| PRO_E_HLE_STAN_TYPE       | Mandatory                            |
| PRO_E_HLE_THRDSERIS       | Mandatory                            |
| PRO_E_HLE_FITTYPE         | Mandatory                            |
| PRO_E_HLE_SCREWSIZE       | Mandatory                            |
| PRO_E_HLE_ADD_THREAD      | Mandatory                            |
| PRO_E_HLE_ADD_CBORE       | Mandatory                            |
| PRO_E_HLE_ADD_CSINK       | Mandatory                            |
| PRO_E_HLE_HOLEDIAM        | Mandatory                            |
| PRO_E_HLE_DRILLANGLE      | Required for variable depth hole     |
| PRO_E_HLE_CSINKANGLE      | Required for countersink option      |
| PRO_E_HLE_CBOREDEPTH      | Required for counterbore option      |
| PRO_E_HLE_CBOREDIAM       | Required for counterbore option      |
| PRO_E_HLE_CSINKDIAM       | Required for countersink option      |
| PRO_E_HLE_DEPTH           | Mandatory                            |
| PRO_E_HLE_CRDIR_FLIP      | Mandatory                            |
| PRO_E_HLE_ADD_EXIT_CSINK  | Required for Thru all hole           |
| PRO_E_HLE_EXIT_CSINKANGLE | Required for exit countersink option |
| PRO_E_HLE_EXIT_CSINKDIAM  | Required for exit countersink option |
| PRO_E_HLE_ADD_NOTE        | Required for Hole note               |
| PRO_E_HOLE_NOTE           | Depends on PRO_E_HLE_ADD_NOTE        |
| PRO_E_HLE_TOP_CLEARANCE   | Mandatory                            |

## Custom Hole

The following table outlines the elements for creating a custom hole.

Custom Hole Elements

| Element              | Status                           |
|----------------------|----------------------------------|
| PRO_E_HLE_TYPE_NEW   | Mandatory                        |
| PRO_E_HLE_ADD_CBORE  | Mandatory                        |
| PRO_E_HLE_ADD_CSINK  | Mandatory                        |
| PRO_E_HLE_HOLEDIAM   | Mandatory                        |
| PRO_E_HLE_DRILLANGLE | Required for variable depth hole |
| PRO_E_HLE_CSINKANGLE | Required for countersink option  |
| PRO_E_HLE_CBOREDEPTH | Required for counterbore option  |
| PRO_E_HLE_CBOREDIAM  | Required for counterbore option  |
| PRO_E_HLE_CSINKDIAM  | Required for countersink option  |
| PRO_E_HLE_DEPTH      | Mandatory                        |

| Element                   | Status                               |
|---------------------------|--------------------------------------|
| PRO_E_HLE_DEPTH_DIM_TYPE  | Depends on PRO_E_HLE_DEPTH           |
| PRO_E_HLE_CRDIR_FLIP      | Mandatory                            |
| PRO_E_HLE_ADD_EXIT_CSINK  | Required for Thru all hole           |
| PRO_E_HLE_EXIT_CSINKANGLE | Required for exit countersink option |
| PRO_E_HLE_EXIT_CSINKDIAM  | Required for exit countersink option |
| PRO_E_HLE_TOP_CLEARANCE   | Mandatory                            |
| PRO_E_HLE_ADD_PARAMETERS  | Mandatory                            |
| PRO_E_HOLE_PARAMETERS     | NA                                   |
| PRO_E_HLE_ADD_NOTE        | Mandatory                            |
| PRO_E_HOLE_NOTE           | Depends on PRO_E_HLE_ADD_NOTE        |

## Standard Tapered Hole

The following table outlines the elements for creating a standard tapered hole.

