set to `PRO_PDF_LAYERS_NONE`.
    - ◆ `PRO_PDFOPT_HYPERLINKS` is set to `FALSE`, that is, hyperlinks are not created in the PDF.
    - ◆ Shaded views will not be transparent and may overlap other data.
    - ◆ `PRO_PDFOPT_PASSWORD_TO_OPEN` is set to `NULL`.
    - ◆ `PRO_PDFOPT_MASTER_PASSWORD` is set to `NULL`.
    - ◆ `PRO_PDF_FULL`—Exports the object to the standard PDF format. This is the default value.
  - `PRO_PDFOPT_FONT_STROKE`—Enables you to switch between using TrueType fonts in the resulting document and drawing or "stroking" text as line segments. The values are:
    - `PRO_PDF_USE_TRUE_TYPE_FONTS`—Specifies TrueType fonts. This is the default.
    - `PRO_PDF_STROKE_ALL_FONTS`—Specifies the option to stroke all fonts.
  - `PRO_PDFOPT_COLOR_DEPTH`—Enables you to choose between color, grayscale, or monochrome output. The values are:
    - `PRO_PDF_CD_COLOR`—Specifies color output. This is the default.
    - `PRO_PDF_CD_GRAY`—Specifies grayscale output.
    - `PRO_PDF_CD_MONO`—Specifies monochrome output.
  - `PRO_PDFOPT_HIDDENLINE_MODE`—Enables you to set the style for hidden lines in the resulting PDF document. The values are:
    - `PRO_PDF_HLM_DASHED`—Specifies dashed hidden lines. This is the default.
    - `PRO_PDF_HLM_SOLID`—Specifies solid hidden lines.
  - `PRO_PDFOPT_RASTER_DPI`—Enables you to set the resolution for the output of any shaded views in DPI. The value is restricted to the values in `ProDotsPerInch`, and the default is `PRORASTERDPI_300`.
  - `PRO_PDFOPT_LAYER_MODE`—Enables you to set the availability of layers in the document. The values are:

- 
- `PRO_PDF_LAYERS_VISIBLE`—Exports only visible layers in a drawing.
  - `PRO_PDF_LAYERS_NONE`—Exports only the visible entities in the drawing, but not the layers on which they are placed.
  - `PRO_PDF_LAYERS_ALL`—Exports the visible layers and entities. This is the default.
  - `PRO_PDFOPT_PARAM_MODE`—Enables you to set the availability of model parameters as searchable metadata in the PDF document. The values are:
    - `PRO_PDF_PARAMS_DESIGNATED`—Exports only the specified model parameters in the PDF metadata.
    - `PRO_PDF_PARAMS_NONE`—Exports the drawing to PDF without the model parameters.
    - `PRO_PDF_PARAMS_ALL`—Exports the drawing and the model parameters to PDF. This is the default.
  - `PRO_PDFOPT_ALLOW_MODE`—Defines the changes that you can make in the PDF document. This option can be set only if `PRO_PDFOPT_RESTRICT_OPERATIONS` is set to true. The permitted viewer operations are given by the following values:
    - `PRO_PDF_RESTRICT_NONE`—This is the default value and it restricts you from performing all operations in the PDF document.
    - `PRO_PDF_RESTRICT_FORMS_SIGNING`—Allows you to fill in the fields of the form, create templates, and add digital signatures to the PDF document.
    - `PRO_PDF_RESTRICT_INSERT_DELETE_ROTATE`—Allows you to insert, delete, and rotate pages in the PDF document.
    - `PRO_PDF_RESTRICT_COMMENT_FORM_SIGNING`—Allows you to add or edit comments, fill in the fields of the form, create templates, and add digital signatures to the PDF document.
    - `PRO_PDF_RESTRICT_EXTRACTING`—Allows you to perform all viewer operations, except for extracting pages from the PDF document.
  - `PRO_PDFOPT_ALLOW_PRINTING_MODE`—Allows you to set the print resolution. This option can be set only if the options `PRO_PDFOPT_RESTRICT_OPERATIONS` and `PRO_PDFOPT_ALLOW_PRINTING` are set to true. The values are:
    - `PRO_PDF_PRINTING_LOW_RES`—Specifies low resolution for printing.
    - `PRO_PDF_PRINTING_HIGH_RES`—Specifies high resolution for printing. This is the default.

- 
- **PRO\_PDFOPT\_LINECAP**—Enables you to control the treatment of the ends of the geometry lines exported to PDF. The values are:
    - **PRO\_PDF\_LINECAP\_BUTT**—Specifies the butt cap square end. This is the default.
    - **PRO\_PDF\_LINECAP\_ROUND**—Specifies the round cap end.
    - **PRO\_PDF\_LINECAP\_PROJECTING\_SQUARE**—Specifies the projecting square cap end.
  - **PRO\_PDFOPT\_LINEJOIN**—Enables you to control the treatment of the joined corners of connected lines exported to PDF. The values are:
    - **PRO\_PDF\_LINEJOIN\_MITER**—Specifies the miter join. This is the default.
    - **PRO\_PDF\_LINEJOIN\_ROUND**—Specifies the round join.
    - **PRO\_PDF\_LINEJOIN\_BEVEL**—Specifies the bevel join.
  - **PRO\_PDFOPT\_SHEETS**—Enables you to specify the sheets from a Creo Parametric drawing that are to be exported to PDF. The values are:
    - **PRINT\_CURRENT\_SHEET**—Specifies that only the current sheet will be exported to the PDF file.
    - **PRINT\_ALL\_SHEETS**—Specifies that all the sheets will be exported to the PDF file. This is the default.
    - **PRINT\_SELECTED\_SHEETS**—Specifies that sheets of a specified range will be exported to the PDF file. If this value is assigned, then the value of the string property **PRO\_PDFOPT\_SHEET\_RANGE** must also be included.
  - **PRO\_PDFOPT\_LIGHT\_DEFAULT**—Enables you to set the default lighting style used while exporting Creo Parametric models in the U3D format to a one-page PDF file. The values are:
    - **PRO\_PDF\_U3D\_LIGHT\_NONE**—Specifies no lights.
    - **PRO\_PDF\_U3D\_LIGHT\_WHITE**—Specifies white lights.
    - **PRO\_PDF\_U3D\_LIGHT\_DAY**—Specifies day lights.
    - **PRO\_PDF\_U3D\_LIGHT\_BRIGHT**— Specifies bright lights.
    - **PRO\_PDF\_U3D\_LIGHT\_PRIMARY**—Specifies primary color lights.
    - **PRO\_PDF\_U3D\_LIGHT\_NIGHT**—Specifies night lights.
    - **PRO\_PDF\_U3D\_LIGHT\_BLUE**—Specifies blue lights.
    - **PRO\_PDF\_U3D\_LIGHT\_RED**—Specifies red lights.
    - **PRO\_PDF\_U3D\_LIGHT\_CUBE**—Specifies cube lights.
    - **PRO\_PDF\_U3D\_LIGHT\_CAD**—Specifies CAD optimized lights. This is the default value.

- 
- PRO\_PDF\_U3D\_LIGHT\_HEADLAMP—Specifies headlamp lights.
  - PRO\_PDFOPT\_RENDER\_STYLE\_DEFAULT—Enables you to set the default rendering style used while exporting Creo Parametric models in the U3D format to a one-page PDF file. The values are:
    - PRO\_PDF\_U3D\_RENDER\_BOUNDING\_BOX—Specifies bounding box rendering.
    - PRO\_PDF\_U3D\_RENDER\_TRANSPARENT\_BOUNDING\_BOX—Specifies transparent bounding box rendering.
    - PRO\_PDF\_U3D\_RENDER\_TRANSPARENT\_BOUNDING\_BOX\_OUTLINE—Specifies transparent bounding box outline rendering.
    - PRO\_PDF\_U3D\_RENDER\_VERTICES—Specifies vertices rendering.
    - PRO\_PDF\_U3D\_RENDER\_SHADED\_VERTICES—Specifies shaded vertices rendering.
    - PRO\_PDF\_U3D\_RENDER\_WIREFRAME—Specifies wireframe rendering.
    - PRO\_PDF\_U3D\_RENDER\_SHADED\_WIREFRAME—Specifies shaded wireframe rendering.
    - PRO\_PDF\_U3D\_RENDER\_SOLID—Specifies solid rendering. This is the default.
    - PRO\_PDF\_U3D\_RENDER\_TRANSPARENT—Specifies transparent rendering.
    - PRO\_PDF\_U3D\_RENDER\_SOLID\_WIREFRAME—Specifies solid wireframe rendering.
    - PRO\_PDF\_U3D\_RENDER\_TRANSPARENT\_WIREFRAME—Specifies transparent wireframe rendering.
    - PRO\_PDF\_U3D\_RENDER\_ILLUSTRATION—Specifies illustrated rendering.
    - PRO\_PDF\_U3D\_RENDER\_SOLID\_OUTLINE—Specifies solid outlined rendering.
    - PRO\_PDF\_U3D\_RENDER\_SHADED\_ILLUSTRATION—Specifies shaded illustrated rendering.
    - PRO\_PDF\_U3D\_RENDER\_HIDDEN\_WIREFRAME—Specifies hidden wireframe rendering.
  - PRO\_PDFOPT\_SIZE—Enables you to specify the page size of the exported PDF file. The values are restricted to the value of ProPlotPaperSize. If the value is VARIABLE\_SIZE\_IN\_MM\_PLOT or VARIABLE\_SIZE\_PLOT,

---

the size must be specified in the `PRO_PDFOPT_HEIGHT` and `PRO_PDFOPT_WIDTH` properties.

- `PRO_PDFOPT_ORIENTATION`—Enables you to specify the orientation of the pages in the exported PDF file. The values are:
  - `PRO_ORIENTATION_PORTRAIT`—Exports the pages in portrait orientation. This is the default.
  - `PRO_ORIENTATION_LANDSCAPE`—Exports the pages in landscape orientation.

The option `PRO_PDFOPT_ORIENTATION` is not available if the property `PRO_PDFOPT_SIZE` is set to `VARIABLE_SIZE_IN_MM_PLOT` or `VARIABLE_SIZE_PLOT`.

- `PRO_PDFOPT_VIEW_TO_EXPORT`—Enables you to specify the view or views to be exported to the PDF file. The values are:
  - `PRO_PDF_VIEW_SELECT_CURRENT`—Exports the current graphical area to a one-page PDF file.
  - `PRO_PDF_VIEW_SELECT_BY_NAME`—Exports the selected view to a one-page PDF file with the view name printed at the bottom center of the view port. If this value is assigned, then the value of the string property `PRO_PDFOPT_SELECTED_VIEW` must also be included.
  - `PRO_PDF_VIEW_SELECT_ALL`—Exports all the views to a multi-page PDF file. Each page contains one view with the view name displayed at the bottom center of the view port.
- `PRO_PDFOPT_INCL_ANNOT`—Enables you to specify if annotations must be included when Creo Parametric models are exported as U3D graphics in a PDF file. The values are:
  - `PRO_PDF_INCLUDE_ANNOTATION`—Includes annotations when models are exported.
  - `PRO_PDF_EXCLUDE_ANNOTATION`—Excludes annotations when models are exported. This is the default value.

The function `ProPDFoptionsBoolpropertySet()` sets the value for a boolean property of the PDF options structure. The types of export options are as follows:

- `PRO_PDFOPT_SEARCHABLE_TEXT`—If true, stroked text is searchable. The default value is true.
- `PRO_PDFOPT_LAUNCH_VIEWER`—If true, launches the Adobe Acrobat Reader. The default value is true.

- 
- `PRO_PDFOPT_HYPERLINKS`—Sets Web hyperlinks to be exported as label text only or sets the underlying hyperlink URLs as active. The default value is true, specifying that the hyperlinks are active.
  - `PRO_PDFOPT_BOOKMARK_ZONES`—If true, adds bookmarks to the PDF showing zoomed in regions or zones in the drawing sheet. The zone on an A4-size drawing sheet is ignored.
  - `PRO_PDFOPT_BOOKMARK_VIEWS`—If true, adds bookmarks to the PDF document showing zoomed in views on the drawing.
  - `PRO_PDFOPT_BOOKMARK_SHEETS`—If true, adds bookmarks to the PDF document showing each of the drawing sheets.
  - `PRO_PDFOPT_BOOKMARK_FLAG_NOTES`—If true, adds bookmarks to the PDF document showing the text of the flag note.
  - `PRO_PDFOPT_RESTRICT_OPERATIONS`—If true, allows you to restrict or limit operations on the PDF document using the `ProPDFRestrictOperationsMode` modification flags. The default is false.
  - `PRO_PDFOPT_ALLOW_PRINTING`—If true, allows you to print the PDF document. The default value is true.
  - `PRO_PDFOPT_ALLOW_COPYING`—If true, allows you to copy content from the PDF document. The default value is true.
  - `PRO_PDFOPT_ALLOW_ACCESSIBILITY`—If true, enables visually-impaired screen reader devices to extract data independent of the value of the enum `ProPDFRestrictOperationsMode`. The default value is true.
  - `PRO_PDFOPT_PENTABLE`—If true, uses the standard Creo Parametric pentable to control the line weight, line style, and line color of the exported geometry. The default value is false.
  - `PRO_PDFOPT_PENTAB_FOR_TEXT`—If true, the standard Creo Parametric pentable is used to control the thickness of the stroked text of the exported geometry. If false, the stroked text will be exported with their original thickness and the thickness value defined by the pentable will be ignored. The default value is true.
  - `PRO_PDFOPT_ADD_VIEWS`—If true, allows you to add view definitions to the U3D model from a file. The default value is true.

The function `ProPDFOptionsStringpropertySet()` sets the value for a string property of the PDF options structure. The types of export options are as follows:

- `PRO_PDFOPT_TITLE`—Specifies a title for the PDF document.
- `PRO_PDFOPT_AUTHOR`—Specifies the name of the person generating the PDF document.

- 
- `PRO_PDFOPT_SUBJECT`—Specifies the subject of the PDF document.
  - `PRO_PDFOPT_KEYWORDS`—Specifies relevant keywords in the PDF document.
  - `PRO_PDFOPT_PASSWORD_TO_OPEN`—Sets a password to open the PDF document. If the value is not set or `NULL`, anyone can open the PDF document without a password.
  - `PRO_PDFOPT_MASTER_PASSWORD`—Sets a password to restrict or limit the viewer operations that you can perform on the opened PDF document. If the value is set to `NULL`, you can make any changes to the PDF document regardless of the settings of the `PRO_PDFOPT_ALLOW_*` modification flags.
  - `PRO_PDFOPT_SHEET_RANGE`—Specifies the range of sheets in a Creo Parametric drawing that are to be exported to a PDF file. If this property is assigned, then the integer property `PRO_PDFOPT_SHEETS` is set to the value `PRINT_SELECTED_SHEETS`.
  - `PRO_PDFOPT_SELECTED_VIEW`—Sets the option `PRO_PDFOPT_VIEW_TO_EXPORT` to the value `PRO_PDF_VIEW_SELECT_BY_NAME`, if the corresponding view is successfully found.

The function `ProPDFOptionsDoublepropertySet()` sets the value for a double property of the PDF options structure. The types of export options are as follows:

- `PRO_PDFOPT_HEIGHT`—Enables you to set the height for a user-defined page size of the exported PDF file. The default value is 0.0. This option is available only if the enum `PRO_PDFOPT_SIZE` is set to `VARIABLE_SIZE_IN_MM_PLOT` or `VARIABLE_SIZE_PLOT`.
- `PRO_PDFOPT_WIDTH`—Enables you to set the width for a user-defined page size of the exported PDF file. The default value is 0.0. This option is available only if the enum `PRO_PDFOPT_SIZE` is set to `VARIABLE_SIZE_IN_MM_PLOT` or `VARIABLE_SIZE_PLOT`.
- `PRO_PDFOPT_TOP_MARGIN`—Enables you to specify the top margin of the view port. The default value is 0.0.
- `PRO_PDFOPT_LEFT_MARGIN`—Enables you to specify the left margin of the view port. The default value is 0.0.
- `PRO_PDFOPT_BACKGROUND_COLOR_RED`—Enables you to specify the default red background color that appears behind the U3D model. You can set any value within the range of 0.0 through 255.0. The default value is 255.0.
- `PRO_PDFOPT_BACKGROUND_COLOR_GREEN`—Enables you to specify the default green background color that appears behind the U3D model. You can set any value within the range of 0.0 through 255.0. The default value is 255.0.

- `PRO_PDFOPT_BACKGROUND_COLOR_BLUE`—Enables you to specify the default blue background color that appears behind the U3D model. You can set any value within the range of 0.0 through 255.0. The default value is 255.0.

The function `ProPDFExport()` exports the file to a PDF document based on the export settings defined in the PDF options structure. Specify the complete name and path, including the extension of the output file.

Use the function `ProPDFWithProfileExport()` to repeatedly export 2D drawings to the PDF format with the same export options. These options are stored in an XML file called a profile. You can have several such profiles. The input arguments to this function are:

- *model*—A drawing model to export. This drawing model must be open and the drawing window must be active.
- *output\_file*—The complete path to the output file with extension.
- *profile*—The path to the profile to be used.

Use the function `ProPDFOptionsFree()` to free the memory contained in the PDF options structure.

## Importing Parameter Files

Functions Introduced:

- **ProInputFileRead()**
- **ProInputFileReadWithFlags()**

The function `ProInputFileRead()` imports files of several types to create data in Creo Parametric. The file types are declared in `ProUtil.h`. The import formats and their type constants are as listed in the following table:

| Import Format                 | Creo TOOLKIT Functions          | Type Constant                          |
|-------------------------------|---------------------------------|----------------------------------------|
| Relations file                | <code>ProInputFileRead()</code> | <code>PRO_RELATION_FILE</code>         |
| Program file                  |                                 | <code>PRO_PROGRAM_FILE</code>          |
| Configuration options file    |                                 | <code>PRO_CONFIG_FILE</code>           |
| Setup file                    |                                 | <code>PRO_DWG_SETUP_FILE</code>        |
| Spool file                    |                                 | <code>PRO_SPOOL_FILE</code>            |
| Cable Parameters file         |                                 | <code>PRO_CABLE_PARAMS_FILE</code>     |
| Connector Parameters file     |                                 | <code>PRO_CONNECTOR_PARAMS_FILE</code> |
| Model Tree Configuration file |                                 | <code>PRO_ASSEM_TREE_CFG_FILE</code>   |
| Wirelist file                 |                                 | <code>PRO_WIRELIST_FILE</code>         |
| SLD Variant file              |                                 | <code>SLD_VARIANT_FILE</code>          |

The option `PRO_RELATION_FILE` reads a text file that contains a list of all the model relations and parameters relations in exactly the same format as the Creo Parametric user enters them.

---

Use the function `ProInputFileRead()` with the argument `PRO_CONNECTOR_PARAMS` to identify the connectors. To access parameters on connectors and their entry ports use the following arguments:

- *arg1*—Represents the integer pointer to `ProIdTable`. `ProIdTable` is an integer array of component identifiers.
- *arg2*—Represents the integer pointer to the number of component identifiers.

Use the function `ProInputFileRead()` with the argument `PRO_CABLE_PARAMS_FILE` to read cable parameters. You need to set the following arguments:

- *arg1*—Represents a `ProSolid` (part pointer).
- *arg2*—Represents the cable name.

Use the function `ProInputFileRead()` with the argument `PRO_WIRELIST_FILE` to read files in Mentor Graphics LCABLE format. This function does not create wires, but provides parameters from a wire list for use when creating in a harness assembly a wire with the same name as that in the LCABLE file.

Use the function `ProInputFileRead()` with the argument `PRO_RELATION_FILE` to get the individual feature relations. To access feature relations use the following arguments:

- *arg2*—Represents the individual feature relations. It is an integer pointer to the feature identifier that gets the relations contained in a feature. If this is `NULL` you get the relations contained in the model.
- *arg3*—It is an integer pointer. If it points to 1, then the relations in the file must be added to the current relations, otherwise the relations in the file must replace the current relations.

Use function `ProInputFileRead()` with argument `PRO_SPOOL_FILE` to create new spools or update existing ones.

The function `ProInputFileReadWithFlags()` imports files of several types to create data in Creo Parametric. The input arguments are:

- *model*—A valid object in memory.
- *filename*—Input file name with the file extension.
- *file\_type*—File type to be read or imported. This argument is specified using the enumerated data type `ProImportExportFile`. The valid values are:
  - `PRO_RELATION_FILE`
  - `PRO_IGES_SECTION`
  - `PRO_PROGRAM_FILE`
  - `PRO_CONFIG_FILE`

- 
- PRO\_DWG\_SETUP\_FILE
  - PRO\_SPOOL\_FILE
  - PRO\_CABLE\_PARAMS\_FILE
  - PRO\_CONNECTOR\_PARAMS\_FILE
  - PRO\_ASSEM\_TREE\_CFG\_FILE
  - PRO\_WIRELIST\_FILE
  - SLD\_VARIANT\_FILE

 **Note**

| If the input argument <i>file_type</i> has the valid value                             | then                                                                                                                                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_CONFIG_FILE                                                                        | The input argument <i>model</i> is ignored.                                                                                                                                                                                                                                                                                   |
| PRO_RELATION_FILE                                                                      | The function <code>ProInputFileReadWithFlags()</code> does not regenerate after reading the file, it checks for the syntax errors. To regenerate the object, use the function <code>ProSolidRegenerate()</code> .                                                                                                             |
| PRO_DWG_SETUP_FILE                                                                     | The function <code>ProInputFileReadWithFlags()</code> does not repaint the screen. If the input argument <i>model</i> is NULL, the function <code>ProInputFileReadWithFlags()</code> uses the current drawing.                                                                                                                |
| PRO_CABLE_PARAMS_FILE, PRO_CONNECTOR_PARAMS_FILE, PRO_DWG_SETUP_FILE or PRO_SPOOL_FILE | The input argument <i>filename</i> should be a file name and extension, not a full path.                                                                                                                                                                                                                                      |
| PRO_IGES_SECTION                                                                       | This operates only on the active section of the model. You have to place the imported section geometry in the active section with a mouse click.                                                                                                                                                                              |
| PRO_CONNECTOR_PARAMS_FILE                                                              | The input argument <i>arg1</i> is the <code>int</code> pointing to <code>ProIdTable</code> . <code>ProIdTable</code> is an integer array of component identifiers.<br><br>The input argument <i>arg2</i> is the integer pointer <code>int</code> pointing to the number which is equal to the number of component identifiers |
| PRO_CABLE_PARAMS_FILE                                                                  | The input argument <i>arg1</i> is the <code>ProSolid</code> part pointer.<br><br>The input argument <i>arg2</i> is the <code>wchar_t*</code> to the cable name.                                                                                                                                                               |
| PRO_RELATION_FILE                                                                      | The input argument <i>arg2</i> is the integer pointer <code>int</code> pointing to feature ID. Pass it as NULL to get relations of the model.<br><br>The input argument <i>arg3</i> is the integer pointer <code>int</code> pointing to the feature ID. Pass it as NULL to get relations of the model.                        |

- *flags*—Bitwise flags or `PRO_IMPORT_EXPORT_NO_FLAGS`. This flag enables the interactive user interface in Creo Parametric. For example, if an error occurs while reading or executing an imported `PRO_PROGRAM_FILE` file, an interactive dialog box opens in Creo Parametric asking you if you want to continue with the operation.
- *arg1*, *arg2*, and *arg3*—The application data.
- *arg4*—unused

## Importing 2D Models

| Import Format                                            | Creo TOOLKIT Functions                    | Type Constant                     |
|----------------------------------------------------------|-------------------------------------------|-----------------------------------|
| STEP file                                                | <code>Pro2dImportMdlnameCreate()</code> , | <code>PRO_STEP_FILE</code>        |
| IGES (2D) file                                           | <code>Pro2dImportAppend()</code>          | <code>PRO_IGES_FILE</code>        |
| DXF file                                                 |                                           | <code>PRO_DXF_FILE</code>         |
| DWG file                                                 |                                           | <code>PRO_DWG_FILE</code>         |
| CGM file                                                 |                                           | <code>PRO_CGM_FILE</code>         |
| MEDUSA file                                              |                                           | <code>PRO_MEDUSA_FILE</code>      |
| Creo Elements/Direct drafting files (.mi, .bi, and .bdl) |                                           | <code>PRO_CCD_DRAWING_FILE</code> |
| IGES (2D) file                                           | <code>ProInputFileRead()</code>           | <code>PRO_IGES_SECTION</code>     |

Functions Introduced:

- **`Pro2dImportMdlnameCreate()`**
- **`Pro2dImportAllSheets()`**
- **`Pro2dImportAppend()`**
- **`ProInputFileRead()`**

The function `Pro2dImportMdlnameCreate()` imports interface files and creates a new two-dimensional model with the specified name. The created models can be drawings, layouts, diagrams, drawing formats. Use the argument to control whether or not to import two-dimensional views.

If you want to import all the drawing sheets for formats that support multiple drawing sheets, use the function `Pro2dImportAllSheets()`. The function imports interface files with all the drawing sheets, and creates a new two-dimensional model. For the model type `PRO_MDL_DWGFORM`, only the first two drawing sheets are imported.

The function `Pro2dImportAppend()` appends a two-dimensional model to the specified model.

You can import and append the Creo Elements/Direct drafting files using the functions `Pro2dImportMdlnameCreate()` and `Pro2dImportAppend()`.

Use the function `Pro2dImportMdlnameCreate()` to import the Creo Elements/Direct drafting file to a Creo Parametric drawing file. The following data is imported from the .mi, .bi, and .bdl format files:

- Basic entities such as point, line, arc, fillet, circle, polygon, text, spline, b-spline, center line, symmetry line, reference text line, and projected reference points
- 2D construction geometry such as lines, arcs, circles, splines, and so on
- Linear, angular, radial, diameter, ordinate, and leader dimensions
- Tolerance values in dimensions
- Leader and non-leader notes
- Annotation views
- Drawing sheets, symbol, views, and layers
- The attributes of color, layers, line types, and text fonts
- All types of hatch including user-defined hatches

You can set the mapping options in the mapping file `mi_import.pro`. The entity attributes such as color, line type, text fonts, leader arrow styles and so on are imported from Creo Elements/Direct drafting files to Creo Parametric drawing files depending on the settings in the mapping file.

Refer to the Creo Parametric Data Exchange Help for more information on importing Creo/Elements Direct drafting files in Creo Parametric drawing file.

Use the function `ProInputFileRead()` with the argument `PRO_IGES_SECTION` to import a 2D IGES section into a sketch.

## Importing 3D Models

The functions described in this section are used to import files of different format types into Creo Parametric.

Functions Introduced:

- **ProIntfimportSourceTypeGet()**
- **ProIntfimportWithProfileSourceTypeGet()**
- **ProIntfimportModelWithOptionsMdlnameCreate()**
- **ProIntfimportLayerFilter()**

| Import Format         | Creo TOOLKIT Functions                       | Type Constant                 |
|-----------------------|----------------------------------------------|-------------------------------|
| ACIS file             | ProIntfimportModelWithOptionsMdlnameCreate() | PRO_INTF_IMPORT_ACIS          |
| CADDS file            |                                              | PRO_INTF_IMPORT_CADDS         |
| CATIA (.model) file   |                                              | PRO_INTF_IMPORT_CATIA_MODEL   |
| CATIA (.session) file |                                              | PRO_INTF_IMPORT_CATIA_SESSION |
| DXF file              |                                              | PRO_INTF_IMPORT_DXF           |

| Import Format                                                                                                                                                                                           | Creo TOOLKIT Functions | Type Constant                          |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|----------------------------------------|
| ICEM file                                                                                                                                                                                               |                        | PRO_INTF_IMPORT_ICEM                   |
| IGES file                                                                                                                                                                                               |                        | PRO_INTF_IMPORT_IGES                   |
| Neutral file                                                                                                                                                                                            |                        | PRO_INTF_IMPORT_NEUTRAL                |
| Parasolid-based CADDs system file                                                                                                                                                                       |                        | PRO_INTF_IMPORT_PARASOLID              |
| POLTXT file                                                                                                                                                                                             |                        | PRO_INTF_IMPORT_POLTXT                 |
| STEP file                                                                                                                                                                                               |                        | PRO_INTF_IMPORT_STEP                   |
| VDA file                                                                                                                                                                                                |                        | PRO_INTF_IMPORT_VDA                    |
| CATIA (.CATpart) file                                                                                                                                                                                   |                        | PRO_INTF_IMPORT_CATIA_PART             |
| UG file                                                                                                                                                                                                 |                        | PRO_INTF_IMPORT_UG                     |

| Solid Edge Sheet metal (.psm) file                                                                                                                                                                      |                        | PRO_INTF_IMPORT_SEEDGE_SHEETMETAL_PART |
| 3D Manufacturing Format (3MF)                                                                                                                                                                           |                        | PRO_INTF_IMPORT_3MF                    |

The following data is included during the import of models from other formats to Creo Parametric:

- **3D Manufacturing Format (3MF)**—From Creo Parametric 5.0.1.0 onward, you can import 3MF files containing part and assembly models to Creo Parametric. You can import part-level colors, top-assembly parameters, and facet geometry from 3MF models to Creo Parametric.

- 
- Autodesk Inventor—You can import Autodesk Inventor models to Creo Parametric. The import includes basic geometry such as solids, quilts, and surfaces from Autodesk Inventor models to Creo Parametric. You can also import datum features, colors, attributes, and wire body datum curves from Inventor part and assembly models.

---

 **Note**

Depending on the Autodesk Inventor model, Creo Parametric imports the model as a part or an assembly. To let Creo Parametric decide if the Autodesk Inventor model must be imported as a part or assembly, in the function

`ProIntfimportModelWithOptionsMdlnameCreate()`, you must specify the input argument `ProMdlType` as `PRO_MDL_UNUSED`.

---

- JT—JT models are imported to Creo Parametric with their color overrides. Components with color overrides at any level in an assembly structure are supported.

From Creo Parametric 3.0 onward, the Product Manufacturing Information (PMI) of the annotations is imported as semantic representation from JT models to Creo Parametric models. The semantic import is supported only for 3D notes and basic dimensions. All the other types of annotations are imported as graphical entities. You can import the planar and zonal cross-sections of part and assembly models from JT files to Creo Parametric.

---

 **Note**

From Creo Parametric M200 2.0 onward, the license `INTF_for_JT` is required to import a JT file to Creo Parametric. If the license is not available the functions return the error `PRO_TK_NO_LICENSE`.

---

- Creo Elements/Direct—From Creo Parametric 3.0 onward, the Product Manufacturing Information (PMI) of the annotations is imported as semantic representation from Creo Elements/Direct models to Creo Parametric models. The semantic import is supported only for 3D notes and basic dimensions. All the other types of annotations are imported as graphical entities. You can also import the clipping features owned by the Creo Elements/Direct part and assembly models as cross-sections in Creo Parametric.
- Creo View—You can import colors assigned to the components of assemblies and their sub-assembly models, including the colors of the sub-level entities such as parts, quilts, and faces from Creo View to Creo Parametric. Creo View models are imported to Creo Parametric with their color overrides.

---

Components with color overrides at any level in an assembly structure are supported. Along with components, color overrides are also supported for component model items, such as, face and quilts.

- SolidWorks—You can import basic geometry such as solids, quilts, and surfaces from SolidWorks models to Creo Parametric. The import includes datum features, colors, attributes, and layers.

---

 **Note**

Depending on the SolidWorks model, Creo Parametric imports the model as a part or an assembly. To let Creo Parametric decide if the SolidWorks model must be imported as a part or assembly, in the function

`ProIntfimportModelWithOptionsMdlnameCreate()`, you must specify the input argument `ProMdlType` as `PRO_MDL_UNUSED`.

---

- Solid Edge—From Creo Parametric 3.0 M010 onward, you can import Solid Edge part and assembly models to Creo Parametric. The import includes boundary representation geometry, datum features, colors, and attributes.

From Creo Parametric 3.0 M030 onward, Solid Edge models are imported to Creo Parametric with their color overrides. Components with color overrides at any level in an assembly structure are supported.

From Creo Parametric 3.0 M020 onward, you can also import a Solid Edge sheet metal part to Creo Parametric.

---

 **Note**

Depending on the Solid Edge model, Creo Parametric imports the model as a part or an assembly. To let Creo Parametric decide if the Solid Edge model must be imported as a part or assembly, in the function

`ProIntfimportModelWithOptionsMdlnameCreate()`, you must specify the input argument `ProMdlType` as `PRO_MDL_UNUSED`.

---

- 
- **Unigraphics**—You can import basic geometry such as solids, quilts, and surfaces from Unigraphics models to Creo Parametric. The import includes datum features, colors, attributes, and layers.

---

 **Note**

Depending on the Unigraphics model, Creo Parametric imports the model as a part or an assembly. To let Creo Parametric decide if the Unigraphics model must be imported as a part or assembly, in the function `ProIntfimportModelWithOptionsMdlnameCreate()`, you must specify the input argument `ProMdlType` as `PRO_MDL_UNUSED`.

---

---

 **Note**

Refer to the Creo Parametric Data Exchange Help for more information on importing geometry to Creo Parametric. Refer to the compatibility matrix on PTC.com for the supported software versions.

---

The function `ProIntfimportSourceTypeGet()` is a utility that returns the type of model that can be created from the geometry file. This function is not applicable for all formats. If this function is not valid for a geometric file, you will need to know the type of model you want to create (part, assembly, or drawing).

The function `ProIntfimportWithProfileSourceTypeGet()` determines the type of model expected to be created by the import operation based on the profile settings. The input arguments follow:

- *import\_file*—Full path to the import file.
- *profile\_file*—Full path to the profile file. If the value of this argument is passed as `NULL`, the default profile is used.
- *type*—The type of file to be imported.

The output argument of the function `mdl_type` is the type of model that can be created from the specified import file and profile settings.

The function `ProIntfimportModelWithOptionsMdlnameCreate()` imports objects of other formats using a profile and creates a new model or set of models with the specified name and representation. Once the profile is set, it remains valid for the entire session unless it is reset with another profile. The input arguments of this function are:

- *import\_file*—Full path to file to be imported.
- *profile*—The import profile path. An import profile is an XML file with the extension `.dip`. It contains the options that control an import operation. It

---

also contains all the options for the supported 3D import formats. Refer to the Creo Parametric Online Help for more information on creation and modification of import profiles.

---

 **Note**

The input argument *profile* allows you to include the import of Creo Elements/Direct containers, face parts, wire parts, and empty parts.

---

- *type*—The type of file to be imported.

The following formats are supported for importing structure and graphics level of details:

- Creo View (i.e. Product View, .ol, .ed, .edz, .pvs, .pvz) files (PRO\_INTF\_IMPORT\_PRODUCTVIEW)
- CATIA V5 (CATPart (PRO\_INTF\_IMPORT\_CATIA\_PART, CATProduct (PRO\_INTF\_IMPORT\_CATIA\_PRODUCT), CGR (PRO\_INTF\_IMPORT\_CATIA\_CGR)) files
- SolidWorks (.sldprt (PRO\_INTF\_IMPORT\_SW\_PART), .sldasm (PRO\_INTF\_IMPORT\_SW\_ASSEM)) files
- Unigraphics NX (PRO\_INTF\_IMPORT\_UG) files
- *create\_type*—The type of model to create. This could be part, assembly, or drawing (for STEP associative drawings).
- *rep\_type*—The representation type to be used for importing. The enumerated type `ProImportRepType` defines the representation type and has the following values:
  - PRO\_IMPORTREP\_MASTER—This is the default import type. It imports the geometric and the nongeometric data (annotations, datums, coordinate systems, creation of features and so on) of the assembly and displays the full representation of the assembly.
  - PRO\_IMPORTREP\_STRUCTURE—Imports the product structure or the meta data of the assemblies.
  - PRO\_IMPORTREP\_GRAPHICS—Imports the display data of the assemblies.

---

 **Note**

The import representation types `PRO_IMPORTREP_STRUCTURE` and `PRO_IMPORTREP_GRAPHICS` do not create model geometry in Creo Parametric, although they allow the import of the fully-functional assemblies.

---

- *new\_model\_name*— The name of the new top level import model.
- *filter\_func*—Callback to the function `ProIntfimportLayerFilter()` that determines how to display and map layers from the imported model. If this is `NULL`, the default layer handling will take place.
- *application\_data*—The application data to be passed to the filter function. Can be `NULL`.
- *created\_model*—The handle to the created model (in case of an assembly – the handle to the top assembly). Even if this is `NULL`, the model is created.

---

## Note

- When importing an assembly using the function `ProIntfimportModelWithOptionsMdlnameCreate()` if any component of the assembly is missing, then during import an empty placeholder with the missing component name is created in the model tree. For example, during import if the missing component is a part, an empty part is created. Similarly, if the missing component is a subassembly, then an empty subassembly is created. Placeholders for missing components are created only for the following formats:
  - CATIA V5
  - CATIA V4
  - Unigraphics
  - CADD5 5
  - SolidWorks
  - Creo View (.ol and .ed) files
  - JT Open format
- Use the function `ProIntfimportModelWithOptionsMdlnameCreate()` with *profile* as NULL and *rep type* (representation type) as `PRO_IMPORTREP_MASTER`.
  - From Creo Parametric 3.0 M080 onward, the function `ProIntfimportModelWithOptionsMdlnameCreate()` imports a JT file to Creo Parametric only if the license `INTF_for_JT` is available. If the license is not available the functions return the error `PRO_TK_NO_LICENSE`.
  - From Creo Parametric 2.0 M200 onward, the function `ProIntfimportModelWithProfileCreate()` imports a JT file to Creo Parametric only if the license `INTF_for_JT` is available. If the license is not available the functions return the error `PRO_TK_NO_LICENSE`.

---

The function `ProIntfimportModelWithProfileCreate()` imports objects of other formats using a profile and creates a new model or set of models with the specified name.

The function `ProIntfimportModelWithProfileCreate()` has been deprecated. Use the function `ProIntfimportModelWithOptionsMdlnameCreate()` instead with `PRO_IMPORTREP_MASTER` as the representation type.

---

The function `ProIntfimportLayerFilter()` is a callback function that allows your application to determine the status of each of the imported layers. You can modify the layer information using the functions described in the next section.

## Modifying the Imported Layers

Layers help you organize model items so that you can perform operations on those items collectively. These operations primarily include ways of showing the items in the model, such as displaying or blanking, selecting, and suppressing. The methods described in this section modify the attributes of the imported layers.

Functions Introduced:

- **ProLayerfilterdataNameGet()**
- **ProLayerfilterdataNameSet()**
- **ProLayerfilterdataCountsGet()**
- **ProLayerfilterdataActionSet()**

Imported layers are identified by their names. The function `ProLayerfilterdataNameGet()` returns the name of the layer while the function `ProLayerfilterdataNameSet()` can be used to set the name of the layer.

The function `ProLayerfilterdataCountsGet()` specifies the following:

- Number of curves on the specified layer
- Number of surfaces on the specified layer
- Number of trimmed surfaces on the specified layer

The function `ProLayerfilterdataActionSet()` sets the display status of the imported layers. You can set the display status of the layers to one of the following:

- Show—Display the specified layer.
- Blank—Make the specified layer blanked.
- Hidden—(Assembly mode only) Make the specified layer hidden.
- Skip—Do not import the entities on this layer.
- Ignore—Import only entities on this layer but not the layer

### Example 5: Importing a 3D Model With Layer Filter Options

The sample code in `UgInterfaceImport.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_interface` shows how to import from an IGES file while filtering out a certain layer to be renamed and blanked, using the filter function `UserLayerFilter()`. It also demonstrates how to use the function `ProIntfimportSourceTypeGet()` to determine the type of the model.

---

## Validation Score for Imports

Functions Introduced:

- **ProIntfimportValidationscoreCalculate()**
- **ProIntfimportValidationscoreGet()**
- **ProIntfimportValidationpreferencesLoad()**

You can import CATIA V5, NX, SolidWorks, SolidEdge, Autodesk Inventor, and Creo View files with various properties such as surface area, volume, and the coordinates for the center of gravity (COG) into Creo Parametric. After import, Creo Parametric has to calculate the value of these properties and report if there are any differences in the values. Also general failures during import, such as, failure to import an assembly component or failure to solidify a part must be reported.

To report the value differences and failures, the validation score for a model is created. The validation score is created for imported, regenerated, or updated models. The properties such as, surface area, volume, and the coordinates for the center of gravity (COG) are converted in to geometrical validation properties. Assembly models include the validation property that is related to the product structure. Creo Parametric compares the validation properties of the imported models with the mass properties of the source models and computes a score of the data conversion. The validation score of a model `PTC_VAL_IMP_SCORE` is a model parameter. The score is created for the parent assembly and its individual components and has the following values:

- `PASS`
- `PASS_WITH_WARNINGS`
- `FAIL`

Use the function `ProIntfimportValidationscoreCalculate()` to calculate the validation score for the specified model. The function `ProIntfimportValidationscoreGet()` retrieves the validation score for the specified model, where the score is already calculated using the function `ProIntfimportValidationscoreCalculate()`.

The validation score depends on the data conversion from source files to Creo Parametric. If you want certain parameters to be ignored and passed, you can set these preferences for validation data in the `config.val` file. Use the function `ProIntfimportValidationpreferencesLoad()` to specify the `config.val` file that must be used to load the preferences for data validation while calculating validation score.

Refer to the Creo Parametric Data Exchange online help, for more information.

---

# Interface: Importing Features

## Interface: Importing Features

This section describes how to create import features in Creo Parametric.

---

### Note

PTC strongly recommends that you create import features in a Creo Parametric session that has only those models open where the feature is to be created. It is also recommended not to follow the creation of import features with calls to the functions `ProMdlErase()` or `ProMdlEraseAll()` until the control returns to Creo Parametric, since this may interfere with erasing temporary objects at the end of the import.

---

## Creating Import Features from Files

To create import features in Creo Parametric from external format files use the functions described in this section.

Functions Introduced:

- **ProIntfDataSourceInit()**
- **ProImportfeatCreate()**
- **ProImportfeatureWithProfileCreate()**

Superseded Functions

- **ProImportfeatWithProfileCreate()**

The function `ProIntfDataSourceInit()` is used to build the interface data source required by the functions `ProImportfeatCreate()` and `ProImportfeatureWithProfileCreate()`.

The input arguments of this function are:

- *intf\_type*—Specifies the type of file to import. The valid format files from which the user can create the import features are specified in the enumerated data type `ProIntfType`:

| Type Constant                      | Import Format |
|------------------------------------|---------------|
| <code>PRO_INTF_NEUTRAL_FILE</code> | Neutral file  |
| <code>PRO_INTF_IGES</code>         | IGES 3D file  |
| <code>PRO_INTF_STEP</code>         | STEP file     |
| <code>PRO_INTF_VDA</code>          | VDA file      |
| <code>PRO_INTF_SET</code>          | SET file      |

| Type Constant               | Import Format                               |
|-----------------------------|---------------------------------------------|
| PRO_INTF_PDGS               | PDGS file                                   |
| PRO_INTF_ICEM               | ICEM file                                   |
| PRO_INTF_ACIS (*.sat)       | ACIS format file                            |
| PRO_INTF_DXF                | DXF file                                    |
| PRO_INTF_CDRS               | CDRS file                                   |
| PRO_INTF_STL                | STL file                                    |
| PRO_INTF_VRML               | VRML file                                   |
| PRO_INTF_PARASOLID          | Parasolid-based CADDs system file           |
| PRO_INTF_AI                 | AI file                                     |
| PRO_INTF_CATIA_PART         | CATIA (.CATpart) file                       |
| PRO_INTF_UG                 | UG file                                     |
| PRO_INTF_PRODUCTVIEW        | Creo View (.ol) files                       |
| PRO_INTF_CATIA_PRODUCT      | CATIA V5 Assembly file                      |
| PRO_INTF_CATIA_CGR          | CATIA Graphical Representation (CGR) format |
| PRO_INTF_JT                 | JT Open Interface                           |
| PRO_INTF_INVENTOR_PART      | Inventor Part (.ipt) file                   |
| PRO_INTF_INVENTOR_ASM       | Inventor Assembly (.iam) file               |
| PRO_INTF_SE_PART            | Solid Edge part (.par) file                 |
| PRO_INTF_SE_SHEETMETAL_PART | Solid Edge Sheet metal (.psm) file          |
| PRO_INTF_3MF                | 3D Manufacturing Format (3MF)               |

- *p\_source*—the name of the file with extension. The specified format file should exist in the current working directory or in a path specified in the *search\_path* configuration option.

This function returns the handle to the `ProIntfDataSource` object, which should be passed to the functions `ProImportfeatCreate()` and `ProImportfeatureWithProfileCreate()`.

The function `ProImportfeatCreate()` is used to create a new import feature in the Creo Parametric solid model. The input arguments of this function are:

- *p\_solid*—Specifies the part in which the user wants to create the import feature.
- *data\_source*—Specifies a pointer to the interface data source. Use the function `ProIntfDataSourceInit()` to get the handle to the `ProIntfDataSource` object.
- *p\_csys* — Specifies the coordinate system of the part with which the user wants to align the import feature. If this is `NULL`, the function uses the default coordinate system in the Creo Parametric model and the import feature will be aligned with respect to this coordinate system.

- 
- *p\_attributes*—Specifies the attributes for the creation of the new import feature. Please see the section [Import Feature Attributes on page 746](#) for more information.

---

 **Note**

From Creo Parametric 2.0 M200 onward, the function `ProImportfeatCreate()` imports a JT file to Creo Parametric only if the license `INTF_for_JT` is available. If the license is not available the function returns the error `PRO_TK_NO_LICENSE`.

---

The function `ProImportfeatCreate()` returns the `ProFeature` handle for the created import feature.

In Creo Parametric 7.0.0.0 and later, the function `ProImportfeatWithProfileCreate()` is deprecated. Use the function `ProImportfeatureWithProfileCreate()` instead.

The function `ProImportfeatureWithProfileCreate()` is used to create a new import feature in the Creo Parametric solid model. The input arguments follow:

- *p\_solid*—Pointer to the solid part. Assembly case is not supported.
- *data\_source*—Source of data to create the import feature.
- *p\_csys*—Pointer to the reference coordinate system. If this is `NULL`, the function uses the default coordinate system.
- *profile*—Path to the import file. If this value is `NULL`, the function `ProImportfeatureWithProfileCreate()` works same as `ProImportfeatCreate()`.

---

 **Note**

An import profile is an XML file with the extension `dip` (Dex In Profile) and contains the options that control an import operation. It contains all the options for the supported 3D import formats. Refer to the Creo Parametric Help for more information on creation and modification of import profiles.

---

- *cut\_or\_add*—Set to `PRO_B_TRUE` for imported geometry representing a cut or `PRO_B_FALSE` otherwise.
- *body\_use\_opt*—Generic body options.
- *body\_arr*—`ProArray` of bodies. Size of `ProArray` must be 1.

---

The output argument `p_feat_handle` is the handle to the new import feature. If this is `NULL`, the feature is still created.

---

 **Note**

- The function `ProImportfeatureWithProfileCreate()` cannot create an import feature using an import profile for the STL and VRML formats. Once a profile is set, it remains valid for the entire session unless it is reset with another profile.
  - From Creo Parametric 2.0 M200 onward, the function `ProImportfeatureWithProfileCreate()` imports a JT file to Creo Parametric only if the license `INTF_for_JT` is available. If the license is not available the function returns the error `PRO_TK_NO_LICENSE`.
- 

The function `ProDatumcurveFromfileCreate()` creates a new import feature containing a datum curve in the Creo Parametric model. The input arguments of this function are:

- *p\_solid*—Specifies the part in which you create the import feature.
- *full\_file\_name*—Specifies the name of the file from which you create the import feature.
- *file\_type*—Specifies the file type to import. It is given by the `ProIntfType` enumerated type. The file types supported by this function are as follows.

| Type Constant                      | Import Format         |
|------------------------------------|-----------------------|
| <code>PRO_INTF_NEUTRAL_FILE</code> | Neutral file          |
| <code>PRO_INTF_IGES</code>         | IGES 3D file          |
| <code>PRO_INTF_STEP</code>         | STEP file             |
| <code>PRO_INTF_VDA</code>          | VDA file              |
| <code>PRO_INTF_ACIS</code>         | ACIS format file      |
| <code>PRO_INTF_DXF</code>          | DXF file              |
| <code>PRO_INTF_AI</code>           | AI file               |
| <code>PRO_INTF_CATIA_PART</code>   | CATIA (.CATpart) file |
| <code>PRO_INTF_UG</code>           | UG file               |
| <code>PRO_INTF_JT</code>           | JT Open Interface     |
| <code>PRO_INTF_IBL</code>          | IBL file              |
| <code>PRO_INTF_PTS</code>          | PTS file              |

For all other file types that are not supported, the function `ProDatumcurveFromfileCreate()` returns `PRO_TK_INVALID_TYPE`.