### Standard Tapered Hole Elements

| Element                          | Status                                                                                                                                                                                                                            |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_HLE_TYPE_NEW               | Mandatory                                                                                                                                                                                                                         |
| PRO_E_HLE_STAN_TYPE              | Mandatory                                                                                                                                                                                                                         |
| PRO_E_HLE_THRDSERIS              | Mandatory                                                                                                                                                                                                                         |
| PRO_E_HLE_THRDSERIS              | Mandatory                                                                                                                                                                                                                         |
| PRO_E_HLE_ADD_THREAD             | Mandatory                                                                                                                                                                                                                         |
| PRO_E_HLE_ADD_CBORE              | Mandatory                                                                                                                                                                                                                         |
| PRO_E_HLE_ADD_CSINK              | Mandatory                                                                                                                                                                                                                         |
| PRO_E_HLE_HOLEDIAM               | Mandatory                                                                                                                                                                                                                         |
| PRO_E_HLE_DRILLANGLE             | Required for variable depth hole                                                                                                                                                                                                  |
| PRO_E_HLE_CSINKANGLE             | Required for countersink option                                                                                                                                                                                                   |
| PRO_E_HLE_CBOREDEPTH             | Required for counterbore option                                                                                                                                                                                                   |
| PRO_E_HLE_CBOREDIAM              | Required for counterbore option                                                                                                                                                                                                   |
| PRO_E_HLE_CSINKDIAM              | Required for countersink option                                                                                                                                                                                                   |
| PRO_E_HLE_THRDDEPTH              | Mandatory                                                                                                                                                                                                                         |
| PRO_E_HLE_DRILLDEPTH             | Mandatory                                                                                                                                                                                                                         |
| PRO_E_HLE_TAPERED_STRT_DEPTH_OPT | It is an option for different straight drill depth types of type ProHleTaperStrDepType. The valid values are: <ul style="list-style-type: none"> <li>PRO_HOLE_NONE_DEPTH_TYPE</li> <li>PRO_HOLE_BLIND_DEPTH_TYPE—blind</li> </ul> |

| Element                         | Status                                                                                                                                                                                                                                                                                          |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 | <ul style="list-style-type: none"> <li>• PRO_HOLE_THRUNEXT_DEPTH_TYPE—through next</li> <li>• PRO_HOLE_THRUALL_DEPTH_TYPE—through all</li> <li>• PRO_HOLE_THRUNTIL_DEPTH_TYPE—through until</li> <li>• PRO_HOLE_TOREF_DEPTH_TYPE—upto reference</li> </ul>                                      |
| PRO_E_HLE_ADD_TAPERED_TIP_ANGLE | <p>It is an option for tapered tip of type ProHleAddTaperedTipAngFlag. The valid values are:</p> <ul style="list-style-type: none"> <li>• PRO_HLE_NO_TAPERED_TIP_ANGLE—No tip angle in the tapered hole.</li> <li>• PRO_HLE_ADD_TAPERED_TIP_ANGLE—Add tip angle in the tapered hole.</li> </ul> |
| PRO_E_HLE_TAPERED_STRT_DIA      | Stores taper straight hole diameter double value.                                                                                                                                                                                                                                               |
| PRO_E_HLE_TAPERED_STRT_DEPTH    | <p>Stores taper straight hole depth double value. Available for tapered hole, with blind depth option, that is</p> <ul style="list-style-type: none"> <li>• PRO_E_HLE_STAN_TYPE == PRO_HLE_TAPERED_TYPE</li> <li>• PRO_E_HLE_TAPERED_STRT_DEPTH_OPT == HOLE_BLIND_DEPTH_TYPE</li> </ul>         |
| PRO_E_HLE_TAPERED_TIP_ANGLE     | <p>Stores tapered tip angle double value. Available for tapered tip option, that is</p> <ul style="list-style-type: none"> <li>• PRO_E_HLE_ADD_TAPERED_TIP_ANGLE == PRO_HLE_ADD_TAPERED_TIP_ANGLE</li> </ul>                                                                                    |
| PRO_E_HLE_CRDIR_FLIP            | Mandatory                                                                                                                                                                                                                                                                                       |
| PRO_E_HLE_ADD_EXIT_CSINK        | Required for Thru all hole                                                                                                                                                                                                                                                                      |
| PRO_E_HLE_EXIT_CSINKANGLE       | Required for exit countersink option                                                                                                                                                                                                                                                            |
| PRO_E_HLE_EXIT_CSINKDIAM        | Required for exit countersink option                                                                                                                                                                                                                                                            |