- 
- *p\_csys* — Specifies the coordinate system of the part with which you align the import feature. If this is `NULL`, the function uses the default coordinate system and the import feature is aligned with respect to this coordinate system.

---

 **Note**

From Creo Parametric 2.0 M200 onward, the function `ProDatumcurveFromFileCreate()` creates a new import JT feature only if the license `INTF_for_JT` is available. If the license is not available the function returns the error `PRO_TK_NO_LICENSE`.

---

## Creating Import Features from Arbitrary Geometric Data

You can create an import feature in a Creo Parametric model by building the required entity data in the Creo TOOLKIT application.

The advantages of importing features from a Creo TOOLKIT application are:

- You can create virtually non-parametric user-defined geometry at a desired location. This is sometimes an alternative to parametric feature creation, which can be more complicated.
- Import features are regenerated more quickly than corresponding groups of parametric features.
- You can integrate Creo Parametric with non-Creo Parametric supported geometry file formats.

The following sequence of steps is required to create the import feature from memory:

- Allocate the interface data.
- Add surfaces, edges, quilts, and datums.
- Create the import feature from the interface data.

These steps are described in detail in the following sections.

### Allocating `ProInterfacedata`

Function Introduced:

- **`ProIntfDataAlloc()`**

Use the function `ProIntfDataAlloc()` to allocate memory for the interface data structure.

---

## Adding Surfaces

Function Introduced:

- **ProSurfacedataAlloc()**

Use the function `ProSurfacedataAlloc()` to allocate memory for the surface data. Once the surface data is initialized, it will be appended to the interface data.

## Initializing Surface Data

Functions Introduced:

- **ProSurfacedataInit()**
- **ProPlanedataInit()**
- **ProCylinderdataInit()**
- **ProConedataInit()**
- **ProTorusdataInit()**
- **ProSrfreldataInit()**
- **ProTabcylldataInit()**
- **ProRulsrfddataInit()**
- **ProSplinesrfddataInit()**
- **ProCylsplrsrfddataInit()**
- **ProBsplinesrfddataInit()**
- **ProFilsrfddataInit()**

Use the function `ProSurfacedataInit()` to initialize the surface data structure.

The input arguments of this function are:

- *Surface\_type*—Specifies the type of surface to be created. The types of surfaces are:
  - `PRO_SRF_PLANE`—Plane
  - `PRO_SRF_CYL`—Cylinder
  - `PRO_SRF_CONE`—Cone
  - `PRO_SRF_TORUS`—Torus
  - `PRO_SRF_COONS`—Coons Patch
  - `PRO_SRF_SPL`—Spline Surface
  - `PRO_SRF_FIL`—Fillet Surface
  - `PRO_SRF_RUL`—Ruled Surface

- PRO\_SRF\_REV—General Surface of Revolution
- PRO\_SRF\_TABCYL—Tabulated Cylinder
- PRO\_SRF\_B\_SPL—B-spline surface
- PRO\_SRF\_FOREIGN—Foreign Surface
- PRO\_SRF\_CYL\_SPL—Cylindrical Spline Surface

The type of the surface determines the function to be used to initialize the surface data structure. For example, if the type of surface to be created is PRO\_SRF\_PLANE, then the function `ProPlanedataInit()` should be used to initialize the surface data structure

- *surf\_uv\_min*—Specifies the minimum uv extents of the surface.
- *surf\_uv\_max*—Specifies the maximum uv extents of the surface.
- *surf\_orient*—Specifies the orientation of the surface. By default the value is PRO\_SURF\_ORIENT\_OUT
- *p\_surf\_shape*—The data containing the information about the shape of the surface.
- *Surface\_Id*—Specifies a unique identifier of the Surface.

Depending on the shape of the surface, call one of the following functions to create the surface data structure `ProSurfaceshapedata` and assign it to variable `p_surf_shape` of function `ProSurfacedataInit()`. Ensure that the function used to create the `ProSurfaceshapedata` matches with the `ProSrftype` value used in `ProSurfacedataInit()`.

- `ProPlanedataInit()`
- `ProCylinderdataInit()`
- `ProConedataInit()`
- `ProTorusdataInit()`
- `ProSrfrevdataInit()`
- `ProTabcyldataInit()`
- `ProRulsrfddataInit()`
- `ProSplinesrfddataInit()`
- `ProCylsplsrfddataInit()`
- `ProBsplinesrfddataInit()`

---

### **Note**

Set the configuration option `intf_in_keep_high_deg_bspl_srfs` to YES to preserve the B-spline surfaces returned by `ProBsplinesrfddataInit()` in the `ProIntData` data structure. If this configuration option is not set, these surfaces are interpreted as spline surfaces.

---

- `ProFilsrfddataInit()`

Refer to the [Geometry Representations on page 2078](#) appendix for more information on how to use the above functions.

---

### **Note**

The following return values for the functions `ProBsplinesrfddataInit()`, `ProRulsrfddataInit()`, `ProSrfrevdataInit()`, and `ProTabcyldataInit()` should be treated as warnings:

`PRO_TK_BSPL_UNSUITABLE_DEGREE`

`PRO_TK_BSPL_NON_STD_END_KNOTS`

`PRO_TK_BSPL_MULTI_INNER_KNOTS`

They indicate that the geometry finally imported in Creo Parametric is different from the geometry initially supplied to the above functions. The geometry is not rejected by the functions and is used to generate the `ProSurfacedata` data structure.

---

## Surfacedata Contours

The geometric representation of the surface created above is unbounded, that is the nature of the surface boundaries is determined by its array of contours. Multiple contours can be used for surfaces with internal voids.

Functions Introduced:

- **`ProSurfacedataContourArraySet()`**
- **`ProContourdataAlloc()`**
- **`ProContourdataInit()`**
- **`ProContourdataEdgeIdArraySet()`**

---

Use the function `ProSurfacedataContourArraySet()` to set an array of contours on the surface.

The input arguments of this function are:

- *p\_surf\_data*—Specifies the surface data to which the array of contour data is to be set.
- *contour\_array*—Specifies an array of contours on the surface. The `ProContourdata` handle can be obtained by using the following functions in sequence:

`ProContourdataAlloc()`

`ProContourdataInit()`

`ProContourdataEdgeIdArraySet()`

Use the function `ProContourdataAlloc()` to allocate memory to the contour data structure.

Use the function `ProContourdataInit()` to initialize the contour data structure. The input argument of this function is:

- *contour\_trav* — Specifies the contour traversal. This parameter has the following values:
  - `PRO_CONTOUR_TRAV_INTERNAL`—Internal Contour
  - `PRO_CONTOUR_TRAV_EXTERNAL`—External Contour

The function returns the allocated contour data structure.

Use the function `ProContourdataEdgeIdArraySet()` to set identifiers to an array of edges, that form the boundary of the specified surface.

The input arguments of this function are:

- *p\_contour\_data*—Specifies the contour data to which the array of edge identifiers have to be set.
- *edge\_id\_arr*—Specifies the array of edge identifiers. These identifiers must be same as those provided in the `ProEdgedata` structures described below.

For example, if the surface is bounded by 4 edges, then the identifier of each edge should be assigned to each element of an array of integers of size 4.

## Appending the Surface Data to the Interface Data

Function Introduced:

- **`ProIntfDataSurfaceAppend()`**

Use the function `ProIntfDataSurfaceAppend()` to append the surface data into the interface data.

---

Repeat the sequence for each surface desired in the import feature.

## Adding Edges

Functions Introduced:

- **ProEdgedataAlloc()**
- **ProEdgedataInit()**
- **ProCurvedataAlloc()**
- **ProLinedataInit()**
- **ProArcdataInit()**
- **ProEllipsedataInit()**
- **ProSplinedataInit()**
- **ProBsplinedataInit()**

If the import feature to be created requires any edge information, then call the functions list above in sequence, else skip this section.

Use the function `ProEdgedataAlloc()` to allocate memory for the edge data structure. After initialization, this data will be appended to the interface data.

Use the function `ProEdgedataInit()` to initialize the edge data structure. The following are the input arguments:

- *edge\_id* — Specifies a unique identifier of the edge.
- *edge\_surf\_ids*—Specifies the ID of the surfaces on either side of the edge.
- *edge\_directions* —Specifies the edge directions on the surface.
- *edge\_uv\_point\_arr* —Specifies an array of UV points on the surfaces. The value can be `NULL`.
- *p\_edge\_uv\_curve\_data*—Specifies the edge UV curves on the surfaces. The value can be `NULL`.
- *p\_edge\_curve\_data*—Specifies the curve data handle in the form of the `ProCurvedata` structure. This data handle is returned by the functions `ProLinedataInit()`, `ProArcdataInit()`, `ProEllipsedataInit()`, `ProSplinedataInit()`, or `ProBsplinedataInit()`. Use the function `ProCurvedataFree` to free the `ProCurvedata` data handle.

---

 **Note**

PTC recommends that you split the closed loop edge into two or more continuous edges while specifying the inputs to the function `ProEdgedataInit()`. For example, to create a circular edge, instead of specifying the start angle as 0 and the end angle as 360, split the circular edge into 2 or more edges. The angular measurements of the split edges could be 0 to 30 for the first split and 30 to 360 for the second split. The function `ProEdgedataInit()` must be called for each split.

---

Use the function `ProCurvedataAlloc()` to allocate memory for the curve data structure. The curve data structure defines the edge profile.

Depending on the type of curve specified for the edge, call one of the following functions to initialize the curve data.

- `ProLinedataInit()`
- `ProArcdataInit()`
- `ProEllipsedataInit()`
- `ProSplinedataInit()`
- `ProBsplinedataInit()`

Use the function `ProLinedataInit()` to initialize the line data structure. Specify the start of the line and end of the line as inputs of this function.

Use the function `ProArcdataInit()` to initialize an arc data structure. The input arguments of this function are:

- *vector1*—Specifies the first vector of the arc coordinate system.
- *vector2*—Specifies the second vector of the arc coordinate system.
- *origin*—Specifies the center of the arc coordinate system
- *start\_angle*—Specifies the starting angle (in radians) of the arc.
- *end\_angle*—Specifies the end angle (in radians) of the arc.
- *radius*—Specifies the radius of the arc.

Use the function `ProEllipsedataInit()` to initialize an ellipse data structure. The input arguments of this function are:

- *center*—Specifies the center of the ellipse.
- *x\_axis*—Specifies the first (x) axis vector of the ellipse.
- *plane\_normal*—Specifies the axis vector that is normal to the plane of the ellipse.
- *x\_radius*—Specifies the radius of the ellipse in the direction of 'x' axis.

- *y\_radius*—Specifies the radius of the ellipse in the direction of ‘y’ axis. The ‘y’ axis can be found as a vector product of the `plane_normal` on `x_axis`.
- *start\_ang*—Specifies the starting angle (in radians) of the ellipse.
- *end\_ang*—Specifies the end angle (in radians) of the ellipse.

Use the function `ProSplinedataInit()` to initialize the spline data structure. The input arguments of this function are:

- *par\_arr*—Specifies an array of spline parameters
- *pnt\_arr*—Specifies an array of spline interpolant points
- *tan\_arr*—Specifies an array of tangent vectors at each point
- *num\_points*—Specifies the size for all the arrays

Use the function `ProBsplinedataInit()` to initialize the B-spline data structure. The input arguments of this function are:

- *degree*—Specifies the degree of the basis function.
- *params*—Specifies an array of knots on the parameter line.
- *weights*—In the case of rational B-splines, it specifies an array of the same dimension as the array of *c\_pnts*. Else, the value of this argument is `NULL`.
- *c\_pnts*—Specifies an array of knots on control points.
- *num\_knots*—Specifies the size of the *params* array.
- *num\_c\_points*—Specifies the size of the *c\_pnts* and the size of *weights* if it is not `NULL`.

---

### **Note**

Although `ProBsplinedataInit()` returns B-spline curves, these curves are interpreted as spline curves in the `ProIntData` data structure used by the function `ProImportfeatCreate()` while creating the import feature.

The values `PRO_TK_BSPL_UNSUITABLE_DEGREE` and `PRO_TK_BSPL_NON_STD_END_KNOTS` returned by `ProBsplinedataInit()` should be treated as warnings. These values indicate that the geometry finally imported in Creo Parametric is different from the geometry initially supplied to the function. The geometry is not rejected by `ProBsplinedataInit()` and is used to generate the `ProCurvedata` data structure.

---

---

## Appending the Edge Data to the Interface Data

Function Introduced:

- **ProIntfDataEdgeAppend()**

Use the function `ProIntfDataEdgeAppend()` to append the edge data into the interface data.

Repeat the sequence for each edge required by the import feature.

## Adding Quilts

Functions Introduced:

- **ProQuiltdataAlloc()**
- **ProQuiltdataInit()**
- **ProQuiltdataSurfArraySet()**
- **ProIntfDataQuiltAppend()**

Use the function `ProQuiltdataAlloc()` to allocate memory to the quilt data structure.

Use the function `ProQuiltdataInit()` to assign the user defined identity to the quilt data structure. Specify a unique identity for the quilt as the input argument. The function returns the handle to the quilt data structure.

Use the function `ProQuiltdataSurfArraySet()` to define an array of surfaces as a quilt. The input arguments of this function are:

- *p\_quilt\_data*—Specifies a handle to the quilt data to which we want to assign the set of surfaces.
- *arr\_p\_surf*—Specifies an array of surfaces that will be defined as a quilt.

Use the function `ProIntfDataQuiltAppend()` to append the quilt data to the interface data. The input arguments of this function are:

- *p\_intfdata* —Specifies a handle to the interface data to which you want to append the quilt data.
- *p\_quiltdata* —Handle to the quilt data.

Repeat the sequence for each quilt required in the import feature.

## Adding Datums

Functions Introduced:

- **ProDatumdataAlloc()**

Use the function `ProDatumdataAlloc()` to allocate memory to the datum data structure.

---

## Initializing Datums

- **ProDatumdataInit()**
- **ProDatumCsysdataInit()**
- **ProDatumCurvedataInit()**
- **ProDatumPlannedataInit()**
- **ProDatumdataMemoryFree()**

Use the function `ProDatumdataInit()` to initialize the datum data structure. The input arguments of this function are:

- *datum\_id*—Specifies a unique identifier of the datum.
- *datum\_type*—Specifies the datum type. The types of datums are:
  - `PRO_CSYS`
  - `PRO_CURVE`
  - `PRO_DATUM_PLANE`
- *datum\_name*—Specifies the name to be assigned to the datum.
- *p\_datum\_obj*—The datum object that contains the geometrical information about the datum. Depending on the type of the datum to be created, one of the following functions must be used to create the `ProDatumobject` data structure.
  - `ProDatumCsysdataInit()`
  - `ProDatumCurvedataInit()`
  - `ProDatumPlannedataInit()`

---

### Note

The value `PRO_TK_BSPL_MULTI_INNER_KNOTS` returned by `ProDatumCurvedataInit()` should be treated as a warning. This value indicates that the geometry finally imported in Creo Parametric is different from the geometry initially supplied to the function. The geometry is not rejected by `ProDatumCurvedataInit()` and is used to generate the `ProCurvedata` data structure.

---

Use the function `ProDatumdataMemoryFree()` to free the top-level memory used by the datum data structure.

---

## Appending the Datum Data to the Interface Data

Use the function `ProIntfDataDatumAppend()` to append the datum data to the interface data required to create the import feature. The input arguments are:

- *p\_intfdata*—Specifies the interface data to which the datum data must be appended.
- *p\_datumdata* —Specifies a handle to the datum data obtained from the function `ProDatumdataInit()`.
- Repeat the sequence for each datum member required to be in the import feature.

## Creating Features from the Interface Data

Functions Introduced:

- **ProIntfDataSourceInit()**
- **ProImportfeatCreate()**
- **ProIntfDataFree()**

Use the function `ProIntfDataSourceInit()` to build the interface data source required by the functions `ProImportfeatCreate()` and `ProImportfeatureWithProfileCreate()`. The input arguments of this function are:

- *intf\_type*—Specifies the type of the interface. Since the user builds all the data required by the interface, the value should be `PRO_INTF_NEUTRAL`.
- *p\_source*—Specifies the handle to the interface data source.

The function returns the handle `ProIntfDataSource`, which must be passed to the functions `ProImportfeatCreate()` and `ProImportfeatureWithProfileCreate()`.

Use the function `ProImportfeatCreate()` to create the import feature in the Creo Parametric solid model. The input arguments of this function are:

- *p\_solid*—Specifies the part or assembly in which the user wants to create the import feature.
- *data\_source*—Specifies a pointer to the interface data source. Use the function `ProIntfDataSourceInit()` to get the handle to the interface data source.
- *p\_csys*—Specifies the co-ordinate system of the part with which you want to align the import feature. If this is `NULL`, the function uses the default coordinate system in the Creo Parametric model and the import feature will be aligned with respect to that coordinate system.

- 
- *p\_attributes*—Specifies the attributes for the creation of the new import feature. Refer to the section [Import Feature Attributes on page 746](#) for more information.

The function `ProImportfeatCreate()` returns the `ProFeature` handle for the created import feature.

If your Creo TOOLKIT application is built using Creo Parametric 6.0 and you have the function `ProImportfeatCreate()` in your application, then the same application works as it is in Creo Parametric 7.0.0.0.

---

 **Note**

If you are planning to recompile your Creo TOOLKIT in Creo Parametric 7.0.0.0, you must set the default value of the enumerated data type `body_use_opt` to `PRO_IMPORT_BODY_USE_DEFAULT`, add `bodies` to 0, and `body_arr` to `NULL` otherwise the behavior of Creo Parametric may be unpredictable.

---

The function `ProImportfeatureWithProfileCreate()` is used to create a new import feature in the Creo Parametric solid model. This function takes the same input arguments as the function `ProImportfeatCreate()`, except for the argument *profile* that specifies the path to the import profile used. An import profile is an XML file with the extension `.dip` (Dex In Profile) and contains the options that control an import operation. It contains all the options for the supported 3D import formats. Refer to the Creo Parametric Online Help for more information on creation and modification of import profiles.

---

 **Note**

The function `ProImportfeatureWithProfileCreate()` cannot create an import feature using an import profile for the STL and VRML formats.

---

Use the function `ProIntfDataFree()` to release the memory occupied by the interface data.

## Import Feature Attributes

Attributes define the action to be taken when creating the import feature. Following are the defined attributes:

- *attempt\_make\_solid*—Specifies whether the import feature is to be created as a solid or a surface type. Set the value to 1 to create an import feature of solid type. Set it to 0 to create a surface type of import feature.

---

 **Note**

If the import feature is an open surface, setting `attempt_make_solid` to 1 does not make the import feature of solid type.

---

- `cut_or_add`—Specifies whether the solid type of import feature is to be created as a cut or a protrusion. This argument is valid only if `attempt_make_solid` is set to 1. Set the value to 1 to cut the solid import feature from the intersecting solid. Set it to 0 to create it as a protrusion.

---

 **Note**

When `attempt_make_solid` is set to 0, the value assigned to `cut_or_add` is not considered.

---

- `join_surfaces`—Specifies whether the import feature is created as a single quilt (joined surface) or separate surfaces (as it was in the original file) if it is of surface type. This argument is valid only if `attempt_make_solid` is set to 0. If the value is set to 1, all surfaces that can be joined are joined to form a single quilt.
- `add_bodies`—Creates the same body structure as is present in the source file.
- `body_use_opt`—Specifies the body options you can use while importing a feature and is defined by the enumerated data type `ProImportBodyUseOpts`. The valid values are as follows:
  - `PRO_IMPORT_BODY_USE_DEFAULT`—Imports feature in the default body.
  - `PRO_IMPORT_BODY_USE_NEW`—Imports feature in a new body.
  - `PRO_IMPORT_BODY_USE_ALL`—Currently not supported.
  - `PRO_IMPORT_BODY_USE_SELECTED`—Imports feature in a selected body.
- `body_arr`—`ProArray` of bodies to be selected. By default, the size is 1. Set this value as `NULL` if you do not want to use any bodies in the import operation.

## Redefining the Import Feature

Use the following functions in sequence to redefine the import feature.

---

Functions Introduced:

- **ProImportfeatRedefSourceInit()**
- **ProImportfeatRedefine()**

Use the function `ProImportfeatRedefSourceInit()` to initialize the redefine source. Currently Creo TOOLKIT users may

- Redefine the attributes of any import feature.

---

 **Note**

When redefining the attributes of the import feature, Creo Parametric will not use the value of the attribute `join_surfaces`, because this attribute is valid only for import feature creation.

---

- Redefine the geometry of an import feature created from a geometric file. Import features created from memory may not be redefined.

The input arguments are:

- *operation*—Specifies the type of operation to use when redefining the import feature.
- *p\_source*—Specifies the handle to the new interface data or the new attributes structure.

The function `ProImportfeatRedefSourceInit()` returns the handle to a structure, that is passed as an input argument to the function `ProImportfeatRedefine()`.

Use the function `ProImportfeatRedefine()` to redefine the import feature. The input arguments are:

- *p\_feat\_handle*—Specifies the handle for the import feature to be redefined.
- *p\_source*—The handle to be used for redefinition from the function `ProImportfeatRedefSourceInit()`.

---

 **Note**

`ProImportfeatRedefine()` does not support ATB-enabled features. It returns `PRO_TK_BAD_CONTEXT` while accessing such features.

---

## Import Feature Properties

Functions Introduced:

- **ProImportfeatIdArrayCreate()**
- **ProImportfeatIdArrayMapCount()**
- **ProImportfeatIdArrayMapGet()**
- **ProImportfeatIdArrayFree()**
- **ProImportfeatUserIdToItemId()**
- **ProImportfeatItemIdToUserId()**
- **ProImportfeatDataGet()**

Use the function `ProImportfeatIdArrayCreate()` to create an array of mappings between the user defined ids and the ids assigned by Creo Parametric to the entity items in the import feature.

Specify the handle to the feature, for which the user defined ids and ids assigned by Creo Parametric have to be mapped, as the input argument of the function. The function returns an array of mapped ids.

Use the function `ProImportfeatIdArrayMapCount()` to get the number of elements in the array of mappings. Use the function `ProImportfeatIdArrayMapGet()` to get the mapping of a particular element in the array.

Use the function `ProImportfeatIdArrayFree()` to free the array.

Use the function `ProImportfeatUserIdToItemId()` to obtain the id or ids assigned by Creo Parametric for a user defined id. The function returns multiple ids in an array if the import operation split a particular entity.

For example, if you create a circular edge as a single edge data defined by a single id, Creo Parametric creates the circle by splitting it into two. If you pass the user defined id as an input to the function `ProImportfeatUserIdToItemId()`, the function will return an array of the ids assigned to each half of the circle.

The input arguments of this function are:

- *p\_feat\_handle*—Specifies the handle of the import feature.
- *user\_id*—Specifies the identifier of the geometry item.
- *item\_type*—Specifies the type of the geometry item. The types of geometry are:
  - `PRO_SURFACE`
  - `PRO_EDGE`
  - `PRO_QUILT`

Use the function `ProImportfeatItemIdToUserId()` to convert a Creo Parametric item id to an array of user defined ids.

---

For example, if the edges defined by the user are created as a single edge by Creo Parametric, and you pass a single item id assigned by Creo Parametric to the function `ProImportfeatItemIdToUserId()`, it will return an array of user ids.

- *p\_feat\_handle*—Specifies the handle of the import feature.
- *item\_id*—Specifies the identifier of the geometry item.
- *item\_type*—Specifies the type of the geometry item. The types of geometry are:
  - `PRO_SURFACE`
  - `PRO_EDGE`
  - `PRO_QUILT`

Use the function `ProImportfeatDataGet()` to retrieve the parameters assigned to the import feature. The output returned by this function will contains the following:

- Information about the interface type of the import feature.
- The filename from which the import feature is created. This is applicable for import features created from a file.
- The coordinate system with respect to which the import feature is aligned.
- The attributes of the import feature.

## Extracting Creo Parametric Geometry as Interface Data

Functions Introduced:

- **`ProPartToProInterfaceData()`**
- **`ProIntfDataAccuracyGet()`**
- **`ProIntfDataAccuracytypeGet()`**
- **`ProIntfDataOutlineGet()`**
- **`ProIntfDataDatumCount()`**
- **`ProIntfDataDatumGet()`**
- **`ProIntfDataEdgeCount()`**
- **`ProIntfDataEdgeGet()`**
- **`ProIntfDataQuiltCount()`**
- **`ProIntfDataQuiltGet()`**
- **`ProIntfDataSurfaceCount()`**
- **`ProIntfDataSurfaceGet()`**

---

Superseded Functions:

- **ProPartToProIntfData()**

Use the function `ProPartToProIntfData()` to extract a `ProIntfData` structure describing the geometry of a part as if it were an import feature. This provides a single interface to extract all geometric data in order to convert it to another geometric format. The function `ProPartToProIntfData()` extracts the `ProIntfData` structure only if the model has a single body, else returns the error `PRO_TK_MULTIBODY_UNSUPPORTED`.

In Creo Parametric 7.0.0.0 and later, the function `ProPartToProIntfData()` has been deprecated. Use the function `ProPartToProInterfaceData()` to convert a `ProPart` structure to a `ProIntfData` structure. The input arguments follow:

- *ptk\_part*—The `ProPart` data structure that needs to be converted.
- *p\_cnv\_opts*—The options for the conversion defined by the structure `ProPartConversionOptions`.

The interface data is returned by the output argument `p_intfdata`. You must preallocate the memory for this argument by calling the function `ProIntfDataAlloc()`.

The functions `ProIntfDataAccuracytypeGet()`, `ProIntfDataAccuracyGet()`, and `ProIntfDataOutlineGet()` provide access to properties of the interface data structure.

The other functions allow you to count and access each individual geometric data structure in the interface data.

## Associative Topology Bus Enabled Interfaces

The following interfaces are ATB-enabled by default:

- CADD5 5
- CATIA V4
- CATIA V5
- Creo Elements/Direct
- Creo View
- Creo Granite file
- ICEM
- Neutral
- OPTEGRA
- SolidWorks
- NX
- Inventor

---

You can indicate in the import profile to disable ATB. You can do this in the **Import Profile Editor** (under **Tools ► Utilities** in the Creo Parametric user interface) by clearing the option **Enable ATB**.

Refer to the Creo Parametric Data Exchange Help for more information on profile editing and ATB (Associative Topology Bus).

## Associative Topology Bus Enabled Models and Features

Associative Topology Bus (ATB) propagates changes made to the original CAD system data in the heterogeneous design environment. All geometric IDs preserved by the native system after the change to the native file are also preserved in the imported geometry by the ATB update. With ATB, you can work with Creo Parametric part or assembly that is:

- A Translated Image Model (TIM) representation of a model imported from the ATB interface, such as, CADDs or CATIA.
- A Creo Parametric assembly containing one or more components which are models imported from an ATB Interface, such as, CADDs or CATIA.
- A Creo Parametric part containing an Import Feature that is imported from an ATB Interface such as, ICEM.

Only import operations in Creo Parametric create TIM parts and assemblies. You can open CATIA, CADDs model files as TIMs. Neutral part files and files of other ATB-enabled formats are imported as native Creo Parametric parts with ATB-enabled features.

The TIM parts and assemblies store their ATB information at the model level. However, ATB-enabled import features store ATB information at the feature-level. The TIMs are displayed in the Model Tree with ATB icons that indicate their status with respect to their reference file as up-to-date, out-of-date, and so on.

The functions related to ATB models or features are available in the header file `ProATB.h`. These functions enable you to perform the following actions on a TIM model or ATB-enabled feature or the entire geometry of the imported model:

- Check the status of the TIMs or the ATB-enabled features.
- Update TIMs or ATB-enabled features that are identified as out-of-date.
- Change the link of a TIM or ATB-enabled feature.
- Break the association between a TIM or the ATB-enabled feature and the original reference model.

Functions Introduced:

- **ProModelIsTIM()**
- **ProModelHasTIMFeature()**

- **ProModelListTIMFeatures()**
- **ProATBMdlnameVerify()**
- **ProATBMarkAsOutOfDate()**
- **ProATBUpdate()**
- **ProATBRelink()**

The function `ProModelIsTIM()` checks if the specified model is a TIM.

The function `ProModelHasTIMFeature()` checks if the specified model contains a TIM feature.

The function `ProModelListTIMFeatures()` lists all the TIMs or ATB-enabled features present in the specified model. This function can be called after the function `ProModelHasTIMFeature()` which determines if the specified model has one or more TIM features.

The function `ProATBMdlnameVerify()` verifies if the specified ATB model is out of date with the source CAD model. The function first checks if the specified model is a TIM. If the model is not a TIM, this function checks if the ATB-enabled model was created by importing or appending ICEM or neutral surfaces to existing Creo Parametric part models. The input arguments for this function are:

- **Model**—Specify a Creo Parametric Part or Assembly that is—
  - A Translated Image Model (TIM) representation of a model imported from the ATB interface, such as, CADDs or CATIA.
  - A Creo Parametric assembly containing one or more components which are models imported from an ATB Interface, such as, CADDs or CATIA.
  - A Creo Parametric part containing an Import Feature that is imported from an ATB Interface such as, ICEM.
- **feat\_ids**—Specify an array of feature ids for the ATB-enabled features in the model. If a model contains more than one ATB-enabled feature, the verify function works only on the specified feature. If you do not specify a feature id, the `ProATBMdlnameVerify()` function verifies the entire model including TIMs from non-native CAD models.
- **search\_paths**—Specify the complete location to the source CAD model. You can specify multiple directories to search for the model. If no search path is specified, then the function will search in current working directory or locations set in config-option `atb_search_path`.

The output arguments of this function represent the status of the TIMs and are as follows:

- **models\_out\_of\_date**—Specifies an array of TIMs or the ATB-enabled features that are out-of-date with the source model and require an update. These models are represented by a red icon in the Model Tree in the Creo Parametric user interface.

- 
- `models_unlinked`—Specifies an array of TIMs or the ATB-enabled features that have missing links because the reference model is missing from the designated search path. These models are represented by a yellow icon in the Model Tree in the Creo Parametric user interface.
  - `models_old_version`—Specifies an array of TIMs for which the source CAD model is older than the one with which the TIM was last updated. These models are represented by a yellow icon in the Model Tree in the Creo Parametric user interface. Use the function `ProArrayFree()` to free the array of output arguments.

The function `ProATBMarkAsOutOfDate()` identifies all the ATB-enabled features that are out of date for the update operation.

The function `ProATBUpdate()` updates only those ATB-enabled models or features that are displayed in the session. The update action synchronizes the derived structure and the contents of the TIMs with the primary structure and the content of the source non-native CAD models. This function returns an error if there are non-displayed models in the session or if the input model is not displayed.

---

 **Note**

- If the link of a TIM or ATB-enabled feature is broken, you cannot re-establish the link or update the part that is independent and has lost its association with the reference model.
- The geometry added or removed from the model before the update is added or removed from the TIM after the update.
- The geometry added or removed from the model before the update is added or removed from the TIM after the update.
- ATB incorrectly identifies the imported geometry as up-to-date based on the old reference file which is found before the updated reference file.

---

The function `ProATBRelink()` relinks a TIM to a source CAD model specified by the input argument `master_model_path`. This function relinks all those models or features that have lost their association or link with their master model. In order to relink a model, provide the name and location of the master model, using the `master_model_path` to which the specified model or feature is to be linked. If the master model with the same name is found, the Creo Parametric TIM model is linked to that master model.

---

## Interface: Customized Plot Driver

### Interface: Customized Plot Driver

This section describes the customized plot driver functions supported by Creo TOOLKIT .

### Using the Plot Driver Functionality

The functions described in this section enable you to plot the two-dimensional entities, such as, lines, circles, arcs, and text that are used by Creo Parametric. These functions enable you to implement a customized plot format in Creo Parametric. You can do this by providing your own function for plotting each of the two-dimensional entities and then binding them to Creo Parametric so that it uses these functions to plot the contents of the object currently in session.

The following restrictions apply while using this functionality:

1. You cannot plot shaded models using these functions. This applies to plots of models generated from 3D model modes as well as shaded drawing views.
2. The contents of OLE objects embedded in drawings will not be included in the output.
3. Text contents provided to the implementation may include special Creo Parametric symbols. The Creo TOOLKIT application must transform this text into something that can be displayed correctly in the output format.
4. User defined plotter formats registered using the functions listed here will not be accessible from the Creo Parametric Print dialog box, or from the Creo TOOLKIT function `ProPrintExecute()` . In order to export the model with this custom plot driver, you must use `ProPlotdriverExecute()` .

Functions Introduced:

- **ProPlotdriverInterfaceCreate()**
- **ProPlotdriverInterfaceobjectsSet()**
- **ProPlotdriverArcPlot()**
- **ProPlotdriverArcfunctionSet()**
- **ProPlotdriverCirclePlot()**
- **ProPlotdriverCirclefunctionSet()**
- **ProPlotdriverLinePlot()**
- **ProPlotdriverLinefunctionSet()**
- **ProPlotdriverPolygonPlot()**
- **ProPlotdriverPolygonfunctionSet()**

- **ProPlotdriverPolylinePlot()**
- **ProPlotdriverPolylinefunctionSet()**
- **ProPlotdriverTextPlot()**
- **ProPlotdriverTextfunctionSet()**
- **ProPlotdriverExecute()**

The function `ProPlotdriverInterfaceCreate()` searches for a plot interface with a specified name. If the interface does not exist, then the function creates a new interface with this name. Each plot format that you define must have a unique name. This name is referenced in calls to other functions described in this section.

The function `ProPlotdriverInterfaceobjectsSet()` specifies the types of objects that are supported by a particular plot format. Specify a list of file extensions, such as, prt, drw, asm, and so on, that define the types of object to plot.

Use the `ProPlotdriver` functions to plot circles, lines, arcs, polygons, polylines, and text. These functions accept as input a call back function whose signature matches the call backs specified in the table below. The input arguments of the call back function describe the actual entity to be plotted.

The following table lists the names of the plot functions and their corresponding call backs. For example, use the function

`ProPlotdriverLinefunctionSet()` to plot a line. The function accepts as input a call back function whose signature matches

`ProPlotdriverLinePlot()`. The input arguments of the function `ProPlotdriverLinePlot()` define the line to be plotted.

| Plot Function                                   | Call Back Function                       |
|-------------------------------------------------|------------------------------------------|
| <code>ProPlotdriverArcfunctionSet()</code>      | <code>ProPlotdriverArcPlot()</code>      |
| <code>ProPlotdriverCirclefunctionSet()</code>   | <code>ProPlotdriverCirclePlot()</code>   |
| <code>ProPlotdriverLinefunctionSet()</code>     | <code>ProPlotdriverLinePlot()</code>     |
| <code>ProPlotdriverPolygonfunctionSet()</code>  | <code>ProPlotdriverPolygonPlot()</code>  |
| <code>ProPlotdriverPolylinefunctionSet()</code> | <code>ProPlotdriverPolylinePlot()</code> |
| <code>ProPlotdriverTextfunctionSet()</code>     | <code>ProPlotdriverTextPlot()</code>     |

The function `ProPlotdriverExecute()` is used to invoke the user-defined plot on the current object.

### Example 1: Sample Plot Driver Program

The sample code in `UgPlotUse.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_plot` shows how to use the customized plot driver functions.

---

# Working with Multi-CAD Models Using Creo Unite

## Overview

This section describes how to work with non-Creo parts and assemblies using Creo Unite.

Creo Unite enables you to open non-Creo parts and assemblies in Creo Parametric and other Creo applications, such as, Creo Simulate without creating separate Creo models. You can then assemble the part and assembly models that you opened as components of Creo assemblies to create multi-CAD assemblies of mixed content.

The non-Creo components of these heterogeneous assemblies retain their original names in Creo and continue to use their original source CAD applications as the design tool. They appear as foreign models and not as native Creo models.

You can open the part and assembly models of the following non-Creo file formats in Creo applications:

- CATIA V5 (.CATPart, .CATProduct)
- CATIA V5 CGR
- CATIA V4 (.Model)
- SolidWorks (.sldasm, .sldprt)
- NX (.prt)
- Autodesk Inventor (.ipt, .iam)
- Creo Elements/Direct (.sdpc, .sdac, .sdcc, and .sdrcc)

From Creo Parametric 4.0 F000 onward, the following Creo Elements/Direct files can be opened in Creo Parametric and other Creo applications, such as, Creo Simulate without creating separate Creo models:

- Part content file (.sdpc)
- Assembly content file (.sdac)

You can modify the non-Creo models in Creo applications, without altering the original design intent. For example, you can add annotations to the non-Creo models in a Creo application.

You can also make design changes to the non-Creo models in a multi-CAD assembly. Depending on the configuration options set in Creo, user confirmation may be required to apply the design changes. Refer to the Creo Parametric Data Exchange online help, for more information.

---

In applications where user confirmation cannot be obtained for design changes, for example, when Creo is running in batch mode, the appropriate functions such as, `ProFeatureWithoptionsCreate()`, return an error.

While working with a multi-CAD model, when you call the function `ProFeatureWithoptionsCreate()`, the output may vary depending on the value of the configuration option `confirm_on_edit_foreign_models`. The default value of the configuration option `confirm_on_edit_foreign_models` is *yes*. The following scenarios are possible depending on the value of the configuration option `confirm_on_edit_foreign_models`:

- If the configuration option `confirm_on_edit_foreign_models` is set to *no*, the non-Creo model is modified without any notification.
- If the configuration option `confirm_on_edit_foreign_models` is set to *yes*, or the option is not defined in the configuration file, then in batch mode the application returns the error `PRO_TK_GENERAL_ERROR`.
- In some situations, you may need to provide input in the interactive mode with Creo. Refer to the Creo Parametric Data Exchange online help, for more information.

## Support for File Names in Non-Creo Models

Creo applications support the original file names of non-Creo models. File name can contain a maximum of 80 characters and file paths can contain a maximum of 260 characters. The Creo TOOLKIT functions that work with multi-CAD models support file names with a maximum of 31 or 80 characters, depending on the type of function.

The functions that read information from Creo applications do not have any restriction on character length. These functions can read file names of any length. However, the functions that compute a result, or create or set features, item, properties, and so on, may have restrictions on character length. Refer to the Creo TOOLKIT header files, or the section [Restrictions on Character Length for Multi-CAD Functions on page 766](#), for more information on functions that have restrictions on character length.

## Character Support for File Names in Non-Creo Models

The following special characters are supported for file names in non-Creo models:

- % (percent)
- ^ (caret)
- & (ampersand)
- + (plus)
- = (equal)

- 
- ' (apostrophe)
  - ` (grave accent)
  - , (comma)
  - ! (exclamation mark)
  - \$ (dollar sign)
  - @ (at sign)
  - ; (semicolon)
  - # (hash)
  - - (dash, hyphen)
  - ~ (tilde)
  - ( ) (round brackets)
  - [ ] (square brackets)
  - { } (curly brackets)
  - . (period)
  - \ (backslash)
  - / (forward slash)
  - “ (quotation marks)
  - (space)

---

 **Note**

Do not use space as the first character in file names for models.

---

## Working with Multi-CAD Models in Creo Toolkit

Most of the Creo TOOLKIT functions support multi-CAD assemblies. The functions, which do not support assemblies with mixed content, return the error `PRO_TK_UNSUPPORTED`.

You can perform basic operations, such as, locating and retrieving non-Creo models from Windchill and opening them in Creo applications. However, you must use Windchill Workgroup Manager to initially check in the non-Creo models to Windchill. After checking out models from Windchill, you can work on them in Creo applications and then check in the models to Windchill.

## Working with Notifications

Notifications allow the Creo TOOLKIT application to detect certain types of events in Creo Parametric. You can call functions before or after such events.

Notifications to all of the file management operations in Creo Parametric, such as save, retrieve, copy, rename, and so on, are supported for Creo assemblies with non-Creo components.

The following types of file management notifications are supported for multi-CAD assemblies:

- **File Management Events**—Notifications that are called after successful file management operations in Creo Parametric.
  - **Pre-file Management Events**—Your callback function is called before the file management event. The functions are called only for models that are the explicit objects of the file management operation.
  - **Pre-All File Management Events**—Your callback function is called before all file management events on models, even if those models were not explicitly specified by the user.
  - **Post-file Management Events**—Your callback function is called after the file management operation. The functions are called only for models that are the explicit objects of the file management operation.
  - **Post All File Management Events**—Your callback function is called after all file management events on models, even if those models were not explicitly specified by the user.
- **File Management Failure Events**—Notifications that are called after the file management operations in Creo Parametric fail.

The following events and callback functions are supported for multi-CAD assemblies:

| New Event                       | New Signature                 |
|---------------------------------|-------------------------------|
| Pre-file Management Events      |                               |
| PRO_MODEL_RETRIEVE_PRE          | (*ProModelRetrievePreAction)  |
| PRO_MODEL_SAVE_PRE              | (*ProModelSavePreAction)      |
| PRO_MODEL_COPY_PRE              | (*ProModelCopyPreAction)      |
| PRO_MODEL_RENAME_PRE            | (*ProModelRenamePreAction)    |
| Pre-All File Management Events  |                               |
| PRO_MODEL_SAVE_PRE_ALL          | (*ProModelSavePreAllAction)   |
| Post File Management Events     |                               |
| PRO_MODEL_COPY_POST             | (*ProModelCopyPostAction)     |
| PRO_MODEL_RENAME_POST           | (*ProModelRenamePostAction)   |
| PRO_MODEL_ERASE_POST            | (*ProModelErasePostAction)    |
| PRO_MODEL_RETRIEVE_POST         | (*ProModelRetrievePostAction) |
| PRO_MODEL_SAVE_POST             | (*ProModelSavePostAction)     |
| Post All File Management Events |                               |

| New Event                     | New Signature                    |
|-------------------------------|----------------------------------|
| PRO_MODEL_SAVE_POST_ALL       | (*ProModelSavePostAllAction)     |
| PRO_MODEL_ERASE_POST_ALL      | (*ProModelErasePostAllAction)    |
| PRO_MODEL_RETRIEVE_POST_ALL   | (*ProModelRetrievePostAllAction) |
| PRO_MODEL_COPY_POST_ALL       | (*ProModelCopyPostAllAction)     |
| PRO_MODEL_RENAME_POST_ALL     | (*ProModelRenamePostAllAction)   |
| File Management Failed Events |                                  |
| PRO_MODEL_DBMS_FAILURE        | (*ProModelDbmsFailureAction)     |

## Working with Basic Graphics

You can create windows, which contain the specified multi-CAD assemblies. The functions `ProObjectwindowMdlnameCreate()`, `ProAccessorywindowWithTreeMdlnameCreate()`, and `ProBarewindowMdlnameCreate()` are used to create windows. To use these functions with non-Creo components, pass one of the following values as the input argument `object_type`, depending on the type of non-Creo model:

- PRO\_CATIA\_PART
- PRO\_CATIA\_PRODUCT
- PRO\_CATIA\_CGR
- PRO\_CATIA\_MODEL
- PRO\_UG
- PRO\_SW\_PART
- PRO\_SW\_ASSEM
- PRO\_CC\_ASSEMBLY
- PRO\_CC\_PART

## Working with Simplified Representations

You can create simplified representations, that is, master, geometric, graphics, and user-defined representations, for multi-CAD assemblies. You can also retrieve these representations in the session using the Creo TOOLKIT functions. You can edit a simplified representation created in a Creo application for a non-Creo assembly.

### Note

The function `ProSolidSimpRepVisit()` visits only user-defined representations. Multi-CAD assemblies can have user-defined representations, but the non-Creo parts cannot have user-defined representations. Therefore, the function `ProSolidSimpRepVisit()` returns `PRO_TK_E_NOT_FOUND` error for non-Creo parts.

## Working with Constraints

You can retrieve the constraints of non-Creo models in multi-CAD assemblies. For retrieving the constraints, you must redefine the non-Creo models using the **Edit Definition** command in the Creo Parametric user interface. After redefinition, retrieve the constraints using the Creo TOOLKIT functions.

## Working with User-Defined Features (UDF)

You can insert user-defined features created in Creo applications in a multi-CAD assembly, only if it does not alter the structure of the non-Creo models. You cannot create UDFs in a non-Creo model.

## Functions that Support Multi-CAD Assemblies

The following functions support working with Creo assemblies with mixed content:

- **ProIntfimportModelWithOptionsMdlnameCreate()**
- **ProMdlDependenciesDataList()**
- **ProMdlMdlnameGet()**
- **ProMdlfileMdlnameCopy()**
- **ProMdlnameBackup()**
- **ProMdlnameCopy()**
- **ProMdlnameInit()**
- **ProMdlnameRename()**
- **ProMdlnameRetrieve()**
- **ProMdlDirectoryPathGet()**

For some of these functions, you may have to specify the type of the non-Creo CAD model using the data type `ProMdlfileType`. The valid values of `ProMdlfileType` are:

- `PRO_CATIA_PART`
- `PRO_CATIA_PRODUCT`
- `PRO_CATIA_CGR`
- `PRO_CATIA_MODEL`
- `PRO_UG`
- `PRO_SW_PART`

- PRO\_SW\_ASSEM
- PRO\_INVENTOR\_PART
- PRO\_INVENTOR\_ASSEM

## Superseded Functions

The following table lists the functions that have been superseded and the corresponding new functions to support multi-CAD assemblies:

| Superseded Function                     | New Function                                                                          |
|-----------------------------------------|---------------------------------------------------------------------------------------|
| ProIntfimportModelWithOptionsCreate()   | ProIntfimportModelWithOptionsMdlnameCreate()                                          |
| ProMdlDependenciesList()                | ProMdlDependenciesDataList()                                                          |
| ProMdlNameGet()                         | ProMdlMdlnameGet()                                                                    |
| ProMdlfileCopy()                        | ProMdlfileMdlnameCopy()                                                               |

## Restrictions on Character Length for Multi-CAD Functions

This section describes the restriction on character lengths for Creo TOOLKIT functions that support Creo assemblies with mixed content.

The following table lists the maximum number of characters supported by these functions:

| <b>Function Name</b>                | <b>Character Length Supported</b> | <b>Additional Comment</b> |
|-------------------------------------|-----------------------------------|---------------------------|
| ProSolidShrinkwrapMdlnameCreate()   | 31 characters                     |                           |
| ProSolidMdlnameCreate()             | 31 characters                     |                           |
| ProSolidMdlnameInit()               | 80 characters                     |                           |
| ProAssemblySimprepMdlnameRetrieve() | 80 characters                     |                           |
| ProSimprepMdlnameRetrieve()         | 80 characters                     |                           |
| ProAsmSkeletonMdlnameCreate()       | 31 characters                     |                           |
| ProOutputFileMdlnameWrite()         | 31 characters                     |                           |
| ProFileMdlnameParse()               | 80 characters                     |                           |
| ProFileMdlnameOpen()                | 80 characters                     |                           |
| ProFileMdlnameSave()                | 80 characters                     |                           |
| ProFileMdlfiletypeOpen()            | 80 characters                     |                           |
| ProFileMdlfiletypeSave()            | 80 characters                     |                           |

| Function Name                | Character Length Supported | Additional Comment                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ProMdlDependenciesDataList() | 80 characters              |                                                                                                                                                                                                                                                                                                                                                                                       |
| ProMdlfileMdlnameCopy()      | 31 characters              | In Creo Parametric 3.0, this API is functionally similar to the superseded function <code>ProMdlfileCopy()</code> . It returns an error for model names longer than 31 characters.                                                                                                                                                                                                    |
| ProMdlnameBackup()           | 80 characters              |                                                                                                                                                                                                                                                                                                                                                                                       |
| ProMdlnameCopy()             | 31 characters              | In Creo Parametric 3.0, this API is functionally similar to the superseded function <code>ProMdlCopy()</code> . It returns an error for model names longer than 31 characters.<br><br> <b>Note</b><br>This function is not supported for non-Creo models and Creo assemblies with mixed content. |
| ProMdlnameInit()             | 80 characters              |                                                                                                                                                                                                                                                                                                                                                                                       |
| ProMdlnameRetrieve()         | 80 characters              |                                                                                                                                                                                                                                                                                                                                                                                       |
| ProMdlnameRename()           | 31 characters              | In Creo Parametric 3.0, this API is functionally similar to the superseded function <code>ProMdlRename()</code> . ## Functional Areas in Creo that do not Support Multi-CAD Assemblies

You cannot work with multi-CAD assemblies in the following functional areas:

- Family tables
- Flexible components
- Rename, delete, and copy operations for non-Creo models in a multi-CAD assembly

### Note

When you save a copy, the non-Creo models are saved as Creo models.

- Add, delete, replace, reorder, and suppress components in a non-Creo assembly
- Move components to a new subassembly in a non-Creo assembly
- Creation of external references. However, you can create external references, only if you have set the external reference option in Creo Parametric user interface.

## Sample Applications for Multi-CAD Assemblies

The sample applications provided with the Creo TOOLKIT 3.0 installation use the functions that support multi-CAD assemblies. The sample applications are available at <creo\_loadpoint>\<datecode>\Common Files\protoolkit\protk\_appls. See the sample examples for more information on how to migrate your existing applications to support multi-CAD assemblies using the Creo TOOLKIT 3.0 functions.

---

## Migrating Applications Using Tools

PTC recommends migrating your applications to the new interfaces, which would support multi-CAD models in future releases.

A mapping table `mcm_map.txt`, provided with the Creo TOOLKIT 3.0 installation, lists all the functions that support multi-CAD assemblies and also lists the deprecated functions.

You can migrate the applications using the perl script `mark_deprecated.pl`, which is available at the location `<creo_loadpoint>\<datecode>\Common Files\protoolkit\scripts`. Refer to the section [Tools Available for Migration on page 2026](#) in the section appendix [Migrating Older Applications on page 2026](#), for more information on the script.

## Element Trees: Principles of Feature Creation

### Element Trees: Principles of Feature Creation

This section describes the basic principles of programmatic feature creation that are applicable to all types of feature that can be created in the current version of Creo TOOLKIT. This section also describes how to extract the internal description of features of those feature types in the Creo TOOLKIT database, and how to modify them.

### Overview\_of\_Feature\_Creation

#### References to Feature Creation Data

This section provides references to additional material on feature creation and an overview of creating features.

The creation of specific feature types is dealt with in more detail in the following sections:

- [Element Trees: Datum Features on page 811](#)
- [Element Trees: Sketched Features on page 1002](#)
- [Production Applications: Manufacturing on page 1433](#)

This section defines and describes the following Creo TOOLKIT objects:

- ProElement
- ProElempath
- ProValue

---

For a definition of the `ProFeature` object, see the section [Core: Features on page 137](#).

## Feature Creation

There are many kinds of feature in Creo Parametric and each one can contain a large and varied amount of information. All this information must be complete and consistent before a feature can be used in regeneration and give rise to geometry. This raises several problems for programmatic creation of features through an API.

It is necessary to build all the information needed by a feature into a data structure before passing that whole structure to Creo Parametric. However, the object-oriented style of Creo TOOLKIT requires that such a data structure is not directly visible to the application. Therefore, Creo TOOLKIT defines this structure as a workspace object that can be allocated and filled using special functions for that purpose, but that is not part of the Creo Parametric database.

There are three steps in creating a feature in Creo Parametric:

1. Allocate the workspace structure.
2. Fill the workspace structure.
3. Pass the workspace structure to Creo Parametric to create the feature.

---

### Note

Creating sketched features requires a few more steps. For detailed information, see the section [Element Trees: Sketched Features on page 1002](#).

---

The procedure described above allows a feature of arbitrary complexity to be built up in a sequence of manageable steps, with the maximum of error checking along the way.

Although it is not yet possible to create all feature types using Creo TOOLKIT, the workspace structure must be capable of defining any feature type so the range of features can be extended without affecting the techniques already in use. For this reason, the workspace structure for feature creation takes the form of a tree of data elements. This has the advantage of being simple for simple features, yet is flexible enough to provide for all possible feature types without introducing new principles.

The root and branch points in the tree are called “elements,” and the complete tree is called the “feature element tree.” Each element is modeled by the object `ProElement`, which is a pointer to an opaque structure.

---

The feature element tree contains all the information required to define the feature. This includes the following:

- All options and attributes, such as the material side and depth type for an extrusion or slot, placement method for a hole, and so on.
- All references to existing geometry items, such as placement references, “up to” surfaces, sketching planes, and so on.
- References to Sketcher models used for sections in the feature.
- All dimension values.

---

 **Note**

Because Creo TOOLKIT is the same toolkit used to build Creo Parametric, improvements to Creo Parametric may require the definition of the element tree to be altered for some features. PTC will make every effort to maintain upward compatibility. However, there may be cases where the old application will not run with the new version of Creo Parametric, unless you rewrite the application's code to conform to the new definition of the feature tree.

---

Note that although the values of dimensions used by the feature are in the element tree, there are no descriptions of, or references to, the dimension objects themselves. The only exception is as follows: for an element tree for a feature already in the Creo Parametric database, you can ask the identifier of the dimension used for a particular element using the function `ProFeatureElemDimensionIdGet()`. This is explained in detail in the section [Feature Inquiry on page 792](#). For more general functions that access dimensions, see the section [Core: Relations on page 211](#).

Each element in the tree is assigned an element ID, which is really a description of the role it is playing in this feature—the kind of information it is supplying. It is called an element ID because no two elements at the same level in the tree will have the same identifier, unless they belong to an array element, so the element ID also acts as a unique identifier.

The possible element roles are values in an enumerated type called `ProElemId`, declared in `ProElemId.h`. Example values are as follows:

- `PRO_E_FEATURE_TYPE`
- `PRO_E_FEATURE_FORM`
- `PRO_E_EXT_DEPTH`
- `PRO_E_THICKNESS`
- `PRO_E_4AXIS_PLANE`

---

There are four different element types:

- Single-valued
- Multivalued
- Compound
- Array

A single-valued element can contain various types of value. The simplest is an integer used to define, for example, the type of the feature, or one of the option choices, such as the material side for a thin protrusion. The value can be a wide string (for example, the name of the feature), or a double (for example, the depth of a blind extrusion). If the element defines a reference to an existing geometry item in the solid, its value contains an entire `ProSelection` object so it can refer to anything in an entire assembly.

A multivalued element contains several values of one of these types. Multivalued elements occur at the lowest level of the element tree—the “leaves.” An example is the element with the identifier `PRO_E_FIXT_COMPONENTS` in a Fixture Setup feature in Creo NC. That element specifies the components in the assembly that belong to the fixture; in general, there can be any number of such components, so the element contains several component identifiers.

A compound element is one that acts as a branch point in the tree. It does not have a value of its own, but acts as a container for elements further down in the hierarchy.

An array element is also a branch point, but one that contains many child elements of the same element ID. An example of this is the `PRO_E_DTMLN_CONSTRAINTS` element in a datum plane feature, which contains an array of elements of type `PRO_E_DTMLN_CONSTRAINT` (note the singular), each of which is a compound element whose contents describe one of the constraints that determine the position of the datum plane.

The feature element tree enables you to build a complex feature in stages, with only a small set of functions. However, the form of the tree required for a particular feature needs to be clearly defined so you know exactly what elements and values to add, and so Creo TOOLKIT can check for errors each time you add a new element to the tree.

Creo TOOLKIT documents the necessary contents of the element tree for each type of feature that can be created programmatically. It does this through two types of description:

- Feature element tree
- Feature element table

The feature element tree defines the structure of the tree, specifying the element ID (or role) for the elements at all levels in the tree, and which elements are optional.

The feature element table defines the following for each of the element IDs in the tree:

- A description of its role in the feature
- The value type it has (that is, whether it is single value or compound; or an array of integer, double, or string)
- The range of values valid for it in this context

Each type of feature that can be created using Creo TOOLKIT has its own header file that contains the feature element tree and table, in the form of code comments. The header files for the feature types that can be created in the current version are as follows:

| Header File        | Feature Type                                                                              |
|--------------------|-------------------------------------------------------------------------------------------|
| ProAnalysis.h      | External Analysis                                                                         |
| ProAsmcomp.h       | Assembly component, mechanism connection                                                  |
| ProChamfer.h       | Chamfer or corner chamfer                                                                 |
| ProDataShareFeat.h | General merge (merge, cutout, inheritance), copy geom., publish geom., shrinkwrap         |
| ProDraft.h         | Draft                                                                                     |
| ProDtmAxis.h       | Datum axis                                                                                |
| ProDtmCrv.h        | Datum curve                                                                               |
| ProDtmCsys.h       | Datum coordinate system                                                                   |
| ProDtmPln.h        | Datum plane                                                                               |
| ProDtmPnt.h        | Datum point                                                                               |
| ProExtrude.h       | Extruded protrusion, cut, surface, surface trim, thin, sheetmetal wall, or sheetmetal cut |
| ProFixture.h       | Fixture (for Creo NC)                                                                     |
| ProFlatSrf.h       | Fill surface or sheetmetal flat wall                                                      |
| ProForeignCurve.h  | Foreign datum curve                                                                       |
| ProHole.h          | Hole                                                                                      |
| ProMerge.h         | Merge                                                                                     |
| ProMirror.h        | Mirror (geometry only)                                                                    |
| ProMove.h          | Move and copy (geometry only)                                                             |
| ProMfgoper.h       | Manufacturing operation                                                                   |
| ProNcseq.h         | Manufacturing Creo NC sequence                                                            |
| ProProcstep.h      | Process step                                                                              |
| ProReplace.h       | Surface replacement feature                                                               |
| ProRevolve.h       | Revolved protrusion, cut, surface, surface trim or thin                                   |
| ProRib.h           | Rib                                                                                       |
| ProRound.h         | Round                                                                                     |
| ProShell.h         | Shell                                                                                     |
| ProSmtFlangeWall.h | Sheetmetal flange wall                                                                    |
| ProSmtFlatWall.h   | Sheetmetal flat wall                                                                      |
| ProSolidify.h      | Solidify                                                                                  |
| ProStdSection.h    | Standard section                                                                          |

| Header File  | Feature Type                 |
|--------------|------------------------------|
| ProSweep.h   | Simple swept protrusion, cut |
| ProThicken.h | Thicken                      |
| ProTrim.h    | Trim                         |
| ProWcell.h   | Manufacturing workcell       |

The feature element tree for the Fixture Setup feature defined in the header file `ProFixture.h` is deprecated. Use the element tree defined in the header file `ProMfgFeatFixture.h` instead. For more information, please refer to the section [Manufacturing Holmaking Step on page 1561](#).

The first two elements are common to all features. The root of a feature tree is always a compound element with the identifier `PRO_E_FEATURE_TREE`. The first element within the root always specifies the feature type; it is a single-valued element with the element ID `PRO_E_FEAT_TYPE`, whose value is one of the integers in the list of feature types in `ProFeatType.h`. In this case, the element table shows that the value must be `PRO_FEAT_FIXSETUP`.

The next element in a fixture setup gives the name of the feature; its element ID is `PRO_E_FEAT_NAME`, and it contains a single wide string. The element tree shows that this is optional.

The `PRO_E_FIXT_COMPONENTS` is a multivalued element, with the value type integer, which contains the identifiers of the assembly components that belong to the fixture.

The last element in a fixture setup is `PRO_E_SETUP_TIME`, which contains a double.

As you build the elements into the workspace element tree, Creo TOOLKIT checks the correctness of their types against the structure described by the element tree and table in the corresponding header file. This makes it easy to diagnose errors when you are creating features. The geometrical correctness is checked only when you try to create the feature in the Creo Parametric database.

The following sections of this section describe the functions used to build an element tree and create a feature. The sections are as follows:

- [Feature Element Values on page 777](#)—Introduces the object `ProValue`, used to represent the value of a feature element.
- [Feature Element Paths on page 779](#)—Introduces the object `ProElemPath`, used to describe the location of an element in an element tree.
- [Feature Elements on page 780](#)—Introduces the `ProElement` functions used to build and analyze an element tree.
- [Feature Element Diagnostics on page 784](#)—Introduces the `ProElementDiagnostics` functions used to obtain the diagnostics for a feature element.

- [Calling ProFeatureCreate\(\) on page 785](#)—Describes the `ProFeatureCreate()` function in detail.
- [Example of Complete Feature Creation on page 787](#)—Shows how to use functions from the other sections to perform all the steps needed to create a feature.

## Feature Element Values

Functions introduced:

- **ProValueAlloc()**
- **ProValueDataGet()**
- **ProElementDirectionGet()**
- **ProValueDataSet()**
- **ProValueFree()**
- **ProWstringArrayToValueArray()**
- **ProValueArrayToWstringArray()**
- **ProValuedataTransformGet()**
- **ProValuedataTransformSet()**

The object `ProValue` is an opaque workspace handle used to contain the value of a feature element. It is the output of the functions `ProElementValueGet()` and `ProElementValuesGet()`, which read the values of a feature element, and is the input to `ProElementValueSet()` and `ProElementValuesSet()`.

You can access the contents of a `ProValue` object by translating it into an object of type `ProValueData`, which is declared as a visible data structure. The declaration is as follows:

```
typedef struct pro_value_data
{
 ProValueDataType type;
 union
 {
 int i; /* integer */
 double d; /* double */
 void *p; /* pointer or reference */
 char *s; /* string */
 wchar_t *w; /* wchar_t */
 ProSelection r; /* selection */
 } v;
} ProValueData;
typedef enum pro_value_data_type
{
 PRO_VALUE_TYPE_INT = 1,
```

```

PRO_VALUE_TYPE_DOUBLE,
PRO_VALUE_TYPE_POINTER,
PRO_VALUE_TYPE_STRING,
PRO_VALUE_TYPE_WSTRING,
PRO_VALUE_TYPE_SELECTION
} ProValueDataType;

```

ProValueData is simply a holder for data values of many different types.

### **Note**

From Pro/ENGINEER Wildfire 2.0 onwards, elements with multiple values, for example, PRO\_E\_FIXT\_COMPONENTS, are deprecated. In subsequent releases, these elements will be superseded by reference elements or single-value, type-specific elements. Use the function ProElementValuetypeGet () to determine the type of the element.

### **Note**

To access reference elements use the functions ProElementReferencesGet () or ProElementReferencesSet (). To access single-value, type-specific elements, use the functions ProElement<type>Get () or ProElement<type>Set (), such as, ProElementDoubleGet (), ProElementIntegerGet () and so on.

The functions in this section access the contents of a ProValue through the ProValueData object.

The function ProElementDirectionGet () calculates the direction vector and origin point based on the direction reference and flip orientation stored inside the direction element. The input argument element is the PRO\_E\_DIRECTION\_COMPOUND compound element, which contains two sub elements inside PRO\_E\_DIRECTION\_REFERENCE and PRO\_E\_DIRECTION\_FLIP. The output argument are:

- vector—calculated ProVector direction vector.
- origin—calculated Pro3dPnt direction origin point.

The function ProValueDataGet () provides the ProValueData object for the specified ProValue object.

The function ProValueAlloc () allocates a new ProValue in memory, as the first step towards setting the value of a feature element.

The function ProValueDataSet () sets the value of a ProValue object using the contents of a ProValueData structure.

---

The function `ProValueFree()` frees a `ProValue` object in memory.

The function `ProWstringArrayToValueArray()` provides a convenient way to allocate and fill an array of `ProValue` structures that all contain wide string values.

The function `ProValueArrayToWstringArray()` performs the reverse translation, allocating and filling an array of wide strings. In both cases, the output array is an expandable array, so you should release the memory using `ProArrayFree()`.

The transform member of the union `ProValueData` is declared as `double**`. It must be passed a `double[][]` (a `ProMatrix` structure). The utility functions `ProValuedataTransformGet()` and `ProValuedataTransformSet()` specify how to assign the `ProValueData` in order to access the matrix correctly.

## Feature Element Paths

Functions introduced:

- **`ProElempathAlloc()`**
- **`ProElempathFree()`**
- **`ProElempathDataSet()`**
- **`ProElempathDataGet()`**
- **`ProElempathCopy()`**
- **`ProElempathCompare()`**
- **`ProElempathSizeGet()`**

An element path is used to describe the location of an element in an element tree. It is used by some of the `ProElement` functions as a convenient way to refer to elements already in a tree.

The object `ProElempath` is declared as an opaque pointer. It contains a description of the path from the root of the tree down to the element referred to. At most levels in the tree hierarchy, the relevant path member is the element ID of the element (which is unique at that level). When the path steps from an array element to one of its member arrays, the element path instead contains the array index of that element.

To be able to set the value of a `ProElempath`, Creo TOOLKIT provides a structure called `ProElempathItem` that can describe an element ID, or the index into an array element. An array of `ProElempathItem` structures is therefore a visible equivalent to the opaque contents of `ProElempath`.

The declaration of `ProElempathItem` is as follows:

```
typedef struct path
{
```

```

ProElempathItemtype type;
union
{
 int elem_id;
 int elem_index;
} path_item;
} ProElempathItem;
typedef enum
{
 PRO_ELEM_PATH_ITEM_TYPE_ID,
 PRO_ELEM_PATH_ITEM_TYPE_INDEX
} ProElempathItemtype;

```

The object `ProElempath`, the structure `ProElempathItem`, and all the functions in this section are declared in the header file `ProElempath.h`.

The function `ProElempathAlloc()` allocates a new empty `ProElempath` object, whereas `ProElempathFree()` frees a `ProElempath`.

The function `ProElempathDataSet()` enables you to set the contents of a `ProElempath` by copying from an array of `ProElempathItem` structures.

The function `ProElempathDataGet()` reads the contents of a `ProElempath` into an array of `ProElempathItem` structures. The array is an expandable array that must be allocated by a call to `ProArrayAlloc()` before you call the function.

The function `ProElempathCopy()` copies the contents of one `ProElempath` object into another. The output object is allocated by the function.

The function `ProElempathCompare()` tells you whether two `ProElempath` objects refer to the same element.

The function `ProElempathSizeGet()` tells you the length of the element path contained in a `ProElempath` object.

## Feature Elements

Functions introduced:

- **ProElementAlloc()**
- **ProElementFree()**
- **ProElementIdGet()**
- **ProElementIdSet()**
- **ProElemIdStringGet()**
- **ProElemtreeElementGet()**
- **ProElemtreeElementAdd()**
- **ProElemtreeElementRemove()**

- 
- **ProElementIsMultival()**
  - **ProElementIsCompound()**
  - **ProElementIsArray()**
  - **ProElementChildrenGet()**
  - **ProElementChildrenSet()**
  - **ProElementArraySet()**
  - **ProElementArrayGet()**
  - **ProElementArrayCount()**
  - **ProElemtreeElementVisit()**

The function `ProElementAlloc()` allocates a new `ProElement` object with a specified element ID. The function `ProElementFree()` frees a `ProElement`.

The function `ProElementIdGet()` outputs the element ID of a specified `ProElement`. The function `ProElementIdSet()` enables you to set the element ID of a specified `ProElement`.

The function `ProElemIdStringGet()` returns the string representation of the specified element ID.

The function `ProElemtreeElementGet()` enables you to read a specified element in a tree. The inputs are the root of the tree, specified as a `ProElement` object, and the path to the element, specified by a `ProElempath`. The output is a `ProElement` object.

The function `ProElemtreeElementAdd()` adds a new element to the specified element tree. The inputs are the `ProElement` for the tree root, the `ProElempath` to the new element, and the `ProElement` for the new element.

The function `ProElemtreeElementRemove()` removes an element from a specified tree and path. It outputs a `ProElement` for the element removed.

The functions `ProElementIsMultival()`, `ProElementIsCompound()`, and `ProElementIsArray()` tell you the type of a specified element in a tree. See the section [Overview of Feature Creation on page 771](#) for an explanation of the types.

The function `ProElementChildrenGet()` provides an expandable array of `ProElement` objects for the children of the specified compound element in a tree. The array must be allocated using `ProArrayAlloc()` before you call this function. The function `ProElementChildrenSet()` adds a set of elements, specified by an expandable array of `ProElement` objects, as the children of the specified element in a tree.

The function `ProElementArraySet()` adds an expandable array of `ProElement` objects as the members of a specified array element in an element tree.

---

The function `ProElementArrayGet()` fills an expandable `ProElement` array with the members of an array element in an element tree. The function `ProElementArrayCount()` tells you how many members are in an array element in the specified element tree.

The function `ProElementtreeElementVisit()` visits the elements that are members of the specified array element in an element tree.

## Access to ProElement Data

In earlier releases, Pro/TOOLKIT recommended using functions that access the element value(s) as `ProValue` objects. These functions are maintained for compatibility. PTC recommends using the functions in this section to provide greater flexibility for all new development related to any Pro/ENGINEER feature type. Use of these new functions is required for features first supported in Pro/ENGINEER Wildfire 2.0 and later.

Functions introduced:

- **`ProElementValuetypeGet()`**
- **`ProElementReferenceGet()`**
- **`ProElementReferenceSet()`**
- **`ProElementReferencesGet()`**
- **`ProElementReferencesSet()`**
- **`ProElementIntegerGet()`**
- **`ProElementIntegerSet()`**
- **`ProElementDoubleGet()`**
- **`ProElementDoubleSet()`**
- **`ProElementDecimalsGet()`**
- **`ProElementDecimalsSet()`**
- **`ProElementwstropsAlloc()`**
- **`ProElementwstropsExpressionsSet()`**
- **`ProElementwstropsSignoptionsSet()`**
- **`ProElementwstropsFree()`**
- **`ProElementWstringGet()`**
- **`ProElementWstringSet()`**
- **`ProElementStringGet()`**
- **`ProElementStringSet()`**
- **`ProElementSpecialvalueGet()`**
- **`ProElementSpecialvalueSet()`**

- 
- **ProElementBooleanGet()**
  - **ProElementBooleanSet()**
  - **ProElementTransformGet()**
  - **ProElementTransformSet()**

These functions are the preferred method of accessing element values information over `ProElementValueGet()` or `ProElementValueSet()` and `ProValueDataGet()` or `ProValueDataSet()`.

The function `ProElementValuetypeGet()` returns the nominal value type for the element.

The functions `ProElementReferenceGet()` and `ProElementReferenceSet()` returns and sets a single reference value for the element.

The function `ProElementReferencesGet()` returns an array of reference values for the element. The function outputs a reference array, which is a `ProArray`. Free this output using `ProReferencearrayFree()`.

The function `ProElementReferencesSet()` sets the multiple reference values for the element.

The function `ProElementIntegerGet()` returns an integer value representation for the element. The function `ProElementIntegerSet()` sets the integer value for the element.

The function `ProElementDoubleGet()` returns a double value representation for the element. The function `ProElementDoubleSet()` sets the double value for the element.

The function `ProElementDecimalsGet()` obtains the number of decimal places to be used for the double value of an element in the feature.

The function `ProElementDecimalsSet()` assigns the number of decimals to be used for the double value of an element in the feature. The double value is used in the feature dimension related to this element.

#### **Note**

Use the function `ProElementDecimalsSet()` before using the function `ProElementDoubleSet()` to ensure that the double value is assigned with the correct number of decimal places.

---

The following functions show how options are constructed and set for `ProElement*Get()` functions.

The function `ProElementwstoptsAlloc()` allocates the options used to retrieve wide string values.

---

The function `ProElementwstoptsExpressionsSet()` sets the options to retrieve values as expressions or relations, if they exist, instead of a string representations of the actual value. This function is applicable to nominal double and integer value elements only.

The function `ProElementwstoptsSignoptionsSet()` sets the options to retrieve values with special sign formatting (+/-), etc. This function is applicable to nominal double and integer value elements only.

The function `ProElementwstoptsFree()` frees the options used to retrieve string values.

The function `ProElementWstringGet()` returns a string value representation for the element. The function allows, optionally, a `ProElementWstrOpts()` structure that dictates the format of the output. Use the function `ProWstringFree()` to free this string.

The function `ProElementWstringSet()` sets the string value for the element.

The function `ProElementStringGet()` returns an ASCII string value representation for the element. The inputs for this function are the element and options for how the string should be obtained. The output is the ASCII string value. Free this string using `ProStringFree()`.

The function `ProElementStringSet()` sets the ASCII string value for the element.

The function `ProElementSpecialvalueGet()` returns the pointer representation for the element and the function `ProElementSpecialvalueSet()` sets the pointer representation for the element.

The function `ProElementBooleanGet()` returns the boolean representation for the element and the function `ProElementBooleanSet()` sets the boolean value for the element.

The function `ProElementTransformGet()` returns the transform representation for the element and the function `ProElementTransformSet()` sets the transform value for the element.

## Feature Element Diagnostics

Functions Introduced:

- **`ProElementDiagnosticsCollect()`**
- **`ProElemndiagnosticProarrayFree()`**
- **`ProElemndiagnosticSeverityGet()`**
- **`ProElemndiagnosticMessageGet()`**
- **`ProElemndiagnosticFree()`**

---

- **ProReferenceDiagnosticsCollect()**

The function `ProElementDiagnosticsCollect()` obtains a `ProArray` of diagnostics for the element. These diagnostics include warnings and errors regarding the value of the element within the context of the feature and remainder of the element tree. Use the function

`ProElemDiagnosticProarrayFree()` to free the `ProArray` of diagnostic items.

The function `ProElemDiagnosticSeverityGet()` returns the severity of the diagnostic item for the element.

The function `ProElemDiagnosticMessageGet()` obtains the message describing the diagnostic item for the element. This message is in the user's localized language.

The function `ProElemDiagnosticFree()` frees the diagnostic item for the element.

The function `ProReferenceDiagnosticsCollect()` obtains a `ProArray` of diagnostics for the reference element. These diagnostics include warnings and errors regarding the state of the reference element within the context of the feature.

## Calling ProFeatureCreate()

Function introduced:

- **ProFeatureCreate()**

The syntax of `ProFeatureCreate()` is as follows:

```
ProError ProFeatureCreate (
 ProSelection model, /* (In) The part on which
the feature is being
 created. If the
feature is created in an
 assembly, you
must specify the
component path. */
 ProElement elemtree, /* (In) The element tree.
*/
 ProFeatureCreateOptions options[], /* (In) An array of user
options. */
 int num_opts, /* (In) The number of
options in the options
array. */
```

---

```

 ProFeature *p_feature, /* (Out) The feature
handle. */
 ProErrorlist *p_errors /* (Out) The list of
errors. */
)

```

The first input argument to `ProFeatureCreate()` identifies the solid that is to contain the new feature. This is expressed in the form of a `ProSelection` object.

---

### **Note**

The `ProSelection` object input to `ProFeatureCreate()`, and all the `ProSelection` objects assigned to elements in the feature element tree, must all refer to the same root assembly.

---

The second input argument is the `ProElement` object that forms the root of the feature element tree.

The next two inputs are an array of creation options and the size of the array. The creation options specify what `ProFeatureCreate()` should do if the element tree is incomplete, or if the geometry cannot be constructed. Each option is one of the following values of the enumerated type `ProFeatureCreateOptions`:

- `PRO_FEAT_CR_NO_OPTS`—No options were chosen.
- `PRO_FEAT_CR_DEFINE_MISS_ELEMS`—Prompt the user to complete the feature if any elements are missing.
- `PRO_FEAT_CR_INCOMPLETE_FEAT`—Create the feature, even if some elements are missing. The feature will appear in the Creo Parametric feature list and model tree, but will not be used in regeneration.
- `PRO_FEAT_CR_FIX_MODEL_ON_FAIL`—If the feature geometry cannot be constructed, prompt the user to fix the problem.

If no options are needed, you can set the array to `NULL`, and the size to zero. If you do not specify any options, `ProFeatureCreate()` fails and reports errors if the element tree is incomplete, or if the geometry cannot be constructed.

To check whether a feature is incomplete, use the function `ProFeatureIsIncomplete()`.

The next argument is an output that provides a `ProFeature` object that identifies the newly created feature.

The final argument is an output that reports errors found in the feature element tree. This is designed as an aid to application developers because it is reporting errors that occur only as a result of incorrect application code; it is not designed as

---

a way of reporting errors to the Creo Parametric user. The errors are written to a structure called `ProErrorlist` whose declaration, in `ProItemerr.h`, is as follows:

```
typedef struct
{
 ProItemerror *error_list;
 int error_number;
} ProErrorlist;
typedef struct
{
 int err_item_id;
 ProErritemType err_item_type;
 ProError error;
} ProItemerror;
typedef enum ProErritemTypes
{
 PRO_ERRITEM_NONE = -1,
 PRO_ERRITEM_FEATELEM = 1
} ProErritemType;
```

The field `error_list` is an array of all the errors in the feature element tree found by `ProFeatureCreate()`. Each error has a value expressed in terms of the standard Creo TOOLKIT error type `ProError`, and can refer to an element of a specified identifier, or be a more general error.

---

#### **Note**

- There are many useful utilities located in the Creo TOOLKIT sample code under the Creo TOOLKIT loadpoint. Utilities such as `ProUtilElementtreePrint()` are particularly useful when building and debugging element trees.
  - From Pro/ENGINEER Wildfire 5.0 onward, the function `ProFeatureCreate()` has been deprecated. Instead, use the function `ProFeatureWithoptionsCreate()` with its input argument *flags* set to `PRO_REGEN_NO_FLAGS` for the equivalent behavior. `ProFeatureWithoptionsCreate()` has been described in detail in the [Manipulating Features based on Regeneration Flags on page 146](#) section in the [Core: Features on page 137](#) section.
- 

## Example of Complete Feature Creation

This section illustrates all the techniques explained so far in this section by showing the code required to create a datum plane in a part or an assembly. The datum plane created here is offset from a plane surface, and therefore has the following element tree:

## Example Element Tree: Offset Datum Plane

(The full element tree for datum plane features is described in the section [Element Trees: Datum Features](#) on page 811.)

In the code examples that follow, no checks of function return statuses are shown, for clarity. No variable declarations are shown, but the style of the code samples should make these self-explanatory.

The example assumes that the datum plane is being created by a utility function that has two inputs describing the offset surface as a `ProSelection` relative to the current part or assembly, and the offset distance, as follows:

```
int ProDatumPlaneCreate (ProSelection offset_surface,
 double offset_dist);
```

The first step is to create the element that forms the root of the element tree. This element has the element ID `PRO_E_FEATURE_TREE` but has no value, so it can be created simply by a call to `ProElementAlloc()`:

```
/*-----*
\
 Create the root of the element tree.

*/
 ProElementAlloc (PRO_E_FEATURE_TREE, &elem_tree);
```

The first element inside the root is, as for all features, the feature type. Its ID is `PRO_E_FEATURE_TYPE`, and it has the single value `PRO_FEAT_DATUM`. To set the value, you must first create a `ProValue` object of type integer.

```
/*-----*
\
```

```

 Allocate the feature type element.
/*-----
*/
 ProElementAlloc (PRO_E_FEATURE_TYPE, &elem_ftype);
/*-----*
\
 Set the value of the feature type element.
/*-----
*/
 value_data.type = PRO_VALUE_TYPE_INT;
 value_data.v.i = PRO_FEAT_DATUM;
 ProValueAlloc (&value);
 ProValueDataSet (value, &value_data);
 ProElementValueSet (elem_ftype, value);
/*-----*
\
 Add the feature type element as a child of the tree root.
/*-----
*/
 ProElemtreeElementAdd (elem_tree, NULL, elem_ftype);

```

The next element is simply the holder for the datum plane constraints, and this in turn contains a single constraint element (to be used for the offset constraint).

```

/*-----*
\
 Add a PRO_E_DTMLN_CONSTRAINTS element to the root of the
 tree.
/*-----
*/
 ProElementAlloc (PRO_E_DTMLN_CONSTRAINTS, &elem_consts);
 ProElemtreeElementAdd (elem_tree, NULL, elem_consts);
/*-----*
\
 Add a PRO_E_DTMLN_CONSTRAINT element to the constraints
 element.
/*-----
*/
 ProElementAlloc (PRO_E_DTMLN_CONSTRAINT, &elem_offset);
 ProElemtreeElementAdd (elem_consts, NULL, elem_offset);

```

Inside the single constraint element, add an element of type PRO\_E\_DTMLN\_CONSTR\_TYPE that specifies the constraint type to be PRO\_DTMLN\_OFFS.

```

/*-----*
\
 Allocate the constraint type element.
/*-----
*/
 ProElementAlloc (PRO_E_DTMLN_CONSTR_TYPE,
 &elem_const_type);
/*-----*
\

```

---

```

 Set its value to be PRO_DTMLN_OFFS.
/*-----
*/
 value_data.type = PRO_VALUE_TYPE_INT;
 value_data.v.i = PRO_DTMLN_OFFS;
 ProValueAlloc (&value);
 ProValueDataSet (value, &value_data);
 ProElementValueSet (elem_const_type, value);
/*-----
\
 Add it as a member of the constraint element.
/*-----
*/
 ProElemtreeElementAdd (elem_offset, NULL, elem_const_type);

```

**Also in the constraint element, you need an element to identify the reference plane surface, PRO\_E\_DTMLN\_CONSTR\_REF, with value type ProSelection.**

```

/*-----
\
 Allocate the offset reference element.
/*-----
*/
 ProElementAlloc (PRO_E_DTMLN_CONSTR_REF, &elem_offset_ref);
/*-----
\
 Set its value to be the ProSelection for the offset
 reference surface.
/*-----
*/
 value_data.type = PRO_VALUE_TYPE_SELECTION;
 value_data.v.r = offset_surface;
 ProValueAlloc (&value);
 ProValueDataSet (value, &value_data);
 ProElementValueSet (elem_offset_ref, value);
/*-----
\
 Add it to the constraint element.
/*-----
*/
 ProElemtreeElementAdd (elem_offset, NULL, elem_offset_ref);

```

**Finally, you need an element of type PRO\_E\_DTMLN\_CONSTR\_REF\_OFFSET to contain the double value of the offset distance.**

```

/*-----
\
 Allocate the offset distance element.
/*-----
*/
 ProElementAlloc (PRO_E_DTMLN_CONSTR_REF_OFFSET,
 &elem_offset_dist);

```

```

/*-----*
\
 Set its value to be the offset distance.
/*-----*
*/
 value_data.type = PRO_VALUE_TYPE_DOUBLE;
 value_data.v.d = offset_dist;
 ProValueAlloc (&value);
 ProValueDataSet (value, &value_data);
 ProElementValueSet (elem_offset_dist, value);
/*-----*
\
 Add it to the constraint element.
/*-----*
*/
 ProElemtreeElementAdd (elem_offset, NULL, elem_offset_dist);

```

The element tree is complete.

The next step is to set up a ProSelection object that refers to the solid in which you will create the datum plane.

You have the information about the context, in the form of the ProSelection object, for the offset surface that was an input to the function you are writing. The component path you need is the same one used to specify that surface. The solid to contain the new feature is the one that owns the offset surface. Therefore, you can build the ProSelection object for it as follows:

```

/*-----*
\
 Get the component path for the offset surface.
/*-----*
*/
 ProSelectionAsmcomppathGet (offset_surface, &comppath);
/*-----*
\
 Get the model item for the offset surface.
/*-----*
*/
 ProSelectionModelitemGet (offset_surface, &surf_modelitem);
/*-----*
\
 Make a ProModelitem that refers to the owner of the offset
 surface.
/*-----*
*/
 ProMdlToModelitem (surf_modelitem.owner, &model_modelitem);
/*-----*
\
 Make a ProSelection for the solid that will contain the
 new feature.

```

---

```

*-----
*/
 ProSelectionAlloc (&comppath, &model_modelitem, &featsel);

```

If the offset surface belongs to a part in a current assembly, and your function is required to add the datum plane not to the part but to the assembly, the code above would be replaced by this:

```

\
 Get the component path for the offset surface.
*-----
*/
 ProSelectionAsmcomppathGet (offset_surface, &comppath);

\
 Make a ProModelitem that refers to the root of the assembly.
*-----
*/
 ProMdlToModelitem (comppath.owner, &model_modelitem);

\
 Make a ProSelection for the root of the assembly.
*-----
*/
 ProSelectionAlloc (NULL, &model_modelitem, &featsel);

```

Finally, call `ProFeatureCreate()`.

```

\
 Create the datum plane feature.
*-----
*/
 ProFeatureCreate (featsel, elem_tree, NULL, 0, &feature,
 &errors);

```

## Feature Inquiry

Functions introduced:

- **ProFeatureElemtreeCreate()**
- **ProFeatureElemtreeExtract()**
- **ProFeatureElemtreeFree()**
- **ProFeatureElemValueGet()**
- **ProFeatureElemValuesGet()**
- **ProFeatureElemDimensionIdGet()**
- **ProFeatureElemIsVisible()**
- **ProFeatureIsIncomplete()**

---

- **ProFeatureElemIsIncomplete()**

This section describes how to extract the element tree from a feature and analyze it. To find out how to inquire about the feature as a whole and its role in the owning solid, see the section [Feature Inquiry](#) in the section [Core: Features on page 137](#).

The function `ProFeatureElemtreeCreate()` creates a copy of the feature element tree that describes the contents of a specified feature in the Creo Parametric database. It is applicable only to those feature types that can be created using `ProFeatureCreate()` (as described in [Overview of Feature Creation on page 771](#)). The tree can then be analyzed using the read-access functions, such as `ProElement*Get()`, `ProElement*Visit()`, and `ProElementArrayCount()` described in the sections [Feature Elements on page 780](#) and [Feature Element Paths on page 779](#).

#### **Note**

The function `ProFeatureElemtreeCreate()` has been deprecated as it does not provide options to resolve the paths of external references of the feature in case of assemblies. Use `ProFeatureElemtreeExtract()` instead.

---

The function `ProFeatureElemtreeExtract()` creates a copy of the feature element tree of a specified feature. It also provides options to resolve the paths of external references of the feature in case of assemblies.

Use the function `ProFeatureElemtreeFree()` to free a copy of the feature element tree extracted using `ProFeatureElemtreeCreate()` `ProFeatureElemtreeExtract()`. The function `ProElementFree()` does not free all of the feature-specific runtime data associated with the element tree, and thus can result in a memory leak for certain features.

Instead of copying the entire element tree to analyze it, you can extract information about particular elements directly from the feature. The remaining functions in this section serve that purpose.

The function `ProFeatureElemValueGet()` provides the value of a single-valued element specified by the `ProFeature` object and a `ProElemPath`. The function `ProFeatureElemValuesGet()` provides the values of a multivalued element in a feature.

The function `ProFeatureElemDimensionIdGet()` gives you the integer identifier of the dimension in the Creo Parametric database used to define the value of the specified single-valued element.

---

The function `ProFeatureElemIsVisible()` distinguishes elements added to the tree by Creo Parametric for internal reasons only, and are neither defined as needed for creation of that type of feature, nor otherwise documented.

The function `ProFeatureIsIncomplete()` identifies features in the Creo Parametric database whose element trees are still incomplete. Such a feature can arise by using the option `PRO_FEAT_CR_INCOMPLETE_FEAT` when calling `ProFeatureCreate()`, and does not give rise to geometry until completed. If a feature is incomplete, you can find out which element in its tree is at fault using the function `ProFeatureElemIsIncomplete()`. Its input is a `ProFeature` and a `ProElemPath`.

## Feature Redefine

Function introduced:

- **ProFeatureRedefine()**

The function `ProFeatureRedefine()` enables you to redefine a feature. It is applicable only to those feature types that can be created using `ProFeatureCreate()`.

The function `ProFeatureRedefine()` has arguments for the create options and for the resulting element errors, like those for `ProFeatureCreate()`

### To Redefine a Feature

1. Call `ProFeatureElemtreeExtract()` to get a copy of the element tree.
2. Analyze and modify the tree using functions `ProFeatureElem*()`, `ProElement*()`, and `ProElemPath*()`
3. Call `ProFeatureRedefine()` to replace the old element tree with the new one.

## XML Representation of Feature Element Trees

Creo TOOLKIT offers the capability of representing most feature element trees in the XML format. The XML representation of element trees simplifies the procedure of using Creo TOOLKIT access to Creo Parametric features. The Creo TOOLKIT API's that access the XML for element trees are capable of converting the XML content to and from an element tree structure (`ProElement`.)

In Pro/ENGINEER Wildfire 2.0, PTC recommends the use of XML representation for the core Pro/ENGINEER features and for the new sheetmetal wall features. Manufacturing features support is not available in this release.

---

## Introduction to Feature Element Trees in XML

In Creo TOOLKIT, the access to Creo Parametric features is available using a generic data-structure called element tree. You can use the element tree APIs to query, modify, and redefine the Creo Parametric features. To simplify the access to Creo Parametric feature using Creo TOOLKIT, the concept of XML representation of the element trees has been introduced. The XML representation shows the details of the element tree in text format. The XML files are easy to edit and you can recycle them back to create or to redefine features. All the Creo TOOLKIT supported features have support for their respective XML representations.

The function `ProElemtreeWrite()` writes the XML version of the element tree in a text file and the function `ProElemtreeFromXMLCreate()` is used to convert the XML version from a text file to the Creo TOOLKIT native element trees.

Functions Introduced:

- **ProElemtreeWrite()**
- **ProElemtreeFromXMLCreate()**
- **ProXmlerrorlistProarrayFree()**

The function `ProElemtreeWrite()` writes the feature element tree in XML format to the specified file. This function uses the Creo TOOLKIT native element tree as an input. The type of output required should be specified. Currently only XML format for the output is supported. The only output argument is the name of the output file included with the location and the extension.

The function `ProElemtreeFromXMLCreate()` reads in the XML file and converts into a corresponding Creo TOOLKIT native element tree. This function takes the name with location of the output XML file as an input and returns the generated element tree as the output.

The created element tree can be used as an input to `ProFeatureCreate` or `ProFeatureRedefine`.

In case of error in execution of this function, an error objects is populated and returned. This error object is a `ProArray` of errors. It contains the information like type of the error, path of the XML file, line number, column number, and the error message. The memory for the error object is allocated by the function is required to be freed in the Creo TOOLKIT application using `ProXmlerrorlistProarrayFree()`. The function has three levels of error on the basis of the severity warning, general error and fatal error. Upon encountering warning and general errors, the function continues parsing the input XML till the end and collects all the errors in the error object. For a fatal error, the function stops the parsing and returns immediately.

---

## Validation Using XML Schema

XML schemas are used for validation of element tree which is used for feature creation. Element tree in the form of XML representations are validated and passed to `ProFeatureCreate()` and `ProFeatureRedefine()`.

To use the Schema validation, the following config option must be set

The XML Schema defines the structure and data type for XML. The element name is compared with the element specified in schema for validation. In the case of compound elements, validation is done for name, order and number of the sub-elements. The Schema validates the accuracy of data to be passed as it supports the data type of the element. The Schema also checks whether the element is optional or compulsory.

The location of the Schema is `<install_dir>/proe/xmlelem/schema/ProTKFeature.xsd` contains the representation of different feature element. `ProTKObjects.xsd` contains the representation of basic and Creo TOOLKIT objects.

The schema validation of element tree takes place if the config option `enable_protk_xml_schema` is set to "yes" before passing XML file to `ProElementTreeFromXMLCreate()`.

If the validation fails, the corresponding error is populated into the error object which can be printed out and can be used to correct the input XML file. The error object contains the line number, column number and the error message as debug information.

The following is an example of Schema for Solidify Feature:

```
<xsd:sequence>
 <xsd:element name="PRO_E_FEATURE_TYPE"
type="StringData"
minOccurs="1" maxOccurs="1"/>
 <xsd:element name="PRO_E_FEATURE_FORM" type="StringData"
minOccurs="1" maxOccurs="1"/>
 <xsd:element name="PRO_E_PATCH_QUILT" type="Selection"
minOccurs="1" maxOccurs="1"/>
 <xsd:element name="PRO_E_PATCH_TYPE" type="IntegerData"
minOccurs="0" maxOccurs="1"/>
 <xsd:element name="PRO_E_PATCH_MATERIAL_SIDE" type=
"IntegerData"
minOccurs="0" maxOccurs="1"/>
 <xsd:element name="PRO_E_STD_FEATURE_NAME" type="StringData"
minOccurs="0" maxOccurs="1"/>
</xsd:sequence>
<!-- End Solidify -->
```

Following code demonstrate how to use the error object to print the information

```

status = ProElemtreeFromXMLCreate (input_file, &elemtree, &errors
);
if ((status == PRO_TK_GENERAL_ERROR) || (status == PRO_TK_
BAD_CONTEXT))
{
 printf ("ProElemtreeFromXMLCreate FAILURE :: %d \n", status);
 status = ProArraySizeGet (errors, &size_errors);
 printf("Size of the Error Object is %d \n", size_errors);
 printf("Content of the Error Object are \n");
 for (error_count = 0; error_count < size_errors; error_count++
)
 {
 printf("Error No = %d\n", error_count);
 printf("\t+ Error Type = %d\n", errors[error_count].error_
type);
 if (status == PRO_TK_GENERAL_ERROR)
 {
 printf("\t+ Error Path = %s\n",
 ProWstringToString (temp_string, errors[error_count].
error_source));
 printf("\t+ Line No = %d\n", errors[error_count].line_
number);
 printf("\t+ Column No = %d\n", errors[error_count].
column_number);
 }
 else if (status == PRO_TK_BAD_CONTEXT)
 {
 printf("\t+ Element Sr No = %d\n",
errors[error_count].line_number);
 printf("\t+ Element ID = %d\n",
errors[error_count].column_number);
 }
 ProWstringLengthGet (errors[error_count].message,
&string_length);
 temp_message_string = (char *) calloc (1, (string_length+1) *
sizeof (char));
 printf("\t+ Error Message = %s\n",
 ProWstringToString (temp_message_string,
errors[error_count].message));
 free (temp_message_string);
 }
}

```

The list of features supported for XML schema validation are as follows:

| Feature Type         | Feature Name                    |
|----------------------|---------------------------------|
| PRO_FEAT_DATUM_AXIS  | Datum Axis Feature              |
| PRO_FEAT_DATUM       | Datum Plane Feature             |
| PRO_FEAT_CSYS        | Datum Coordinate System Feature |
| PRO_FEAT_CURVE       | Datum Curve Feature             |
| PRO_FEAT_DATUM_POINT | Datum Point Feature             |

| Feature Type          | Feature Name                            |
|-----------------------|-----------------------------------------|
| PRO_FEAT_CHAMFER      | Chamfer Feature                         |
| PRO_FEAT_ROUND        | Round Feature                           |
| PRO_FEAT_DRAFT        | Draft Feature                           |
| PRO_FEAT_HOLE         | Hole Feature                            |
| PRO_FEAT_WALL         | Sheetmetal Flat or Flange Wall Feature  |
| PRO_FEAT_COMPONENT    | Assembly Component Feature              |
| PRO_FEAT_DATUM_QUILT  | Surface Merge Feature                   |
| PRO_FEAT_PATCH        | Solidify Feature of the type Patch      |
| PRO_FEAT_GEN_MERGE    | General Merge Feature                   |
| PRO_FEAT_SRF_MDL      | Mirror or Move Feature                  |
| PRO_FEAT_PROTRUSION   | Solidify Feature of the type Protrusion |
| PRO_FEAT_SHELL        | Shell Feature                           |
| PRO_FEAT_FIRST_FEAT   | First Feature                           |
| PRO_FEAT_CUT          | Solidify Feature of the type Cut        |
| PRO_FEAT_SLOT         | Slot Feature                            |
| PRO_FEAT_GEOM_COPY    | Copy Geometry Feature                   |
| PRO_FEAT_RIB          | Rib Feature                             |
| PRO_FEAT_REPLACE_SURF | Replace Surface Feature                 |

## XML Representations for Common Elements

The following section gives details about the XML representation of the common elements. The elements can represent a primitive type e.g. an integer or some complex Creo TOOLKIT object e.g. ProReference or ProCollection. The purpose of this representation is to enable externalize these objects in a model specific text format. The examples of the XML representations are also provided for easier understanding.