| PRO_E_HLE_HOLEDIAM   | Stores Drill Diameter double value. See Hole Diameter.                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_HLE_DRILLANGLE | Stores Drill Angle. Double value. Available for tapped hole with variable depth (when PRO_E_HLE_STAN_TYPE equals PRO_HLE_TAPPED_TYPE and PRO_E_HLE_DEPTH is PRO_HLE_STD_VAR_DEPTH.                                                                                                                                                                                                            |
| PRO_E_HLE_ADD_THREAD | Option for adding thread. Available for tapped hole (when PRO_E_HLE_STAN_TYPE equals PRO_HLE_TAPPED_TYPE). Type ProHleAddThrdFlag. For add thread option it's value is PRO_HLE_ADD_THREAD. For no thread option, the value is PRO_HLE_NO_THREAD.                                                                                                                                              |
| PRO_E_HLE_THRD_DEPTH | Option for different type of thread depth. Type ProHleThrdDepType. Available for tapped hole with thread option, when PRO_E_HLE_STAN_TYPE equals PRO_HLE_TAPPED_TYPE and PRO_E_HLE_ADD_THREAD equals PRO_HLE_ADD_THREAD.<br><br> <b>Note</b><br><br>All options are available in both assembly & part level. |
| PRO_E_HLE_THRDDEPTH  | Stores thread depth. Double value. Available for tapped hole, with variable thread option. That is, when PRO_E_HLE_STAN_TYPE equals PRO_HLE_TAPPED_TYPE, PRO_E_HLE_ADD_THREAD equals PRO_HLE_ADD_THREAD, and PRO_E_HLE_THRD_DEPTH equals PRO_HLE_VARIABLE_THREAD.                                                                                                                             |
| PRO_E_HLE_ADD_CBORE  | Option for Counter Bore. Type ProHleAddCboreFlag. For counter bore it's value is PRO_HLE_ADD_CBORE. For the no counterbore option, set to PRO_HLE_NO_CBORE.                                                                                                                                                                                                                                   |
| PRO_E_HLE_CBOREDEPTH | Stores counterbore depth. Double value. Available for counterbore option, when PRO_E_HLE_ADD_CBORE equals PRO_HLE_ADD_CBORE.                                                                                                                                                                                                                                                                  |
| PRO_E_HLE_CBOREDIAM  | Stores counterbore diameter. Double value. Available for counterbore option, when PRO_E_HLE_ADD_CBORE is PRO_HLE_ADD_CBORE.                                                                                                                                                                                                                                                                   |
| PRO_E_HLE_ADD_CSINK  | It is an option for Counter Sink. Type ProHleAddCsinkFlag. For counter sink it's value is PRO_HLE_ADD_CSINK. For no countersink, set to PRO_HLE_NO_CSINK.                                                                                                                                                                                                                                     |
| PRO_E_HLE_CSINKANGLE | Stores counter sink angle. Double value. Available for countersink option, when PRO_E_HLE_ADD_CSINK equals PRO_HLE_ADD_CSINK.                                                                                                                                                                                                                                                                 |
| PRO_E_HLE_CSINKDIAM  | Stores countersink diameter. Double value. Available for countersink option, when PRO_E_HLE_ADD_CSINK PRO_HLE_ADD_CSINK.                                                                                                                                                                                                                                                                      |
| PRO_E_HLE_DRILLDEPTH | Stores drill depth double value. Available for tapped hole, with variable depth option. That is, when PRO_E_                                                                                                                                                                                                                                                                                  |

| Element ID                | Comment/Description                                                                                                                                                                                                                                                                                                                                  |

## Hole Placement Types

Creo TOOLKIT supports several placement types for holes.

### Hole Placement

The elements discussed in the following sections specify how to place a hole in relation to the model geometry. The reference entity elements are carried as selection objects, and the other elements carrying actual values of distances, offsets or angles.

Creo TOOLKIT supports the following types of hole placement:

- [Linear Hole on a Plane on page 953](#)
- [Radial Hole on Plane with Radial Dimensioning on page 954](#)
- [Radial Hole on Plane with Diameter Dimensioning on page 955](#)
- [Radial Hole on Plane with Linear Dimensioning on page 955](#)
- [Radial Hole on Cone or Cylinder on page 955](#)
- [Coaxial Hole with Axis as Primary Reference on page 956](#)
- [Coaxial Hole with Primary Reference not Axis on page 956](#)
- [Onpoint Hole with Primary Reference as a Point on Surface on page 956](#)
- [Onpoint Hole with Primary Reference as Datum Point on page 956](#)
- [Onpoint Hole with Primary Reference as Datum Point with Orientation References on page 957](#)
- [Hole with Primary Reference as Sketch on page 957](#)

### Linear Hole on a Plane

Linear placement requires as references either

- Two linear non-parallel edges in the plane of placement

or

- Two planar non-parallel surfaces, both normal to the plane of placement.

| Element ID               | Comment/Description                                                                                                                                                                                                             |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_HLE_PRIM_REF       | Primary selection, that is, planar surface or datum plane.                                                                                                                                                                      |
| PRO_E_HLE_PL_TYPE        | Set to PRO_HLE_PL_TYPE_LIN                                                                                                                                                                                                      |
| PRO_E_HLE_DIM_REF1       | First secondary selection, that is, plane, edge, or axis.<br><br>If edge or axis is normal to placement plane, another selection is required for dimensioning the hole. So this may require two selections.                     |
| PRO_E_HLE_PLD_ALIGN_OPT1 | - Set to PRO_HLE_PLD_ALIGN to align the hole to the reference.<br><br>- Set to PRO_HLE_PLD_NOT_ALIGN to use the DIST1 reference.                                                                                                |
| PRO_E_HLE_DIM_DIST1      | Distance with regard to PRO_E_HLE_DIM_REF1.                                                                                                                                                                                     |
| PRO_E_HLE_DIM_REF2       | Second secondary selection, that is, plane, edge, or axis.<br><br>- If edge or axis is normal to placement plane another selection is required for dimensioning the hole. So this may require two selections.                   |
| PRO_E_HLE_PLD_ALIGN_OPT2 | - Set to PRO_HLE_PLD_ALIGN to align the hole to the reference.<br><br>- Set to PRO_HLE_PLD_NOT_ALIGN to use the DIST2 reference.                                                                                                |
| PRO_E_HLE_DIM_DIST2      | Distance with regard to PRO_E_HLE_DIM_REF2.                                                                                                                                                                                     |
| PRO_E_LIN_HOLE_DIR_REF   | Uses this reference to define the direction of the placement dimension scheme. This element is available if the secondary element PRO_E_HLE_DIM_REF1 contains an axis reference normal to the current hole's primary reference. |

## Radial Hole on Plane with Radial Dimensioning

Locating radial holes requires the first reference to be the axis of placement. This axis is a polar placement (r-theta), where r is the radial distance from a plane, and theta is the angle with respect to a plane.

| Element ID         | Comment/Description                           |
|--------------------|-----------------------------------------------|
| PRO_E_HLE_PRIM_REF | Primary Selection, planar surface/datum plane |
| PRO_E_HLE_PL_TYPE  | set to PRO_HLE_PL_TYPE_RAD                    |
| PRO_E_HLE_AXIS     | Axis for radial hole                          |
| PRO_E_HLE_DIM_RAD  | Radial distance with regard to PRO_E_HLE_AXIS |

| Element ID            | Comment/Description                                             |
|-----------------------|-----------------------------------------------------------------|
| PRO_E_HLE_REF_PLANE_1 | Reference plane against which angular distance will be measured |
| PRO_E_HLE_REF_ANG_1   | Angular distance with regard to PRO_E_HLE_REF_PLANE_1           |