### Single Valued Element

A single valued element contains an element of type Integer, Double, String, or Boolean. Its value will be shown as the XML tags. For example:

```
<PRO_E_REV_ANGLE_FROM_VAL type="double">0.00</PRO_E_REV_ANGLE_FROM_VAL>
```

### Empty or Optional Element

An empty element in XML does not have any data value, but just the opening and closing XML tags. Empty elements are ignored by

`ProElemtreeFromXMLCreate()`. Unused optional elements in the feature's element tree appear as empty in the XML output from `ProElemtreeWrite()`.

```
<PRO_E_REV_ANGLE_FROM_REF type="selection" />
```

OR

```
<PRO_E_REV_ANGLE_FROM_REF type="selection"></PRO_E_REV_ANGLE_FROM_REF type>
```

## XML Representation for ProSelection or ProReference

This represents the contents of the ProSelection or ProReference object. If the reference is currently not active or fully available, the reference is included. Consult the function ProReferenceStatusGet() for more information. The reference XML includes details like UV parameters and 3D point for specific elements that require them. The assembly component path will be available for references that include the assembly context.

```
<PRO_E_DPOINT_PLA_CONSTR_REF type="selection">
<PRO_XML_REFERENCE type="reference">
<PRO_XML_REFERENCE_STATUS type="int">PRO_REF_NOT_FOUND</PRO_XML_REFERENCE_STATUS>
<PRO_XML_REFERENCE_OWNER type="owner">COMP2.prt</PRO_XML_REFERENCE_OWNER>
<PRO_XML_REFERENCE_ID type="id">46</PRO_XML_REFERENCE_ID>
<PRO_XML_REFERENCE_TYPE type="prototype">PRO_EDGE</PRO_XML_REFERENCE_TYPE>
<PRO_XML_ASMCOMP_PATH comppath="compound">
<PRO_XML_ASMCOMP_PATH_OWNER type="model">ASM_PNT.asm</PRO_XML_ASMCOMP_PATH_OWNER>
<PRO_XML_ASMCOMP_PATH_ARRAY type="array">
<PRO_XML_ASMCOMP_PATH_ITEM index="1">40</PRO_XML_ASMCOMP_PATH_ITEM>
</PRO_XML_ASMCOMP_PATH_ARRAY>
</PRO_XML_ASMCOMP_PATH>
<PRO_XML_UV_PARAM uv_parameter="array">
<PRO_XML_DOUBLE_VALUE type="u">0.000000</PRO_XML_DOUBLE_VALUE>
<PRO_XML_DOUBLE_VALUE type="v">0.000000</PRO_XML_DOUBLE_VALUE>
</PRO_XML_UV_PARAM>
</PRO_XML_REFERENCE>
</PRO_E_DPOINT_PLA_CONSTR_REF>
```

## XML Representation for ProCollection

This represents the contents of the ProCollection object. Collection type, collection instructions, instruction types, references, reference types are some of the contents. These are classified into surface and curve collections. Surface collection represents a set of surfaces in the model governed by rules like seed and boundary. Curve collection represents a set of edges or curves in the model governed by rules like one-by-one, surface-loop etc. The instruction type for the particular collection identifies the rule.

### Curve Collection

```
<PRO_E_STD_CURVE_COLLECTION_APPL type="collection">
 <PRO_XML_COLLECTION type="curve">
```

```

 <PRO_XML_COLLECTION_INSTRUCTIONS type="array">
 <PRO_XML_COLLECTION_INSTRUCTION type="compound">
 <PRO_XML_COLLECTION_INSTRUCTION_TYPE type="int">105</PRO_XML_
COLLECTION_INSTRUCTION_TYPE>
 <PRO_XML_CRV_COLL_REFS type="array">
 <PRO_XML_CRV_COLL_REF type="selection">
 <PRO_XML_REFERENCE type="reference">
 <PRO_XML_REFERENCE_OWNER type="owner">CRV_COLLECTION_PART.prt
</PRO_XML_REFERENCE_OWNER>
 <PRO_XML_REFERENCE_ID type="id">703</PRO_XML_REFERENCE_ID>
 <PRO_XML_REFERENCE_TYPE type="prototype">PRO_QUILT</PRO_XML_
REFERENCE_TYPE>
 </PRO_XML_REFERENCE>
 </PRO_XML_CRV_COLL_REF>
 <PRO_XML_CRV_COLL_REF type="selection">
 <PRO_XML_REFERENCE type="reference">
 <PRO_XML_REFERENCE_OWNER type="owner">CRV_COLLECTION_PART.prt
</PRO_XML_REFERENCE_OWNER>
 <PRO_XML_REFERENCE_ID type="id">679</PRO_XML_REFERENCE_ID>
 <PRO_XML_REFERENCE_TYPE type="prototype">PRO_EDGE</PRO_XML_
REFERENCE_TYPE>
 </PRO_XML_REFERENCE>
 </PRO_XML_CRV_COLL_REF>
 </PRO_XML_CRV_COLL_REFS>
 </PRO_XML_COLLECTION_INSTRUCTION>
 </PRO_XML_COLLECTION_INSTRUCTIONS>
 </PRO_XML_COLLECTION>
</PRO_E_STD_CURVE_COLLECTION_APPL>

```

## Surface Collection

```

<PRO_E_STD_SURF_COLLECTION_APPL type="collection">
 <PRO_XML_COLLECTION type="surface">
 <PRO_XML_COLLECTION_INSTRUCTIONS type="array">
 <PRO_XML_COLLECTION_INSTRUCTION type="compound">
 <PRO_XML_COLLECTION_INSTRUCTION_TYPE type="int">2
</PRO_XML_COLLECTION_INSTRUCTION_TYPE>
 <PRO_XML_SRFCOLL_INCLUDE type="boolean">1</PRO_XML_SRFCOLL_
INCLUDE>
 <PRO_XML_SRFCOLL_REFS type="array">
 <PRO_XML_SRFCOLL_REF type="compound">
 <PRO_XML_SRFCOLL_REFITEM_TYPE type="int">3</PRO_XML_SRFCOLL_
REFITEM_TYPE>
 <PRO_XML_SRFCOLL_REFITEM type="selection">
 <PRO_XML_REFERENCE type="reference">
 <PRO_XML_REFERENCE_OWNER type="owner">
 SRF_COLLECTION_PART.prt</PRO_XML_REFERENCE_OWNER>
 <PRO_XML_REFERENCE_ID type="id">17</PRO_XML_REFERENCE_ID>
 <PRO_XML_REFERENCE_TYPE type="prototype">PRO_SURFACE</PRO_XML_
REFERENCE_TYPE>
 </PRO_XML_REFERENCE>

```

```

 </PRO_XML_SRFCOLL_REFITEM>
 </PRO_XML_SRFCOLL_REF>
 <PRO_XML_SRFCOLL_REF type="compound">
 <PRO_XML_SRFCOLL_REFITEM_TYPE type="int">4</PRO_XML_SRFCOLL_
REFITEM_TYPE>
 <PRO_XML_SRFCOLL_REFITEM type="selection">
 <PRO_XML_REFERENCE type="reference">
 <PRO_XML_REFERENCE_OWNER type="owner">
 SRF_COLLECTION_PART.prt</PRO_XML_REFERENCE_OWNER>
 <PRO_XML_REFERENCE_ID type="id">26</PRO_XML_REFERENCE_ID>
 <PRO_XML_REFERENCE_TYPE type="prototype">PRO_SURFACE</PRO_
XML_REFERENCE_TYPE>
 </PRO_XML_REFERENCE>
 </PRO_XML_SRFCOLL_REFITEM>
 </PRO_XML_SRFCOLL_REF>
</PRO_XML_SRFCOLL_REFS>
</PRO_XML_COLLECTION_INSTRUCTION>
</PRO_XML_COLLECTION_INSTRUCTIONS>
</PRO_XML_COLLECTION>
</PRO_E_STD_SURF_COLLECTION_APPL>

```

## Pointer Element

Most pointer elements are written with their value appearing as “\*\*\*”. Elements with this value type are not supported by `ProElementFromXMLCreate()` (this element is not added to the created element tree.) The most common pointer element of this type is the Creo Parametric sketch element `PRO_E_SKETCHER`.

```
<PRO_E_SKETCHER type="pointer">***</PRO_E_SKETCHER>
```

## Compound Element

A compound element represents a collection of different types of sub-elements. Following is an example in XML format.

```

<PRO_E_REV_ANGLE type="compound">
 <PRO_E_REV_ANGLE_FROM type="compound">
 <PRO_E_REV_ANGLE_FROM_TYPE type="int">262144</PRO_E_REV_
ANGLE_FROM_TYPE>
 <PRO_E_REV_ANGLE_FROM_VAL type="double">0.00</PRO_E_REV_
ANGLE_FROM_VAL>
 <PRO_E_REV_ANGLE_FROM_REF type="selection" />
 <PRO_E_REV_ANGLE_FROM_LIMIT type="int">0</PRO_E_REV_ANGLE_
FROM_LIMIT>
 </PRO_E_REV_ANGLE_FROM>
 <PRO_E_REV_ANGLE_TO type="compound">
 <PRO_E_REV_ANGLE_TO_TYPE type="int">4194304</PRO_E_REV_
ANGLE_TO_TYPE>
 <PRO_E_REV_ANGLE_TO_VAL type="double">120.00</PRO_E_REV_
ANGLE_TO_VAL>
 <PRO_E_REV_ANGLE_TO_REF type="selection" />
 </PRO_E_REV_ANGLE_TO>
</PRO_E_REV_ANGLE>

```

```

 <PRO_E_REV_ANGLE_TO_LIMIT type="int">0</PRO_E_REV_ANGLE_
TO_LIMIT>
 </PRO_E_REV_ANGLE_TO>
</PRO_E_REV_ANGLE>

```

## Array Element

An array element represents a collection of elements of the same type. Following is an example of an array of PRO\_E\_RNDCH\_RADIUS elements in XML format.

```

<PRO_E_RNDCH_RADII type="array">
 <PRO_E_RNDCH_RADIUS type="compound">
 <PRO_E_STD_POINT_COLLECTION_APPL type="selection">
 <PRO_XML_REFERENCE type="reference">
 <PRO_XML_REFERENCE_OWNER type="owner">K01_X_COLLECTION_PART.prt
 </PRO_XML_REFERENCE_OWNER>
 <PRO_XML_REFERENCE_ID type="id">1268</PRO_XML_REFERENCE_ID>
 <PRO_XML_REFERENCE_TYPE type="prototype">PRO_CRV_END</PRO_XML_
REFERENCE_TYPE>
 </PRO_XML_REFERENCE>
 <PRO_E_STD_POINT_COLLECTION_APPL>
 <PRO_E_RNDCH_LEG1 type="compound">
 <PRO_E_RNDCH_LEG_TYPE type="int">1</PRO_E_RNDCH_LEG_TYPE>
 <PRO_E_RNDCH_LEG_VALUE type="double">36.00</PRO_E_RNDCH_LEG_VALUE>
 <PRO_E_RNDCH_REFERENCE_EDGE type="selection" />
 <PRO_E_RNDCH_REFERENCE_POINT type="selection" />
 </PRO_E_RNDCH_LEG1>
 <PRO_E_RNDCH_LEG2 type="compound">
 <PRO_E_RNDCH_LEG_TYPE type="int">0</PRO_E_RNDCH_LEG_TYPE>
 <PRO_E_RNDCH_LEG_VALUE type="double">0.00</PRO_E_RNDCH_LEG_VALUE>
 <PRO_E_RNDCH_REFERENCE_EDGE type="selection" />
 <PRO_E_RNDCH_REFERENCE_POINT type="selection" />
 </PRO_E_RNDCH_LEG2>
 </PRO_E_RNDCH_RADIUS>
 <PRO_E_RNDCH_RADIUS type="compound">
 <PRO_E_STD_POINT_COLLECTION_APPL type="selection">
 <PRO_XML_REFERENCE type="reference">
 <PRO_XML_REFERENCE_OWNER type="owner">K01_X_COLLECTION_PART.prt
 </PRO_XML_REFERENCE_OWNER>
 <PRO_XML_REFERENCE_ID type="id">1268</PRO_XML_REFERENCE_ID>
 <PRO_XML_REFERENCE_TYPE type="prototype">PRO_CRV_START</PRO_XML_
REFERENCE_TYPE>
 </PRO_XML_REFERENCE>
 <PRO_E_STD_POINT_COLLECTION_APPL>
 <PRO_E_RNDCH_LEG1 type="compound">
 <PRO_E_RNDCH_LEG_TYPE type="int">1</PRO_E_RNDCH_LEG_TYPE>
 <PRO_E_RNDCH_LEG_VALUE type="double">55.39</PRO_E_RNDCH_LEG_VALUE>
 <PRO_E_RNDCH_REFERENCE_EDGE type="selection" />
 <PRO_E_RNDCH_REFERENCE_POINT type="selection" />
 </PRO_E_RNDCH_LEG1>
 <PRO_E_RNDCH_LEG2 type="compound">

```

```

<PRO_E_RNDCH_LEG_TYPE type="int">0</PRO_E_RNDCH_LEG_TYPE>
<PRO_E_RNDCH_LEG_VALUE type="double">0.00</PRO_E_RNDCH_LEG_VALUE>
<PRO_E_RNDCH_REFERENCE_EDGE type="selection" />
<PRO_E_RNDCH_REFERENCE_POINT type="selection" />
</PRO_E_RNDCH_LEG2>
</PRO_E_RNDCH_RADIUS>
</PRO_E_RNDCH_RADII>

```

## Multivalued Element

The multi-valued element represents an array of same types of elements. The difference between the array and multi-valued elements lies in the Creo TOOLKIT handling of these elements. In the XML format both the representations are similar.

```

<PRO_E_SHELL_SRF type="multivalue">
 <PRO_E_SHELL_SRF_MULTI type="selection">
 <PRO_XML_REFERENCE type="reference">
 <PRO_XML_REFERENCE_OWNER type="owner">X_SHELL_REDEF.prt</PRO_XML_
REFERENCE_OWNER>
 <PRO_XML_REFERENCE_ID type="id">76</PRO_XML_REFERENCE_ID>
 <PRO_XML_REFERENCE_TYPE type="prototype">PRO_SURFACE</PRO_XML_
REFERENCE_TYPE>
 </PRO_XML_REFERENCE>
 </PRO_E_SHELL_SRF_MULTI>
 <PRO_E_SHELL_SRF_MULTI type="selection">
 <PRO_XML_REFERENCE type="reference">
 <PRO_XML_REFERENCE_OWNER type="owner">X_SHELL_REDEF.prt</PRO_XML_
REFERENCE_OWNER>
 <PRO_XML_REFERENCE_ID type="id">72</PRO_XML_REFERENCE_ID>
 <PRO_XML_REFERENCE_TYPE type="prototype">PRO_SURFACE</PRO_XML_
REFERENCE_TYPE>
 </PRO_XML_REFERENCE>
 </PRO_E_SHELL_SRF_MULTI>
 <PRO_E_SHELL_SRF_MULTI type="selection">
 <PRO_XML_REFERENCE type="reference">
 <PRO_XML_REFERENCE_OWNER type="owner">X_SHELL_REDEF.prt</PRO_XML_
REFERENCE_OWNER>
 <PRO_XML_REFERENCE_ID type="id">68</PRO_XML_REFERENCE_ID>
 <PRO_XML_REFERENCE_TYPE type="prototype">PRO_SURFACE</PRO_XML_
REFERENCE_TYPE>
 </PRO_XML_REFERENCE>
 </PRO_E_SHELL_SRF_MULTI>
</PRO_E_SHELL_SRF>

```

## Tips for Recycling XML Output of Element Trees

The easiest way to create an XML file for any feature element tree is to call `ProFeatureElemtreeExtract()` followed by `ProElemtreeWrite()`. The `pt_userguide` application includes this capability. While running this

application, select a feature. Click the right mouse button and choose **Export XML**. The output XML produced can be used and reused with modifications by passing it to `ProElemtreeFromXMLCreate()` to create an element tree. The resulting element tree can be used for new feature creation or redefinition of an existing feature. The following tips would help easier reuse and understanding failures.

- Creo Parametric models can have only a single feature with a specific name - before using the XML for creating a new feature, modify the value of the element `PRO_E_STD_FEATURE_NAME` appropriately. Since, feature name is an optional element, the XML tag for this element can be deleted from the XML file to promote reuse.
- The function `ProElemtreeWrite()` writes all of the elements in the input Creo TOOLKIT native element tree. Optional elements with empty data within XML tags from the XML file can be removed before reusing the XML file. It is also permitted to keep the optional elements as they are in the XML, but these elements are ignored by `ProElemtreeFromXMLCreate()`.
- `ProElemtreeFromXMLCreate()` converts the XML file to an element tree without validating that the data is appropriate for that feature type (for example, ensuring that the correct type is selected for references.) The error is detected when the element tree is used by `ProFeatureCreate()` or `ProFeatureRedefine()`.
- `ProElemtreeFromXMLCreate()` supports some enumerated symbols or the actual integer values. Use the output XML file as a guide to see which enumerated type names are accepted.
- The tag names used in the XML representation are derived from the list of `ProElemId` from `ProElemId.h`. These names must be used exactly as found in the `ProElemId.h` file.
- XML files created by one version of Creo Parametric are not guaranteed to be usable by other Creo Parametric versions, because the structure of the element tree also change between versions.

## A Sample Element Tree in XML for a Shell Feature

```
<?xml version="1.0" encoding="UTF-8"?>
<!--Sample XML File for shell feature -->
<PRO_E_FEATURE_TREE AppName="Creo Parametric" AppVersion="2003440"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation="ProTKFeature.xsd" type="compound">
 <PRO_E_FEATURE_TYPE type="int">PRO_FEAT_SHELL</PRO_E_FEATURE_
TYPE>
 <PRO_E_STD_FEATURE_NAME type="wstring">SHELL</PRO_E_STD_FEATURE_
NAME>
 <PRO_E_SHELL_SRF type="multivalued">
```

```

</PRO_E_ST_SHELL_LOCL_CMPD>
</PRO_E_ST_SHELL_LOCL_LIST>
</PRO_E_FEATURE_TREE>

```

The following example shows how to use `ProElemtreeWrite()` to export a feature element tree to XML.

```

#include <ProToolkit.h>
#include <ProMenuBar.h>
#include <ProMdl.h>
#include <ProSelection.h>
#include <ProFeature.h>
#include <ProWstring.h>
static
wchar_t MSGFIL[] =
{'u','t','i','l','i','t','i','e','s','.','t','x','t','\0'};
/*=====
=====*\
FUNCTION: UserFeatXMLWrite
PURPOSE: Write a feature's element tree to an XML file.
*=====
=====*/
int UserFeatXMLWrite (ProFeature* feat)
{
 ProElement elemtree;
 wchar_t wFilename [PRO_FILE_NAME_SIZE];
 /-
 -----\
 Prompt for the filename
 -----/
 ProMessageDisplay (MSGFIL, "USER Enter the XML file name:");
 if (ProMessageStringRead (PRO_FILE_NAME_SIZE, wFilename)
 != PRO_TK_NO_ERROR)
 return (0);
 /*-----*\
 Extract the element tree and convert it to XML
 -----/
 status = ProFeatureElemtreeExtract (feat,NULL,PRO_FEAT_EXTRACT_NO_OPTS,
 &elemtree);

 if (status == PRO_TK_NO_ERROR)
 {
 status = ProElemtreeWrite (elemtree, PRO_ELEMTREE_XML, wFilename);
 ProElementFree (&elemtree);
 }
 return status;
}

```

---

# Element Trees: References

## Overview of Reference Objects

This section describes functions that provide access to reference objects as an alternative for accessing the information as selections.

Reference objects are an alternative method for representing a geometric reference in Creo Parametric. Geometric references are usually represented using the `ProSelection` structure. Since `ProSelection` is designed as the result of an interactively selected item, it lacks some capabilities to provide complete meaning as a geometric reference.

The opaque handle `ProReference` provides complete functionality for geometric referencing including functions to access multiple or missing references.

## Reading References

Functions Introduced:

- **`ProReferenceStatusGet()`**
- **`ProReferenceIsLocalcopy()`**
- **`ProReferenceTypeGet()`**
- **`ProReferenceIdGet()`**
- **`ProReferenceOwnerGet()`**
- **`ProReferenceOwnerMdlnameGet()`**
- **`ProReferenceOriginaltypeGet()`**
- **`ProReferenceOriginalidGet()`**
- **`ProReferenceOriginalownerGet()`**
- **`ProReferenceOriginalownerMdlnameGet()`**
- **`ProReferenceAsmcomppathGet()`**
- **`ProReferenceParamsGet()`**
- **`ProReferencePointGet()`**
- **`ProReferenceToSelection()`**
- **`ProSelectionToReference()`**
- **`ProReferencearrayToSelections()`**
- **`ProSelectionarrayFree()`**
- **`ProSelectionarrayToReferences()`**
- **`ProReferenceFree()`**

---

- **ProReferencearrayFree()**

The function `ProReferenceStatusGet()` identifies the status of the reference. Typically references are of status `PRO_REF_ACTIVE`, indicating that the reference is available and its geometry is usable for construction of features. Other reference statuses include:

- `PRO_REF_MISSING` – The reference is to geometry that is inactive in the model. When reading the element tree of a feature that modifies the geometry it references (for example, a round of edge removes the edge) the references will have this status.
- `PRO_REF_NOT_FOUND` – Similar to `PRO_REF_MISSING`. The function indicates a reference that is critical to the feature that uses the function.
- `PRO_REF_FROZEN` – The reference is to geometry in a component frozen due to other missing references.
- `PRO_REF_FROZEN_PLACE`, `PRO_REF_SUPPRESSED`, `PRO_REF_EXCLUDED` – Not returned by `ProReferenceStatusGet()`.
- `PRO_REF_INVALID` – The reference is invalid in the context of the feature and the element in which it is used (for example, a non-linear edge used as direction reference for drafts or translations.)
- `PRO_REF_ALTERNATE` – The reference is using an alternate reference. The original reference information is available.

---

 **Note**

Reference status is highly dependent on the model state at the time the reference was obtained. References obtained from a feature via `ProFeatureElementTreeExtract()` may become “Missing” or “Not found” due to changes in the geometry applied later in the feature list. To obtain the reference status for a given reference as it is seen by a feature, use `ProInsertModeActivate()` to revert the model to the state just after that feature is created.

---

- `PRO_REF_WARNING`—The referenced entity has a warning.

---

 **Note**

References obtained from a feature that removes a geometric empty body can have a “Warning” or “Invalid” state. The statuses of the references are not stored in the models and are thrown at run time during feature creation, redefinition, or regeneration.

---

- `PRO_REF_NOT_IN_GEOM`—The reference is not within the geometry but is still being utilized.
- `PRO_REF_ALTERNATE2`—The alternate reference is adjusted to accommodate flex movement.

The function `ProReferenceIsLocalcopy()` identifies if the reference is a local copy of the external reference. If the reference is a local copy, the original reference information is available as well.

The function `ProReferenceTypeGet()` gets the type of handle that is referenced.

The function `ProReferenceIdGet()` gets the item identity of the reference handle.

The function `ProReferenceOwnerGet()` gets the `ProMdl` handle of the owner model for the reference. The output of these three functions provides access to the basic `ProModelItem` referenced by the `ProReference` handle. If the reference status is not `PRO_REF_ACTIVE`, some or all of this information may not be accessible (for example, the reference owner model is not accessible if the reference is to a geometry item in an unretrieved component). The function `ProReferenceOwnerMdlnameGet()` gets the reference owner name of the referenced geometry item, which may be available even if the model itself has not been retrieved.

The functions `ProReferenceOriginaltypeGet()`, `ProReferenceOriginalidGet()`, `ProReferenceOriginalownerGet()`, `ProReferenceOriginalownerMdlnameGet()` get the original properties of a geometric reference handle. These could be different from the actively used type if the reference has been backed up, copied locally, or replaced with an alternate.

The function `ProReferenceAsmcompmpathGet()` gets the component path of a reference handle.

The function `ProReferenceParamsGet()` gets the u-v parameters of a reference handle.

The function `ProReferencePointGet()` gets the selected point of a reference handle.

The function `ProReferenceToSelection()` gets and allocates a `ProSelection` containing a representation for this reference. The output of this function is the resulting `ProSelection` handle. This selection is independently allocated and should be freed using `ProSelectionFree()`.

The function `ProSelectionToReference()` gets and allocates a `ProReference` containing a representation for this selection. The output of this function is the resulting `ProReference` handle. This reference is independently allocated and should be freed using `ProReferenceFree()`.

---

The function `ProReferencearrayToSelections()` converts a reference `ProArray` to a selection `ProArray`. The input arguments for this function are

- *references* – The `ProArray` of reference handles.
- *skip\_unusable* – `PRO_B_TRUE` to skip the processing of missing references that cannot be valid selections. `PRO_B_FALSE` to process all references.

The output for this function is a selection that is a `ProArray` of selection handles. You can free this array using the function `ProSelectionarrayFree()`.

The function `ProSelectionarrayToReferences()` converts a selection `ProArray` to a reference `ProArray`. `ProArray` of selection handles is given as the input and the `ProArray` of reference handles is the output. Free this array using `ProReferencearrayFree()`.

The function `ProReferenceFree()` frees a reference handle.

The function `ProReferencearrayFree()` frees a reference `ProArray`. This function also free each `ProReference` handle using `ProReferenceFree()`.

## Modifying References

Functions Introduced:

- **`ProReferenceAlloc()`**
- **`ProReferenceSet()`**
- **`ProReferenceParamsSet()`**
- **`ProReferencePointSet()`**

The function `ProReferenceAlloc()` allocates a reference handle.

The function `ProReferenceSet()` sets the referenced model item and optionally component path for the reference handle.

The function `ProReferenceParamsSet()` sets the u-v parameters of a reference handle.

The function `ProReferencePointSet()` sets the selected point of a reference handle.

---

# Element Trees: Datum Features

## Element Trees: Datum Features

This section describes how to use the include files `ProDtmPln.h`, `ProDtmPnt.h`, `ProDtmAxis.h`, and `ProDtmCsys.h` to create datum features programmatically. The section on [Datum Plane Features on page 811](#) provides necessary background for creating datum features; we recommend you read that material first.

## Datum Plane Features

The element tree for a datum plane feature is documented in the header file `ProDtmPln.h`, and has a simple structure. Apart from the usual elements for the tree root and feature type, a datum plane contains the positioning constraints, an optional flip direction, and an optional fit type.

The constraints element `PRO_E_DT MPLN_CONSTRAINTS` is an array element that contains a `PRO_E_DT MPLN_CONSTRAINT` element for each constraint. Many elements forming the constraint element `PRO_E_DT MPLN_CONSTRAINT` are used only for certain constraint types, so any given datum plane may contain fewer elements than are shown in the tree. Similarly, all the elements forming the constraint element `PRO_E_DT MPLN_FIT` are not always essential.

The following figure shows the element tree for datum planes.

Many elements forming the constraint element `PRO_E_DTMLN_CONSTRAINT` are used only for the following constraint types:

- `PRO_E_DTMLN_CONSTR_REF_OFFSET`—Used if the constraint type is “offset.”
- `PRO_E_DTMLN_CONSTR_REF_ANGLE`—Used if the constraint type is “angle.”
- `PRO_E_DTMLN_CONSTR_SEC_IND`—Used if the constraint type is “section.”
- `PRO_E_DTMLN_OFF_CSYS`—Used if the constraint type is “offset” and the reference is “Csys.”
- `PRO_E_DTMLN_OFF_CSYS_OFFSET`—Used if the constraint type is “offset” and the reference is “Csys.”

Similarly, elements of the optional element `PRO_E_DTMLN_FIT` are used for the following fit types:

- PRO\_E\_DTMPN\_FIT\_REF—Used if the fit type is not “default” or “fit.”
- PRO\_E\_DTMLN\_FIT\_DIM\_RAD—Used if the fit type is “fit radius.”

The following table describes the tree elements in detail:

| Element ID                    | Element Name                   | Data Type                | Valid Value                                                |
|-------------------------------|--------------------------------|--------------------------|------------------------------------------------------------|
| PRO_E_FEATURE_TYPE            | Feature type                   | PRO_VALUE_TYPE_INT       | PRO_FEAT_DATUM                                             |
| PRO_E_STD_FEATURE_NAME        | Feature Name                   | PRO_VALUE_TYPE_WSTRING   |                                                            |
| PRO_E_DTMLN_CONSTRAINTS       | Constraints                    | Array                    |                                                            |
| PRO_E_DTMLN_CONSTRAINT        | Constraints                    | Compound                 |                                                            |
| PRO_E_DTMLN_CONSTR_TYPE       | Type                           | PRO_VALUE_TYPE_INT       | See ProDtmplnConstr Type                                   |

## Constraint Reference Types

The following table does not describe the entire list of combinations of geometrical constraints that can be applied, or the rules for what geometry items they can refer to. These are partially documented in Note 1 of the elements table in ProDtmPln.h, which includes the following information:

| Constraint Type         | Valid Reference Types                                                                                                                                                                             |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_DTMPLN_THRU         | PRO_AXIS, PRO_EDGE, PRO_CURVE, Channel, PRO_POINT, PRO_EDGE_START, PRO_EDGE_END, PRO_CRV_START, PRO_CRV_END, PRO_SURFACE (Plane, Cylinder)                                                        |
| PRO_DTMPLN_NORM         | PRO_AXIS, PRO_EDGE, PRO_CURVE, Channel PRO_SURFACE (plane)                                                                                                                                        |
| PRO_DTMPLN_PRL          | PRO_SURFACE (plane)                                                                                                                                                                               |
| PRO_DTMPLN_OFFS         | PRO_SURFACE (plane), PRO_CSYS                                                                                                                                                                     |
| PRO_DTMPLN_ANG          | PRO_SURFACE (plane)                                                                                                                                                                               |
| PRO_DTMPLN_TANG         | PRO_SURFACE (cylinder)                                                                                                                                                                            |
| PRO_DTMPLN_SEC          | PRO_FEATURE (blend)                                                                                                                                                                               |
| PRO_DTMPLN_DEF_X        | No reference needed                                                                                                                                                                               |
| PRO_DTMPLN_DEF_Y        | No reference needed                                                                                                                                                                               |
| PRO_DTMPLN_DEF_Z        | No reference needed                                                                                                                                                                               |
| PRO_DTMPLN_THRU_CSYS_XY | PRO_CSYS                                                                                                                                                                                          |
| PRO_DTMPLN_THRU_CSYS_YZ | PRO_CSYS                                                                                                                                                                                          |
| PRO_DTMPLN_THRU_CSYS_ZX | PRO_CSYS                                                                                                                                                                                          |

| PRO_DTMPLN_BISECTOR2    | Planar reference type: PRO_SURFACE<br><br>Linear reference types: PRO_AXIS, PRO_EDGE, PRO_CURVE                                                                                                   |

### Note

For constraint type PRO\_DTMPLN\_TANG, there can be two tangents to a cylindrical surface passing through a single point. Specify a point on the cylindrical surface so that the tangent plane is created through this point or a point nearer to this specified point keeping the tangency condition.

See Creo Parametric online help on datum planes for a detailed description of the valid constraint combinations and references.

## Fit Reference Types

The following table describes the corresponding rules for the fit options in detail:

| Fit Type              | Valid Reference Types |
|-----------------------|-----------------------|
| PRO_DTMLN_FIT_DEFAULT | —                     |
| PRO_DTMLN_FIT_PART    | PRO_PART              |
| PRO_DTMLN_FIT_FEATURE | PRO_FEATURE           |
| PRO_DTMLN_FIT_SURFACE | PRO_SURFACE           |
| PRO_DTMLN_FIT_EDGE    | PRO_EDGE              |
| PRO_DTMLN_FIT_AXIS    | PRO_AXIS              |
| PRO_DTMLN_FIT_RADIUS  | —                     |
| PRO_DTMLN_FIT_POINT   | PRO_POINT             |

### Example 1: Creating a Datum Plane

The sample code in the file `UgDatumCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_datum` shows how to create a datum plane that is offset from the specified plane. The user selects the reference plane and supplies the offset.

## Examples

### Example 1: Through a Plane

The element tree structure of a plane through a plane or planar surface is shown in the following figure:

The following table specifies the element tree constraints for this type:

| Placement Constraint Element             | Placement Constraint Member Elements | Valid Value         |
|------------------------------------------|--------------------------------------|---------------------|
| PRO_E_DTMLN_CONSTRAINT<br>(Constraint 1) | PRO_E_DTMLN_CONSTR_TYPE              | PRO_DTMLN_THRU      |
|                                          | PRO_E_DTMLN_CONSTR_REF               | PRO_SURFACE (Plane) |

## Example 2: Offset to a Plane

The element tree structure of a plane offset to a plane or to a planar surface is shown in the following figure.

```
|--PRO_E_DTMLN_CONSTRAINT
 |--PRO_E_DTMLN_CONSTR_TYPE
 |--PRO_E_DTMLN_CONSTR_REF
 |--PRO_E_DTMLN_CONSTR_REF_OFFSET
```

The following table specifies the element tree constraints for this type.

| Placement Constraint Element             | Placement Constraint Member Elements | Valid Value         |
|------------------------------------------|--------------------------------------|---------------------|
| PRO_E_DTMLN_CONSTRAINT<br>(Constraint 1) | PRO_E_DTMLN_CONSTR_TYPE              | PRO_DTMLN_OFFS      |
|                                          | PRO_E_DTMLN_CONSTR_REF               | PRO_SURFACE (Plane) |
|                                          | PRO_E_DTMLN_CONSTR_REF_OFFSET        | Offset value        |

## Example 3: Offset along a Csys Axis

The element tree structure of a plane offset along the coordinate system axis is shown in the following figure.

```
|--PRO_E_DTMLN_CONSTRAINT
 |--PRO_E_DTMLN_CONSTR_TYPE
 |--PRO_E_DTMLN_CONSTR_REF
 |--PRO_E_DTMLN_OFF_CSYS
 |--PRO_E_DTMLN_OFF_CSYS_OFFSET
```

The following table specifies the element tree constraints for this type.

| Placement Constraint Element             | Placement Constraint Member Elements | Valid Value                                                                |
|------------------------------------------|--------------------------------------|----------------------------------------------------------------------------|
| PRO_E_DTMLN_CONSTRAINT<br>(Constraint 1) | PRO_E_DTMLN_CONSTR_TYPE              | PRO_E_DTMLN_OFF_CSYS_OFFSET                                                |
|                                          | PRO_E_DTMLN_CONSTR_REF               | PRO_CSYS                                                                   |
|                                          | PRO_E_DTMLN_OFF_CSYS                 | PRO_DTMLN_OFF_CSYS_X or<br>PRO_DTMLN_OFF_CSYS_Y or<br>PRO_DTMLN_OFF_CSYS_Z |
|                                          | PRO_E_DTMLN_OFF_CSYS_OFFSET          | Offset value                                                               |

## Example 4 : Through a Csys Plane

The element tree structure of a plane passing through a coordinate system plane (XY/YZ/ZX) is shown in the following figure.

```
|--PRO_E_DTMPLN_CONSTRAINT
 |--PRO_E_DTMPLN_CONSTR_TYPE
 |--PRO_E_DTMPLN_CONSTR_REF
```

The following table specifies the element tree constraints for this type.

| Placement Constraint Element              | Placement Constraint Member Elements | Valid Value                                                                         |
|-------------------------------------------|--------------------------------------|-------------------------------------------------------------------------------------|
| PRO_E_DTMPLN_CONSTRAINT<br>(Constraint 1) | PRO_E_DTMPLN_CONSTR_TYPE             | PRO_DTMPLN_THRU_CSYS_XY<br>or PRO_DTMPLN_THRU_CSYS_YZ<br>or PRO_DTMPLN_THRU_CSYS_ZX |
|                                           | PRO_E_DTMPLN_CONSTR_REF              | PRO_CSYS                                                                            |

## Example 5: Parallel to a Plane and Through a Point

The element tree structure of a plane parallel to a plane or a planar surface and passing through a point is shown in the following figure.

```
--PRO_E_DTMPLN_CONSTRAINT
 |--PRO_E_DTMPLN_CONSTR_TYPE
 |--PRO_E_DTMPLN_CONSTR_REF
--PRO_E_DTMPLN_CONSTRAINT
 |--PRO_E_DTMPLN_CONSTR_TYPE
 |--PRO_E_DTMPLN_CONSTR_REF
```

The following table specifies the element tree constraints for this type.

| Placement Constraint Element              | Placement Constraint Member Elements | Valid Value                                                     |
|-------------------------------------------|--------------------------------------|-----------------------------------------------------------------|
| PRO_E_DTMPLN_CONSTRAINT<br>(Constraint 1) | PRO_E_DTMPLN_CONSTR_TYPE             | PRO_DTMPLN_PRL                                                  |
|                                           | PRO_E_DTMPLN_CONSTR_REF              | PRO_SURFACE (Plane)                                             |
| PRO_E_DTMPLN_CONSTRAINT<br>(Constraint 2) | PRO_E_DTMPLN_CONSTR_TYPE             | PRO_DTMPLN_THRU                                                 |
|                                           | PRO_E_DTMPLN_CONSTR_REF              | PRO_POINT,PRO_EDGE_START,PRO_EDGE_END,PRO_CRV_START,PRO_CRV_END |

## Example 6 : Through an Axis and Angle to a Plane

The element tree structure of a plane passing through an axis and at an angle to a plane is shown in the following figure.

```
--PRO_E_DTMLN_CONSTRAINT
 |--PRO_E_DTMLN_CONSTR_TYPE
 |--PRO_E_DTMLN_CONSTR_REF
--PRO_E_DTMLN_CONSTRAINT
 |--PRO_E_DTMLN_CONSTR_TYPE
 |--PRO_E_DTMLN_CONSTR_REF
 |--PRO_E_DTMLN_CONSTR_REF_ANGLE
```

The following table specifies the element tree constraints for this type.

| Placement Constraint Element             | Placement Constraint Member Elements | Valid Value                                         |
|------------------------------------------|--------------------------------------|-----------------------------------------------------|
| PRO_E_DTMLN_CONSTRAINT<br>(Constraint 1) | PRO_E_DTMLN_CONSTR_TYPE              | PRO_DTMLN_THRU                                      |
|                                          | PRO_E_DTMLN_CONSTR_REF               | PRO_AXIS, PRO_CURVE (STRAIGHT), PRO_EDGE (STRAIGHT) |
| PRO_E_DTMLN_CONSTRAINT<br>(Constraint 2) | PRO_E_DTMLN_CONSTR_TYPE              | PRO_DTMLN_ANG                                       |
|                                          | PRO_E_DTMLN_CONSTR_REF               | PRO_SURFACE (Plane),                                |
|                                          | PRO_E_DTMLN_CONSTR_REF_ANGLE         | Angle value (-360.0, 360.0)                         |

## Example 7: Through a Linear Reference (Axis, Inferred Axis, Straight Edge or Curve) and a Point

The element tree structure of a plane passing through an axis or an inferred axis and a point is shown in the following figure. An inferred axis is the axis of a surface of revolution like, Cylinder, Cone, Sphere, Torus or any other general surface of revolution.

```
--PRO_E_DTMLN_CONSTRAINT
 |--PRO_E_DTMLN_CONSTR_TYPE
 |--PRO_E_DTMLN_CONSTR_REF
--PRO_E_DTMLN_CONSTRAINT
 |--PRO_E_DTMLN_CONSTR_TYPE
 |--PRO_E_DTMLN_CONSTR_REF
```

The following table specifies the element tree constraints for this type.

| Placement Constraint Element             | Placement Constraint Member Elements | Valid Value                                                                                                                 |
|------------------------------------------|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| PRO_E_DTMLN_CONSTRAINT<br>(Constraint 1) | PRO_E_DTMLN_CONSTR_TYPE              | PRO_DTMLN_THRU                                                                                                              |
|                                          | PRO_E_DTMLN_CONSTR_REF               | PRO_AXIS, PRO_CURVE (STRAIGHT), PRO_EDGE (STRAIGHT, PRO_SURFACE (CYLINDER/CONE/ SPHERE/TORUS/General surface of revolution) |
| PRO_E_DTMLN_CONSTRAINT<br>(Constraint 2) | PRO_E_DTMLN_CONSTR_TYPE              | PRO_DTMLN_THRU                                                                                                              |
|                                          | PRO_E_DTMLN_CONSTR_REF               | PRO_POINT, PRO_EDGE_START, PRO_EDGE_END, PRO_CRV_START, PRO_CRV_END                                                         |

### Example 8: Normal to a Linear Reference (Axis, Inferred Axis, Straight Edge or Curve) and a Point

The element tree structure of a plane normal to an axis or inferred axis and passing through a point is shown in the following figure.

```
--PRO_E_DTMLN_CONSTRAINT
 |--PRO_E_DTMLN_CONSTR_TYPE
 |--PRO_E_DTMLN_CONSTR_REF
--PRO_E_DTMLN_CONSTRAINT
 |--PRO_E_DTMLN_CONSTR_TYPE
 |--PRO_E_DTMLN_CONSTR_REF
```

The following table specifies the element tree constraints for this type.

| Placement Constraint Element             | Placement Constraint Member Elements | Valid Value                                                                                                                  |
|------------------------------------------|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_DTMLN_CONSTRAINT<br>(Constraint 1) | PRO_E_DTMLN_CONSTR_TYPE              | PRO_DTMLN_NORM                                                                                                               |
|                                          | PRO_E_DTMLN_CONSTR_REF               | PRO_AXIS, PRO_CURVE (STRAIGHT), PRO_EDGE (STRAIGHT), PRO_SURFACE (CYLINDER/CONE/ SPHERE/TORUS/General surface of revolution) |
| PRO_E_DTMLN_CONSTRAINT<br>(Constraint 2) | PRO_E_DTMLN_CONSTR_TYPE              | PRO_DTMLN_THRU                                                                                                               |

| Placement Constraint Element | Placement Constraint Member Elements | Valid Value                                                         |
|------------------------------|--------------------------------------|---------------------------------------------------------------------|
|                              | PRO_E_DTMPN_CONSTR_REF               | PRO_POINT, PRO_EDGE_START, PRO_EDGE_END, PRO_CRV_START, PRO_CRV_END |

## Example 9: Midplane to a Plane and Parallel to Another Plane

The element tree structure of a midplane to a plane or a planar surface and parallel to another plane or planar surface, when these two references are parallel, is shown in the following figure.

```
--PRO_E_DTMPN_CONSTR
```

```
 |--PRO_E_DTMPN_CONSTR_TYPE
```

```
 |--PRO_E_DTMPN_CONSTR_REF
```

```
--PRO_E_DTMPN_CONSTR
```

```
 |--PRO_E_DTMPN_CONSTR_TYPE
```

```
 |--PRO_E_DTMPN_CONSTR_REF
```

The following table specifies the element tree constraints for this type.

| Placement Constraint Element         | Placement Constraint Member Elements | Valid Value         |
|--------------------------------------|--------------------------------------|---------------------|
| PRO_E_DTMPN_CONSTR<br>(Constraint 1) | PRO_E_DTMPN_CONSTR_TYPE              | PRO_DTMPN_MIDPLN    |
|                                      | PRO_E_DTMPN_CONSTR_REF               | PRO_SURFACE (Plane) |
| PRO_E_DTMPN_CONSTR<br>(Constraint 2) | PRO_E_DTMPN_CONSTR_TYPE              | PRO_DTMPN_PRL       |
|                                      | PRO_E_DTMPN_CONSTR_REF               | PRO_SURFACE (Plane) |

## Example 10: Midplane to a Plane and at an Angle to Another Plane

The element tree structure of a midplane to a plane or a planar surface and angular to another plane or planar surface, when these two references are intersecting, is shown in the following figure.

```
--PRO_E_DTMLN_CONSTRAINT
|--PRO_E_DTMLN_CONSTR_TYPE
|--PRO_E_DTMLN_CONSTR_REF
--PRO_E_DTMLN_CONSTRAINT
|--PRO_E_DTMLN_CONSTR_TYPE
|--PRO_E_DTMLN_CONSTR_REF
```

The following table specifies the element tree constraints for this type.

| Placement Constraint Element             | Placement Constraint Member Elements | Valid Value                                |
|------------------------------------------|--------------------------------------|--------------------------------------------|
| PRO_E_DTMLN_CONSTRAINT<br>(Constraint 1) | PRO_E_DTMLN_CONSTR_TYPE              | PRO_DTMLN_MIDPLN                           |
|                                          | PRO_E_DTMLN_CONSTR_REF               | PRO_SURFACE (Plane)                        |
| PRO_E_DTMLN_CONSTRAINT<br>(Constraint 2) | PRO_E_DTMLN_CONSTR_TYPE              | PRO_DTMLN_BISECTOR1<br>PRO_DTMLN_BISECTOR2 |
|                                          | PRO_E_DTMLN_CONSTR_REF               | PRO_SURFACE (Plane)                        |

## Example 11: Midplane to a Plane and Midplane to a Point

The element tree structure of a midplane to a plane or a planar surface and midplane to a point, where the point does not lie on the plane, is shown in the following figure.

```
--PRO_E_DTMLN_CONSTRAINT
|--PRO_E_DTMLN_CONSTR_TYPE
|--PRO_E_DTMLN_CONSTR_REF
--PRO_E_DTMLN_CONSTRAINT
|--PRO_E_DTMLN_CONSTR_TYPE
|--PRO_E_DTMLN_CONSTR_REF
```

The following table specifies the element tree constraints for this type.

| Placement Constraint Element             | Placement Constraint Member Elements | Valid Value         |
|------------------------------------------|--------------------------------------|---------------------|
| PRO_E_DTMLN_CONSTRAINT<br>(Constraint 1) | PRO_E_DTMLN_CONSTR_TYPE              | PRO_DTMLN_MIDPLN    |
|                                          | PRO_E_DTMLN_CONSTR_REF               | PRO_SURFACE (Plane) |

| Placement Constraint Element             | Placement Constraint Member Elements | Valid Value                                                                     |
|------------------------------------------|--------------------------------------|---------------------------------------------------------------------------------|
| PRO_E_DTMLN_CONSTRAINT<br>(Constraint 2) | PRO_E_DTMLN_CONSTR_TYPE              | PRO_DTMLN_MIDPLN                                                                |
|                                          | PRO_E_DTMLN_CONSTR_REF               | PRO_POINT,<br>PRO_EDGE_START,<br>PRO_EDGE_END,<br>PRO_CRV_START,<br>PRO_CRV_END |

## Example 12: Through Three Points

The element tree structure of a plane passing through three non-collinear points is shown in the following figure.

```
--PRO_E_DTMLN_CONSTRAINT
 |--PRO_E_DTMLN_CONSTR_TYPE
 |--PRO_E_DTMLN_CONSTR_REF
--PRO_E_DTMLN_CONSTRAINT
 |--PRO_E_DTMLN_CONSTR_TYPE
 |--PRO_E_DTMLN_CONSTR_REF
--PRO_E_DTMLN_CONSTRAINT
 |--PRO_E_DTMLN_CONSTR_TYPE
 |--PRO_E_DTMLN_CONSTR_REF
```

The following table specifies the element tree constraints for this type.

| Placement Constraint Element             | Placement Constraint Member Elements | Valid Value                                                         |
|------------------------------------------|--------------------------------------|---------------------------------------------------------------------|
| PRO_E_DTMLN_CONSTRAINT<br>(Constraint 1) | PRO_E_DTMLN_CONSTR_TYPE              | PRO_DTMLN_THRU                                                      |
|                                          | PRO_E_DTMLN_CONSTR_REF               | PRO_POINT, PRO_EDGE_START, PRO_EDGE_END, PRO_CRV_START, PRO_CRV_END |
| PRO_E_DTMLN_CONSTRAINT<br>(Constraint 2) | PRO_E_DTMLN_CONSTR_TYPE              | PRO_DTMLN_THRU                                                      |
|                                          | PRO_E_DTMLN_CONSTR_REF               | PRO_POINT, PRO_EDGE_START, PRO_EDGE_END, PRO_CRV_START, PRO_CRV_END |
| PRO_E_DTMLN_CONSTRAINT<br>(Constraint 3) | PRO_E_DTMLN_CONSTR_TYPE              | PRO_DTMLN_THRU                                                      |
|                                          | PRO_E_DTMLN_CONSTR_REF               | PRO_POINT, PRO_EDGE_START, PRO_EDGE_END, PRO_CRV_START, PRO_CRV_END |

### Example 13: To Flip Direction

The datum plane normal that is the Z-direction can be flipped for any of the types. The following table specifies the element tree to flip the plane.

| Element ID            | Valid Value                                       |
|-----------------------|---------------------------------------------------|
| PRO_E_DTMPLN_FLIP_DIR | PRO_DTMPLN_FLIP_DIR_NO or PRO_DTMPLN_FLIP_DIR_YES |

### Example 14: To Fit Outline to a Reference

The datum plane outline can be fit to a reference. The following figure shows the element tree structure using the fit elements.

|                         |
|-------------------------|
| --PRO_E_DTMPLN_FIT      |
| --PRO_E_DTMPLN_FIT_TYPE |
| --PRO_E_DTMPLN_FIT_REF  |

The following table specifies the element tree to use fit elements.

| Fit Compound Element | Fit Member Elements   | Valid Value         |
|----------------------|-----------------------|---------------------|
| PRO_E_DTMPLN_FIT     | PRO_E_DTMPLN_FIT_TYPE | PRO_DTMPLN_FIT_PART |
|                      | PRO_E_DTMPLN_FIT_REF  | PRO_PART            |

## Datum Point Features

The element tree for a datum point feature is documented in the header file `ProDtmPnt.h`. Apart from the usual elements for the tree root and feature type, a datum point contains the datum point type. The types of datum points available are:

- [Sketched Datum Point on page 824](#)
- [Field Datum Point on page 825](#)
- [Offset Csys Datum Point on page 826](#)
- [General Datum Point on page 827](#)

---

## Sketched Datum Point

A sketched datum point is created by sketching the point in the sketcher mode after specifying the plane on which the user wants to create a point.

---

### Note

The sketched datum point is obsolete. Hence, the element tree for sketched datum point defined in the header file `ProDtmPnt.h` is no longer supported. The sketched datum points are consolidated within the sketched feature as a geometry point. The geometry entities within the sketched feature generate the corresponding datum entities. To create new sketched datum points, you must use the element tree for sketched datum curves defined in the header file `ProDtmCrv.h`. Refer to the section [Sketched Datum Curves on page 854](#), for more information on sketched datum curves.

---

The following figure shows the element tree for a sketched datum point.

Define the following sub elements of `PRO_E_STD_SECTION` to complete the sketched datum point feature.

See the section [Element Trees: Sketched Features on page 1002](#) for techniques that must be used to create a sketched feature, like a sketched datum point.

## Feature Elements

The following table describes the elements of the element tree for sketched datum points:

| Element ID             | Element Name     | Data Type              | Valid Value              |
|------------------------|------------------|------------------------|--------------------------|
| PRO_E_FEATURE_TYPE     | Feature Type     | PRO_VALUE_TYPE_INT     | PRO_FEAT_DATUM_POINT     |
| PRO_E_DPOINT_TYPE      | Datum Point Type | PRO_VALUE_TYPE_INT     | PRO_DPOINT_TYPE_SKETCHED |
| PRO_E_STD_FEATURE_NAME | Feature Name     | PRO_VALUE_TYPE_WSTRING |                          |
| PRO_E_STD_SECTION      | Section          | Compound               | See ProStdSection.h      |

## Example 2: Creating a Sketched Datum Point

The sample code in the file `UgSketchedPointCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a Sketched Datum Point. The user is prompted to select the sketching planes, orientation planes, and then the reference edges for the sketch. The user is also required to enter the X and Y offsets to be applied to the sketch from the projected edges.

## Field Datum Point

A field datum point is created by selecting any point on a surface, edge, curve, or quilt. The point is located depending on the UV parameters. The location of the field point depends on the UV values of the point on the surface, edge, curve, or quilt.

The following figure shows the element tree for the field datum point.

## Feature Elements

The following table describes the elements of the element tree for the field datum points:

| Element ID             | Element Name        | Data Type                | Valid Value                                                                 |
|------------------------|---------------------|--------------------------|-----------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE     | Feature Type        | PRO_VALUE_TYPE_INT       | PRO_FEAT_DATUM_POINT                                                        |
| PRO_E_DPOINT_TYPE      | Datum Point Type    | PRO_VALUE_TYPE_INT       | PRO_DPOINT_TYPE_FIELD                                                       |
| PRO_E_STD_FEATURE_NAME | Feature Name        | PRO_VALUE_TYPE_WSTRING   |                                                                             |
| PRO_E_DPOINT_FIELD_REF | Placement reference | PRO_VALUE_TYPE_SELECTION | Surface, Edge, Curve, or Quilt. Note: UV is used to specify exact location. |

### Example 3: Creating a Field Datum Point

The sample code in the file `UgFieldPointCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a Field Datum Point on an edge or surface. The user is prompted to select a point on a curve or a surface.

### Offset Csys Datum Point

An Offset Csys Datum point is created using the coordinate system and values along the coordinate axes. Three types of coordinate systems can be used:

- Cartesian—Requires values along X, Y, Z axis.
- Cylindrical—Requires values along R, theta, Z axis.
- Spherical—Requires values along r, phi theta axis.

The following figure shows the element tree for Offset Csys Datum Point.

## Feature Elements

The following table describes the elements in the element tree for datum points.

| Element ID                        | Element Name                                      | Data Type                | Valid Value                            |
|-----------------------------------|---------------------------------------------------|--------------------------|----------------------------------------|
| PRO_E_FEATURE_TYPE                | Feature Type                                      | PRO_VALUE_TYPE_INT       | PRO_FEAT_DATUM_POINT                   |
| PRO_E_DPOINT_TYPE                 | Datum Point Type                                  | PRO_VALUE_TYPE_INT       | PRO_DPOINT_TYPE_OFFSET_CSYS            |
| PRO_E_STD_FEATURE_NAME            | Feature Name                                      | PRO_VALUE_TYPE_WSTRING   |                                        |
| PRO_E_DPOINT_OFST_CSYS_TYPE       | Reference Csys Type                               | PRO_VALUE_TYPE_INT       | See ProDtmpntOffCsys Type              |

### Example 4: Creating an Offset Csys Datum Point

The sample code in the file `UgOffsetPointCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create an Offset Datum Point at an offset from a specified coordinate system. The user is prompted to select the coordinate system.

### General Datum Point

A general datum point is created and constrained based on the selection context. The supported types are:

- Point on vertex
- Offset point

- Project point
- Point at intersection of three surfaces
- On or Offset surface
- Point at intersection of curve and surface
- Center of curve or surface
- Point at intersection of two curves
- Point on curve

When there are multiple intersections, the point location of general datum point depends on the following:

- Point at intersection of edge and edge—t value of point on second edge
- Point at intersection of edge and plane—t value of point on edge
- Point at intersection of curve and plane—t value of point on curve
- Point at intersection of two curves—t value of point on second curve
- Point at intersection of curve and surface—t value of point on curve
- Point at intersection of curve and axis—t value of point on curve

The following figure shows the element tree of a general datum point.

## Feature Elements

The following table describes the elements of the element tree for datum points.

| Element ID                   | Element Name             | Data Type                | Valid Value                                                               |
|------------------------------|--------------------------|--------------------------|---------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE           | Feature Type             | PRO_VALUE_TYPE_INT       | PRO_FEAT_DATUM_POINT                                                      |
| PRO_E_DPOINT_TYPE            | Datum Point Type         | PRO_VALUE_TYPE_INT       | PRO_DPOINT_TYPE_GENERAL                                                   |
| PRO_E_STD_FEATURE_NAME       | Feature Name             | PRO_VALUE_TYPE_WSTRING   |                                                                           |
| PRO_E_DPOINT_POINTS_ARRAY    | Points List              | Array                    | Not applicable                                                            |
| PRO_E_DPOINT_POINT           | One Point                | Compound                 | Not applicable                                                            |

## Placement Constraint References

Valid values for the PRO\_E\_DPOINT\_PLA\_CONSTR\_REF placement reference are as follows:

- Curve—SEL\_3D\_CURVE, SEL\_3D\_CABLE, SEL\_IGES\_WF
- Edge—SEL\_3D\_EDG
- Axis—SEL\_3D\_AXIS

- Vertex—SEL\_3D\_VERT or SEL\_CURVE\_END
- CSYS—SEL\_3D\_CSYS
- Surface—SEL\_3D\_SRF, SEL\_3D\_SRF\_LIST
- Datum Pnt—SEL\_3D\_PNT

## Placement Constraint Type

Valid values for PRO\_E\_DPOINT\_PLA\_CONSTR\_TYPE are as follows:

- PRO\_DTMPNT\_CONSTR\_TYPE\_ON
- PRO\_DTMPNT\_CONSTR\_TYPE\_OFFSET
- PRO\_DTMPNT\_CONSTR\_TYPE\_CENTER
- PRO\_DTMPNT\_CONSTR\_TYPE\_PARALLEL
- PRO\_DTMPNT\_CONSTR\_TYPE\_NORMAL
- PRO\_DTMPNT\_CONSTR\_TYPE\_PROJECT
- PRO\_DTMPNT\_CONSTR\_TYPE\_CARTESIAN
- PRO\_DTMPNT\_CONSTR\_TYPE\_CYLINDRICAL
- PRO\_DTMPNT\_CONSTR\_TYPE\_SPHERICAL

The last three are used when defining a point offset to a coordinate system.

## Constraint References

Valid values for the PRO\_E\_DPOINT\_DIM\_CONSTR\_REF dimension references are as following:

- Curve—SEL\_3D\_CURVE, SEL\_3D\_CABLE, SEL\_CRV\_PNT, SEL\_IGES\_WF
- Edge—SEL\_3D\_EDG, SEL\_EDG\_PNT
- Axis—SEL\_3D\_AXIS
- Coordinate system—SEL\_3D\_CSYS
- Vertex—SEL\_3D\_VERT or SEL\_CURVE\_END
- Surface—SEL\_3D\_SRF, SEL\_SRF\_PNT, SEL\_3D\_SRF\_LIST
- Coordinate system axis—SEL\_3D\_CSYS\_AXIS
- Datum Point—SEL\_3D\_PNT

## Constraint Type

Valid values for PRO\_E\_DPOINT\_DIM\_CONSTR\_TYPE are as follows:

- PRO\_DTMPNT\_CONSTR\_TYPE\_OFFSET

- PRO\_DTMPNT\_CONSTR\_TYPE\_LENGTH
- PRO\_DTMPNT\_CONSTR\_TYPE\_RATIO
- PRO\_DTMPNT\_CONSTR\_TYPE\_LENGTH\_END
- PRO\_DTMPNT\_CONSTR\_TYPE\_RATIO
- PRO\_DTMPNT\_CONSTR\_TYPE\_RATIO\_END
- PRO\_DTMPNT\_CONSTR\_TYPE\_ALONG\_X
- PRO\_DTMPNT\_CONSTR\_TYPE\_ALONG\_Y
- PRO\_DTMPNT\_CONSTR\_TYPE\_ALONG\_Z

## Example 5: Creating General Datum Point

The sample code in the file `UgGeneralPointCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a General Datum Point formed at the intersection of three selected surfaces. The user is prompted to select the three surfaces.

## Examples

### Example 1: Point on a Vertex

To create a datum point on the vertex, the following constraints are required.

| Placement Constraint Element                   | Reference Element                | Valid Value                   |
|------------------------------------------------|----------------------------------|-------------------------------|
| PRO_E_DPOINT_PLA_<br>CONSTRAINT (Constraint 1) | PRO_E_DPOINT_PLA_<br>CONSTR_REF  | Vertex                        |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_<br>ON |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_VAL  | Not applicable                |

### Example 2: Offset Point

To create one or more datum points at an offset, the following constraints are required.

| Placement Constraint Element                   | Reference Element                | Valid Value                       |
|------------------------------------------------|----------------------------------|-----------------------------------|
| PRO_E_DPOINT_PLA_<br>CONSTRAINT (Constraint 1) | PRO_E_DPOINT_PLA_<br>CONSTR_REF  | Vertex, Csys, or DPnt             |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_<br>OFFSET |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_VAL  | Offset value.                     |

The following tables provide valid values for Constraint 2. You can create a point at an offset using values from one of the following tables for Constraint 2.

| Placement Constraint Element                   | Reference Element                | Valid Value                         |
|------------------------------------------------|----------------------------------|-------------------------------------|
| PRO_E_DPOINT_PLA_<br>CONSTRAINT (Constraint 2) | PRO_E_DPOINT_PLA_<br>CONSTR_REF  | Curve, Edge or Axis                 |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_<br>PARALLEL |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_VAL  | Not applicable                      |

OR

| Placement Constraint Element                   | Reference Element                | Valid Value                       |
|------------------------------------------------|----------------------------------|-----------------------------------|
| PRO_E_DPOINT_PLA_<br>CONSTRAINT (Constraint 2) | PRO_E_DPOINT_PLA_<br>CONSTR_REF  | Surface                           |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_<br>NORMAL |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_VAL  | Not applicable                    |

OR

| Placement Constraint Element                   | Reference Element                | Valid Value                         |
|------------------------------------------------|----------------------------------|-------------------------------------|
| PRO_E_DPOINT_PLA_<br>CONSTRAINT (Constraint 2) | PRO_E_DPOINT_PLA_<br>CONSTR_REF  | Csys Axis                           |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_<br>PARALLEL |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_VAL  | Not applicable                      |

OR

| Placement Constraint Element                   | Reference Element                | Valid Value                                                                                                                       |
|------------------------------------------------|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_DPOINT_PLA_<br>CONSTRAINT (Constraint 2) | PRO_E_DPOINT_PLA_<br>CONSTR_REF  | Csys                                                                                                                              |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_<br>CARTESIAN or<br><br>PRO_DTMPNT_CONSTR_TYPE_<br>CYLINDRICAL or PRO_<br>DTMPNT_CONSTR_TYPE_<br>SPHERICAL |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_VAL  | Not applicable                                                                                                                    |

The following table provides valid values for dimension constraints.

| Dimension Constraint Element                   | Reference Element                | Valid Value                        |
|------------------------------------------------|----------------------------------|------------------------------------|
| PRO_E_DPOINT_DIM_<br>CONSTRAINT (Constraint 3) | PRO_E_DPOINT_DIM_<br>CONSTR_REF  | Not applicable                     |
|                                                | PRO_E_DPOINT_DIM_<br>CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_<br>ALONG_X |
|                                                | PRO_E_DPOINT_DIM_<br>CONSTR_VAL  | Offset Value                       |
| PRO_E_DPOINT_DIM_<br>CONSTRAINT (Constraint 4) | PRO_E_DPOINT_DIM_<br>CONSTR_REF  | Not applicable                     |
|                                                | PRO_E_DPOINT_DIM_<br>CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_<br>ALONG_Y |
|                                                | PRO_E_DPOINT_DIM_<br>CONSTR_VAL  | Offset Value                       |
| PRO_E_DPOINT_DIM_<br>CONSTRAINT (Constraint 5) | PRO_E_DPOINT_DIM_<br>CONSTR_REF  | Not applicable                     |
|                                                | PRO_E_DPOINT_DIM_<br>CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_<br>ALONG_Z |
|                                                | PRO_E_DPOINT_DIM_<br>CONSTR_VAL  | Offset Value                       |

As per Offset types the values are as follows:

|                                        | CARTESIAN | CYLINDRICAL | SPHERICAL |
|----------------------------------------|-----------|-------------|-----------|
| PRO_DTMPNT_<br>CONSTR_TYPE_<br>ALONG_X | X         | R           | RHO       |
| PRO_DTMPNT_<br>CONSTR_TYPE_<br>ALONG_Y | Y         | THETA       | PHI       |
| PRO_DTMPNT_<br>CONSTR_TYPE_<br>ALONG_Z | Z         | Z           | THETA     |

### Example 3: Point at Intersection of Three Surfaces

To create a datum point at the intersection of three surfaces, use the following constraints. Each surface can be a part surface, surface feature, or datum plane.

| Placement Constraint Element                   | Reference Element                | Valid Value                   |
|------------------------------------------------|----------------------------------|-------------------------------|
| PRO_E_DPOINT_PLA_<br>CONSTRAINT (Constraint 1) | PRO_E_DPOINT_PLA_<br>CONSTR_REF  | Surface                       |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_<br>ON |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_VAL  | Not applicable                |
| PRO_E_DPOINT_PLA_<br>CONSTRAINT (Constraint 2) | PRO_E_DPOINT_PLA_<br>CONSTR_REF  | Surface                       |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_<br>ON |

| Placement Constraint Element           | Reference Element            | Valid Value               |
|----------------------------------------|------------------------------|---------------------------|
|                                        | PRO_E_DPOINT_PLA_CONSTR_VAL  | Not applicable            |
| PRO_E_DPOINT_PLA_CONSTR (Constraint 3) | PRO_E_DPOINT_PLA_CONSTR_REF  | Surface                   |
|                                        | PRO_E_DPOINT_PLA_CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_ON |
|                                        | PRO_E_DPOINT_PLA_CONSTR_VAL  | Not applicable            |

### Example 4: Point On a Surface or Offset from a Surface

The following constraints are required to create a point on a surface or at an offset distance from a surface:

| Placement Constraint Element           | Reference Element            | Valid Value                                                |
|----------------------------------------|------------------------------|------------------------------------------------------------|
| PRO_E_DPOINT_PLA_CONSTR (Constraint 1) | PRO_E_DPOINT_PLA_CONSTR_REF  | Surface                                                    |
|                                        | PRO_E_DPOINT_PLA_CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_ON or PRO_DTMPNT_CONSTR_TYPE_OFFSET |
|                                        | PRO_E_DPOINT_PLA_CONSTR_VAL  | Not applicable                                             |
| PRO_E_DPOINT_PLA_CONSTR (Constraint 2) | PRO_E_DPOINT_PLA_CONSTR_REF  | Edge or Surface                                            |
|                                        | PRO_E_DPOINT_PLA_CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_OFFSET                              |
|                                        | PRO_E_DPOINT_PLA_CONSTR_VAL  | Offset value                                               |
| PRO_E_DPOINT_PLA_CONSTR (Constraint 3) | PRO_E_DPOINT_PLA_CONSTR_REF  | Edge or Surface                                            |
|                                        | PRO_E_DPOINT_PLA_CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_OFFSET                              |
|                                        | PRO_E_DPOINT_PLA_CONSTR_VAL  | Offset value                                               |

### Example 5: Point at Intersection of a Curve and a Surface

To create a datum point at the intersection of a curve and a surface, use the following constraints. The curve can be a part edge, surface feature edge, datum curve, axis, or an imported datum curve. The surface can be a part surface, surface feature, or datum plane.

| Placement Constraint Element           | Reference Element            | Valid Value                   |
|----------------------------------------|------------------------------|-------------------------------|
| PRO_E_DPOINT_PLA_CONSTR (Constraint 1) | PRO_E_DPOINT_PLA_CONSTR_REF  | Curve, axis, edge, or surface |
|                                        | PRO_E_DPOINT_PLA_CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_ON     |

| Placement Constraint Element                   | Reference Element                | Valid Value                                                                                                                                                                                |
|------------------------------------------------|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                | CONSTR_TYPE                      | ON                                                                                                                                                                                         |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_VAL  | Not applicable                                                                                                                                                                             |
| PRO_E_DPOINT_PLA_<br>CONSTRAINT (Constraint 2) | PRO_E_DPOINT_PLA_<br>CONSTR_REF  | - If value of constraint 1 is Curve, Axis, or Edge, the value of constraint 2 is surface.<br><br>- If value of constraint 1 is surface, the value of constraint 2 is Curve, Axis, or Edge. |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_<br>ON                                                                                                                                                              |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_VAL  | Not applicable                                                                                                                                                                             |

#### Note

If more than one intersections exist, the point is created at the intersection nearest to the curve reference parameter value.

### Example 6: Point At Center of Curve or Surface

To create a datum point at the center of an arc or circle entity, use the following constraints.

| Placement Constraint Element                   | Reference Element                | Valid Value                       |
|------------------------------------------------|----------------------------------|-----------------------------------|
| PRO_E_DPOINT_PLA_<br>CONSTRAINT (Constraint 1) | PRO_E_DPOINT_PLA_<br>CONSTR_REF  | Curve, edge, or surface (Sphere)  |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_<br>CENTER |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_VAL  | Not applicable                    |

### Example 7: Point at Intersection of Two Curves

To create a point at intersection of two curves, use the following constraints.

| Placement Constraint Element                   | Reference Element                | Valid Value                   |
|------------------------------------------------|----------------------------------|-------------------------------|
| PRO_E_DPOINT_PLA_<br>CONSTRAINT (Constraint 1) | PRO_E_DPOINT_PLA_<br>CONSTR_REF  | Curve, edge, or axis          |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_<br>ON |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_VAL  | Not applicable                |

| Placement Constraint Element                   | Reference Element                | Valid Value                   |
|------------------------------------------------|----------------------------------|-------------------------------|
| PRO_E_DPOINT_PLA_<br>CONSTRAINT (Constraint 2) | PRO_E_DPOINT_PLA_<br>CONSTR_REF  | Curve, edge, or axis          |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_<br>ON |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_VAL  | Not applicable                |

### Note

If more than one intersections exist, the point is created at the intersection nearest to the second reference parameter value.

## Example 8: Point On Curve

To create a datum point on a curve, the following constraints are required.

| Placement Constraint Element                   | Reference Element                | Valid Value                                          |
|------------------------------------------------|----------------------------------|------------------------------------------------------|
| PRO_E_DPOINT_PLA_<br>CONSTRAINT (Constraint 1) | PRO_E_DPOINT_PLA_<br>CONSTR_REF  | Curve, edge, or axis (It is valid with offset plane) |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_<br>ON                        |
|                                                | PRO_E_DPOINT_PLA_<br>CONSTR_VAL  | Not applicable                                       |

The following tables provide valid values for constraint 2. You can create a point on curve using values from one of the following tables for constraint 2.

Use the following values for constraint 2 if the length of curve from the start point or the end point is used to locate the point.

| Placement Constraint Element                   | Reference Element                | Valid Value                                                                |
|------------------------------------------------|----------------------------------|----------------------------------------------------------------------------|
| PRO_E_DPOINT_DIM_<br>CONSTRAINT (Constraint 2) | PRO_E_DPOINT_DIM_<br>CONSTR_REF  | Curve (Use the same curve as used in Constraint 1)                         |
|                                                | PRO_E_DPOINT_DIM_<br>CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_<br>LENGTH or PRO_DTMPNT_<br>CONSTR_TYPE_LENGTH_END |
|                                                | PRO_E_DPOINT_DIM_<br>CONSTR_VAL  | Length value (from curve start point or end point)                         |

Use the following values for constraint 2 if the ratio of distance from the start point or the end point is used to locate the point.

| Placement Constraint Element                   | Reference Element               | Valid Value                                        |
|------------------------------------------------|---------------------------------|----------------------------------------------------|
| PRO_E_DPOINT_DIM_<br>CONSTRAINT (Constraint 2) | PRO_E_DPOINT_DIM_<br>CONSTR_REF | Curve (Use the same curve as used in contrarian 1) |

| Placement Constraint Element | Reference Element            | Valid Value                                                      |
|------------------------------|------------------------------|------------------------------------------------------------------|
|                              | PRO_E_DPOINT_DIM_CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_RATIO or PRO_DTMPNT_CONSTR_TYPE_RATIO_END |
|                              | PRO_E_DPOINT_DIM_CONSTR_VAL  | Ratio value (from curve start or end)                            |

Use the following values for constraint 2 if the offset surface is used to locate the point on curve.

| Placement Constraint Element           | Reference Element            | Valid Value                   |
|----------------------------------------|------------------------------|-------------------------------|
| PRO_E_DPOINT_DIM_CONSTR (Constraint 2) | PRO_E_DPOINT_DIM_CONSTR_REF  | Surface                       |
|                                        | PRO_E_DPOINT_DIM_CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_OFFSET |
|                                        | PRO_E_DPOINT_DIM_CONSTR_VAL  | Offset value                  |

### Example 9: Project Datum Point On a Planar surface, Datum Plane, Datum Axis, Linear Curve or Linear Edge

To project a datum point on a planar surface, datum plane, or datum axis, the following constraints are required.

| Placement Constraint Element           | Reference Element            | Valid Value                          |
|----------------------------------------|------------------------------|--------------------------------------|
| PRO_E_DPOINT_PLA_CONSTR (Constraint 1) | PRO_E_DPOINT_PLA_CONSTR_REF  | Datum point, end of curve, or vertex |
|                                        | PRO_E_DPOINT_PLA_CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_PROJECT       |
|                                        | PRO_E_DPOINT_PLA_CONSTR_VAL  | Not applicable                       |
| PRO_E_DPOINT_PLA_CONSTR (Constraint 2) | PRO_E_DPOINT_PLA_CONSTR_REF  | Axis, curve, or edge                 |
|                                        | PRO_E_DPOINT_PLA_CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_ON            |
|                                        | PRO_E_DPOINT_PLA_CONSTR_VAL  | Not applicable                       |

OR

| Placement Constraint Element           | Reference Element            | Valid Value               |
|----------------------------------------|------------------------------|---------------------------|
| PRO_E_DPOINT_PLA_CONSTR (Constraint 2) | PRO_E_DPOINT_PLA_CONSTR_REF  | Surface                   |
|                                        | PRO_E_DPOINT_PLA_CONSTR_TYPE | PRO_DTMPNT_CONSTR_TYPE_ON |
|                                        | PRO_E_DPOINT_PLA_CONSTR_VAL  | Not applicable            |

## Datum Axis Features

The basic element tree for creating axes is available in the include file `ProDtmAxis.h`. The following figure shows the basic structure of the element tree.

Creo TOOLKIT supports creation of the following types of datum axes:

- [Point on Surface on page 839](#)
- [Tangent on page 840](#)
- [Example 3: Normal to a Linear Reference \(Axis, Inferred Axis, Straight Edge or Curve\) on page 840](#)
- [Example 4: Parallel to a Linear Reference \(Axis, Inferred Axis, Straight Edge or Curve\) on page 841](#)
- [Example 5: Through Edge or Surface on page 842](#)
- [Two Planes on page 843](#)
- [Two Points on page 843](#)
- [Normal Planes on page 844](#)

There is no single element that indicates the type in constraints element tree. The type is determined implicitly based on the constraint type and references. The types of the datum axis constraints for the references are defined by the enumerated type `ProDtmaxisConstrType` and are as follows:

- `PRO_DTMAXIS_CONSTR_TYPE_NORMAL`— Positions the datum axis normal to the selected reference.

- `PRO_DTMAXIS_CONSTR_TYPE_THRU`— Positions the datum axis through the selected reference.
- `PRO_DTMAXIS_CONSTR_TYPE_TANGENT`— Positions the datum axis tangent to the selected reference.
- `PRO_DTMAXIS_CONSTR_TYPE_CENTER`— Positions the datum axis through the center of the selected planar circular edge or curve and normal to the plane on which the selected curve or edge lies.
- `PRO_DTMAXIS_CONSTR_TYPE_PARALLEL`— Positions the datum axis parallel to the selected reference.

## Example 6: Creating a Datum Axis

The sample code in the file `UgDatumAxisCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a datum axis at the intersection of two selected surfaces. The user is prompted to select the two surfaces.

## Examples

### Example 1: Point on Surface

The element tree structure of the axis, created with type as `PRO_DTMAXIS_PNT_SURF`, is shown in the following figure.

The following table specifies the constraints for the `PRO_E_DTMAXIS_CONSTRAINT` elements in the element tree for the point on surface type of axis.

| Placement Constraint Element            | Placement Constraint Member Elements | Valid Value                    |
|-----------------------------------------|--------------------------------------|--------------------------------|
| PRO_E_DTMAXIS_CONSTRAINT (Constraint 1) | PRO_E_DTMAXIS_CONSTR_TYPE            | PRO_DTMAXIS_CONSTR_TYPE_THRU   |
|                                         | PRO_E_DTMAXIS_CONSTR_REF             | PRO_POINT                      |
| PRO_E_DTMAXIS_CONSTRAINT (Constraint 2) | PRO_E_DTMAXIS_CONSTR_TYPE            | PRO_DTMAXIS_CONSTR_TYPE_NORMAL |

| Placement Constraint Element | Placement Constraint Member Elements | Valid Value |
|------------------------------|--------------------------------------|-------------|
|                              | PRO_E_DTMAXIS_CONSTR_REF             | PRO_SURFACE |

## Example 2: Tangent

The element tree structure of the axis, created with type as Tangent, is shown in the following figure.

The following table specifies the constraints for the PRO\_E\_DTMAXIS\_CONSTRAINT elements in the element tree for the tangent type of axis.

| Placement Constraint Element            | Placement Constraint Member Elements | Valid Value                                                         |
|-----------------------------------------|--------------------------------------|---------------------------------------------------------------------|
| PRO_E_DTMAXIS_CONSTRAINT (Constraint 1) | PRO_E_DTMAXIS_CONSTR_TYPE            | PRO_DTMAXIS_CONSTR_TYPE_TANGENT                                     |
|                                         | PRO_E_DTMAXIS_CONSTR_REF             | PRO_EDGE, PRO_CURVE                                                 |
| PRO_E_DTMAXIS_CONSTRAINT (Constraint 2) | PRO_E_DTMAXIS_CONSTR_TYPE            | PRO_DTMAXIS_CONSTR_TYPE_THRU                                        |
|                                         | PRO_E_DTMAXIS_CONSTR_REF             | PRO_POINT, PRO_EDGE_START, PRO_EDGE_END, PRO_CRV_START, PRO_CRV_END |

## Example 3: Normal to a Linear Reference (Axis, Inferred Axis, Straight Edge or Curve)

The element tree structure of the axis, created with type as Normal, is shown in the following figure.

The following table specifies the constraints for the PRO\_E\_DTMAXIS\_CONSTRAINT elements in the element tree for the Normal type of axis.

| Placement Constraint Element            | Placement Constraint Member Elements | Valid Value                                                                                                                                                                   |
|-----------------------------------------|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_DTMAXIS_CONSTRAINT (Constraint 1) | PRO_E_DTMAXIS_CONSTR_TYPE            | PRO_DTMAXIS_CONSTR_TYPE_THRU                                                                                                                                                  |
|                                         | PRO_E_DTMAXIS_CONSTR_REF             | PRO_POINT, PRO_EDGE_START, PRO_EDGE_END, PRO_CRV_START, PRO_CRV_END                                                                                                           |
| PRO_E_DTMAXIS_CONSTRAINT (Constraint 2) | PRO_E_DTMAXIS_CONSTR_TYPE            |                                                                                                                                                                               |
|                                         | PRO_E_DTMAXIS_CONSTR_REF             | PRO_EDGE (STRAIGHT), PRO_CURVE (STRAIGHT), PRO_AXIS, PRO_SURFACE (CYLINDER/CONE/SPHERE/TORUS/General surface of revolution). The inferred axis will be used as the reference. |

#### Note

For the Normal type of datum axis creation, the reference provided for the first constraint that is, PRO\_DTMAXIS\_CONSTR\_TYPE\_THRU should not lie on the reference provided for second constraint that is PRO\_DTMAXIS\_CONSTR\_TYPE\_NORMAL.

### Example 4: Parallel to a Linear Reference (Axis, Inferred Axis, Straight Edge or Curve)

The element tree structure of the axis, created with type as Parallel, is shown in the following figure.

The following table specifies the constraints for the `PRO_E_DTMAXIS_CONSTRAINT` elements in the element tree for the Parallel type of axis.

| Placement Constraint Element            | Placement Constraint Member Elements | Valid Value                                                                                                                                                               |
|-----------------------------------------|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_DTMAXIS_CONSTRAINT (Constraint 1) | PRO_E_DTMAXIS_CONSTR_TYPE            | PRO_DTMAXIS_CONSTR_TYPE_THRU                                                                                                                                              |
|                                         | PRO_E_DTMAXIS_CONSTR_REF             | PRO_POINT, PRO_EDGE_START, PRO_EDGE_END, PRO_CRV_START, PRO_CRV_END                                                                                                       |
| PRO_E_DTMAXIS_CONSTRAINT (Constraint 2) | PRO_E_DTMAXIS_CONSTR_TYPE            | PRO_DTMAXIS_CONSTR_TYPE_PARALLEL                                                                                                                                          |
|                                         | PRO_E_DTMAXIS_CONSTR_REF             | PRO_EDGE (STRAIGHT), PRO_CURVE (STRAIGHT), PRO_AXIS, PRO_SURFACE (CYLINDER/CONE/SPHERE/TORUS/General surface of revolution). The inferred axis will be used as reference. |

## Example 5: Through Edge or Surface

The element tree structure of the axis, created with type Through an Edge or a Surface, is shown in the following figure.

The following table specifies the constraints for the `PRO_E_DTMAXIS_CONSTRAINT` elements in the element tree for the through type of axis.

| Placement Constraint Element            | Placement Constraint Member Elements | Valid Value                  |
|-----------------------------------------|--------------------------------------|------------------------------|
| PRO_E_DTMAXIS_CONSTRAINT (Constraint 1) | PRO_E_DTMAXIS_CONSTR_TYPE            | PRO_DTMAXIS_CONSTR_TYPE_THRU |

| Placement Constraint Element | Placement Constraint Member Elements | Valid Value                                 |
|------------------------------|--------------------------------------|---------------------------------------------|
|                              | PRO_E_DTMAXIS_CONSTR_REF             | PRO_EDGE (Straight), PRO_SURFACE (Cylinder) |

## Example 6: Two Planes

The element tree structure of the axis, created using the type as two planes, is as shown in the following figure.

The following table specifies the constraints for the PRO\_E\_DTMAXIS\_CONSTR elements in the element tree for the two planes reference scheme.

| Placement Constraint Element        | Placement Constraint Member Elements | Valid Value                  |
|-------------------------------------|--------------------------------------|------------------------------|
| PRO_E_DTMAXIS_CONSTR (Constraint 1) | PRO_E_DTMAXIS_CONSTR_TYPE            | PRO_DTMAXIS_CONSTR_TYPE_THRU |
|                                     | PRO_E_DTMAXIS_CONSTR_REF             | PRO_SURFACE (Planar)         |
| PRO_E_DTMAXIS_CONSTR (Constraint 2) | PRO_E_DTMAXIS_CONSTR_TYPE            | PRO_DTMAXIS_CONSTR_TYPE_THRU |
|                                     | PRO_E_DTMAXIS_CONSTR_REF             | PRO_SURFACE (Planar)         |

## Example 7: Two Points

The element tree structure of the axis, created using the type as two points, is shown in the following figure.

The following table specifies the constraints for the PRO\_E\_DTMAXIS\_CONSTRAINT elements in the element tree for the two points type of axis.

| Placement Constraint Element            | Placement Constraint Member Elements | Valid Value                                                         |
|-----------------------------------------|--------------------------------------|---------------------------------------------------------------------|
| PRO_E_DTMAXIS_CONSTRAINT (Constraint 1) | PRO_E_DTMAXIS_CONSTR_TYPE            | PRO_DTMAXIS_CONSTR_TYPE_THRU                                        |
|                                         | PRO_E_DTMAXIS_CONSTR_REF             | PRO_POINT, PRO_EDGE_START, PRO_EDGE_END, PRO_CRV_START, PRO_CRV_END |
| PRO_E_DTMAXIS_CONSTRAINT (Constraint 2) | PRO_E_DTMAXIS_CONSTR_TYPE            | PRO_DTMAXIS_CONSTR_TYPE_THRU                                        |
|                                         | PRO_E_DTMAXIS_CONSTR_REF             | PRO_POINT, PRO_EDGE_START, PRO_EDGE_END, PRO_CRV_START, PRO_CRV_END |

## Example 8: Normal Planes

The element tree structure of the axis, created using the type as Normal Planes, is shown in the following figure.

The following table specifies the constraints for the PRO\_E\_DTMAXIS\_CONSTRAINT elements in the element tree for the normal plane type of axis.

| Placement Constraint Element                | Placement Constraint Member Elements | Valid Value                              |
|---------------------------------------------|--------------------------------------|------------------------------------------|
| PRO_E_DTMAXIS_CONSTRAINT (Constraint 1)     | PRO_E_DTMAXIS_CONSTR_TYPE            | PRO_DTMAXIS_CONSTR_TYPE_NORMAL           |
|                                             | PRO_E_DTMAXIS_CONSTR_REF             | PRO_SURFACE (Planar)                     |
| PRO_E_DTMAXIS_DIM_CONSTRAINT (Constraint 2) | PRO_E_DTMAXIS_DIM_CONSTR_REF         | PRO_SURFACE (Planar), PRO_AXIS, PRO_EDGE |
|                                             | PRO_E_DTMAXIS_DIM_CONSTR_VAL         | Valid dimension                          |
| PRO_E_DTMAXIS_DIM_CONSTRAINT (Constraint 3) | PRO_E_DTMAXIS_DIM_CONSTR_REF         | PRO_SURFACE (Planar), PRO_AXIS, PRO_EDGE |
|                                             | PRO_E_DTMAXIS_DIM_CONSTR_VAL         | Valid dimension                          |

## Datum Coordinate System Features

The following figure illustrates the general structure of the element tree for coordinate system features.

Specifies that the coordinate system is independent of the zoom of the model. The coordinate system does not zoom when the model is zoomed.</li> <li>PRO_CSYS_DISPLAY_ZOOM_DEP_YES—Specifies</li> </ul> | PRO_VALUE_TYPE_INT | ProCsysDisplayZoomDepOpt |

| Element Id             | Element Name                                                                                                                    | Data Type             | Valid Values |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------|-----------------------|--------------|
|                        | that the size of the coordinate system is dependent on the zoom of the model. The coordinate system zooms when the model zooms. |                       |              |
| PRO_E_CSYS_AXIS_LENGTH | Axis length<br><br>Specifies the default length for the coordinate system axes.                                                 | PRO_VALUE_TYPE_DOUBLE |              |

### Note

To determine whether a coordinate system is a default coordinate system, query the number of PRO\_E\_CSYS\_ORIGIN\_CONSTRS and the number of PRO\_E\_CSYS\_ORIENTMOVES. If both of the numbers are zero, then Csys is the default coordinate system.

The following elements are common for all the cases of the coordinate system feature creation:

| Element ID             | Value         | Comments  |
|------------------------|---------------|-----------|
| PRO_E_FEATURE_TYPE     | PRO_FEAT_CSYS | Mandatory |
| PRO_E_STD_FEATURE_NAME | Feature Name  | Optional  |

## Example 7: Creating a Datum Coordinate System

The sample code in the file UgGeneralCsysCreate.c located at <creo\_toolkit\_loadpoint>/protk\_appls/pt\_userguide/ptu\_featcreat shows how to create a General Csys at an offset to the specified Csys. The user is prompted to select a Csys.

## Examples

### Example 1: Using Three Planes or Two Edges and Axes

Use the following elements if the origin of the coordinate system is defined using three planes or using two edges and axes:

| Element ID                | Comments  |
|---------------------------|-----------|
| PRO_E_CSYS_ORIGIN_CONSTRS | Mandatory |
| PRO_E_CSYS_ORIGIN_CONSTR  | Mandatory |

| Element ID                        | Comments                                                       |
|-----------------------------------|----------------------------------------------------------------|
| PRO_E_CSYS_ORIGIN_CONSTR_REF      | Mandatory                                                      |
| PRO_E_CSYS_ORIENTSELAXIS1_REF     | Optional, using default if not set                             |
| PRO_E_CSYS_ORIENTSELAXIS1_REF_OPT | Optional, using default if not set                             |
| PRO_E_CSYS_ORIENTSELAXIS1_OPT     | Mandatory if PRO_E_CSYS_ORIENTSELAXIS1_REF is a Csys reference |
| PRO_E_CSYS_ORIENTSELAXIS1_FLIP    | Optional                                                       |
| PRO_E_CSYS_ORIENTSELAXIS2_REF     | Optional, using default if not set                             |
| PRO_E_CSYS_ORIENTSELAXIS2_REF_OPT | Optional, using default if not set                             |
| PRO_E_CSYS_ORIENTSELAXIS2_OPT     | Mandatory if PRO_E_CSYS_ORIENTSELAXIS2_REF is a Csys reference |
| PRO_E_CSYS_ORIENTSELAXIS2_FLIP    | Optional                                                       |
| Others                            | Not applicable                                                 |

## Example 2: Using Curve, Edges, or Plane and Axis

Use the following elements if the origin of the coordinate system is defined with a plane and an axis, curve, or edges:

| Element ID                        | Comments                                                       |
|-----------------------------------|----------------------------------------------------------------|
| PRO_E_CSYS_ORIGIN_CONSTRS         | Mandatory                                                      |
| PRO_E_CSYS_ORIGIN_CONSTR          | Mandatory                                                      |
| PRO_E_CSYS_ORIGIN_CONSTR_REF      | Mandatory                                                      |
| PRO_E_CSYS_ORIENTSELAXIS1_REF     | Optional, using default if not set                             |
| PRO_E_CSYS_ORIENTSELAXIS1_REF_OPT | Optional, using default if not set                             |
| PRO_E_CSYS_ORIENTSELAXIS1_OPT     | Mandatory if PRO_E_CSYS_ORIENTSELAXIS1_REF is a Csys reference |
| PRO_E_CSYS_ORIENTSELAXIS1_FLIP    | Optional                                                       |
| PRO_E_CSYS_ORIENTSELAXIS2_REF     | Mandatory                                                      |
| PRO_E_CSYS_ORIENTSELAXIS2_REF_OPT | Optional, using default if not set                             |
| PRO_E_CSYS_ORIENTSELAXIS2_OPT     | Mandatory if PRO_E_CSYS_ORIENTSELAXIS2_REF is a Csys reference |
| PRO_E_CSYS_ORIENTSELAXIS2_FLIP    | Optional                                                       |
| Others                            | Not applicable                                                 |

## Example 3: Using a Vertex or a Datum Point

Use the following elements if the origin of the coordinate system is defined using a vertex or a datum point:

| Element ID                        | Comments                           |
|-----------------------------------|------------------------------------|
| PRO_E_CSYS_ORIGIN_CONSTRS         | Mandatory                          |
| PRO_E_CSYS_ORIGIN_CONSTR          | Mandatory                          |
| PRO_E_CSYS_ORIGIN_CONSTR_REF      | Mandatory                          |
| PRO_E_CSYS_ORIENTSELAXIS1_REF     | Mandatory                          |
| PRO_E_CSYS_ORIENTSELAXIS1_REF_OPT | Optional, using default if not set |

| Element ID                        | Comments                                                       |
|-----------------------------------|----------------------------------------------------------------|
| PRO_E_CSYS_ORIENTSELAXIS1_OPT     | Mandatory if PRO_E_CSYS_ORIENTSELAXIS1_REF is a Csys reference |
| PRO_E_CSYS_ORIENTSELAXIS1_FLIP    | Optional                                                       |
| PRO_E_CSYS_ORIENTSELAXIS2_REF     | Mandatory                                                      |
| PRO_E_CSYS_ORIENTSELAXIS2_REF_OPT | Optional, using default if not set                             |
| PRO_E_CSYS_ORIENTSELAXIS1_OPT     | Mandatory if PRO_E_CSYS_ORIENTSELAXIS2_REF is a Csys reference |
| PRO_E_CSYS_ORIENTSELAXIS2_FLIP    | Optional                                                       |
| Others                            | Not applicable                                                 |

### Example 4: Orienting by Selecting References

Use the following elements if PRO\_E\_CSYS\_ORIENT\_BY\_METHOD is PRO\_CSYS\_ORIENT\_BY\_SEL\_REFS:

| Element ID                        | Comments                           |
|-----------------------------------|------------------------------------|
| PRO_E_CSYS_ORIENTSELAXIS1_REF     | Mandatory                          |
| PRO_E_CSYS_ORIENTSELAXIS1_REF_OPT | Optional, using default if not set |
| PRO_E_CSYS_ORIENTSELAXIS1_OPT     | Optional, using default if not set |
| PRO_E_CSYS_ORIENTSELAXIS1_FLIP    | Optional, using default if not set |
| PRO_E_CSYS_ORIENTSELAXIS2_REF     | Mandatory                          |
| PRO_E_CSYS_ORIENTSELAXIS2_REF_OPT | Optional, using default if not set |
| PRO_E_CSYS_ORIENTSELAXIS2_OPT     | Optional, using default if not set |
| PRO_E_CSYS_ORIENTSELAXIS2_FLIP    | Optional, using default if not set |
| Others                            | Not applicable                     |

### Example 5: Orienting by Selecting Coordinate System Axes

Use the following elements if PRO\_E\_CSYS\_ORIENT\_BY\_METHOD is PRO\_CSYS\_ORIENT\_BY\_SEL\_CSYS\_AXES:

| Element ID                  | Comments                                                                                                          |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------|
| PRO_E_CSYS_NORMAL_TO_SCREEN | Optional, valid only if PRO_E_CSYS_ORIENT_BY_METHOD = PRO_CSYS_ORIENT_BY_SEL_CSYS_AXES. Otherwise, it is ignored. |
| Others                      | Not applicable                                                                                                    |

### Example 6: Using a Coordinate System

Use the following elements if the origin of the coordinate system is determined using a Csys:

| Element ID                   | Comments  |
|------------------------------|-----------|
| PRO_E_CSYS_ORIGIN_CONSTRS    | Mandatory |
| PRO_E_CSYS_ORIGIN_CONSTR     | Mandatory |
| PRO_E_CSYS_ORIGIN_CONSTR_REF | Mandatory |

| Element ID                      | Comments                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_CSYS_OFFSET_TYPE          | Optional, using default PRO_CSYS_OFFSET_CARTESIAN if not set                                                                                                                                                                                                                                                                                                                                                |
| PRO_E_CSYS_ORIENTMOVES          | Mandatory for non PRO_CSYS_OFFSET_CARTESIAN                                                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_CSYS_ORIENTMOVE           | Mandatory for non PRO_CSYS_OFFSET_CARTESIAN                                                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_CSYS_ORIENTMOVE_MOVE_TYPE | Mandatory for non PRO_CSYS_OFFSET_CARTESIAN                                                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_CSYS_ORIENTMOVE_MOVE_VAL  | <p>Mandatory for non PRO_CSYS_OFFSET_CARTESIAN</p> <p>For PRO_CSYS_OFFSET_CYLINDRICAL, the elements PRO_CSYS_ORIENTMOVE_MOVE_OPT_RAD, PRO_CSYS_ORIENTMOVE_MOVE_OPT_THETA, and PRO_CSYS_ORIENTMOVE_MOVE_OPT_ZI are required.</p> <p>For PRO_CSYS_OFFSET_SPHERICAL, the elements PRO_CSYS_ORIENTMOVE_MOVE_OPT_RAD, PRO_CSYS_ORIENTMOVE_MOVE_OPT_PHI, and PRO_CSYS_ORIENTMOVE_MOVE_OPT_THETA are required.</p> |
| PRO_E_CSYS_ORIENT_BY_METHOD     | Mandatory, using default PRO_CSYS_ORIENT_BY_SEL_REFS if not set                                                                                                                                                                                                                                                                                                                                             |

The function `ProDtmcsysTransformfileRead()` allocates required steps of the element tree to create CSYS from a transformation file.

The input file name to `ProDtmcsysTransformfileRead()` should have the name of a `.trf` file, with the extension. The name must be lowercase only. The file should contain a coordinate transform such as:

```

X1 X2 X3 Tx
Y1 Y2 Y3 Ty
Z1 Z2 Z3 Tz

```

where

- X1 Y1 Z1 is the X-axis direction,
- X2 Y2 Z2 is the Y-axis direction,
- X3 Y3 Z3 is not used (the right hand rule determines the Z direction), and
- Tx Ty Tz is the origin of the coordinate system.

## Element Trees: Datum Curves

This section describes how to create, redefine, and access data for datum curve features using Creo TOOLKIT. The section [Element Trees: Datum Features on page 811](#) provides necessary background for creating features; we recommend you read that material first.

---

## Datum Curve Features

The element trees for datum curve features supported in Creo TOOLKIT are documented in the header file `ProDtmCrv.h`. Each datum feature type has a unique element tree containing the parameters and references necessary to create that type of feature.

Not all datum curve types are currently supported in Creo TOOLKIT. Some curve feature types are yet to be converted into element tree form. Other curve types have element trees with data that is not yet accessible through Creo TOOLKIT.