## Radial Hole on Plane with Diameter Dimensioning

Locating these holes is similar to radial holes with radial dimensioning. The difference is the distance specified is in the form of diametrical distance.

| Element ID                                           | Comment/Description                                             |
|------------------------------------------------------|-----------------------------------------------------------------|
| PRO_E_HLE_PRIM_REF                                   | Primary Selection, planar surface/datum plane                   |
| PRO_E_HLE_PL_TYPE set to PRO_HLE_PL_TYPE_RAD_DIA_DIM |                                                                 |
| PRO_E_HLE_AXIS                                       | Axis for radial hole                                            |
| PRO_E_HLE_DIM_DIA                                    | Diameter distance with regard to PRO_E_HLE_AXIS                 |
| PRO_E_HLE_REF_PLANE_1                                | Reference plane against which angular distance will be measured |
| PRO_E_HLE_REF_ANG_1                                  | Angular distance with regard to PRO_E_HLE_REF_PLANE_1           |

## Radial Hole on Plane with Linear Dimensioning

This type of hole placement uses an angle with respect to a plane and a linear distance from the axis of placement.

This placement type is available when you set the configuration option radial\_hole\_linear\_dim to “YES”.

| Element ID                                              | Comment/Description                                             |
|---------------------------------------------------------|-----------------------------------------------------------------|
| PRO_E_HLE_PRIM_REF                                      | Primary Selection, planar surface/datum plane                   |
| PRO_E_HLE_PL_TYPE is set to PRO_HLE_PL_TYPE_RAD_LIN_DIM |                                                                 |
| PRO_E_HLE_AXIS                                          | Axis for radial hole                                            |
| PRO_E_HLE_DIM_LIN                                       | Linear distance with regard to PRO_E_HLE_AXIS                   |
| PRO_E_HLE_REF_PLANE_1                                   | Reference plane against which angular distance will be measured |
| PRO_E_HLE_REF_ANG_1                                     | Angular distance with regard to PRO_E_HLE_REF_PLANE_1           |

## Radial Hole on Cone or Cylinder

This hole placement type requires the selection of a cone or cylinder for primary placement.

| Element ID                                      | Comment/Description                 |
|-------------------------------------------------|-------------------------------------|
| PRO_E_HLE_PRIM_REF                              | Primary Selection, Cone or Cylinder |
| PRO_E_HLE_PL_TYPE is set to PRO_HLE_PL_TYPE_RAD |                                     |

| Element ID           | Comment/Description                                             |
|----------------------|-----------------------------------------------------------------|
| PRO_E_HLE_REF_PLANE  | Reference plane against which angular distance will be measured |
| PRO_E_HLE_REF_ANG    | Angular distance with regard to PRO_E_HLE_REF_PLANE             |
| PRO_E_HLE_NORM_PLA   | Reference plane for linear measurement                          |
| PRO_E_HLE_NORM_OFFST | Distance with regard to PRO_E_HLE_NORM_PLA                      |

## Coaxial Hole with Axis as Primary Reference

Coaxial hole placement requires an axis and a placement plane to complete the placement.

| Element ID                                       | Comment/Description     |
|--------------------------------------------------|-------------------------|
| PRO_E_HLE_PRIM_REF                               | Primary Selection, Axis |
| PRO_E_HLE_PL_TYPE is set to PRO_HLE_PL_TYPE_COAX |                         |
| PRO_E_HLE_PLCMNT_PLANE                           | Placement surface       |

## Coaxial Hole with Primary Reference not Axis

This is a special case of coaxial hole in which the primary selection is a surface. The axis must be normal to the selected surface:

| Element ID                                       | Comment/Description        |
|--------------------------------------------------|----------------------------|
| PRO_E_HLE_PRIM_REF                               | Primary Selection, Surface |
| PRO_E_HLE_PL_TYPE is set to PRO_HLE_PL_TYPE_COAX |                            |
| PRO_E_HLE_AXIS                                   | Axis                       |