## Common Elements

All datum curve features support the following common elements.

| Element ID             | Value                                                                      |
|------------------------|----------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE     | PRO_FEAT_CURVE                                                             |
| PRO_E_CURVE_TYPE       | As listed in ProCurveType. This element identifies the subtree to be used. |
| PRO_E_STD_FEATURE_NAME | Wstring (feature name)                                                     |

## Datum Curve Types

Creo TOOLKIT considers the following curve types for providing element tree access:

- [Sketched Datum Curves on page 854](#)
- [Trim Datum Curves on page 855](#)
- [Intersect Datum Curves on page 855](#)
- [Wrap Datum Curves on page 856](#)
- [Offset Datum Curves on page 856](#)
- [Tangent Offset Datum Curves on page 857](#)
- [Datum Curves from Cross Section on page 857](#)
- [Datum Curves from Equation on page 858](#)
- [Datum Curves from Point and Direction on page 858](#)

## Sketched Datum Curves

Creo TOOLKIT provides complete element tree access to the sketched datum curves. The sketched datum curves are sketched features, and therefore must be created using the techniques described in the [Element Trees: Sketched Features on page 1002](#).

| Element ID                 | Value                                  |
|----------------------------|----------------------------------------|
| PRO_E_CURVE_TYPE           | PRO_CURVE_TYPE_SKETCHED                |
| PRO_E_STD_SECTION          | Section element tree                   |
| PRO_E_DTMCRV_DISPLAY_HATCH | Integer (PRO_B_TRUE, PRO_B_FALSE)      |
| PRO_E_DTMCRV_HATCH_DENSITY | Double (if DISPLAY_HATCH = PRO_B_TRUE) |

## Trim Datum Curves

Creo TOOLKIT provides complete element tree access to trim datum curves (previously called Split datum curve).

| Element ID                | Value                                                |
|---------------------------|------------------------------------------------------|
| PRO_E_CURVE_TYPE          | PRO_CURVE_TYPE_SPLIT                                 |
| PRO_E_STD_CRV_SPLIT_CURVE | The PRO_CURVE geometric item selected for splitting. |
| PRO_E_STD_CRV_DIVIDER     | The geometric item used to divide the curve.         |
| PRO_E_STD_CRV_SPLIT_SIDE  | One of the ProSplit Sides enumerations               |

## Intersect Datum Curves

Creo TOOLKIT provides complete element tree access to intersect datum curves. In the user interface, the intersect curve type results in one of the following curve types depending upon the references selected:

- A curve based on the intersection of two surfaces
- A curve based on the projections of two sections

The feature element tree for Intersect curve type contains two independent sets of elements to support both these feature types. The curve type determines which elements are required. As the two projections curve type contains two independent PRO\_E\_STD\_SECTION elements, it must be created using the techniques described in the section [Element Trees: Sketched Features on page 1002](#).

| Element ID                 | Value                                                                                                                                                                                                                                                                 |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_CURVE_TYPE           | PRO_CURVE_TYPE_INTSRF                                                                                                                                                                                                                                                 |
| PRO_E_CRV_IP_REF_TYPE      | PRO_CURVE_TYPE_INTSRF                                                                                                                                                                                                                                                 |
| PRO_E_CRV_IP_COMP_REF1     | Compound                                                                                                                                                                                                                                                              |
| PRO_E_CRV_IP_REF_SEL1_TYPE | PRO_CURVE_TYPE_WHOLE for the whole surface selection; PRO_CURVE_TYPE_MULTIPLE_SEL for multiple independent surface selections.                                                                                                                                        |
| PRO_E_CRV_IP_REF1          | Based on the value of PRO_E_CRV_IP_SEL1_TYPE.<br><br>If the value is whole, specifies a single selection of a datum plane, quilt, or solid geometry entity.<br><br>If the value is multiple, specifies a multi-valued element containing any number of surface items. |
| PRO_E_CRV_IP_COMP_REF2     | Compound                                                                                                                                                                                                                                                              |

| Element ID                 | Value                                                                                                                                                                                                                                                                 |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_CRV_IP_REF_SEL2_TYPE | PRO_CURVE_TYPE_WHOLE for the whole surface selection; PRO_CURVE_TYPE_MULTIPLE_SEL for multiple independent surface selections.                                                                                                                                        |

| PRO_E_STD_SECTION          | Section element tree                                                                                                                                                                                                                                                  |
| PRO_E_CRV_IP_COMP_SEC2     | Compound                                                                                                                                                                                                                                                              |
| PRO_E_STD_SECTION          | Section element tree                                                                                                                                                                                                                                                  |

## Wrap Datum Curves

Creo TOOLKIT provides complete element tree access to wrap datum curves (also called Formed datum curves). Because the curve type contains a PRO\_E\_STD\_SECTION element, you must create it using the techniques described in the section [Element Trees: Sketched Features on page 1002](#).

| Element ID               | Value                                                                    |
|--------------------------|--------------------------------------------------------------------------|
| PRO_E_CURVE_TYPE         | PRO_CURVE_TYPE_WRAP                                                      |
| PRO_E_CRV_WRAP_SRF_TYPE  | One of ProWrapSrfType                                                    |
| PRO_E_CRV_WRAP_SRF       | Selection containing the wrap surface (surface, quilt or solid geometry) |
| PRO_E_STD_SECTION        | Section                                                                  |
| PRO_E_CRV_WRAP_FLIP      | One of ProWrapFlip                                                       |
| PRO_E_CRV_WRAP_COORD_SYS | ID of the section coordinate system                                      |

## Offset Datum Curves

Creo TOOLKIT provides partial element tree access to offset datum curves. In the user interface, the Offset curve type results in one of the following curve types depending upon the selected references:

- A curve offset normal to a surface
- A curve offset along a quilt

The feature element tree for Offset curve type contains elements that support both these feature types. The curve type determines which elements are required:

- PRO\_CURVE\_TYPE\_OFFSET is offset normal to a surface

- `PRO_CURVE_TYPE_OFFSET_IN_QUILT` is offset along a quilt. Offset along a quilt is not supported in Creo TOOLKIT.

Creation, redefinition or inspection of the curve type `PRO_CURVE_TYPE_OFFSET_IN_QUILT` is not supported. This is because the curve type contains elements that require data at run-time, which is not currently accessible to Creo TOOLKIT.

The following table lists all the elements that are used to create the curve type `PRO_CURVE_TYPE_OFFSET`.

| Element ID                                | Value                                                     |
|-------------------------------------------|-----------------------------------------------------------|
| <code>PRO_E_CURVE_TYPE</code>             | <code>PRO_CURVE_TYPE_OFFSET</code>                        |
| <code>PRO_E_CRV_OFFS_FEAT_TYPE</code>     | <code>PRO_OFFSET_FROM_SURFACE</code>                      |
| <code>PRO_E_CRV_OFFS_SRF_REF</code>       | Selection of surface or quilt                             |
| <code>PRO_E_CRV_OFFS_DIR_FLIP</code>      | One of <code>ProOffsetDirFlip</code>                      |
| <code>PRO_E_DATUM_CURVE_OFFSET_VAL</code> | The offset value or scale if a graph is used for offset   |
| <code>PRO_E_CRV_OFFS_CRV_REF</code>       | Selection of datum curve to be offset                     |
| <code>PRO_E_CRV_OFFS_GRAPH_REF</code>     | Selection of graph used for offset calculation (optional) |
| <code>PRO_E_CRV_OFFS_ST_END</code>        | One of <code>ProOffsetStEnd</code>                        |

## Tangent Offset Datum Curves

The curve type Tangent Offset is obsolete in Creo Parametric. As the existing models created in earlier releases may contain this curve type, Creo TOOLKIT provides read and redefine access only for these curves.

| Element ID                               | Value                                              |
|------------------------------------------|----------------------------------------------------|
| <code>PRO_E_CURVE_TYPE</code>            | <code>PRO_CURVE_TYPE_TANGENT_OFFSET</code>         |
| <code>PRO_E_CRV_TANG_OFFSET_CURVE</code> | Selection of curve to be offset                    |
| <code>PRO_E_CRV_TANG_OFFSET_SURF</code>  | Selection of surface in which to create the offset |
| <code>PRO_E_CRV_TANG_OFFSET_DIR</code>   | One of <code>ProOffsetDirection</code>             |
| <code>PRO_E_CRV_TANG_OFFSET_DIST</code>  | Offset value                                       |

## Datum Curves from Cross Section

Creo TOOLKIT provides complete element tree access to datum curves created using existing planar cross sections in the model. The elements for this feature type are described below:

| Element ID                                | Value                                                                                               |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>PRO_E_CURVE_TYPE</code>             | <code>PRO_CURVE_TYPE_FROM_XSEC</code>                                                               |
| <code>PRO_E_CRV_FROM_XSEC_REF_XSEC</code> | Mandatory element. Specifies the selection of a cross section to be used to create the datum curve. |

## Datum Curves from Equation

Creo TOOLKIT provides complete element tree access to datum curves created using an equation. Some of the elements for this feature type are described below:

| Element ID                | Value                                                                                                                                  |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_CURVE_TYPE          | PRO_CURVE_TYPE_FROM_EQUATION                                                                                                           |
| PRO_E_CRV_FR_EQ_REF_CSYS  | Selection of coordinate system used as a reference. The coordinate system represents the location of the 'zero point' of the equation. |
| PRO_E_CRV_FR_EQ_CSYS_TYPE | One of ProCrvFrEquatCsysTypes                                                                                                          |
| PRO_E_CRV_FR_EQ_PARAM_MIN | Value of the lower limit for the domain of the curve                                                                                   |
| PRO_E_CRV_FR_EQ_PARAM_MAX | Value of the upper limit for the domain of the curve                                                                                   |
| PRO_E_CRV_ENTER_EQUATION  | Parametric equation in terms the variables of the selected coordinate system type                                                      |

## Datum Curves from Point and Direction

Creo TOOLKIT provides complete element tree access to geodesic curve created on a surface using a start point and direction. Some of the elements for this feature type are described below:

| Element ID                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_CURVE_TYPE                | PRO_CURVE_TYPE_FROM_PNT                                                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_CFP_REF_POINT             | Selection of the start point of the curve which can be a datum point, vertex, or coordinate system.                                                                                                                                                                                                                                                                                                                           |
| PRO_E_STD_SURF_COLLECTION_APPL  | Collection of surfaces of a body or a quilt on which to place the curve.                                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_DIRECTION_COMPOUND        | Compound.<br><br>Collection of surface, plane, curve, edge axis, coordinate system axis, or vertex that defines the initial direction of the curve.                                                                                                                                                                                                                                                                           |
| PRO_E_CFP_ANGLE                 | Angle between the initial direction and the tangent to the curve at the start point.                                                                                                                                                                                                                                                                                                                                          |
| PRO_E_CFP_TERMINATION1          | Compound<br><br>Extent of the curve from the start point in the selected direction.                                                                                                                                                                                                                                                                                                                                           |
| PRO_E_CFP_TERM1_TYPE            | Curve extension from start point. One of ProCrvFrPntExtentType. The values are: <ul style="list-style-type: none"><li>• PRO_CRV_FR_PNT_EXTENT_LENGTH—Extends the curve to a specified length</li><li>• PRO_CRV_FR_PNT_EXTENT_REF—Extends the curve to the selected reference.</li><li>• PRO_CRV_FR_PNT_EXTENT_DOMAIN—Extends the curve along all the selected surfaces until the curve reaches the domain boundary.</li></ul> |
| PRO_E_CFP_LENGTH1               | Curve extension to the specified length.                                                                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_STD_CURVE_COLLECTION_APPL | Bounding chain curve collection.                                                                                                                                                                                                                                                                                                                                                                                              |

| Element ID                      | Value                                                                                |
|---------------------------------|--------------------------------------------------------------------------------------|
| PRO_E_CFP_TERMINATION2          | Compound.<br><br>Extent of the curve from the start point in the opposite direction. |
| PRO_E_CFP_TERM2_TYPE            | Curve extension in the opposite direction. One of ProCrvFrPntExtentType.             |
| PRO_E_CFP_LENGTH2               | Curve extension to the specified length in the opposite direction.                   |
| PRO_E_STD_CURVE_COLLECTION_APPL | Bounding chain curve collection.                                                     |

## Closed Loop Curve

Creo TOOLKIT provides complete element tree access to create a composite curve that forms a closed loop by selecting chains that exist in a domain.

The Closed Loop Curve tool automatically identifies a loop that can be created from the curves and edges you select. The tool will automatically trim any excess segments of the chains that are not part of the loop.

Some of the elements for this feature type are described below:

| Element ID                     | Value                                                                                                              |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------|
| PRO_E_CURVE_TYPE               | Curve type defined by the enumerated data type ProCurveType with the valid value PRO_CURVE_TYPE_CLOSED_LOOP.       |
| PRO_E_STD_FEATURE_NAME         | Name of the feature                                                                                                |
| PRO_E_LOOP_CRV_DOMAIN          | Mandatory element. Placement of the curve in the domain. The valid values are PRO_QUILT, PRO_SURFACE, or PRO_BODY. |
| PRO_E_STD_LOOP_COLLECTION_APPL | Mandatory element. Specify the boundary chains to form the closed loop on the placement.                           |

## Other Datum Curve Types

The following curve types contain run-time data in their element trees that is not currently accessible by Creo TOOLKIT. Currently, Creo TOOLKIT does not provide element tree access to the following curve types:

- Copy
- Project
- Boundary Offset

Some other curve types, including Thru Points, From File, and Use Xsec do not currently use element trees in Creo Parametric, and are therefore not accessible via Creo TOOLKIT.

---

## Element Trees: Edit Menu Features

This section describes how to construct and access the element tree for some Edit Menu features in Creo TOOLKIT. It also shows how to redefine, create and access the properties of these features.

### Mirror Feature

The Mirror feature creates a copy of the selected geometry by mirroring about a mirror plane. Creo TOOLKIT supports Mirror features where the initial selection of items was of geometry (curves and /or surfaces). Creo TOOLKIT does not support the element tree for Mirror features where the initial selection was of one or more features. Mirror features made from other features will have sub features listed under the Mirror entry in the Creo Parametric model tree, while Mirror features made from geometry will not include any sub-features.

Mirroring

#### Entity before Mirroring

#### Entity after Mirroring

where,

1—Specifies original entity such as plane, surfaces, axes or parts.

2—Specifies mirror line (mirror plane).

3—Specifies the copy of the original entity.

---

## The Feature Element Tree for Mirror feature in Creo Parametric

The element tree for a Mirror feature is documented in the header file `ProMirror.h`, and has a simple structure. The following figure demonstrates the feature element tree structure:

### Feature Element Tree for Mirror Feature

The Mirror element tree contains no non-standard element types. The following list details special information about some of the elements in this tree:

- `PRO_E_FEATURE_TYPE`—Must be `PRO_FEAT_SRF_MDL`.
- `PRO_E_STD_FEATURE_NAME`—Specifies the feature name.
- `PRO_E_MIRROR_REF_ITEMS`—A multivalued element that includes the mirror item reference. It must be references of the following types: `PRO_CURVE`, `PRO_COMP_CRV`, `PRO_AXIS`, `PRO_QUILT`, `PRO_PART`.
- `PRO_E_MIRROR_REF_PLANE`—Specifies the mirror plane and is a mandatory element and must be `PRO_DATUM_PLANE` or `PRO_SURFACE` (only planar surfaces).
- `PRO_E_COPY_NO_COPY`—Specifies the option to create a copy or not and is a mandatory element. It can have either of the following values:
  - `PRO_MIRROR_KEEP_ORIGINAL`
  - `PRO_MIRROR_HIDE_ORIGINAL`

## Creating a Mirror Feature

### Function Introduced

- **ProFeatureCreate()**

Use the function `ProFeatureCreate()` to create a Mirror Feature based on element tree input. For more information about `ProFeatureCreate()`, refer to the section [Overview of Feature Creation on page 771](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

---

## Redefining a Mirror Feature

Function Introduced

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine a Mirror Feature based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer to the section [Feature Redefine on page 794](#) of [Element Trees: Principles of Feature Creation on page 771](#).

## Accessing a Mirror Feature

Function Introduced

- **ProFeatureElemtreeExtract()**

Use the function `ProFeatureElemtreeExtract()` to create a feature element tree that describes the contents of a Mirror Feature and to retrieve the element tree description of a Mirror Feature. For more information about `ProFeatureElemtreeExtract()`, refer to the section [Feature Inquiry on page 792](#).

## Move Feature

The Move feature can be used to create and move a copy of an existing surface or curve rather than moving the original. Using the Move feature saves time because it enables you to create simple patterns with surfaces and curves.

The Move feature is available for both part and assembly modes. You can apply this feature in different modes:

- Translate mode—Translate surfaces, datum curves, and axes in a direction perpendicular to a reference plane. You can also translate along a linear edge, axis, perpendicular to plane, two points, or coordinate system.
- Rotate mode—Rotate surfaces, datum curves, and axes about an existing axis, linear edge, perpendicular to plane, two points, or coordinate system.

To move a surface or curve relative to its original position, define a move reference. In the Translate mode, the move reference is typically a plane or edge that is perpendicular to the direction in which you want to translate the moved feature. In Rotate mode, the move reference is typically an axis or edge about which you want to rotate the moved feature. In this mode, the moved object moves about the direction reference.

Following types of move references exists in Translate mode:

- Linear curve
- Linear edge
- Axis

- 
- Axis of a coordinate system
  - Plane
  - Two points

---

 **Note**

The direction reference is always perpendicular to the direction in which you want to move.

---

Following types of move references exists in Rotate mode:

- Linear curve
- Edge
- Axis
- Axis of a coordinate system
- Two points

---

 **Note**

You can flip the direction of the move in the Rotate mode.

---

Creo TOOLKIT supports Move features where the initial selection of items was of geometry (curves and /or surfaces). Creo TOOLKIT does not support the element tree for Move features where the initial selection was of one or more features. Move features made from other features will have sub features listed under the Move entry in the Creo Parametric model tree, while Move features made from geometry will not include any sub-features.

## The Feature Element Tree for Move feature in

The element tree for a Move feature is documented in the header file `ProMove.h`, and has a simple structure. The following figure demonstrates the feature element tree structure:

## Feature Element Tree for Move Feature

The move element tree contains no non-standard element types. The following list details special information about some of the elements in this tree:

- `PRO_E_FEATURE_TYPE`—Must be `PRO_FEAT_SRF_MDL`.
- `PRO_E_STD_FEATURE_NAME`—Specifies the feature name.
- `PRO_E_SRF_TR_SURF_SELECTION`—Specifies whether to move or copy the selected geometry. Curves, composite curves, axes and quilts are eligible to for this element.
- `PRO_E_MOVE_NO_COPY`—Specifies an option to control copy of the original geometry.
- Provides the ability to transform geometry with or without a copy.
- `PRO_E_MOVE_WITH_COPY`—Specifies whether to hide or display the original geometry after copy.
- `PRO_E_MOVE_GEOM_TRF_ARR`—Contains an array of movements applied to the selected entities. This can be a combination of translational and rotational transformations.
- `PRO_E_DIRECTION_COMPOUND`—Specifies the direction reference for the translation or rotational movement. This compound element is a standard Creo Parametric element subtree and is described in `ProDirection.h`.

## Creating a Move Feature

Function Introduced

- **ProFeatureCreate()**

---

Use the function `ProFeatureCreate()` to create a Move Feature based on element tree input. For more information about `ProFeatureCreate()`, refer to the section [Overview of Feature Creation on page 771](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

## Redefining a Move Feature

Function Introduced

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine a Move Feature based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer to the section [Feature Redefine on page 794](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

## Accessing a Move Feature

Function Introduced

- **ProFeatureElemtreeExtract()**

Use the function `ProFeatureElemtreeExtract()` to create a feature element tree that describes the contents of a Move Feature and to retrieve the element tree description of a Move Feature. For more information about `ProFeatureElemtreeExtract()`, refer to the section [Feature Inquiry on page 792](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

## Fill Feature

Creo TOOLKIT enables you to create and redefine flat surface features called fill features. A fill feature is simply a flat surface feature that is defined by its boundaries and is used to thicken surfaces.

### Note

All fill features must consist of a flat, closed-loop sketched feature.

---

## The Feature Element Tree for Fill feature in Creo Parametric

The element tree for a Fill feature is documented in the header file `ProFlatSrf.h`, and has a simple structure.

The following figure demonstrates the feature element tree structure:

## Feature Element Tree for Fill Feature

```
PRO_E_FEATURE_TREE
|
|--PRO_E_FEATURE_TYPE
|
|--PRO_E_FEATURE_FORM
|
|--PRO_E_STD_SECTION
|
|--PRO_E_STD_FEATURE_NAME
|
|--PRO_E_IS_UNATTACHED_WALL
|
|--PRO_E_STD_DIRECTION
|
|--PRO_E_STD_SMT_THICKNESS
|
|--PRO_E_STD_SMT_SWAP_DRV_SIDE
```

The fill element tree contains no non-standard element types. The following list details special information about some of the elements in this tree:

- `PRO_E_FEATURE_TYPE`—It should be `PRO_FEAT_DATUM_SURF`.
- `PRO_E_FEATURE_FORM`—Specifies feature form and should be of `PRO_FLAT` type only.
- `PRO_E_STD_SECTION`—Specifies a sketched section. Refer to the section [Creating Features Containing Sections on page 1004](#) for details on how to create features that contain sketched sections.

The element tree for the Fill feature also supports access to Flat Sheetmetal Wall features. Refer to the section [Production Applications: Sheetmetal on page 1307](#) for element details.

## Creating a Fill Feature

Function Introduced

- **ProFeatureCreate()**

Use the function `ProFeatureCreate()` to create a Fill Feature based on element tree input. For more information about `ProFeatureCreate()`, refer to the section [Overview of Feature Creation on page 771](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

## Redefining a Fill Feature

Function Introduced

---

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine a Fill Feature based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer to the section [Feature Redefine on page 794](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

## Accessing a Fill Feature

Function Introduced

- **ProFeatureElemtreeExtract()**

Use the function `ProFeatureElemtreeExtract()` to create a feature element tree that describes the contents of a Fill Feature and to retrieve the element tree description of a Fill Feature. For more information about `ProFeatureElemtreeExtract()`, refer to the section [Feature Inquiry on page 792](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

## Intersect Feature

Refer to the section [Intersect Datum Curves on page 855](#) in the section [Element Trees: Datum Curves on page 853](#) for details about this feature.

## Merge Feature

The Merge Feature is created by merging two or more selected quilts. In case of more than two quilts, every input quilt should have at least one of its edges adjacent to the edge of any other input quilt, and the surfaces must not overlap.

You can merge a number of input quilts by joining two adjacent quilts one after another, that is, by aligning the edges of one quilt to the edges of the other. The first quilt selected for the merge operation becomes the primary reference quilt. The second adjacent quilt is joined to the primary quilt, forming the main body or a newly formed primary quilt. The third quilt is, then, joined to the main body. This process continues until all the input quilts are joined together.

---

 **Note**

- For a successful merge, the selected quilts must be ordered based upon their adjacency.
  - The merge operation fails in case of intersecting quilts, and quilts that are not adjacent to any other input quilt. In either case, remove the problematic quilt to complete the merge.
-

You can also select the input quilts for the merge operation using region selection. In case of region selection, only box selection is available and the quilts to be selected must be completely inside the region. The selected quilts are ordered based on the feature number of the quilt's parent feature.

You can merge only two quilts by intersecting. You can specify which portion of the quilt to include in the merge feature by selecting the sides for each of the quilts.

A merged quilt consists of two or more original quilts that provide the geometry, and a merge feature that contains the information for the surface joining. The input quilts are retained, even if you delete the Merge feature.

---

 **Note**

In Assembly mode, you can merge only assembly-level quilts. If you want to create component-level merge features, you must first activate the component, and then merge the quilts in the component. Surface merge is available only for surfaces that belong to the same component.

---

## Feature Element Tree for Merge feature in Creo Parametric

The element tree for the Merge feature is documented in the header file `ProMerge.h`, and has a simple structure. The following figure demonstrates the feature element tree structure:

### Feature Element Tree for Merge Feature

The following list details special information about the elements in this tree:

- `PRO_E_FEATURE_TYPE`—Specifies the feature type; must be `PRO_FEAT_DATUM_QUILT`.
- `PRO_E_SRF_MRG_QUILT_ARR`—Specifies an array of the following compound element. The array must have at least two elements to create the Merge feature.
  - `PRO_E_SRF_MRG_QUILT_CMPD`—Specifies the set of references and sides to be used for the merge operation. The set consists of the following two elements:
    - ◆ `PRO_E_SRF_MRG_QUILT_REF`—Specifies the quilt of the type `PRO_QUILT` selected for the merge operation. This is a mandatory element.
    - ◆ `PRO_E_SRF_MRG_QUILT_SIDE`—Specifies the side of the selected quilt that should be included in the merge feature in case of intersecting quilts. This element is ignored when the quilt array `PRO_E_SRF_MRG_QUILT_ARR` contains more than two elements.
- `PRO_E_SRF_MRG_TYPE`—Specifies the merge type and can have following merge type options:
  - `PRO_SRF_MRG_JOIN`—For joining quilts.
  - `PRO_SRF_MRG_INTSCT`—For merging two quilts at the intersection. This is the default option.

The merge type must be `PRO_SRF_MRG_JOIN` when the quilt array `PRO_E_SRF_MRG_QUILT_ARR` contains more than two elements.
- `PRO_E_STD_FEATURE_NAME`—Specifies the merge feature name.

## Creating a Merge Feature

Function Introduced

- **ProFeatureCreate()**

Use the function `ProFeatureCreate()` to create a Merge Feature based on element tree input. For more information about `ProFeatureCreate()`, refer to the section [Overview of Feature Creation on page 771](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

## Redefining a Merge Feature

Function Introduced

- **ProFeatureRedefine()**

---

Use the function `ProFeatureRedefine()` to redefine a Merge Feature based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer to the section [Feature Redefine on page 794](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

## Accessing a Merge Feature

Function Introduced

- **ProFeatureElemtreeExtract()**

Use the function `ProFeatureElemtreeExtract()` to create a feature element tree that describes the contents of a Merge Feature and to retrieve the element tree description of a Merge Feature. For more information about `ProFeatureElemtreeExtract()`, refer to the section [Feature Inquiry on page 792](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

## Pattern Feature

Refer to the [Element Trees: Patterns on page 964](#) for details about this feature.

## Wrap Feature

Refer to the section [Wrap Datum Curves on page 856](#) in the section [Element Trees: Datum Curves on page 853](#) for details about this feature.

## Trim Feature

Trim feature is applied to remove portions of an existing surface feature. A trim feature is similar to a solid cut. Following are the existing types of feature creation for the trimming of a surface or a quilt.

- Use Quilts—Cuts a piece from a surface using an intersecting quilt. Creo Parametric consumes the quilt that is used to trim a surface and allows you to keep either or both sides of the trimmed surface. You can trim quilts in the following ways:
  - By adding a cut or slot as you do to remove material from solid features
  - By trimming the quilt at its intersection with another quilt or to its own silhouette edge as it appears in a certain view
  - By filleting corners of the quilt
  - By trimming along a datum curve lying on the quilt
- Use Curves—Trims a surface using selected curves and edges.

---

The rules for defining a surface trim using a datum curve are as follows:

- You can use a continuous chain of datum curves, inner surface edges, or solid model edges to trim a quilt.
- Datum curves used for trimming must lie on the quilt to be trimmed and should not extend beyond the boundaries of this quilt.
- If the curve does not extend to the boundaries of the quilt, the system calculates the shortest distance to the quilt boundary and continues the trim in this direction.
- Silhouette—Trims a surface at its silhouette edge from a specified direction.

### **The Feature Element Tree for Trim feature in**

The element tree for a Trim feature is documented in the header file `ProTrim.h`, and has a simple structure. The following figure demonstrates the feature element tree structure:

## Feature Element Tree for Trim Feature

The trim element tree contains no non-standard element types. The following list details special information about some of the elements in this tree:

- **PRO\_E\_FEATURE\_TYPE**—It should be **PRO\_FEAT\_CUT**.
- **PRO\_E\_FEATURE\_FORM**—Specifies feature form and is a mandatory element applicable only for use quilt and thin types. It has **PRO\_USE\_SURFS** and **PRO\_NOTYPE** as their valid values.
- **PRO\_E\_SRF\_TRIM\_TYPE**—Specifies trim type identity and is a non-redefinable mandatory element. The trim type determines the required

---

structure for the remaining elements in the element tree. Each type requires different mandatory elements. The different trim types are as follows:

- PRO\_SURF\_TRIM\_USE\_CRV—use curves to trim the quilt.
- PRO\_SURF\_TRIM\_USE\_QLT—use another quilt to trim the given quilt.
- PRO\_SURF\_TRIM\_THIN
- PRO\_SURF\_TRIM\_SILH—trim quilt using silhouette edges.
- PRO\_E\_TRIM\_QUILT—Specifies trimmed quilt and should be of type PRO\_SURFACE or PRO\_QUILT only.
- PRO\_E\_STD\_USEQLT\_QLT—Specifies trimming quilts and trimming planes. It should have PRO\_SURFACE, PRO\_QUILT and PRO\_DATUM\_PLANE values only. It is applicable for use quilt and thin types only.
- PRO\_E\_STD\_CURVE\_COLLECTION\_APPL—Specifies the trimming curves and is applicable for use curve only.
- PRO\_E\_TRIM\_SILH\_PLANE—Specifies silhouette plane and can be of type PRO\_SURFACE or PRO\_DATUM\_PLANE only.
- PRO\_E\_MATERIAL\_SIDE—Specifies material side options and has the following values:
  - PRO\_TRIM\_MATL\_SIDE\_ONE
  - PRO\_TRIM\_MATL\_SIDE\_TWO
  - PRO\_TRIM\_MATL\_BOTH\_SIDES
- PRO\_E\_PRIMARY\_QLTSIDE—Specifies the primary quilt side options and they are listed as follows:
  - PRO\_TRIM\_PRIM\_QLT\_SIDE\_ONE
  - PRO\_TRIM\_PRIM\_QLT\_SIDE\_TWO
- PRO\_E\_STD\_USEQLT\_SIDE—Specifies thickness direction options for thin trims and can only be as follows:
  - PRO\_TRIM\_STD\_QUILT\_SIDE\_ONE
  - PRO\_TRIM\_STD\_QUILT\_SIDE\_TWO
  - PRO\_TRIM\_STD\_QUILT\_BOTH\_SIDES
- PRO\_E\_KEEP\_TRIM\_SURF\_OPT—Specifies to keep trimming surface option and is valid only when the trimming quilt is a surface or quilt. It has the following values:
  - PRO\_KEEP\_TRIM\_SURF\_OPT\_NO
  - PRO\_KEEP\_TRIM\_SURF\_OPT\_YES
- PRO\_E\_THICKNESS—Specifies thickness for thin trims.

- **PRO\_E\_SRF\_OFFSETS\_METHOD**—Specifies the types of offset for thin trims and are as follows:
  - **PRO\_TRIM\_SRF\_OFFSETS\_METH\_NORMTOSURF**—The surface or quilt is thickened in a direction normal to the surface.
  - **PRO\_TRIM\_SRF\_OFFSETS\_METH\_AUTOSCALE**—The surface or quilt is thickened by automatically determining scaling coordinate system and fit along all three axes.
  - **PRO\_TRIM\_SRF\_OFFSETS\_METH\_MANUALSCALE**—The surface or quilt is thickened by specifying the scaling coordinate system and control fitting motion.
- **PRO\_E\_SRF\_OFFSETS\_CTRLFIT**—Specifies the control fit and is applicable for thin trims only. It offsets the surface by creating a best-fit offset that is scaled with respect to a selected coordinate system. It allows you to define the axis for translation. It consists of the following elements:
  - **PRO\_E\_SRF\_OFFSETS\_SCALINGCSYS** specifies the control fit coordinate system and should have a value of **PRO\_CSYS**.
  - **PRO\_E\_SRF\_OFFSETS\_AXISES** specifies the control fit axes having the following values:
    - ◆ **PRO\_TRIM\_OFFSETS\_TRF\_NONE**
    - ◆ **PRO\_TRIM\_OFFSETS\_TRF\_X**
    - ◆ **PRO\_TRIM\_OFFSETS\_TRF\_Y**
    - ◆ **PRO\_TRIM\_OFFSETS\_TRF\_Z**
    - ◆ **PRO\_TRIM\_OFFSETS\_TRF\_XY**
    - ◆ **PRO\_TRIM\_OFFSETS\_TRF\_YZ**
    - ◆ **PRO\_TRIM\_OFFSETS\_TRF\_ZX**
    - ◆ **PRO\_TRIM\_OFFSETS\_TRF\_ALL**
- **PRO\_E\_SRF\_OFFSETS\_HANDLINGS**—Specifies an array of **PRO\_E\_SRF\_OFFSETS\_HANDLING** and is applicable for thin trims only.
- **PRO\_E\_SRF\_OFFSETS\_HANDLING**—Specifies special handling item and consists of **PRO\_E\_SRF\_OFFSETS\_REF\_SEL** which are special handling faces which should be from the trimming quilt.

A list of elements required for different types of trims:

| Trim type  | Element Id             |
|------------|------------------------|
| Quilt Type | PRO_E_FEATURE_TYPE     |
|            | PRO_E_FEATURE_FORM     |
|            | PRO_E_SRF_TRIM_TYPE    |
|            | PRO_E_STD_FEATURE_NAME |

| Trim type  | Element Id                      |
|------------|---------------------------------|
|            | PRO_E_SURF_TRIM_TYPE            |
|            | PRO_E_TRIM_QUILT                |
|            | PRO_E_STD_USEQLT_QLT            |
|            | PRO_E_MATERIAL_SIDE             |
|            | PRO_E_PRIMARY_QLTSIDE           |
|            | PRO_E_KEEP_TRIM_SURF_OPT        |
| Use Curve  | PRO_E_FEATURE_TYPE              |
|            | PRO_E_SRF_TRIM_TYPE             |
|            | PRO_E_STD_FEATURE_NAME          |
|            | PRO_E_SURF_TRIM_TYPE            |
|            | PRO_E_TRIM_QUILT                |
|            | PRO_E_STD_CURVE_COLLECTION_APPL |
|            | PRO_E_MATERIAL_SIDE             |
|            | PRO_E_PRIMARY_QLTSIDE           |
| Thin       | PRO_E_FEATURE_TYPE              |
|            | PRO_E_FEATURE_FORM              |
|            | PRO_E_SRF_TRIM_TYPE             |
|            | PRO_E_STD_FEATURE_NAME          |
|            | PRO_E_SURF_TRIM_TYPE            |
|            | PRO_E_TRIM_QUILT                |
|            | PRO_E_STD_USEQLT_QLT            |
|            | PRO_E_STD_USEQLT_SIDE           |
|            | PRO_E_KEEP_TRIM_SURF_OPT        |
|            | PRO_E_THICKNESS                 |
|            | PRO_E_SRF_OFFS_METHOD           |
|            | PRO_E_SRF_OFFS_CTRLFIT          |
|            | PRO_E_SRF_OFFS_HANDLINGS        |
| Silhouette | PRO_E_FEATURE_TYPE              |
|            | PRO_E_SRF_TRIM_TYPE             |
|            | PRO_E_STD_FEATURE_NAME          |
|            | PRO_E_SURF_TRIM_TYPE            |
|            | PRO_E_TRIM_QUILT                |
|            | PRO_E_TRIM_SILH_PLANE           |
|            | PRO_E_MATERIAL_SIDE             |
|            | PRO_E_PRIMARY_QLTSIDE           |
|            | PRO_E_KEEP_TRIM_SURF_OPT        |

## Creating a Trim Feature

Function Introduced

- **ProFeatureCreate()**

---

Use the function `ProFeatureCreate()` to create a Trim Feature based on element tree input. For more information about `ProFeatureCreate()`, refer to the section [Overview of Feature Creation on page 771](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

## Redefining a Trim Feature

Function Introduced

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine a Trim Feature based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer to the section [Feature Redefine on page 794](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

## Accessing a Trim Feature

Function Introduced

- **ProFeatureElemtreeExtract()**

Use the function `ProFeatureElemtreeExtract()` to create a feature element tree that describes the contents of a Trim Feature and to retrieve the element tree description of a Trim Feature. For more information about `ProFeatureElemtreeExtract()`, refer to the section [Feature Inquiry on page 792](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

## Offset Feature

Refer to the section [Offset Datum Curves on page 856](#) in the section [Element Trees: Datum Curves on page 853](#) for details about this feature.

## Thicken Feature

The Thicken feature is available for both part and for assembly modes and can be defined with respect to coordinate systems, axes, and surfaces. You can apply this feature to check the thickness of a part in the model. This feature also forms the basis for model analysis and thickness check. The result of the thickness analysis is as follows:

- The thickness is between the design range.
- The thickness exceeds the maximum design value.
- The thickness is below the minimum design value.

---

Thicken features use predetermined surface features or quilt geometry to add or remove thin material sections in the design. The surface features or quilt geometry provide greater flexibility within the design and enable you to transform the geometry to better meet the design needs.

## The Feature Element Tree for Thicken feature in Creo Parametric

The element tree for a Thicken feature is documented in the header file `ProThicken.h`, and has a simple structure. The following figure demonstrates the feature element tree structure:

### Feature Element Tree for Thicken Feature

```
PRO_E_FEATURE_TREE
|
|-- PRO_E_FEATURE_TYPE
|
|-- PRO_E_FEATURE_FORM
|
|-- PRO_E_FEAT_FORM_ALWAYS_THIN
|
|-- PRO_E_STD_USEQLT_QLT
|
|-- PRO_E_THICKEN_TYPE
|
|-- PRO_E_STD_USEQLT_SIDE
|
|-- PRO_E_USEQLT_SOLID_SIDE
|
|-- PRO_E_THICKNESS
|
|-- PRO_E_SRF_OFFS_METHOD
|
|-- PRO_E_SRF_OFFS_CTRLFIT
| |-- PRO_E_SRF_OFFS_SCALINGCSYS
| |-- PRO_E_SRF_OFFS_AXISES
|
|-- PRO_E_SRF_OFFS_HANDLINGS
| |-- PRO_E_SRF_OFFS_HANDLING
| |-- PRO_E_SRF_OFFS_REF_SEL
|
|-- PRO_E_STD_FEATURE_NAME
```

The Thicken element tree contains no non-standard element types. The following list details special information about some of the elements in this tree:

- `PRO_E_FEATURE_TYPE`—`PRO_FEAT_PROTRUSION` or `PRO_FEAT_CUT`.
- `PRO_E_FEATURE_FORM`—Must be `PRO_E_SURFS`.

- 
- `PRO_E_FEAT_FORM_ALWAYS_THIN`—Must be `PRO_THIN`.
  - `PRO_SRF_OFFSETS_METHOD`—Offset method that can be enumerated as follows:
    - `PRO_OFFSETS_METH_NORMTOSURF`— Specifies the offset of the thickened surface normal to the original surface.
    - `PRO_OFFSETS_METH_AUTOSCALE`— Specifies autoscale and translates the thickened surface with respect to an automatically determined coordinate system.
    - `PRO_OFFSETS_METH_MANUALSCALE`— Specifies manual scale.

---

 **Note**

If you change the offset method for a particular feature, all children of this feature fail.

---

## Creating a Thicken Feature

Function Introduced

- **`ProFeatureCreate()`**

Use the function `ProFeatureCreate()` to create a Thicken Feature based on element tree input. For more information about `ProFeatureCreate()`, refer to the section [Overview of Feature Creation on page 771](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

## Redefining a Thicken Feature

Function Introduced

- **`ProFeatureRedefine()`**

Use the function `ProFeatureRedefine()` to redefine a Thicken Feature based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer to the section [Feature Redefine on page 794](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

## Accessing a Thicken Feature

Function Introduced

- **`ProFeatureElemtreeExtract()`**

---

Use the function `ProFeatureElemtreeExtract()` to create a feature element tree that describes the contents of a Thicken Feature and to retrieve the element tree description of a Thicken Feature. For more information about `ProFeatureElemtreeExtract()`, refer to the section [Feature Inquiry on page 792](#) of [Element Trees: Principles of Feature Creation on page 771](#)

## Solidify Feature

Solidify features are used to create complex geometry that would be difficult to create using regular solid features.

Solidify features use predetermined surface features or quilt geometry and convert them into solid geometry. You can use Solidify features to add, remove, or replace solid material in the designs. The quilt geometry provides greater flexibility within the design, and the Solidify feature enables the designer to transform the geometry to meet design needs.

The attributes of the Solidify feature are:

- Patch—Replaces a portion of the surface with quilt. The quilt boundary must lie on the surface.
- Add Material—Fills a quilt with solid material.
- Remove Material—Removes material from inside or outside a quilt.

---

### Note

add material and remove material attributes are always available. Patch is available only if the selected quilt boundaries lie on solid geometry.

---

## The Feature Element Tree for Solidify Feature in Creo Parametric

The element tree for a Solidify feature is documented in the header file `ProSolidify.h`, and has a simple structure. The following figure demonstrates the feature element tree structure:

## Feature Element Tree for Solidify Feature

```
PRO_E_FEATURE_TREE
|-- PRO_E_FEATURE_TYPE
|-- PRO_E_FEATURE_FORM
|-- PRO_E_PATCH_QUILT
|-- PRO_E_PATCH_TYPE
|-- PRO_E_PATCH_MATERIAL_SIDE
|-- PRO_E_STD_FEATURE_NAME
```

The solidify element tree contains no non-standard element types. The following list details special information about some of the elements in this tree:

- PRO\_E\_STD\_FEATURE\_TYPE—Must be one of the following types—
  - Protrusion—PRO\_FEAT\_PROTRUSION
  - Cut—PRO\_FEAT\_CUT
  - Patch—PRO\_FEAT\_PATCH
- PRO\_E\_FEATURE\_FORM— Must be of the following types:
  - PRO\_USE\_SURFS— Represents protrusion (PRO\_FEAT\_PROTRUSION) and cut (PRO\_FEAT\_CUT).
  - PRO\_NOTYPE— Represents patch (PRO\_FEAT\_PATCH).
- PRO\_E\_PATCH\_QUILT— Specifies the reference quilt and is a mandatory element. A valid quilt or surface satisfies any of the following contexts:

Quilt is open

- CASE 1
  - All boundaries lie on solid surfaces.
  - Solid geometry does not intersect quilt.
  - Solid geometry and quilt form closed empty volume.
- CASE 2
  - All boundaries lie on solid surfaces.
  - Solid geometry intersects quilt.
- CASE 3
  - All one sided edges are inside solid geometry.
- CASE 4
  - All one sided edges are outside solid geometry.

- Solid geometry intersects quilt.
- CASE 5
  - Solid geometry and quilt form closed empty volume.
  - At least, one sided edge intersects geometry.
- CASE 6
  - Quilt intersects geometry.
  - None of the one sided edges intersect geometry.
- CASE 7
  - Solid geometry does not intersect quilt.

Quilt is closed

- CASE 1
  - Solid geometry does not intersect quilt.
- CASE 2
  - Quilt completely buried inside Material.
- CASE 3
  - Solid geometry partly intersects quilt.

## Creating a Solidify Feature

Function Introduced

- **ProFeatureCreate()**

Use the function `ProFeatureCreate()` to create a Solidify Feature based on element tree input. For more information about `ProFeatureCreate()`, refer to the section [Overview of Feature Creation on page 771](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

## Redefining a Solidify Feature

Function Introduced

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine a Solidify Feature based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer to the section [Feature Redefine on page 794](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

## Accessing a Solidify Feature

Function Introduced

---

- **ProFeatureElemtreeExtract()**

Use the function `ProFeatureElemtreeExtract()` to create a feature element tree that describes the contents of a Solidify Feature and to retrieve the element tree description of a Solidify Feature. For more information about `ProFeatureElemtreeExtract()`, refer to the section [Feature Inquiry on page 792](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

## Remove Feature

Use the Remove feature to remove geometry without disturbing the feature history. It allows you to modify existing imported geometry or delete some geometry from a part (not necessarily formed by a single feature) without having to reroute and refine a number of features.

You can select one of the following items for removal:

- Surfaces, surface sets, or intent surfaces
- One closed loop chain of one-sided edges from a single quilt

Geometry removal results in neighboring surfaces being extended or trimmed to converge and close the void. The extended geometry is attached as a solid or surface to the selected surfaces. In case of a one-sided edge chain selected as the reference, the extended geometry can be attached to the selected quilt, or created as a new quilt.

You can exclude contours in multi-contour surfaces from being removed. For periodic features separated by artificial edges (for example, extruded cylinders or revolved features), the feature internally references all the surfaces, even if one of them is selected.

---

 **Note**

- All surfaces that are extended or trimmed must be adjacent to the boundary defined by references.
  - If an adjacent surface does not need to be extended, it will not be copied.
  - Surfaces that are to be extended must be extendable.
  - Extended surfaces must converge to form a defined volume.
  - No new patches are created when the surfaces are extended.
  - If the modified geometry cannot be attached as a solid, it can be manually attached as a quilt.
  - Feature operations such as Suppress, Delete, Redefine, Reroute, Copy/Paste, and Pattern (limited to reference pattern if patterning by itself) are supported.
  - Transformation of this feature by itself is not applicable and allowed.
- 

## Feature Element Tree for the Remove Feature

The element tree for the Remove feature is documented in the header file `ProRemoveSurf.h`. The following figure demonstrates the element tree structure:

## Feature Element Tree for Remove Feature

```
PRO_E_FEATURE_TREE
|
|-- PRO_E_FEATURE_TYPE
|
|-- PRO_E_STD_FEATURE_NAME
|
|-- PRO_E_RM_SURF_REF_TYPE
|
|-- PRO_E_RM_SURF_ATTACH_TYPE
|
|-- PRO_E_RM_SURF_SRF_REFS
| |
| |-- PRO_E_STD_SURF_COLLECTION_APPL
| |
| |-- PRO_E_STD_EXCL_CNTRS
| | |
| | |-- PRO_E_STD_EXCL_CNTRS_ONE_CNTR
| |
| |-- PRO_E_KEEP_REMOVED_SRFS_OPT
|
|-- PRO_E_RM_SURF_CRV_REFS
| |
| |-- PRO_E_STD_CURVE_COLLECTION_APPL
|
|-- PRO_E_RM_SURF_LEAVE_OPEN_OPT
|
|-- PRO_E_RM_SURF_AUTO_SPLIT_SRF
|
|-- PRO_E_RM_SURF_MAINTAIN_TOPO
```

The Remove element tree contains standard element types. The following list details special information about the elements in this tree:

- `PRO_E_FEATURE_TYPE`—Specifies the feature type and should always have the value `PRO_FEAT_RM_SURF`.
- `PRO_E_STD_FEATURE_NAME`—Specifies the name of the remove feature.
- `PRO_E_RM_SURF_REF_TYPE`—Specifies the reference type. This element decides the type of references that you can select for removal. It can have the following values:
  - `PRO_RM_SURF_SRF_REF`—Specifies that surface sets can be selected as the references.
  - `PRO_RM_SURF_CRV_REF`—Specifies that a chain of one-sided edges can be selected as the reference.

- **PRO\_E\_RM\_SURF\_ATTACH\_TYPE**—Specifies the attachment type. It can have the following values:
  - **FM\_RM\_SURF\_ATTACH\_SAME**—Specifies that the extended geometry will be attached to the selected surfaces if **PRO\_E\_RM\_SURF\_REF\_TYPE** is equal to **PRO\_RM\_SURF\_SRF\_REF**, or to the selected quilt if **PRO\_E\_RM\_SURF\_REF\_TYPE** is equal to **PRO\_RM\_SURF\_CRV\_REF**.
  - **FM\_RM\_SURF\_ATTACH\_SEP**—Specifies that the extended geometry will be created as a separate quilt if **PRO\_E\_RM\_SURF\_REF\_TYPE** is equal to **PRO\_RM\_SURF\_CRV\_REF**.
- **PRO\_E\_RM\_SURF\_SRF\_REFS**—Specifies the set of surface references. This element is required if **PRO\_E\_RM\_SURF\_REF\_TYPE** is equal to **PRO\_RM\_SURF\_SRF\_REF**. It consists of the following elements:
  - **PRO\_E\_STD\_SURF\_COLLECTION\_APPL**—Specifies the surfaces selected for removal. You can select multiple surfaces. This element is required if **PRO\_E\_RM\_SURF\_REF\_TYPE** is equal to **PRO\_RM\_SURF\_SRF\_REF**.
  - **PRO\_E\_STD\_EXCL\_CNTRS**—Specifies an array of excluded contours of the type **PRO\_E\_STD\_EXCL\_CNTRS\_ONE\_CNTR**.
  - **PRO\_E\_KEEP\_REMOVED\_SRFS\_OPT**—Specifies the ProBoolean option that allows you to retain the removed surfaces as a separate quilt.
- **PRO\_E\_RM\_SURF\_CRV\_REFS**—Specifies the set of curve references. This element is required if **PRO\_E\_RM\_SURF\_REF\_TYPE** is equal to **PRO\_RM\_SURF\_CRV\_REF**. It consists of the following element:
  - **PRO\_E\_STD\_CURVE\_COLLECTION\_APPL**—Specifies the single closed loop chain of one-sided edges. This element is required if **PRO\_E\_RM\_SURF\_REF\_TYPE** is equal to **PRO\_RM\_SURF\_CRV\_REF**.
- **PRO\_E\_RM\_SURF\_LEAVE\_OPEN\_OPT**—Specifies if the hole that is created after surfaces are removed must be kept open. The solids are converted to quilts and closed quilts are converted to open quilts.
- **PRO\_E\_RM\_SURF\_AUTO\_SPLIT\_SRF**—Specifies if the extending surface for the selected shape surface must be automatically split when geometry is removed. The splitting surface is automatically selected.
- **PRO\_E\_RM\_SURF\_MAINTAIN\_TOPO**—Specifies if the regeneration must fail when the model changes and the same solution type cannot be reconstructed. It is used to indicate if the topology in the model must be maintained.

---

## Note

The Remove feature is available in the parametric modeling environment as well as in the flexible modeling environment. In the parametric modeling environment, a collection of surfaces or curves are used as the references. In the flexible modeling environment, a region or a collection of surfaces that include regions is used as the reference. In the flexible modeling environment with a surface collection that includes regions, the Remove feature replaces each region by the surface it belongs to. The contours that define other regions of the same surface are automatically saved as the `PRO_E_STD_EXCL_CNTRS_ONE_CNTR` element.

---

### Element Details of `PRO_E_STD_EXCL_CNTRS_ONE_CNTR`

Each `PRO_E_STD_EXCL_CNTRS_ONE_CNTR` specifies one excluded contour. It consists of the following elements:

#### `PRO_E_STD_EXCL_CNTRS_ONE_CNTR`

```
PRO_E_STD_EXCL_CNTRS_ONE_CNTR
|
|-- PRO_E_STD_EXCL_CNTR_SRF_REF
|
|-- PRO_E_STD_EXCL_CNTR_EDGE_REF
```

- `PRO_E_STD_EXCL_CNTR_SRF_REF`—Specifies the surface reference for the excluded contour.
- `PRO_E_STD_EXCL_CNTR_EDGE_REF`—Specifies the edge reference for the excluded contour. This element can be any edge of the contour.

## Creating the Remove Feature

### Function Introduced

- **ProFeatureCreate()**

Use the function `ProFeatureCreate()` to create the Remove feature based on the element tree input. For more information about `ProFeatureCreate()`, refer to the section [Overview of Feature Creation on page 771](#) in the section [Element Trees: Principles of Feature Creation on page 771](#).

---

## Redefining the Remove Feature

Function Introduced

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine the Remove feature based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer to the section [Feature Redefine on page 794](#) of [Element Trees: Principles of Feature Creation on page 771](#).

## Accessing the Remove Feature

Function Introduced

- **ProFeatureElemtreeExtract()**

Use the function `ProFeatureElemtreeExtract()` to create a feature element tree that describes the contents of the Remove feature, and to retrieve the element tree description of the Remove feature. For more information about `ProFeatureElemtreeExtract()`, refer to the section [Feature Inquiry on page 792](#) of [Element Trees: Principles of Feature Creation on page 771](#).

## Example 1: Creating a Remove Surface Feature

The sample code in `UgRemoveSurfCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a remove Surface feature.

## Attach Feature

The Attach feature allows you to attach open quilts to solid or quilt geometry, if the open quilt does not intersect the solid or quilt geometry. You can select an open quilt and attach it to another quilt or solid geometry within the same model. You can also select two open quilts within the same model which do not intersect and attach them.

This feature is useful in case of UDF placement when the geometry of the UDF does not intersect the part.

## Feature Element Tree for Attach Feature

The element tree for a Attach feature is documented in the header file `ProFlexAttach.h` and has a simple structure. The following figure demonstrates the structure of the feature element tree.

## Attach Feature Element Tree

```
PRO_E_FEATURE_TREE
|
|--PRO_E_FEATURE_TYPE
|
|--PRO_E_STD_FEATURE_NAME
|
|--PRO_E_REF_ATTACH_PRIM_QLT
|
|--PRO_E_REF_ATTACH_MERG_QLT
|
|--PRO_E_OPT_ATTACH_OPER
|
|--PRO_E_OPT_ATTACH_RMV_MAT
|
|--PRO_E_OPT_ATTACH_PQ_DIR
|
|--PRO_E_OPT_ATTACH_MGQ_DIR
|
|--PRO_E_OPT_ATTACH_PIO
|
|--PRO_E_OPT_ATTACH_RNDCH
|
|--PRO_E_FLEX_OPTS_CMPND
```

The elements in this tree are described below:

- `PRO_E_FEATURE_TYPE`—Specifies the feature type and should be `PRO_FEAT_FLXATTACH`.
- `PRO_E_STD_FEATURE_NAME`—Specifies the name of the feature.
- `PRO_E_ATTACH_QLT_REFS`—Specifies the open quilts you select for attachment.
- `PRO_E_ATTACH_OPT_TYPE`—Specifies the attachment type. It is given by the enumerated type `ProFlexAttachOptType` and is of the following types:
  - `PRO_FLXATT_SOLID_OPT`—Specifies the solid to which the open quilts are attached.
  - `PRO_FLXATT_SURF_OPT`—Specifies the quilt surface to which the open quilts are attached.

## Creating the Attach Feature

Function Introduced

---

- **ProFeatureCreate()**

Use the function `ProFeatureCreate()` to create the Attach feature based on the element tree input. For more information about `ProFeatureCreate()`, refer to the section [Overview of Feature Creation on page 771](#) in the section [Element Trees: Principles of Feature Creation on page 771](#).

## Redefining the Attach Feature

Function Introduced

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine the Attach feature based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer to the section [Feature Redefine on page 794](#) of [Element Trees: Principles of Feature Creation on page 771](#).

## Accessing the Attach Feature

Function Introduced

- **ProFeatureElemtreeExtract()**

Use the function `ProFeatureElemtreeExtract()` to retrieve the element tree description of the Attach feature. For more information about `ProFeatureElemtreeExtract()`, refer to the section [Feature Inquiry on page 792](#) of [Element Trees: Principles of Feature Creation on page 771](#).

## Unify Surfaces Feature

The Unify Surfaces feature is created by unifying multiple surfaces that were previously divided and have the same geometry or have same surface definition.

### The Feature Element Tree for Unify Surface feature in Creo Parametric

The element tree for a datum unify surface feature is documented in the header file `ProUnifySurf.h`, and has a simple structure. Apart from the usual elements for the tree root and feature type, a datum unify surface contains the unified surface target and surfaces to unify. The following figure shows the basic structure of the element tree:

```

PRO_E_FEATURE_TREE
|
|-- PRO_E_FEATURE_TYPE
|
|-- PRO_E_STD_FEATURE_NAME
|
|-- PRO_E_UNIFYSRF_TARGET
|
|-- PRO_E_UNIFYSRF_SRFS
|
|-- PRO_E_UNIFYSRF_UPD_SRF_REF_OPT

```

The following list details special information about the elements in this tree:

- **PRO\_E\_FEATURE\_TYPE**—Specifies the feature type and should always have the value **PRO\_FEAT\_UNIFYSRF**.
- **PRO\_E\_STD\_FEATURE\_NAME**—Specifies the name of the surface region feature. The default value is **Unify\_Surfaces**.
- **PRO\_E\_UNIFYSRF\_TARGET**—Specifies the target surface that can be any surface of a quilt or body, and has at least one split-edge or non-refinable-edge. This surface must be previously divided.
- **PRO\_E\_UNIFYSRF\_SRFS**—Specifies the set of surfaces that are unified into the target. These multiple surfaces should be divided from the target surface and should belong to the same quilt or body as the target surface.

#### **Note**

If a surface is not previously divided, it cannot be used. In such a scenario, you have to select an alternate surface.

- **PRO\_E\_UNIFYSRF\_UPD\_SRF\_REF\_OPT**—Use the option **Update Surface References** to transfer the references of the surfaces you selected to the target surface. If the value is **PRO\_B\_TRUE**, the consumed surface references is forwarded to the target surface.

## Element Trees: Replace

This describes the basic principles of creating a tweak surface replacement feature. The section [Element Trees: Principles of Feature Creation on page 771](#) is a necessary background for this topic. Read that section before this one.

## Introduction

The surface replacement functionality enables you to replace the specified surface on a model with a datum plane or quilt. This is similar to the **Replace** option from **TWEAK** menu in Creo Parametric. See the corresponding section in the *Part Modeling User's Guide* for a detailed description of the restrictions and requirements of the feature.

## The Feature Element Tree

The element tree for a surface replacement feature is documented in the header file `ProReplace.h`, and is shown in the following figure.

### Element Tree for Surface Replacement

The following table describes the elements in the element tree for the surface replacement feature.

| Element ID                 | Data Type                | Description                         |
|----------------------------|--------------------------|-------------------------------------|
| PRO_E_FEATURE_TYPE         | PRO_VALUE_TYPE_INT       | PRO_FEAT_REPLACE_SURF               |
| PRO_E_STD_REPLACED_SURF    | PRO_VALUE_TYPE_SELECTION | The surface to be removed           |
| PRO_E_STD_REPLACEMENT_SURF | PRO_VALUE_TYPE_SELECTION | The replacement surface             |
| PRO_E_STD_KEEP_QUILT       | PRO_VALUE_TYPE_INT       | Specifies whether to keep the quilt |

To keep the replacement surface (datum plane or quilt), add the element `PRO_E_STD_KEEP_QUILT` and set its value to 1. If you omit the element, or its value is 0, the replacement surface will be consumed by the replacement feature.

After you have defined the element tree, call the function `ProFeatureCreate()` to create the tweak surface replacement feature.

---

# Element Trees: Draft Features

## Element Trees: Draft Features

This section introduces and shows how to create, redefine and access draft features.

### Draft Feature

The Draft feature adds a draft angle between  $-89.9^\circ$  and  $+89.9^\circ$  to individual surfaces or to a series of surfaces.

You can draft either solid surfaces or quilt surfaces, but not a combination of both. The first selected surface determines the type of additional surfaces (solid or quilts) that can be selected as draft surfaces for this feature.

Some of the terms associated with the Draft feature are:

- Draft surfaces—The surfaces of the model to be drafted.
- Draft hinges—Lines and curves on the draft surfaces that the surfaces are pivoted about (also called neutral curves), or quilt of surfaces. Draft hinges can be defined by:
  - A plane, in which case the draft surfaces are pivoted about their intersection with the plane.
  - Individual curve chains on the draft surfaces.
  - A quilt, in which case the draft surfaces are pivoted about their intersection with the quilt.
- Draft direction—Direction used to measure the draft angle and can be defined in terms of:
  - A plane, in which case the draft direction is normal to this plane.
  - A straight edge or a datum axis, in which case the draft direction is parallel to the edge or axis.
  - Two points, such as datum points or model vertices, in which case the draft direction is parallel to the line connecting the two points.
  - A coordinate system, in which case the draft direction initially defaults to the direction of its x-axis.
- Draft angle—The angle between the draft direction and the resulting drafted surfaces. If the draft surfaces are split, you can define two independent angles for each side of the drafted surface. Draft angles must be within the range of  $-89.9^\circ$  and  $+89.9^\circ$ .

---

## Feature Element Tree for the Draft Feature

The element tree for a draft feature is documented in the header file `ProDraft.h`, and has a simple structure. The following figure demonstrates the feature element tree structure:

```

```

---

The feature element tree contains no non-standard element types. The following list details special information about some of the elements in this tree:

- `PRO_E_FEATURE_TYPE`—Specifies the feature type.
- `PRO_E_STD_FEATURE_NAME`—Specifies the name of the feature.
- `PRO_E_DRAFT_TWEAK_OR_INTERSEC`—Specifies tweak or intersect depending on whether the resulting draft surface encounters an edge of the model or not suggesting the presence of the extend option. It can have any of the following values:
  - `PRO_DRAFT_UI_TWEAK` for creating regular draft geometry.
  - `PRO_DRAFT_UI_INTERSECT` for adjusting the draft geometry to intersect an existing edge of the model.
  - `PRO_DRAFT_UI_INTERSECT_EXTEND` specifies intersect with extend, when the draft does not extend to the adjacent model surface.

---

 **Note**

It is an option for the earlier versions of Pro/ENGINEER.

---

- `PRO_E_DRAFT_EXTEND`—Specifies extend option of the draft. It is of the following types:
  - `PRO_DRAFT_UI_NO_EXTEND`—Intersect without Extend.
  - `PRO_DRAFT_UI_EXTEND`—Intersect with Extend.

---

 **Note**

It is applicable for features created using Pro/ENGINEER version prior to Pro/ENGINEER Wildfire2.0 Release and is available only when `PRO_E_DRAFT_TWEAK_OR_INTERSEC` is equal to `PRO_DRAFT_UI_INTERSECT`.

---

- `PRO_E_DRAFT_SPLIT`—Specifies split details of the draft. It can be any of the following types:
  - `PRO_DRAFT_UI_SPLIT_NONE`
  - `PRO_DRAFT_UI_SPLIT_NEUT` specifies split on draft hinge.
  - `PRO_DRAFT_UI_SPLIT_SURF` specifies split at surface.
  - `PRO_DRAFT_UI_SPLIT_SCTCH` specifies split at sketch.

---

### **Note**

Draft surfaces can be split either by the draft hinge or by a different curve on the draft surface, such as an intersection with a quilt, or a sketched curve. If you are splitting by a sketch that does not lie on the draft surface, Creo Parametric projects it on the draft surface in the direction normal to the sketching plane.

---

- `PRO_E_STD_SURF_COLLECTION_APPL`—Specifies drafted surfaces.
- `PRO_E_DIRECTION_COMPOUND`—Specifies the direction utility for the draft.
- `PRO_E_DRAFT_CONSTANT_OR_VARIABLE`—Specifies constant or variable draft. For variable draft one can specify more than one angle per draft side. It can be one of the following types:
  - `PRO_DRAFT_UI_VARIABLE`
  - `PRO_DRAFT_UI_CONSTANT`
- `PRO_E_STD_CURVE_COLLECTION_APPL`—Specifies the exclude loop or the draft hinges.
- `PRO_E_DRAFT_SPLIT_GEOM`—Specifies split geometry (sketch, plane, or quilt used for splitting) and is an optional element.
- `PRO_E_STD_SECTION`—Specifies the split geometry and is an optional element. It contains the following element:
  - `PRO_E_SEC_USE_SKETCH`—Specifies the selected split geometry and is an optional element.
- `PRO_E_DRAFT_INCLUDE_TANGENT`—Specifies included tangent. It can be any of the following types:
  - `PRO_DRAFT_UI_NOT_INC_TANG` specifies the non-included tangents.
  - `PRO_DRAFT_UI_INC_TANG` specifies the included tangents.
- `PRO_E_DRAFT_SIDE_1`—Specifies details about first draft's side.
- `PRO_E_DRAFT_SIDE_2`—Specifies details about second draft's side.

### **Element Details of `PRO_E_DRAFT_SIDE_1`**

Each `PRO_E_DRAFT_SIDE_1` has the following elements:

- `PRO_E_DRAFT_NEUTRAL_OBJECT_TYPE_1`—Specifies the type of draft hinge. It can be any of the following types:

- PRO\_DRAFT\_UI\_NO\_NEUT—Specifies that no draft hinge have been fixed.
- PRO\_DRAFT\_UI\_PLANE—Specifies a plane. In this case, the draft surfaces are pivoted about their intersection with this plane.
- PRO\_DRAFT\_UI\_CURVE—Specifies a curve chain located on the draft surfaces.
- PRO\_DRAFT\_UI\_QUILT—Specifies a quilt of surfaces. In this case, the draft surfaces are pivoted about their intersection with the quilt.
- PRO\_DRAFT\_UI\_RND\_HINGE—Specifies a round surface that must be adjacent to the draft surface.
- PRO\_E\_DRAFT\_NEUTRAL\_PLANE\_1—Specifies the plane selected as the draft hinge.
- PRO\_E\_STD\_CURVE\_COLLECTION\_APPL—Specifies exclude loop or draft hinges.
- PRO\_E\_DRAFT\_DEPENDENT\_1—Specifies the dependence and controls whether the corresponding sides are drafted and depends on the type of the draft hinge. It can be any of the following types:
  - PRO\_DRAFT\_UI\_INDEPENDENT specifies that two independent draft angles for each side of the drafted surface.
  - PRO\_DRAFT\_UI\_DEPENDENT specifies a single draft angle, with the second side drafted in the opposite direction.
  - PRO\_DRAFT\_UI\_NONE specifies that none of the sides be drafted.
- PRO\_E\_DRAFT\_ANGLE\_1—Specifies the draft angle and is a constant value.
- PRO\_E\_DRAFT\_ANGLES—This is an option for a variable draft. It specifies a collection of draft angles and points PRO\_E\_DRAFT\_ANG\_PNT. Each PRO\_E\_DRAFT\_ANG\_PNT consists of the following elements:
  - PRO\_E\_STD\_POINT\_COLLECTION\_APPL—Specifies the point collection for the angle.
  - PRO\_E\_DRAFT\_ANGLE—Specifies the draft angle.
- PRO\_E\_DRAFT\_NEUTRAL\_QUILT\_1—Specifies the quilt of surfaces selected as the draft hinge.

## Element Details of PRO\_E\_DRAFT\_SIDE\_2

Each PRO\_E\_DRAFT\_SIDE\_2 has the following elements:

- PRO\_E\_DRAFT\_NEUTRAL\_OBJECT\_TYPE\_2—Specifies the type of draft hinge. It can be any of the following types:

- `PRO_DRAFT_UI_NO_NEUT`—Specifies that no draft hinge has been fixed.
- `PRO_DRAFT_UI_PLANE`—Specifies a plane. In this case, the draft surfaces are pivoted about their intersection with this plane.
- `PRO_DRAFT_UI_CURVE`—Specifies a curve chain located on the draft surfaces.
- `PRO_DRAFT_UI_QUILT`—Specifies a quilt of surfaces. In this case, the draft surfaces are pivoted about their intersection with the quilt.
- `PRO_E_DRAFT_NEUTRAL_PLANE_2`—Specifies the plane selected as the draft hinge.
- `PRO_E_STD_CURVE_COLLECTION_APPL`—Specifies exclude loop or draft hinges.
- `PRO_E_DRAFT_DEPENDENT_2`—Specifies the dependence and controls whether the corresponding sides are drafted and depends on the type of the draft hinge. It can be any of the following types:
  - `PRO_DRAFT_UI_INDEPENDENT` specifies that two independent draft angles for each side of the drafted surface.
  - `PRO_DRAFT_UI_DEPENDENT` specifies a single draft angle, with the second side drafted in the opposite direction.
  - `PRO_DRAFT_UI_NONE` specifies that none of the side be drafted.
- `PRO_E_DRAFT_ANGLE_2`—Specifies the draft angle and is a constant value.
- `PRO_E_DRAFT_ANGLES`—This is an option for a variable draft. It specifies a collection of draft angles and points `PRO_E_DRAFT_ANG_PNT`. Each `PRO_E_DRAFT_ANG_PNT` consists of the following elements:
  - `PRO_E_STD_POINT_COLLECTION_APPL`—Specifies the point collection for the angle.
  - `PRO_E_DRAFT_ANGLE`—Specifies the draft angle.
- `PRO_E_DRAFT_NEUTRAL_QUILT_2`—Specifies the quilt of surfaces selected as the draft hinge.

## Creating a Draft

Function Introduced:

- **ProFeatureCreate()**

---

Use the function `ProFeatureCreate()` to create a Draft based on element tree input. For more information about `ProFeatureCreate()`, refer to the section [Overview of Feature Creation on page 771](#) of the section [Element Trees: Principles of Feature Creation on page 771](#).

## Redefining a Draft

Function Introduced:

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine a Draft based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer to the section [Feature Redefine on page 794](#) of the section [Element Trees: Principles of Feature Creation on page 771](#).

## Accessing a Draft

Function Introduced:

- **ProFeatureElemtreeExtract()**

Use the function `ProFeatureElemtreeExtract()` to create a feature element tree that describes the contents of a Draft and to retrieve the element tree description of a Draft. For more information about `ProFeatureElemtreeExtract()` refer to the section [Feature Inquiry on page 792](#) of the section [Element Trees: Principles of Feature Creation on page 771](#).

## Example 1: Creation of a Draft Feature

The sample code in the file `UgSimpleDraftCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a Simple Draft feature.

The user is prompted to select:

1. The surface to be drafted
2. The hinge (edge / curve)
3. The direction of the draft (axis, edge)

## Example 2: Creation of a Draft Feature using interactive collection

The sample code in the file `UgIntcollectionDraftCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a draft feature using interactive collection.

The user is prompted to create a collection of:

- 
1. The surface to be drafted ( "ProSurfacesCollect" )
  2. The direction of the draft ( axis, edge - "ProSelect" )
  3. The hinge ( edge / curve - "ProCurvesCollect" )

### **Example 3: Creation of a Draft Feature based on the Object-Action paradigm**

The sample code in the file `UgOADraftCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` demonstrates creation of a simple Draft feature based on the Object-Action paradigm using selection buffer access. The user is expected to populate the selection buffer in Creo Parametric user interface with

1. A surface collection for the surfaces to be drafted
2. A curve collection for the hinge ( edge / curve )
3. A selection for the direction of the draft ( axis, edge )

This example parses the selection buffer and uses the information for the programmatic creation of draft feature. The selection buffer may be populated with the above three entries in any order. The success of feature creation depends upon the appropriateness of the data in the selection buffer.

## **Variable Pull Direction Draft Feature**

The Variable Pull Direction Draft (VPDD) feature differs from the regular Draft feature where the pull direction is restricted to be constant. A VPDD is defined by an edge or curve, a surface that specifies the variable pull direction, a depth option, and optionally, splitting surfaces.

### **Feature Element Tree for the Variable Pull Direction Draft Feature**

The element tree for the Variable Pull Direction Draft feature is documented in the header file `ProVPDD.h`. The following figure demonstrates the feature element tree structure:

## Feature Element Tree for Variable Pull Direction Draft Feature

```
PRO_E_FEATURE_TREE
|
|-- PRO_E_FEATURE_TYPE
|
|-- PRO_E_STD_FEATURE_NAME
|
|-- PRO_E_VPDD_PULL_DIR_CMP
| |
| |-- PRO_E_VPDD_PULL_DIR_REF
| |
| |-- PRO_E_VPDD_PULL_DIR_FLIP
|
|-- PRO_E_VPDD_SETS_ARR
| |
| |-- PRO_E_VPDD_SET_CMP
|
|-- PRO_E_VPDD_ATTACH_OPTS
|
|-- PRO_E_VPDD_EXTENT_CMP
| |
| |-- PRO_E_VPDD_EXT_OPTS
| |
| |-- PRO_E_VPDD_EXT_LENGTH
| |
| |-- PRO_E_VPDD_EXT_REF
```

## PRO\_E\_VPDD\_SET\_CMP

```
PRO_E_VPDD_SET_CMP
|
|-- PRO_E_VPDD_HINGES_ARR
| |
| |-- PRO_E_VPDD_HINGE_CMP
| |
| |-- PRO_E_STD_CURVE_COLLECTION_APPL
| |
| |-- PRO_E_VPDD_HINGE_FLIP
|
|-- PRO_E_VPDD_SPLIT_SRFS_OPTS
|
|-- PRO_E_VPDD_SPLIT_SRFS_REFS
|
|-- PRO_E_VPDD_CONST_OR_VAR
|
|-- PRO_E_VPDD_ANGLES_AND_POINTS_ARR
| |
| |-- PRO_E_VPDD_POINT_AND_ANGLES_CMP
| |
| |-- PRO_E_STD_POINT_COLLECTION_APPL
| |
| |-- PRO_E_VPDD_ANGLES_ARR
| |
| |-- PRO_E_VPDD_ONE_ANGLE_CMP
| |
| |-- PRO_E_VPDD_ANG_VAL
```

The elements in this tree are as follows:

- PRO\_E\_FEATURE\_TYPE—Specifies the feature type and should be PRO\_FEAT\_VPDD.
- PRO\_E\_STD\_FEATURE\_NAME—Specifies the name of the feature.
- PRO\_E\_VPDD\_PULL\_DIR\_CMP—Specifies the pull direction reference.  
This compound element consists of the following elements:
  - PRO\_E\_VPDD\_PULL\_DIR\_REF—Specifies the selected reference surface. It could be a single PRO\_QUILT, a single PRO\_DATUM\_PLANE, a single PRO\_LOG\_SRF, or multiple PRO\_SURFACE references that are tangent to each other.
  - PRO\_E\_VPDD\_PULL\_DIR\_FLIP—Specifies the pull direction defined by the normal vectors of the selected reference surfaces. By default, this element is PRO\_B\_TRUE and the pull direction is along the normal vectors. The pull direction can be flipped.

- 
- `PRO_E_VPDD_SETS_ARR`—Specifies an array of the elements of the type `PRO_E_VPDD_SET_CMP`. `PRO_E_VPDD_SET_CMP` is a compound element and specifies a draft set. For more information on the elements contained by this compound element, refer to the section [Element Details of the Subtree `PRO\_E\_VPDD\_SET\_CMP`](#) on page 904.
  - `PRO_E_VPDD_ATTACH_OPTS`—Specifies the attachment option. When all the draft hinges are two-sided edges, you can specify whether to attach the draft geometry to the existing solid or quilt, or create the draft geometry as a separate quilt. The attachment options, specified by the enumerated type `Pro_vpdd_attach_type`, are as follows:
    - `PRO_VPDD_ATTACH_NEW_QUILT`—Creates the draft geometry as a separate quilt.
    - `PRO_VPDD_ATTACH_SAME_QUILT`—Attaches the draft geometry to the existing solid or quilt.
  - `PRO_E_VPDD_EXTENT_CMP`—Specifies the extent (depth) option when unattached draft geometry is created. This compound element is available only if the element `PRO_E_VPDD_ATTACH_OPTS` is set to `PRO_VPDD_ATTACH_NEW_QUILT`.
    - `PRO_E_VPDD_EXT_OPTS`—Specifies the extent options. These options, specified by the enumerated type `Pro_vpdd_ext_type`, are as follows:
      - ◆ `PRO_VPDD_EXT_LENGTH`—Specifies the length dimension option.
      - ◆ `PRO_VPDD_EXT_TO_SEL`—Select the reference bottom surface upto which the draft geometry is extended.
      - ◆ `PRO_VPDD_EXT_TO_NEXT`—The draft geometry is extended up to the next surface it intersects. This excludes any surface or quilt used as a parting surface for a different draft set.
      - ◆ `PRO_VPDD_EXT_UNATTACHED`—Creates the draft geometry ready for attachment but as a separate quilt.
      - ◆ `PRO_E_VPDD_EXT_LENGTH`—Specifies the length value. This element is available only when the element `PRO_E_VPDD_EXT_OPTS` is set to `PRO_VPDD_EXT_LENGTH`.
      - ◆ `PRO_E_VPDD_EXT_REF`—Specifies the selected bottom surface upto which the draft geometry is extended. The valid references are `PRO_QUILT`, `PRO_SURFACE`, and `PRO_DATUM_PLANE`. This element is available only when the element `PRO_E_VPDD_EXT_OPTS` is set to `PRO_VPDD_EXT_TO_SEL`.

---

## Element Details of the Subtree PRO\_E\_VPDD\_SET\_CMP

The compound element PRO\_E\_VPDD\_SET\_CMP contains the following elements:

- PRO\_E\_VPDD\_HINGES\_ARR—Specifies an array of elements of the type PRO\_E\_VPDD\_HINGE\_CMP. PRO\_E\_VPDD\_HINGE\_CMP is a compound element and specifies a collection of draft hinges used to generate the draft geometry.
  - PRO\_E\_STD\_CURVE\_COLLECTION\_APPL—Specifies a chain of two-sided edges, one-sided edges, curves, or a combination of one-sided edges and curves.
  - PRO\_E\_VPDD\_HINGE\_FLIP—Specifies the ProBoolean option to select the sets of surfaces to be drafted on each side of a draft hinge defined by two-sided edges.
- PRO\_E\_VPDD\_SPLIT\_SRFS\_OPTS—Specifies the ProBoolean option to specify if splitting surfaces are used while generating the draft geometry. If this option is set to the default value PRO\_B\_FALSE, then the element PRO\_E\_VPDD\_SPLIT\_SRFS\_REFS becomes unavailable.
- PRO\_E\_VPDD\_SPLIT\_SRFS\_REFS—Specifies a collection of splitting surface references. You can select up to two references that are either PRO\_QUILT or PRO\_DATUM\_PLANE.
- PRO\_E\_VPDD\_CONST\_OR\_VAR—Specifies a constant or variable draft. For a variable draft, there are variable angle attachment points. The values for this element, specified by the enumerated type Pro\_vpdd\_const\_var\_type, are as follows:
  - PRO\_VPDD\_CONST
  - PRO\_VPDD\_VAR
- PRO\_E\_VPDD\_ANGLES\_AND\_POINTS\_ARR—Specifies an array of elements of the type PRO\_E\_VPDD\_POINT\_AND\_ANGLES\_CMP. PRO\_E\_VPDD\_POINT\_AND\_ANGLES\_CMP is a compound element and specifies a collection of points and angles.
  - PRO\_E\_STD\_POINT\_COLLECTION\_APPL—Specifies the selection references (curves, edges, or datum points) where the draft angles are defined.

---

### **Note**

- ◆ If `PRO_E_VPDD_CONST_OR_VAR` is set to `PRO_VPDD_CONST`, then the element `PRO_E_STD_POINT_COLLECTION_APPL` becomes unavailable and the element `PRO_E_VPDD_ANGLES_AND_POINTS_ARR` contains only a single element.
  - ◆ A reference is valid when it belongs to or lies on a draft hinge that belongs to the same draft set.
- 
- `PRO_E_VPDD_ANGLES_ARR`—Specifies an array of elements of the type `PRO_E_VPDD_ONE_ANGLE_CMP`. The size of the array is one plus the number of splitting references. `PRO_E_VPDD_ONE_ANGLE_CMP` is a compound element and specifies the draft angle for the active draft set.
    - ◆ `PRO_E_VPDD_ANG_VAL`—Specifies the value of the draft angle. This value lies in the range of -90 degrees through 90 degrees.

## Creating a VPDD

Function Introduced:

- **ProFeatureCreate()**

Use the function `ProFeatureCreate()` to create a VPDD based on element tree input. For more information about `ProFeatureCreate()`, refer to the section [Overview of Feature Creation on page 771](#) of the section [Element Trees: Principles of Feature Creation on page 771](#).

## Redefining a VPDD

Function Introduced:

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine a VPDD based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer to the section [Feature Redefine on page 794](#) of the section [Element Trees: Principles of Feature Creation on page 771](#).

## Accessing a VPDD

Function Introduced:

- **ProFeatureElemtreeExtract()**

---

Use the function `ProFeatureElemtreeExtract()` to create a feature element tree that describes the contents of a VPDD and to retrieve the element tree description of a Draft. For more information about `ProFeatureElemtreeExtract()` refer to the section [Feature Inquiry on page 792](#) of the section [Element Trees: Principles of Feature Creation on page 771](#).

## Element Trees: Round and Chamfer

This section describes how to create, redefine, and query round and chamfer features through element trees and element tree functions. The section [Overview of Feature Creation on page 771](#) of the section [Element Trees: Principles of Feature Creation on page 771](#) provides a necessary background information for this topic.

See the Part Modeling module in Creo Parametric for further details on round and chamfer feature creation.

The following sections describe the procedure for accessing the chamfers and round features in detail.

## Round Features

### Feature Element Tree for Round Feature

The element tree for a round is documented in the header file `ProRound.h`, and has a simple structure. The following figure demonstrates the feature element tree structure:

#### Feature Element Tree for Round

```
PRO_E_FEATURE_TREE

```

The following list details special information about the elements in this tree:

- **PRO\_E\_FEATURE\_TYPE**—Specifies feature type and should have the value as **PRO\_FEAT\_ROUND** only.

- `PRO_E_STD_FEATURE_NAME`—Specifies the name to the feature. This is an optional element. If not specified then a default name will be assigned internally to the feature.
- `PRO_E_RNDCH_SETS`—Specifies an array of `PRO_E_RNDCH_SET`.
- `PRO_E_RNDCH_ATTACH_TYPE`—Specifies the attachment type and has the following values:
  - `PRO_ROUND_ATTACHED`—Specifying this option, the created round feature consumes the model geometry.
  - `PRO_ROUND_UNATTACHED`
  - `PRO_ROUND_CAPPED_ENDS`
- `PRO_E_RNDCH_TRANSITIONS`—Specifies a set of transition `PRO_E_RNDCH_TRANSITION`.

#### Element Details of `PRO_E_RNDCH_SET` for Round

Each `PRO_E_RNDCH_SET` specifies a round set, which is a round piece (geometry) created as per the placement references and consists of the following elements:

- `PRO_E_RNDCH_SHAPE_OPTIONS`—Specifies the shape options and have the following values:
  - `PRO_ROUND_TYPE_CONSTANT`—Specifies a round piece having a constant radius.
  - `PRO_ROUND_TYPE_VARIABLE`—Specifies a round piece having multiple radii.
  - `PRO_ROUND_TYPE_FULL`—Specifies full round which replaces the selected surface.
  - `PRO_ROUND_TYPE_THROUGH_CURVE`—Allows the radius of the active round to be driven by the selected datum curve.
- `PRO_E_RNDCH_VARIABLE_RADIUS`—Specifies if the round is of a constant or variable type.
- `PRO_E_RNDCH_COMPOUND_CONIC`—Specifies if the round uses a conic section for the shape. It can be defined as:
  - `PRO_E_RNDCH_CONIC_TYPE`—Specifies conic type and can have the following valid values:
    - ◆ `PRO_ROUND_CONIC_ENABLE`
    - ◆ `PRO_ROUND_CONIC_DISABLE`
    - ◆ `PRO_ROUND_CURV_CONTINUOUS`—Used to specify curvature continuous rounds.

- 
- PRO\_E\_RNDCH\_CONIC\_VALUE—Specifies conic value, that controls the sharpness of the conic shape and is required if PRO\_E\_RNDCH\_CONIC\_TYPE is equal to PRO\_ROUND\_CONIC\_ENABLE.
  - PRO\_E\_RNDCH\_CONIC\_DEP\_OPT—Specifies independent options and is required if PRO\_E\_RNDCH\_CONIC\_TYPE is equal to PRO\_ROUND\_CONIC\_ENABLE.
  - The values of ProRoundConicIndependentType are as follows:
    - ◆ PRO\_ROUND\_CONIC\_DEPENDENT
    - ◆ PRO\_ROUND\_CONIC\_INDEPENDENT
    - ◆ PRO\_ROUND\_CONIC\_INDEPENDENT is the default type.
  - PRO\_E\_RNDCH\_REFERENCES—Specifies a set of valid references of the round feature.
  - PRO\_E\_RNDCH\_COMPOUND\_SPINE—This is another option for defining the shape of the round. Specifies the spine and has the following elements:
    - PRO\_E\_RNDCH\_BALL\_SPINE—Specifies rolling ball or normal to spine. Valid values of PRO\_E\_RNDCH\_BALL\_SPINE are:
      - ◆ PRO\_ROUND\_ROLLING\_BALL—Specifies a round surface and is created by rolling a spherical ball along the surfaces.
      - ◆ PRO\_ROUND\_NORMAL\_TO\_SPINE—Specifies a round surface and is created by sweeping a conic or arc cross-section normal to a spine.
      - ◆ PRO\_E\_STD\_CURVE\_COLLECTION\_APPL—Specifies the spine curve and is required if PRO\_E\_RNDCH\_BALL\_SPINE is equal to PRO\_ROUND\_NORMAL\_TO\_SPINE.

---

### Note

During the creation of rounds, the options **D1 x D2 Conic** and **Normal to spine** cannot be used together. Due to this restriction, the existing rounds with their conic type option set as PRO\_ROUND\_CONIC\_INDEPENDENT and with the round creation method set to PRO\_ROUND\_NORMAL\_TO\_SPINE are reset to PRO\_ROUND\_ROLLING\_BALL when the round is redefined. Therefor, for the conic type option PRO\_ROUND\_CONIC\_INDEPENDENT you must specify the round creation method as PRO\_ROUND\_ROLLING\_BALL.

---

- PRO\_E\_RNDCH\_AUTO\_CONTINUE—Specifies whether surfaces will be extended to meet the designated round radius. The valid values are:
  - PRO\_ROUND\_AUTO\_CONT\_DISABLE—This is the default value.

- 
- `PRO_ROUND_AUTO_CONT_ENABLE`

This element is required if `PRO_E_RNDCH_REFERENCE_TYPE = PRO_ROUND_REF_EDGE`.

- `PRO_E_RNDCH_COMPOUND_EXT_OPTIONS`—Specifies the external options. This is an optional element. It has the following elements:
  - `PRO_E_RNDCH_AUTO_BLEND`—Specifies auto blend.
  - `PRO_E_RNDCH_TERM_SURFACE`—Specifies the terminating surface.
- `PRO_E_RNDCH_RADII`—Specifies the radii, as an array of radius or `PRO_E_RNDCH_RADIUS` and is required if `PRO_E_RNDCH_SHAPE_OPTIONS` is not equal to `PRO_ROUND_TYPE_THROUGH_CURVE` and `PRO_E_RNDCH_SHAPE_OPTIONS` is not equal to `PRO_ROUND_TYPE_FULL`.
- `PRO_E_STD_CURVE_COLLECTION_APPL`—Specifies the curve collection and is required if `PRO_E_RNDCH_SHAPE_OPTIONS` is equal to `PRO_ROUND_TYPE_THROUGH_CURVE`.
- `PRO_E_RNDCH_AMBIGUITY`—Specifies round set ambiguity.

---

 **Note**

Ambiguity occurs in round features when other placement locations exist for the round set. The ambiguity condition occurs when two surfaces intersect in multiple locations.

---

### Element Details of `PRO_E_RNDCH_REFERENCES` for Round

Each `PRO_E_RNDCH_REFERENCES` specifies a set of valid references of the round feature and has the following elements:

- `PRO_E_RNDCH_REFERENCE_TYPE`—Specifies the reference types and valid values are:
  - `PRO_ROUND_REF_EDGE`—Specifies that the surfaces border the edge reference and form the rolling tangent attachment for the round.
  - `PRO_ROUND_REF_SURF_SURF`—Specifies that the edges of the round remain tangent to the reference surfaces.
  - `PRO_ROUND_REF_EDGE_SURF`—Specifies that the round remains tangent to the surface. The edge reference does not maintain tangency.
  - `PRO_ROUND_REF_EDGE_EDGE`—Specifies that the surfaces bordering the edge reference form the rolling tangent attachment for the round.

- `PRO_E_STD_CURVE_COLLECTION_APPL`—Specifies the reference edges of the chain collection. It is required if `PRO_E_RNDCH_REFERENCE_TYPE` is equal to `PRO_ROUND_REF_EDGE`.

In Creo TOOLKIT 7.0.0.0 and later, you can select the reference edges from both different solid bodies as well as quilts. The resulting geometry is attached back to the same solid body or quilt from where the referenced edges were selected.

- `PRO_E_RNDCH_REFERENCE_SURFACE1`—Specifies the first reference surface and is required if `PRO_E_RNDCH_REFERENCE_TYPE` is equal to `PRO_ROUND_REF_SURF_SURF`.
- `PRO_E_RNDCH_REFERENCE_SURFACE2`—Specifies the second reference surface and is required if `PRO_E_RNDCH_REFERENCE_TYPE` is equal to `PRO_ROUND_REF_SURF_SURF` or `PRO_E_RNDCH_REFERENCE_TYPE` is equal to `PRO_ROUND_REF_EDGE_SURF`.
- `PRO_E_RNDCH_REFERENCE_EDGE1`—Specifies the first reference edge and is required if `PRO_E_RNDCH_REFERENCE_TYPE` is equal to `PRO_ROUND_REF_EDGE_SURF` or `PRO_E_RNDCH_REFERENCE_TYPE` is equal to `PRO_ROUND_REF_EDGE_EDGE` and `PRO_E_RNDCH_SHAPE_OPTIONS` is equal to `PRO_ROUND_TYPE_FULL`.
- `PRO_E_RNDCH_REFERENCE_EDGE2`—Specifies the second reference edge and is required if `PRO_E_RNDCH_REFERENCE_TYPE` is equal to `PRO_ROUND_REF_EDGE_EDGE` and `PRO_E_RNDCH_SHAPE_OPTIONS` is equal to `PRO_ROUND_TYPE_FULL`.
- `PRO_E_RNDCH_REPLACE_SURFACE`—Specifies the surface to be replaced and is required if `PRO_E_RNDCH_REFERENCE_TYPE` is equal to `PRO_ROUND_REF_SURF_SURF` and `PRO_E_RNDCH_SHAPE_OPTIONS` is equal to `PRO_ROUND_TYPE_FULL`.

### Element Details of `PRO_E_RNDCH_RADIUS` for Round

Each `PRO_E_RNDCH_RADIUS` has the following elements:

- `PRO_E_STD_POINT_COLLECTION_APPL`—Specifies a point, which governs the value of the radius.
- `PRO_E_RNDCH_LEG1`—Specifies the leg1.
- `PRO_E_RNDCH_LEG2`—Specifies the leg2 and is required if `PRO_E_RNDCH_CONIC_DEP_OPT` is equal to `PRO_ROUND_CONIC_INDEPENDENT`.

Each `PRO_E_RNDCH_LEG1` or `PRO_E_RNDCH_LEG2` has the following elements:

- `PRO_E_RNDCH_LEG_TYPE`—`ProRoundRadiusType` specifies leg type and is a mandatory element. It is of the following types:
  - `PRO_ROUND_RADIUS_TYPE_VALUE`
  - `PRO_ROUND_RADIUS_THROUGH_POINT`
- `PRO_E_RNDCH_LEG_VALUE`—Specifies leg value and is required if `PRO_E_RNDCH_LEG_TYPE` is equal to `PRO_ROUND_RADIUS_TYPE_VALUE`.
- `PRO_E_RNDCH_REFERENCE_EDGE`—Specifies reference edge having the value as `PRO_E_EDGE` and is required if `PRO_E_RNDCH_LEG_TYPE` is equal to `PRO_ROUND_RADIUS_THROUGH_POINT`.
- `PRO_E_RNDCH_REFERENCE_POINT`—Specifies reference point having the value as `PRO_E_POINT` and is required if `PRO_E_RNDCH_LEG_TYPE` is equal to `PRO_ROUND_RADIUS_THROUGH_POINT`.

#### Element Details of `PRO_E_RNDCH_TRANSITION` for Round

Each `PRO_E_RNDCH_TRANSITION` represents user-defined transitions for the entire round feature and consists of the following elements:

- `PRO_E_RNDCH_TRANS_TYPE` specifies the type of the transition type. Valid values are:
  - `PRO_ROUND_TRANS_INTERSECT`—Used to extend two or more overlapping round pieces towards each other until they merge forming a sharp boundary.
  - `PRO_ROUND_TRANS_BLEND`—Used to create a fillet surface between the round pieces using an edge reference.
  - `PRO_ROUND_TRANS_STOP`—Used to terminate the round geometry at the specified datum point or datum plane.
  - `PRO_ROUND_TRANS_CONTINUE`—Used to extend round geometry into two round pieces.
  - `PRO_ROUND_TRANS_SPHERE_CORNER`—Used to create a round from the corner transition formed by three overlapping pieces by a spherical corner.
  - `PRO_ROUND_TRANS_PATCH`—Used to create a patched surface at the location where three or four round pieces overlap at a corner.
  - `PRO_ROUND_TRANS_BLEND_3SRF`—Used to create a triangular patch as a transition of three rounds.
  - `PRO_ROUND_TRANS_RBALL`—Used to create a rolling ball transition for three or more rounds.

- PRO\_ROUND\_TRANS\_STOP\_0\_SIDE—Used to terminate the round using geometry configured by Creo Parametric.
- PRO\_ROUND\_TRANS\_STOP\_1\_SIDE—Used to terminate the round using geometry configured by Creo Parametric.
- PRO\_ROUND\_TRANS\_STOP\_2\_SIDE—Used to terminate the round using geometry configured by Creo Parametric.
- PRO\_ROUND\_TRANS\_STOP\_AT\_REF—Used to terminate round geometry at the selected datum point or datum plane.
- PRO\_ROUND\_TRANS\_STOP\_FULL—Used to keep the stop transition close to the boundary of the removed surface.
- PRO\_ROUND\_TRANS\_STOP\_2\_WE—Used to create a stop transition with maximum possible extension of the round by freezing one of round's references and changing the other reference at intersection with tangent edges.
- PRO\_E\_RNDCH\_TRANS\_CAP—Specifies the capping surface for round feature. It has the following values:
  - PRO\_ROUND\_CAPPING\_SURF\_DISABLE = PRO\_B\_FALSE
  - PRO\_ROUND\_CAPPING\_SURF\_ENABLE = PRO\_B\_TRUE
- PRO\_E\_RNDCH\_TRANS\_SPHERE\_DATA—Specifies sphere data and consists of the following elements:
  - PRO\_E\_RNDCH\_TRANS\_RADIUS\_OPTIONS—Specifies radius options and is a mandatory element.
  - PRO\_E\_RNDCH\_TRANS\_SPHERE\_RADIUS—Specifies sphere radius and is required if PRO\_E\_RNDCH\_TRANS\_RADIUS\_OPTIONS is equal to PRO\_ROUND\_TRANS\_RADIUS\_ENTER\_VALUE.
  - PRO\_E\_RNDCH\_TRANS\_LEG1\_OPTIONS—Specifies leg1 options and is a mandatory element.
  - PRO\_E\_RNDCH\_TRANS\_LEG1\_VALUE—Specifies the value of leg1 and is required if PRO\_E\_RNDCH\_TRANS\_LEG1\_OPTIONS is equal to PRO\_ROUND\_TRANS\_RADIUS\_ENTER\_VALUE.
  - PRO\_E\_RNDCH\_TRANS\_LEG2\_OPTIONS—Specifies leg2 options and is a mandatory element.
  - PRO\_E\_RNDCH\_TRANS\_LEG2\_VALUE—Specifies the value of leg2 and is required if PRO\_E\_RNDCH\_TRANS\_LEG2\_OPTIONS is equal to PRO\_ROUND\_TRANS\_RADIUS\_ENTER\_VALUE.
  - PRO\_E\_RNDCH\_TRANS\_LEG3\_OPTIONS—Specifies leg3 options and is a mandatory element.

- PRO\_E\_RNDCH\_TRANS\_LEG3\_VALUE—Specifies the value of leg3 and is required if PRO\_E\_RNDCH\_TRANS\_LEG3\_OPTIONS is equal to PRO\_ROUND\_TRANS\_RADIUS\_ENTER\_VALUE.
- PRO\_E\_RNDCH\_TRANS\_PATCH\_DATA—Specifies the patch data and is required if PRO\_E\_RNDCH\_TRANS\_TYPE is equal to PRO\_ROUND\_TRANS\_PATCH. It has the following elements:
  - PRO\_E\_RNDCH\_TRANS\_PATCH\_REF\_SURF—Specifies the arc surface, which indicates that a valid surface reference has been selected to place a fillet for the active patch transition. It should have the value as PRO\_SURFACE only.
  - PRO\_E\_RNDCH\_TRANS\_PATCH\_RAD\_OPT—Specifies the arc radius options. It indicates the fillet radius for the active patch transition and has following options:
    - ◆ PRO\_ROUND\_TRANS\_RADIUS\_ENTER\_VALUE— Specifies a new radius value.
    - ◆ PRO\_ROUND\_TRANS\_RADIUS\_AUTOMATIC— Specifies the most recently used radius value.
    - ◆ PRO\_E\_RNDCH\_TRANS\_ARC\_RADIUS—Specifies the arc radius.
- PRO\_E\_RNDCH\_TRANS\_STOP\_DATA—Specifies the capping surface. It has the following elements:
  - PRO\_E\_RNDCH\_TRANS\_STOP\_REF\_TYPE—Specifies the reference type. Valid values are:
    - ◆ PRO\_ROUND\_TRANS\_REF\_NO\_REF
  - PRO\_ROUND\_TRANS\_REF\_GEOM
  - PRO\_ROUND\_TRANS\_REF\_PNTVTX
  - PRO\_ROUND\_TRANS\_REF\_DTMLN
  - PRO\_ROUND\_TRANS\_REF\_ISOLINE
  - PRO\_E\_RNDCH\_TRANS\_STOP\_REFERENCE—Specifies the references for the active stop at reference transition. It can either be PRO\_SURFACE or PRO\_POINT.