## Onpoint Hole with Primary Reference as a Point on Surface

This placement type requires a point of type 'On Surface Point'. The hole is placed normal to the surface on which the point was created. The hole passes through the selected point. The depth of hole is measured from the datum point.

| Element ID                                         | Comment/Description                               |
|----------------------------------------------------|---------------------------------------------------|
| PRO_E_HLE_PRIM_REF                                 | Primary Selection, on Surface Created Datum Point |
| PRO_E_HLE_PL_TYPE is set to PRO_HLE_PL_TYPE_ON_PNT |                                                   |

## Onpoint Hole with Primary Reference as Datum Point

This placement type requires a point of type 'Datum Point'. It also requires a surface reference. The datum point is projected on the surface. The depth of the hole is measured from the projected point.

| Element ID                                         | Comment/Description            |
|----------------------------------------------------|--------------------------------|
| PRO_E_HLE_PRIM_REF                                 | Primary Selection, Datum Point |
| PRO_E_HLE_PL_TYPE is set to PRO_HLE_PL_TYPE_ON_PNT |                                |
| PRO_E_HLE_PLCMNT_PLANE                             | Placement surface              |

## Hole with Primary Reference as Sketch

This placement type requires a point of type 'Sketch'. The offset references are used as Sketch references.

| Element ID                                              | Comment/Description              |
|---------------------------------------------------------|----------------------------------|
| PRO_E_STD_SECTION                                       | Primary Selection, Sketch        |
| PRO_E_HLE_PL_TYPE is set to PRO_HLE_PL_TYPE_SKT_DTM_PNT |                                  |
| PRO-E_HOLE_SKDP_OPTIONS                                 | Sketched datum point hole option |

## Onpoint Hole with Primary Reference as Datum Point with Orientation References

This placement type requires a point of type 'Datum Point'. The direction of hole is defined using the orientation references. The hole passes through the selected point. The depth of hole is measured from the datum point.

| Element ID                                         | Comment/Description                                                                                                     |
|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| PRO_E_HLE_PRIM_REF                                 | Primary Selection, Datum Point                                                                                          |
| PRO_E_HLE_PL_TYPE is set to PRO_HLE_PL_TYPE_ON_PNT |                                                                                                                         |
| PRO_E_HLE_FT_DIR_REF                               | References to define the orientation of the hole.                                                                       |
| PRO_E_HLE_FT_DIR_OPT                               | Option to define the direction in which the hole is oriented, perpendicular or parallel, to the orientation references. |

## Miscellaneous Information

The following sections discuss important issues relating to hole feature creation.

### Hole Parameter Files

Hole parameter files are setup files used to build the user interface for the hole. Programmatic hole creation uses the same files. New sets of customized files can be added as required. The values assigned to the elements PRO\_E\_HLE\_THRDSERIS, PRO\_E\_HLE\_SCREWSIZE, and therefore PRO\_E\_HLE\_HOLEDIAM depend on these files.

Creo Parametric and Creo TOOLKIT load the hole parameter file (\*.hol) in following order:

1. Directory specified in configuration option hole\_parameter\_file\_path

2. Current Directory
3. System hole parameter directory, that is,
4. [PROE DIR]/text/hole

Find the hole diameter from the values of `PRO_E_HLE_THRDSERIS` and `PRO_E_HLE_SCREWSIZE` specified in the \*.hol files. In the Creo Parametric User Interface, element `PRO_E_HLE_THRDSERIS` is represented as the selection between UNC, UNF or ISO.

## Hole Diameter

The drill diameter `PRO_E_HLE_HOLEDIAM`, as required for the Standard Type of holes, must be smaller than the thread diameter calculated from the .hol file for the threaded hole. As specified in the \*.hol files, the thread diameter is the element corresponding to `BASIC_DIAM` column and the selected screw size row in the table, as specified in the selected .hol file. If the `PRO_E_HLE_HOLEDIAM` is not smaller than the thread diameter, the `ProFeatureCreate()` function fails and returns a `PRO_TK_GENERAL_ERROR`.