## Creating a Round

Function Introduced:

- **ProFeatureCreate()**

---

Use the function `ProFeatureCreate()` to create a round based on element tree input. For more information about `ProFeatureCreate()`, refer to the section [Overview of Feature Creation on page 771](#) in the [Element Trees: Principles of Feature Creation on page 771](#) section.

---

 **Note**

In Pro/ENGINEER Wildfire 2.0,

- Pro/TOOLKIT does not support the temporary geometry required for user-specified ambiguity and non-default transitions. Therefore, these elements cannot be used for creation of new rounds.
  - If transitions are specified in the input element tree, a round feature with the default transition will be created.
  - In case of ambiguous situation (where more than one valid solutions exist, e.g. for surface-surface round - surfaces having discontinuous edges of intersection), a round feature with default solution will be created.
- 

## Redefining a Round

Function Introduced:

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine a round based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer to the section [Feature Redefine on page 794](#) in the [Element Trees: Principles of Feature Creation on page 771](#).

---

 **Note**

In Pro/ENGINEER Wildfire 2.0,

- A round feature having default transition, can not be redefined to have any transition.
  - A round feature having a Pro/ENGINEER user interface defined transition can be redefined to other type of transition, for example, from intersect type to spherical type. The input element tree must have a valid transition of the required type.
-

---

## Accessing a Round

Function Introduced:

- **ProFeatureElemtreeExtract()**

Use the function `ProFeatureElemtreeExtract()` to create a feature element tree that describes the contents of a round and to retrieve the element tree description of a round. For more information about `ProFeatureElemtreeExtract()`, refer to the section [Feature Inquiry on page 792](#) in the [Element Trees: Principles of Feature Creation on page 771](#) section.

### Example 1: Sample code for creation of a Round Feature

The sample code in `UgEdgeRoundCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create an Edge Round feature. The user is prompted for three edges to be rounded.

## Modify Round Radius Feature

As a part of the flexible modeling capabilities the `Modify Round Radius` feature allows you to modify the radius of existing round geometry. You can modify the radius of both constant and variable rounds, however variable radius rounds are converted to constant radius rounds upon modification. You can also modify the radii of multiple round shape sets.

The creation of the `Modify Round Radius` feature includes the following steps:

1. Identify the round geometry to be modified and its radius value.
2. Creo Parametric removes the identified round geometry using the remove surface algorithm and recreates the rounded edges with the desired radius value.
3. The feature IDs of recreated rounds are updated.

### Feature Element Tree for Modify Round Radius Feature

The element tree for a `Modify Round Radius` feature is documented in the header file `ProModifyRound.h` and has a simple structure. The following figure demonstrates the structure of the feature element tree.

## Modify Round Radius Element Tree

```
PRO_E_FEATURE_TREE
|
|--PRO_E_FEATURE_TYPE
|
|--PRO_E_STD_FEATURE_NAME
|
|--PRO_E_STD_SURF_COLLECTION_APPL
|
|--PRO_E_MODRND_RAD_VAL
|
|--PRO_E_MODRND_OPTS
| |
| |--PRO_E_MODRND_ATTACH
| |
| |--PRO_E_MODRND_CLOSEGEOM
| |
| |--PRO_E_MODRND_RECR_INTERF_RND
| |
|--PRO_E_STD_FLEX_PROPAGATION
```

The elements in this tree are described as follows:

- PRO\_E\_FEATURE\_TYPE—Specifies the feature type and should be PRO\_FEAT\_MOD\_ROUND.
- PRO\_E\_STD\_FEATURE\_NAME—Specifies the name of the feature. The default value of this element is MODIFY\_ROUND.
- PRO\_E\_STD\_SURF\_COLLECTION\_APPL—Specifies a collection of reference surfaces the includes the rounds to be modified.

In Creo TOOLKIT 7.0.0.0 and later, you can select the reference surfaces from both different solid bodies as well as quilts. The resulting geometry is attached back to the same solid body or quilt from where the referenced surfaces were selected.

- PRO\_E\_MODRND\_RAD\_VAL—Specifies the new radius value. This value falls in the range  $[(\text{part epsilon} / 10.0), 1.0\text{e}+06]$ .
- PRO\_E\_MODRND\_OPTS—Specifies the modification options for each round to be recreated. This compound element consists of the following elements:
  - PRO\_E\_MODRND\_ATTACH—Specifies whether the recreated round geometry is attached to the selected reference surface upon creation. The values for this element, specified by the enumerated type ProModRndAttach, are as follows:
    - ◆ PRO\_MODRND\_ATTACH\_GEOM

- 
- ◆ PRO\_MODRND\_DONOT\_ATTACH\_GEOM
  - PRO\_E\_MODRND\_CLOSEGEOM—Specifies if end surfaces are created for the recreated rounds. The values for this element, specified by the enumerated type ProModRndCloseGeom, are as follows:
    - ◆ PRO\_MODRND\_CLOSE\_GEOM
    - ◆ PRO\_MODRND\_DONOT\_CLOSE\_GEOM

---

 **Note**

The element PRO\_E\_MODRND\_CLOSEGEOM is applicable only if the element PRO\_E\_MODRND\_ATTACH has the value PRO\_MODRND\_DONOT\_ATTACH\_GEOM, meaning that the rounds are recreated as new surfaces or quilts.

---

- PRO\_E\_MODRND\_RECR\_INTERF\_RND—Specifies whether interfering rounds are removed and recreated in order to recreate the modified round geometry. The values for this element, specified by the enumerated type ProModRndRecrRounds, are as follows:
  - ◆ PRO\_MODRND\_RECR\_INTERF\_RNDS
  - ◆ PRO\_MODRND\_DONOT\_RECR\_INTERF\_RNDS
- PRO\_E\_STD\_FLEX\_PROPAGATION—Specifies a Pattern feature, a Symmetry Recognition feature, or a Mirror Geometry feature that contains the reference surfaces specified by the element PRO\_E\_STD\_SURF\_COLLECTION\_APPL. If such surfaces exist, then the modification of the round radius is propagated to all corresponding surfaces in the instances of the Pattern feature, the Symmetry Recognition feature, or the Mirror Geometry feature, in order to maintain the pattern or symmetry.

## Auto Round Feature

The Auto Round feature enables you to create round geometry of a constant radius on solid geometry or on a quilt of a part or assembly. The Auto Round Feature creates Round features called Auto-Round Members (ARMs) that are represented in the Model Tree as subnodes of the Auto Round feature, or as groups of individual independent round features. Refer to the Creo Parametric Online Help for more details about this feature type.

Pro/TOOLKIT does not provide access to the Auto Round feature via an element tree for the Wildfire 4.0 release. Some Creo TOOLKIT functionality such as feature deletion, suppression and redefinition are not supported for individual ARMs within an Auto Round feature.

---

Functions Introduced:

- **ProRoundIsAutoRoundMember()**

The function `ProRoundIsAutoRoundMember()` identifies if the specified round feature is a member of the Auto Round feature.

## Chamfer Feature

### Feature Element Tree for Chamfer Feature

The element tree for a chamfer is documented in the header file `ProChamfer.h`, and has a simple structure. The following figure demonstrates the feature element tree structure:

### Feature Element Tree for Chamfer

```
PRO_E_FEATURE_TREE
|
|--PRO_E_FEATURE_TYPE
|
|--PRO_E_STD_FEATURE_NAME

| | |--PRO_E_RNDCH_RADIUS
| | | |--PRO_E_RNDCH_LEG1
| | | | |--PRO_E_RNDCH_LEG_TYPE
| | | | |--PRO_E_RNDCH_LEG_VALUE
| | | | |--PRO_E_RNDCH_REFERENCE_EDGE
| | | | |--PRO_E_RNDCH_REFERENCE_POINT
| | | |--PRO_E_RNDCH_LEG2
| | | | |--PRO_E_RNDCH_LEG_TYPE
| | | | |--PRO_E_RNDCH_LEG_VALUE
| | | | |--PRO_E_RNDCH_REFERENCE_EDGE
| | | | |--PRO_E_RNDCH_REFERENCE_POINT
| |
| |--PRO_E_RNDCH_AMBIGUITY
```

## PRO\_E\_RNDCH\_TRANSITIONS

```
PRO_E_RNDCH_TRANSITIONS
|
|--PRO_E_RNDCH_TRANSITION
|
| |--PRO_E_RNDCH_TRANS_TYPE
| |--PRO_E_RNDCH_TRANS_CAP
|
| |--PRO_E_RNDCH_TRANS_PATCH_DATA
| | |--PRO_E_RNDCH_TRANS_PATCH_REF_SURF
| | |--PRO_E_RNDCH_TRANS_PATCH_RAD_OPT
| | |--PRO_E_RNDCH_TRANS_ARC_RADIUS
|
| |--PRO_E_RNDCH_TRANS_STOP_DATA
| | |--PRO_E_RNDCH_TRANS_STOP_REF_TYPE
| | |--PRO_E_RNDCH_TRANS_STOP_REFERENCE
```

The following list details special information about some of the elements in this tree:

- **PRO\_E\_FEATURE\_TYPE**—Specifies feature type and has the value of **PRO\_FEAT\_CHAMFER**.
- **PRO\_E\_STD\_FEATURE\_NAME**—Specifies the name of the feature.
- **PRO\_E\_RNDCH\_SETS**—Specifies an array of **PRO\_E\_RNDCH\_SET**.
- **PRO\_E\_RNDCH\_ATTACH\_TYPE**—Specifies the attachment type and has the following values:
  - **PRO\_ROUND\_ATTACHED**
  - **PRO\_ROUND\_UNATTACHED**
  - **PRO\_ROUND\_CAPPED\_ENDS**
- **PRO\_E\_RNDCH\_TRANSITIONS**—Specifies a set of transition **PRO\_E\_RNDCH\_TRANSITION**.

## Element Details of PRO\_E\_RNDCH\_SET for Chamfer

Each **PRO\_E\_RNDCH\_SET** specifies a chamfer set for the chamfer feature and must have the following elements:

- **PRO\_E\_RNDCH\_DIMENSIONAL\_SCHEMA**—Specifies the type of chamfer or the dimensional schema **PRO\_E\_RNDCH\_DIMENSIONAL\_SCHEMA** using the enumerated type **ProChmSchema**. The different types of **PRO\_E\_RNDCH\_DIMENSIONAL\_SCHEMA** is as follows:
  - **PRO\_CHM\_45\_X\_D**—Specifies a chamfer that is at an angle of 45 degrees to both surfaces and at a distance D from the edge along each surface.
  - **PRO\_CHM\_D\_X\_D**—Specifies a chamfer that is at a distance D from the edge along each surface. This is the default type.
  - **PRO\_CHM\_D1\_X\_D2**—Specifies a chamfer at a distance D1 from the selected edge along one surface and at a distance D2 from the selected edge along the other surface.
  - **PRO\_CHM\_ANG\_X\_D**—Specifies a chamfer at a distance D from the selected edge along one adjacent surface, at a specified angle to that surface.
  - **PRO\_CHM\_O\_X\_O**—Provides direct control of the surface offset distances.
  - **PRO\_CHM\_O1\_X\_O2**—Provides direct control of the surface offset distances.

---

## Note

For Surf-Surf chamfer, the available schemes are:

- **Offset Surface method**—PRO\_CHM\_O\_X\_O, PRO\_CHM\_O1\_X\_O2, PRO\_CHM\_D\_X\_D, PRO\_CHM\_D1\_X\_D2 are available.
- **Tangent Dist method**—PRO\_CHM\_D\_X\_D, PRO\_CHM\_D1\_X\_D2, PRO\_CHM\_45\_X\_D, PRO\_CHM\_ANG\_X\_D are available.

For Surface-to-Edge chamfer the available schemes are:

- **Offset Surface**: PRO\_CHM\_O\_X\_O, PRO\_CHM\_O1\_X\_O2.
- **Tangent Distance**: PRO\_CHM\_D\_X\_D, PRO\_CHM\_D1\_X\_D2.

These schemes are applicable for constant angle planes or constant 90 degree surfaces and are also available if all members of the edge chain are formed by exactly 2 planes or exactly 2 surfaces at 90 degree, as in the ends of a cylinder.

---

- PRO\_E\_RNDCH\_CHAMFER\_SHAPE—Specifies the shape of the chamfer feature. PRO\_E\_RNDCH\_CHAMFER\_SHAPE has the following valid values:
  - PRO\_CHM\_TANGENT\_LEGS—Specifies the chamfer distance between vectors that are tangent to the neighboring surface of the reference edge.
  - PRO\_CHM\_OFFSET\_SURFACE—Specifies the offset surfaces.
- PRO\_E\_RNDCH\_REFERENCES—Specifies a set of valid references of the chamfer feature and has the following elements:
  - PRO\_E\_STD\_CURVE\_COLLECTION\_APPL—Specifies reference edges and is a required element for edge chamfer.

In Creo TOOLKIT 7.0.0.0 and later, you can select the reference edge chamfers from both different solid bodies as well as quilts. The resulting geometry is attached back to the same solid body or quilt from where the referenced edges were selected.

- PRO\_E\_RNDCH\_REFERENCE\_SURFACE—Specifies reference surfaces and is required if either PRO\_E\_RNDCH\_DIMENSIONAL\_SCHEMA is equal to PRO\_CHM\_D1\_X\_D2 or PRO\_E\_RNDCH\_DIMENSIONAL\_SCHEMA is equal to PRO\_CHM\_ANG\_X\_D.
- PRO\_E\_RNDCH\_COMPOUND\_EXT\_OPTIONS—Specifies the external options. This is an optional element and has the following elements:
  - PRO\_E\_RNDCH\_AUTO\_BLEND—Specifies the auto blend.
  - PRO\_E\_RNDCH\_TERM\_SURFACE—Specifies terminating surface.

- `PRO_E_RNDCH_RADII`—Specifies an array of radius `PRO_E_RNDCH_RADIUS`.
- `PRO_E_RNDCH_AMBIGUITY`—Specifies the ambiguity in the chamfer set.

---

 **Note**

The chamfer set can contain ambiguity if the chamfer set contains chamfer pieces that co-exist and can be placed in various locations in the selected references and in part geometry.

---

## Element Details of `PRO_E_RNDCH_RADIUS` for Chamfer

Each `PRO_E_RNDCH_RADIUS` has the following elements:

- `PRO_E_RNDCH_LEG1`—Specifies leg1 of the chamfer feature.
- `PRO_E_RNDCH_LEG2`—Specifies leg2 of the chamfer feature and is a required element if either `PRO_E_RNDCH_DIMENSIONAL_SCHEMA` is equal to `PRO_CHM_D1_X_D2` or `PRO_E_RNDCH_DIMENSIONAL_SCHEMA` is equal to `PRO_CHM_ANG_X_D`.

Each `PRO_E_RNDCH_LEG1` or `PRO_E_RNDCH_LEG2` has the following elements:

- `PRO_E_RNDCH_LEG_TYPE`—Specifies leg type and is a mandatory element. It is of the following types:
  - `PRO_ROUND_RADIUS_TYPE_VALUE`
  - `PRO_ROUND_RADIUS_THROUGH_POINT`

The definition of `ProRoundRadiusType` is as follows:

- `PRO_E_RNDCH_LEG_VALUE`—Specifies leg value and is required if `PRO_E_RNDCH_LEG_TYPE` is equal to `PRO_ROUND_RADIUS_TYPE_VALUE`.
- `PRO_E_RNDCH_REFERENCE_EDGE`—Specifies reference edge and is required if `PRO_E_RNDCH_LEG_TYPE` is equal to `PRO_ROUND_RADIUS_THROUGH_POINT`.
- `PRO_E_RNDCH_REFERENCE_POINT`—Specifies reference point and is required if `PRO_E_RNDCH_LEG_TYPE` is equal to `PRO_ROUND_RADIUS_THROUGH_POINT`.

---

## Element Details of PRO\_E\_RNDCH\_TRANSITION for Chamfer

Each PRO\_E\_RNDCH\_TRANSITION represents user-defined transitions for the entire chamfer feature and consists of the following elements:

- PRO\_E\_RNDCH\_TRANS\_TYPE—Specifies the type of the transition type.  
Valid values are:
  - PRO\_ROUND\_TRANS\_INTERSECT—Used to extend two or more overlapping chamfer pieces towards each other until they merge forming a sharp boundary.
  - PRO\_ROUND\_TRANS\_BLEND—Used to create a fillet surface between the chamfer pieces using an edge reference.
  - PRO\_ROUND\_TRANS\_STOP—Used to terminate the chamfer geometry at the specified datum point or datum plane.
  - PRO\_ROUND\_TRANS\_CONTINUE—Used to extend chamfer geometry into two chamfer pieces.
  - PRO\_ROUND\_TRANS\_PATCH—Used to create a patched surface at the location where three or four chamfer pieces overlap.
  - PRO\_ROUND\_TRANS\_BLEND\_3SRF—Used to create a triangular patch as a transition of three chamfers.
  - PRO\_ROUND\_TRANS\_PLANE\_CORNER—Used to chamfer the corner transition formed by three overlapping chamfer pieces with a plane.
  - PRO\_ROUND\_TRANS\_RBALL—Used to create a rolling ball transition for three or more chamfers.
  - PRO\_ROUND\_TRANS\_STOP\_0\_SIDE—Used to terminate the chamfer using geometry configured by Creo Parametric.
  - PRO\_ROUND\_TRANS\_STOP\_1\_SIDE—Used to terminate the chamfer using geometry configured by Creo Parametric.
  - PRO\_ROUND\_TRANS\_STOP\_2\_SIDE—Used to terminate the chamfer using geometry configured by Creo Parametric.
  - PRO\_ROUND\_TRANS\_STOP\_AT\_REF—Used to terminate the chamfer geometry at the selected datum point or datum plane.

---

### Note

Only some of the transition types listed above are available for a given context.

---

- **PRO\_E\_RNDCH\_TRANS\_CAP**—Specifies the capping surface for chamfer pieces of the chamfer feature. It has the following values:
  - PRO\_ROUND\_CAPPING\_SURF\_DISABLE = PRO\_B\_FALSE.
  - PRO\_ROUND\_CAPPING\_SURF\_ENABLE = PRO\_B\_TRUE.
- **PRO\_E\_RNDCH\_TRANS\_PATCH\_DATA**—Specifies the patch data and is required if PRO\_E\_RNDCH\_TRANS\_TYPE is equal to PRO\_ROUND\_TRANS\_PATCH. It has the following elements:
  - **PRO\_E\_RNDCH\_TRANS\_PATCH\_REF\_SURF**—Specifies the arc surface, which indicates that a valid surface reference has been selected to place a fillet for the active patch transition. It should have the value as PRO\_SURFACE only.
  - **PRO\_E\_RNDCH\_TRANS\_PATCH\_RAD\_OPT**—Specifies the arc radius options. It indicates the fillet radius for the active Patch transition and has following options:
    - ◆ PRO\_ROUND\_TRANS\_RADIUS\_ENTER\_VALUE— Specifies a new radius value.
    - ◆ PRO\_ROUND\_TRANS\_RADIUS\_AUTOMATIC— Specifies the most recently used value.
    - ◆ PRO\_E\_RNDCH\_TRANS\_ARC\_RADIUS—Specifies the arc radius.
- **PRO\_E\_RNDCH\_TRANS\_STOP\_DATA**—Specifies the capping surface. It has the following elements:
  - **PRO\_E\_RNDCH\_TRANS\_STOP\_REF\_TYPE**—Specifies the reference type. Valid values are:
    - ◆ PRO\_ROUND\_TRANS\_REF\_NO\_REF
    - ◆ PRO\_ROUND\_TRANS\_REF\_GEOM
    - ◆ PRO\_ROUND\_TRANS\_REF\_PNTVTX
    - ◆ PRO\_ROUND\_TRANS\_REF\_DTMLPLN
    - ◆ PRO\_ROUND\_TRANS\_REF\_ISOLINE
    - ◆ PRO\_E\_RNDCH\_TRANS\_STOP\_REFERENCE—Specifies the references for the active stop at reference transition. It can either be PRO\_SURFACE or PRO\_POINT.

## Creating a Chamfer

Function Introduced:

- **ProFeatureCreate()**

---

Use the function `ProFeatureCreate()` to create a Chamfer based on element tree input. For more information about `ProFeatureCreate()`, refer to the section [Overview of Feature Creation on page 771](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

---

 **Note**

In Pro/ENGINEER Wildfire 2.0,

1. Pro/TOOLKIT does not support the temporary geometry required for user-specified ambiguity and non-default transitions. Therefore, these elements cannot be used for creation of new chamfers.
  2. If transitions are specified in the input element tree, a chamfer feature with the default transition will be created.
  3. In case of ambiguous situation (where more than one valid solutions exist, e.g. for surface-surface chamfer - surfaces having discontinuous edges of intersection), a chamfer feature with default solution will be created.
- 

## Redefining a Chamfer

Function Introduced:

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine a Chamfer based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer to the section [Feature Redefine on page 794](#) in the [Element Trees: Principles of Feature Creation on page 771](#) section.

---

 **Note**

In Pro/ENGINEER Wildfire 2.0,

1. A chamfer feature having default transition, can not be redefined to have any transition.
  2. A chamfer feature having a Pro/ENGINEER user interface defined transition can be redefined to other type of transition, for example, from intersect type to corner type. The input element tree must have a valid transition of the required type.
-

---

## Accessing a Chamfer

Function Introduced:

- **ProFeatureElemtreeExtract()**

Use the function `ProFeatureElemtreeExtract()` to create a feature element tree that describes the contents of a Chamfer and to retrieve the element tree description of a Chamfer. For more information about `ProFeatureElemtreeExtract()`, refer to the section [Feature Inquiry on page 792](#) in the [Element Trees: Principles of Feature Creation on page 771](#).

### Example 2: Sample code for creation of a Chamfer Feature

The sample code in `UgChamferTemplate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a Chamfer feature. It includes all possible element assignments. By following the instructions for the feature you want to create, it should be possible to remove element settings not appropriate for your use.

### Example 3: Sample code for creation of a Edge Chamfer Feature

The sample code in `UgEdgeChamferCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a Edge Chamfer feature. The user is prompted to select an edge on which the chamfer will be created.

## Edit Chamfer Feature

As a part of the flexible modeling capabilities the Edit Chamfer feature allows you to modify the existing chamfer geometry of an edge chamfer. You can modify the distance (D) from the edge along each surface, the D1 and D2 values, and so on and also the offset distance (O) from the edge along each surface. The ability to switch from chamfer by offset (O) to chamfer by extension (D) will have the same restrictions as in the chamfer feature.

To create the Edit Chamfer feature follow the steps:

1. Identify the chamfer geometry to be modified and its D or O value.
2. Modify the specified chamfer geometry by using Creo Parametric. The application removes the identified chamfer geometry and recreates the chamfered edges with the desired values. The feature IDs of recreated chamfers are updated.

## Feature Element Tree for Edit Chamfer Feature

The element tree for an Edit Chamfer feature is documented in the header file `ProModifyChamfer.h` and is as shown in the following figure.

### Edit Chamfer Element Tree

```
PRO_E_FEATURE_TREE
|
|--PRO_E_FEATURE_TYPE
|
|--PRO_E_STD_FEATURE_NAME
|
|--PRO_E_STD_SURF_COLLECTION_APPL
|
|--PRO_E_MODRND_REMOVE
|
|--PRO_E_MODRND_DIMENSIONAL_SCHEMA
|
|--PRO_E_MODRND_RAD_VAL
|
|--PRO_E_MODRND_DIM2_VAL
|
|--PRO_E_MODRND_OPTS
| |
| |--PRO_E_MODRND_ATTACH
| |
| |--PRO_E_MODRND_CLOSEGEOM
| |
| |--PRO_E_MODRND_RMV_INTERF_RND
|
|--PRO_E_STD_FLEX_PROPAGATION
```

The following table describes the elements in the element tree:

| Element ID                     | Data Type                | Description                                                                                               |
|--------------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE             | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of feature. The value of this feature must be PRO_FEAT_MOD_CHAMFER. |
| PRO_E_STD_FEATURE_NAME         | PRO_VALUE_TYPE_WSTRING   | Mandatory element. Specifies the name of the feature. The default value is EDIT_CHAMFER.                  |
| PRO_E_STD_SURF_COLLECTION_APPL | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies a collection of reference surfaces                                           |

| Element ID                      | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 |                        | <p>that include the chamfer geometry to be modified.</p> <p>In Creo TOOLKIT 7.0.0.0 and later, you can select the reference surfaces from both different solid bodies as well as quilts. The resulting geometry is attached back to the same solid body or quilt from where the referenced surfaces were selected.</p>                                             |
| PRO_E_MODRND_REMOVE             | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies if the existing chamfer must be removed.                                                                                                                                                                                                                                                                                              |
| PRO_E_MODRND_DIMENSIONAL_SCHEMA | PRO_VALUE_TYPE_INT     | <p>Mandatory element. Specifies the type of chamfer or the dimension schema. The values for this element are defined by the enumerated type <code>ProChmSchema</code>. For more information on the chamfer types, refer to section <a href="#">Element Details of PRO_E_RNDCH_SET for Chamfer on page 922</a>.</p>                                                 |
| PRO_E_MODRND_RAD_VAL            | PRO_VALUE_TYPE_BOOLEAN | <p>Mandatory element. Specifies the first distance or the offset value depending on the type of chamfer defined by the enumerated type <code>ProChmSchema</code>.</p> <p>Specify a value in the range of <math>[(\text{part epsilon} / 10.0), 1.0\text{e}+06]</math> for D type schemas and <math>[-1.0\text{e}+06, 1.0\text{e}+06]</math> for O type schemas.</p> |
| PRO_E_MODRND_DIM2_VAL           | PRO_VALUE_TYPE_BOOLEAN | <p>Specifies the second distance, offset or angular value of the chamfer.</p> <p>Mandatory element if the value of the enumerated type <code>ProChmSchema</code> is one of the following:</p> <ul style="list-style-type: none"> <li>PRO_CHM_D1_X_D2</li> <li>PRO_CHM_O1_X_O2</li> <li>PRO_CHM_ANG_X_D</li> </ul> <p>Specify a value in the range of:</p>          |

| Element ID             | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        |                    | <ul style="list-style-type: none"> <li>• <math>[(\text{part epsilon} / 10.0), 1.0\text{e}+06]</math> for D type schemas</li> <li>• <math>[-1.0\text{e}+06, 1.0\text{e}+06]</math> for O type schemas</li> <li>• <math>[0, 180]</math> for chamfer angle ANG.</li> </ul>                                                                                                                                                |
| PRO_E_MODRND_OPTS      | Compound           | Mandatory element. Specifies the modification options for each chamfer to be recreated.                                                                                                                                                                                                                                                                                                                                |
| PRO_E_MODRND_ATTACH    | PRO_VALUE_TYPE_INT | Mandatory element. Specifies if the chamfer geometry must be attached to the selected reference surface once the chamfer is recreated. The values for this element are defined by the enumerated type <code>ProModRndAttach</code> .                                                                                                                                                                                   |
| PRO_E_MODRND_CLOSEGEOM | PRO_VALUE_TYPE_INT | <p>Mandatory element.</p> <p>Use this element only if the chamfers are recreated as new surfaces or quilts, that is, if the element <code>PRO_E_MODRND_ATTACH</code> has the value <code>PRO_MODRND_DONOT_ATTACH_GEOM</code>.</p> <p>Specifies if end surfaces must be created for the recreated chamfer geometry. The values for this element are defined by the enumerated type <code>ProModRndCloseGeom</code>.</p> |

| Element ID                      | Data Type                    | Description                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MODRND_RMV_<br>INTERF_RND | PRO_VALUE_TYPE_INT           | Mandatory element. Specifies if the interfering chamfers must be removed and recreated in order to recreate the modified chamfer geometry. The values for this element are defined by the enumerated type <i>ProModRndRecrRounds</i> .                                                                                                                                                            |
| PRO_E_STD_FLEX_<br>PROPAGATION  | PRO_VALUE_TYPE_<br>SELECTION | Optional element. Specifies a Pattern feature, a Symmetry Recognition feature, or a Mirror Geometry feature that contains the reference surfaces specified by the element PRO_E_STD_SURF_COLLECTION_APPL. If such surfaces exist, then the modification of the chamfer is propagated to all corresponding surfaces in the instances of the specified feature to maintain the pattern or symmetry. |

## Corner Chamfer Feature

### Feature Element Tree for Corner Chamfer

The element tree for a corner chamfer is documented in the header file *ProCornerChamfer.h*, and has a simple structure. The following figure demonstrates the feature element tree structure:

### Corner Chamfer Element Tree

```

PRO_E_FEATURE_TREE
|
|--PRO_E_FEATURE_TYPE
|
|--PRO_E_STD_FEATURE_NAME
|
|--PRO_E_STD_CORNER_CHAMF_CORNER
|
|--PRO_E_STD_CORNER_CHAMF_EDGE1
|
|--PRO_E_STD_CORNER_CHAMF_EDGE2
|
|--PRO_E_STD_CORNER_CHAMF_EDGE3

```

The elements in this tree are described as follows:

- `PRO_E_STD_FEATURE_TYPE`—Specifies the feature type and should be `PRO_FEAT_CORN_CHAMF`.
- `PRO_E_STD_FEATURE_NAME`—Specifies the name of the feature. The default value for this element is `CORNER_CHAMFER_#`, where # specifies the feature number.
- `PRO_E_STD_CORNER_CHAMF_CORNER`—Specifies the vertex on which the corner chamfer is placed and can be selection of the type `PRO_EDGE`, `PRO_EDGE_PNT`, `PRO_EDGE_START` or `PRO_EDGE_END`. When using `PRO_EDGE` and `PRO_EDGE_PNT` type of reference, an appropriate parameter should be set using the function `ProReferenceParamsSet()`.
- `PRO_E_STD_CORNER_CHAMF_EDGE1`— Specifies the first distance value from the vertex to the chamfer along first direction edge.
- `PRO_E_STD_CORNER_CHAMF_EDGE2`— Specifies the second distance value from the vertex to the chamfer along the second direction edge.
- `PRO_E_STD_CORNER_CHAMF_EDGE3`— Specifies the third distance value from the vertex to the chamfer along the third direction edge.

## Feature Element Tree for Corner Chamfer

The element tree for a corner chamfer is documented in the header file `ProCornerChamfer.h`, and has a simple structure. The following figure demonstrates the feature element tree structure:

### Corner Chamfer Element Tree

```

PRO_E_FEATURE_TREE
|
|--PRO_E_FEATURE_TYPE
|
|--PRO_E_STD_FEATURE_NAME
|
|--PRO_E_STD_CORNER_CHAMF_CORNER
|
|--PRO_E_STD_CORNER_CHAMF_EDGE1
|
|--PRO_E_STD_CORNER_CHAMF_EDGE2
|
|--PRO_E_STD_CORNER_CHAMF_EDGE3

```

The elements in this tree are described as follows:

- `PRO_E_STD_FEATURE_TYPE`—Specifies the feature type and should be `PRO_FEAT_CORN_CHAMF`.

- `PRO_E_STD_FEATURE_NAME`—Specifies the name of the feature. The default value for this element is `CORNER_CHAMFER_#`, where # specifies the feature number.
- `PRO_E_STD_CORNER_CHAMF_CORNER`—Specifies the vertex on which the corner chamfer is placed and can be selection of the type `PRO_EDGE`, `PRO_EDGE_PNT`, `PRO_EDGE_START` or `PRO_EDGE_END`. When using `PRO_EDGE` and `PRO_EDGE_PNT` type of reference, an appropriate parameter should be set using the function `ProReferenceParamsSet()`.
- `PRO_E_STD_CORNER_CHAMF_EDGE1`— Specifies the first distance value from the vertex to the chamfer along first direction edge.
- `PRO_E_STD_CORNER_CHAMF_EDGE2`— Specifies the second distance value from the vertex to the chamfer along the second direction edge.
- `PRO_E_STD_CORNER_CHAMF_EDGE3`— Specifies the third distance value from the vertex to the chamfer along the third direction edge.

## Creating a Corner Chamfer

Function Introduced:

- **ProFeatureCreate()**

Use the function `ProFeatureCreate()` to create a Corner Chamfer based on element tree input. For more information about `ProFeatureCreate()`, refer to the section [Overview of Feature Creation on page 771](#) in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Redefining a Corner Chamfer

Function Introduced:

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine a Corner Chamfer based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer to the section [Feature Redefine on page 794](#) in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Accessing a Corner Chamfer

Function Introduced:

- **ProFeatureElemtreeExtract()**

Use the function `ProFeatureElemtreeExtract()` to create a feature element tree that describes the contents of a Corner Chamfer and to retrieve the element tree description of a Corner Chamfer. For more information about

---

`ProFeatureElementTreeExtract()`, refer to the section [Feature Inquiry on page 792](#) in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Element Trees: Hole

This section describes the programmatic creation of Hole features using the Creo TOOLKIT include file `ProHole.h`.

We recommend you read the section, [Overview of Feature Creation on page 771](#) in the section, [Element Trees: Principles of Feature Creation on page 771](#) It provides the necessary background for creating features using Creo TOOLKIT.

### Overview

Creo TOOLKIT supports four types of Holes:

- Straight
- Standard
- Sketched
- Custom

The Standard Hole type is sub-divided into two categories:

- Standard Clearance Hole
- Standard Threaded Hole

This details the procedure and the sequence of the creation of the element tree for all of the above types.

All Hole types and placement types require entry of specific elements during element tree creation. Elements must be entered in the specified order.

To create a Hole feature, first add to the element tree all elements related to the hole type. Then, add the elements required for Hole placement. Creating Sketched Holes uses techniques similar to creation of the other sketched features (see [Element Trees: Sketched Features on page 1002](#)).

#### Note

All angle elements are specified in degrees.

---

You can use Intent Datums such as Intent Point, Intent Axis, and Intent Plane for hole placement in parts.

---

Lightweight holes can be created only in parts and not in assemblies. You can toggle between a lightweight and regular hole, only in case of simple holes and not in sketched, standard, or custom holes.

## Feature Element Tree for Hole Features

The element tree for the Hole feature is documented in the Creo TOOLKIT header file `ProHole.h`.

## Feature Element Data Types

The following table lists data types for hole type and placement elements.

Element values must be of the specified type.

Hole Element Table

| Element Id          | Element Name  | Data Type          |
|---------------------|---------------|--------------------|
| PRO_E_FEATURE_TYPE  | Feature Type  | PRO_VALUE_TYPE_INT |
| PRO_E_FEATURE_FORM  | Feature Form  | PRO_VALUE_TYPE_INT |
| PRO_E_HLE_COM       | Hole          | Compound           |
| PRO_E_HLE_TYPE_NEW  | Hole Type     | PRO_VALUE_TYPE_INT |
| PRO_E_HLE_STAN_TYPE | Standard Type | PRO_VALUE_TYPE_INT |
| PRO_E_HLE_THRDSERIS | Thread Series | PRO_VALUE_TYPE_INT |
| PRO_E_HLE_FITTYPE   | Fit Type      | PRO_VALUE_TYPE_INT |

| Element Id                       | Element Name           | Data Type                                                                 |
|----------------------------------|------------------------|---------------------------------------------------------------------------|
| PRO_E_HLE_SCREWSIZE              | Screw Size             | PRO_VALUE_TYPE_INT                                                        |
| PRO_E_HLE_ADD_THREAD             | Add Thread             | PRO_VALUE_TYPE_INT                                                        |
| PRO_E_HLE_ADD_CBORE              | Add Counterbore        | PRO_VALUE_TYPE_INT                                                        |
| PRO_E_HLE_ADD_CSINK              | Add Countersink        | PRO_VALUE_TYPE_INT                                                        |
| PRO_E_HLE_MAKE_LIGHTWT           | Make lightweight hole  | PRO_VALUE_TYPE_INT (It is given by the enumerated type ProHleLightWtFlag) |
| PRO_E_DIAMETER                   | Diameter               | PRO_VALUE_TYPE_DOUBLE                                                     |
| PRO_E_HOLE_STD_DEPTH             | Depth Element          | Compound                                                                  |
| PRO_E_HOLE_DEPTH_TO              | Depth Two              | Compound                                                                  |
| PRO_E_HOLE_DEPTH_TO_TYPE         | Depth Two              | PRO_VALUE_TYPE_INT                                                        |

The valid values are:</p> <ul style="list-style-type: none"> <li>PRO_BODY_USE_ALL—Hole is creating on all the existing bodies.</li> </ul> <p> <b>Note</b></p> <p>This option is not available for the following hole depth options:</p> <ul style="list-style-type: none"> <li>To Next</li> <li>Through Until</li> </ul> <ul style="list-style-type: none"> <li>PRO_BODY_USE_SELECTED—Hole is created on the selected bodies.</li> </ul> |
| PRO_E_BODY_SELECT      | PRO_VALUE_TYPE_SELECTION | <p>Specifies the reference to the selected body. Mandatory if the value of PRO_E_BODY_USE is set to PRO_BODY_USE_SELECTED.</p> <p> <b>Note</b></p> <p>Multiple references are allowed.</p>                                                                                                                                                                                                                                                                                                                                |

## Common Element Values

All holes require definition of the feature type and feature form. The following table shows valid values for the common elements in the hole element tree.

### Common Element Values

| Element ID         | Value                                      |
|--------------------|--------------------------------------------|
| PRO_E_FEATURE_TYPE | PRO_FEAT_HOLE                              |
| PRO_E_FEATURE_FORM | PRO_HLE_TYPE_STRAIGHT (for straight holes) |

|                        |                                              |
|------------------------|----------------------------------------------|
|                        | PRO_HLE_TYPE_SKETCHED (for other hole types) |
| PRO_E_STD_FEATURE_NAME | Wstring (feature name)                       |
| PRO_E_BODY             | Compound element that holds Body options.    |

## PRO\_E\_HLE\_COM Values

Values required for PRO\_E\_HLE\_COM compound element vary for different hole types. The following tables show the PRO\_E\_HLE\_COM element values required to define different hole types. Be sure to enter the elements into the element tree in the order specified by these tables.

### Straight Hole

The following table shows elements for creating a straight hole.

#### Straight Hole Elements

| Element                    | Status                                |
|----------------------------|---------------------------------------|
| PRO_E_HLE_TYPE_NEW         | PRO_HLE_NEW_TYPE_STRAIGHT             |
| PRO_E_HLE_MAKE_LIGHTWT     | Mandatory                             |
| PRO_E_DIAMETER             | Mandatory                             |
| PRO_E_HOLE_STD_DEPTH       | Mandatory                             |
| PRO_E_HOLE_DEPTH_TO        | Mandatory                             |
| PRO_E_HOLE_DEPTH_TO_TYPE   | Mandatory                             |
| PRO_E_EXT_DEPTH_TO_VALUE   | Depends on PRO_E_HOLE_DEPTH_TO_TYPE   |
| PRO_E_EXT_DEPTH_TO_REF     | Depends on PRO_E_HOLE_DEPTH_TO_TYPE   |
| PRO_E_HOLE_DEPTH_FROM      | Mandatory                             |
| PRO_E_HOLE_DEPTH_FROM_TYPE | Mandatory                             |
| PRO_E_EXT_DEPTH_FROM_VALUE | Depends on PRO_E_HOLE_DEPTH_FROM_TYPE |
| PRO_E_EXT_DEPTH_FROM_REF   | Depends on PRO_E_HOLE_DEPTH_FROM_TYPE |
| PRO_E_HLE_TOP_CLEARANCE    | Mandatory                             |
| PRO_E_HLE_ADD_PARAMETERS   | Mandatory                             |
| PRO_E_HOLE_PARAMETERS      | NA                                    |
| PRO_E_HLE_ADD_NOTE         | Mandatory                             |
| PRO_E_HOLE_NOTE            | Depends on PRO_E_HLE_ADD_NOTE         |

Figure [Straight Hole with Linear Placement on page 943](#) shows code for creating a straight hole with linear placement and through-all depth. The hole has 100 units diameter, and is placed 100 units distant from the first reference and 200 units distance from the second.

The function `ProDemoHoleCreate()` builds the complete element tree serially. First add all elements required for the straight hole under the PRO\_E\_HLE\_COM element. Then enter the placement elements under the PRO\_E\_HLE\_PLACEMENT element. Use element PRO\_E\_HOLE\_DEPTH\_TO\_TYPE to specify the hole as 'through all'.

The function `UserElemtreeElementAdd()` is a small utility that add an element to the element tree.

## Straight Hole with Linear Placement

The sample code in `UgHoleCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a straight linear hole.

## Sketched Hole

Creo TOOLKIT supports two methods for creating sketched holes. The first is as described in [Element Trees: Sketched Features on page 1002](#), the second uses the function `ProFeatureCreate()` more directly.

The following table describes the required elements for sketched hole features.

Sketched Hole Elements

| Element                              | Status                               |
|--------------------------------------|--------------------------------------|
| <code>PRO_E_HLE_TYPE_NEW</code>      | <code>PRO_HLE_NEW_TYPE_SKETCH</code> |
| <code>PRO_E_SKETCHER</code>          | Mandatory                            |
| <code>PRO_E_HLE_CRDIR_FLIP</code>    | Mandatory                            |
| <code>PRO_E_HLE_TOP_CLEARANCE</code> | Mandatory                            |

## Procedure Using Techniques from Creating Sketched Features

1. Add the required elements for the sketched feature as outlined in the table in section [Sketched Hole on page 943](#).
2. Add all the placement elements.
3. Set the argument `ProFeatureCreateOptions` for `ProFeatureCreate()` to `PRO_FEAT_CR_INCOMPLETE_FEAT` and call `ProFeatureCreate()` with the created element tree.
4. Fetch the section handle for the section of the incomplete feature, using the sequence of calls `ProElemPathAlloc()`, `ProElemPathDataSet()`, and `ProFeatureElemValueGet()`.
5. Create a 2D revolved section with the retrieved section handle. Add the center-line for the axis of revolution as required for the section for revolved feature in Creo Parametric user interface.
6. Attach the new section to the element tree, then call `ProFeatureRedefine()` with the element tree created in these steps.

Refer to [Sketched Hole with Conventional Approach on page 944](#) for a code example of this technique of hole creation.

---

## Sketched Hole with Conventional Approach

### Example 1: Creating a Standard Sketched Hole with Linear Placement

The sample code in `UgHoleCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a standard sketched hole with linear placement. In the conventional approach:

- Use `ProFeatureCreate()` to create incomplete feature
- Use the feature handle to get the section handle
- Build the section
- Give a call to `ProFeatureRedefine()` to redefine
- Complete the feature.

### Procedure Using `ProFeatureCreate()`

In this approach to sketched hole creation, populate the required elements in the element tree (as shown in the table in section [Sketched Hole on page 943](#)), and then call `ProFeatureCreate()`.

Refer to [Standard Threaded Hole on page 944](#) for a code example for creation of this type of hole.

Refer to [Sketched Hole with `ProFeatureCreate\(\)` on page 944](#) for a code example of this technique of hole creation.

## Sketched Hole with `ProFeatureCreate()`

### Example: Creating a Standard Sketched Hole with Linear Placement

The sample code in `UgHoleCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a standard sketched hole with linear placement. Using new approach:

- Create the complete element tree with the sketcher element
- Call `ProFeatureCreate()` to create the hole feature

## Standard Threaded Hole

The following table shows elements for creating a standard threaded hole.

Refer to [Example 2: Creating a Standard Threaded Hole with Linear Placement on page](#) for a code example on creating this type of hole.

| Element                          | Status                                                                                                                                                                                                                |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_HLE_TYPE_NEW               | Mandatory                                                                                                                                                                                                             |
| PRO_E_HLE_STAN_TYPE              | Mandatory                                                                                                                                                                                                             |
| PRO_E_HLE_THRDSERIS              | Mandatory                                                                                                                                                                                                             |
| PRO_E_HLE_FITTYPE                | Mandatory: set to PRO_HLE_CLOSE_FIT                                                                                                                                                                                   |
| PRO_E_HLE_SCREWSIZE              | Mandatory                                                                                                                                                                                                             |
| PRO_E_HLE_ADD_THREAD             | Mandatory                                                                                                                                                                                                             |
| PRO_E_HLE_ADD_CBORE              | Mandatory                                                                                                                                                                                                             |
| PRO_E_HLE_ADD_CSINK              | Mandatory                                                                                                                                                                                                             |
| PRO_E_HLE_HOLEDIAM               | Mandatory                                                                                                                                                                                                             |
| PRO_E_HLE_DRILLANGLE             | Required for variable depth hole                                                                                                                                                                                      |
| PRO_E_HLE_CSINKANGLE             | Required for countersink option                                                                                                                                                                                       |
| PRO_E_HLE_CBOREDEPTH             | Required for counterbore option                                                                                                                                                                                       |
| PRO_E_HLE_CBOREDIAM              | Required for counterbore option                                                                                                                                                                                       |
| PRO_E_HLE_CSINKDIAM              | Required for countersink option                                                                                                                                                                                       |
| PRO_E_HLE_THRDDEPTH              | Mandatory, even for a non-threaded hole or a thru-threaded hole.<br><br>This element is required. If not added, hole creation will succeed but the feature cannot be redefined in the Creo Parametric user interface. |
| PRO_E_HLE_DRILLDEPTH             | Mandatory, even for a through-all hole.<br><br>This element is required. If not added, hole creation will succeed but the feature cannot be redefined in the Creo Parametric user interface.                          |
| PRO_E_HLE_THRD_DEPTH             | Mandatory                                                                                                                                                                                                             |
| PRO_E_HLE_TAPERED_STRT_DEPTH_OPT | Mandatory                                                                                                                                                                                                             |
| PRO_E_HLE_DEPTH                  | Mandatory                                                                                                                                                                                                             |
| PRO_E_STD_HOLE_DEPTH_REF         | Depends on PRO_E_HLE_DEPTH                                                                                                                                                                                            |
| PRO_E_HLE_ADD_TAPERED_TIP_ANGLE  | Mandatory                                                                                                                                                                                                             |
| PRO_E_HLE_TAPERED_STRT_DIA       | Depends on PRO_E_HLE_TAPERED_STRT_DEPTH_OPT                                                                                                                                                                           |
| PRO_E_HLE_TAPERED_STRT_DEPTH     | Depends on PRO_E_HLE_TAPERED_STRT_DEPTH_OPT                                                                                                                                                                           |
| PRO_E_HLE_TAPERED_TIP_ANGLE      | Depends on PRO_E_HLE_ADD_TAPERED_TIP_ANGLE                                                                                                                                                                            |
| PRO_E_HLE_DEPTH_DIM_TYPE         | Depends on PRO_E_HLE_DEPTH                                                                                                                                                                                            |
| PRO_E_HLE_CRDIR_FLIP             | Mandatory                                                                                                                                                                                                             |
| PRO_E_HLE_ADD_EXIT_CSINK         | Required for Thru all hole                                                                                                                                                                                            |
| PRO_E_HLE_EXIT_CSINKANGLE        | Required for exit countersink option                                                                                                                                                                                  |
| PRO_E_HLE_EXIT_CSINKDIAM         | Required for exit countersink option                                                                                                                                                                                  |
| PRO_E_HLE_ADD_NOTE               | Required for Hole note                                                                                                                                                                                                |
| PRO_E_HOLE_NOTE                  | Depends on PRO_E_HLE_ADD_NOTE                                                                                                                                                                                         |
| PRO_E_HLE_TOP_CLEARANCE          | Mandatory                                                                                                                                                                                                             |

## Standard Clearance Hole

The following table outlines elements for standard clearance holes.

Standard Clearance Hole Elements

| Element                   | Status                               |
|---------------------------|--------------------------------------|
| PRO_E_HLE_TYPE_NEW        | Mandatory                            |