Follow these steps to enter the proper value for `PRO_E_HLE_HOLEDIAM`:

1. Determine the values to pass from the Creo Parametric user interface to the following elements:
  - `PRO_E_HLE_THRDSERIS`. Note that UNC corresponds to 0, UNF to 1, and ISO to 2. These values change if you create a local .hol file.
  - `PRO_E_HLE_SCREWSIZE` (the values start with zero).
2. From the Creo Parametric User Interface, set the options to be passed to the elements `PRO_E_HLE_THRDSERIS` and `PRO_E_HLE_SCREWSIZE`. For example, ISO with M1X25 or UNC with 1-64.
3. Observe the value hole diameter in the dialog box. The dialog box appears grayed out unless you set the configuration option `hole_diameter_override` to yes.
4. The value thus obtained for the hole diameter should be greater than the value defined for element `PRO_E_HLE_HOLEDIAM`.

## Order of Element Specification

Be sure to enter the elements into the element tree in the order specified by the tables in [PRO\\_E\\_HLE\\_COM Values on page 942](#). Failure to follow these sequences may result in either `ProFeatureCreate()` failing with a `PRO_TK_GENERAL_ERROR` error return, or in creation of a feature which fails to get redefined.

---

## Hole-specific Functions

Functions Introduced:

- **ProHolePropertyGet()**
- **ProElementHoleThreadSeriesGet()**
- **ProElementHoleThreadSeriesSet()**
- **ProElementHoleScrewSizeGet()**
- **ProElementHoleScrewSizeSet()**
- **ProHoleNoteReset()**
- **ProSketchedHoleMembersCount()**
- **ProSketchedHoleGeomitemVisit()**

You can use the function `ProHolePropertyGet()` to retrieve the value of the indicated hole value property. Only properties listed in the enum `ProHoleProperty` are supported.

The function `ProElementHoleThreadSeriesGet()` returns the type of thread from the hole feature element tree as a wide string.

Use the function `ProElementHoleThreadSeriesSet()` to set the type of thread in the hole feature element tree. The thread type is updated in the element `PRO_E_HLE_THRDSERIS`.

The function `ProElementHoleScrewSizeGet()` gets the size of screw from the hole feature tree elements `PRO_E_HLE_THRDSERIS` and `PRO_E_HLE_SCREWSIZE` as a wide string.

Use the function `ProElementHoleScrewSizeSet()` to set the size of screw in the hole feature element tree. The screw size is updated in the element `PRO_E_HLE_SCREWSIZE`.

---

### Note

The screw size depends on the type of thread. Therefore, before you call the function `ProElementHoleScrewSizeSet()` you must ensure that the thread type is set in the element `PRO_E_HLE_THRDSERIS`.

---

Use the function `ProHoleNoteReset()` to reset the note of the specified hole feature.

Use the function `ProSketchedHoleMembersCount()` to count the number of holes created by a sketched placed hole. The input argument to this function is *hole*, which specifies the hole feature using the `ProFeature` object. The output argument *total\_holes* is the total count of hole instances of the given sketched placement hole. It returns an output value of -1 in case of error.

---

The function `ProSketchedHoleGeomitemVisit()` visits all geometry items created by the sketched hole feature. The input arguments are:

- *hole*—Specifies the hole feature using the `ProFeature` object.
- *item\_type*—The type of items to visit using the `ProType` object.
- *hole\_index*—Indices start from 0 and use the `ProSketchedHoleMembersCount()` function to get the total number of members.
- *action*—Specifies the visiting function `ProSketchedHoleGeomitemAction`. If it does not return the error `PRO_TK_NO_ERROR`, the visiting stops.
- *filter*—Specifies the filter function `ProSketchedHoleGeomitemFilter`. If `NULL`, the action function visits all items. The function `ProSketchedHoleGeomitemVisit()` stops visiting if the filter returns the error `PRO_TK_GENERAL_ERROR`.
- *app\_data*—The application data is passed to the filter and the visiting functions using the `ProAppData` object.

## Element Trees: Shell

This section introduces and shows how to create, redefine and access Shell features in Creo TOOLKIT.

### Introduction to Shell Feature

When Creo Parametric makes a shell, all features that were added to the solid before creating the Shell feature are hollowed. Therefore, the order of feature creation is very important when you use the Shell feature.

The Shell feature hollows the inside of the solid, leaving a shell of a specified wall thickness. It allows you to remove a surface or surfaces from the shell. If you do not select a surface to remove, a “closed shell” is created, with the inside of the part completely hollowed out and no access to the hollow. When defining a shell, you can also select surfaces with different thickness values. On flipping the thickness side, the shell thickness is added to the outside of the part.

You can also shell surfaces that are tangent to their neighbors at one or more boundaries. At the tangent edge where the separation of the shell offset occurs, a normal capping surface is constructed to close the gap.

You can also exclude one or more surfaces from being shelled. This process is called partial shelling. There are two different algorithms for partial shelling – one for concave corner surfaces and the other for convex corner surfaces. These algorithms prevent the shell subtraction volume from penetrating through the

---

solid. In case of a part where both concave and convex corner surfaces are to be excluded, the exclusion can be achieved in multiple partial shells, each using different algorithms.

The following are the restrictions on Shell feature creation:

- You cannot add shells to any part that has a surface that moves from tangency to a point.
- You cannot select a surface to be removed that has a vertex created by the intersection of three curved surfaces.
- The surface to be removed must be surrounded by edges (a fully revolved surface of revolution is not valid) and the surfaces that intersect the edge must form an angle of less than 180 degrees through the solid geometry. As long as this condition is met, you can select any sculpted surface as the surface to be removed.
- When you select surfaces that have other surfaces tangent to them for independent thickness, all surfaces that are tangent must have the same thickness. Otherwise, the Shell feature fails.

For example, if you shell a part that contains a hole and you want the thickness of the hole wall to be different from the overall thickness, you must select both surfaces (cylinders) that make up the hole and offset them at the same distance.

- By default, a shell creates geometry with a constant wall thickness. If the system cannot create a constant thickness, the Shell feature fails.

## Feature Element Tree for the Shell Feature

The element tree for the Shell feature is documented in the header file `ProShell.h`, and has a simple structure. The following figure demonstrates the element tree structure:

## Feature Element Tree for Shell Feature

The shell element tree contains standard element types. The following list details special information about the elements in this tree:

- `PRO_E_FEATURE_TYPE`—Specifies the feature type and should have the value `PRO_FEAT_SHELL`.
- `PRO_E_STD_FEATURE_NAME`—Specifies the name of the Shell feature.
- `PRO_E_BODY`—Specifies the body options and is a branch of the general body options elements defined in the `ProBodyOpts.h` as follows:
  - `PRO_E_BODY_USE`—The valid value is `PRO_BODY_USE_SELECTED`
  - `PRO_E_BODY_SELECTED`—Must contain a single selected body to shell.
- `PRO_E_SHELL_SRF`— Specifies the selected surfaces to be removed from the part to create the Shell feature. This element is optional.
- `PRO_E_SHELL_THICK`—Specifies the default thickness for the shell. It must be positive and greater than zero.

- **PRO\_E\_SHELL\_FLIP**—Specifies the side of the shell to be flipped and has the following values:
  - PRO\_SHELL\_OUTSIDE
  - PRO\_SHELL\_INSIDE
- **PRO\_E\_STD\_SURF\_COLLECTION\_APPL**—Specifies the surfaces to be excluded during the Shell feature creation.
- **PRO\_E\_SHELL\_LACE\_BNDRY**—Specifies the lace boundary that forms the closure of excluded surfaces or inner surfaces. It has the following values:
  - PRO\_SHELL\_LACE
  - PRO\_SHELL\_DONT\_LACE
- **PRO\_E\_SHELL\_ALT\_CUT\_METHOD**—Specifies the alternate cut method used for partial shell volume subtraction. It has the following values:
  - PRO\_SHELL\_ALT\_CUT\_METHOD\_NO—Specifies the algorithm for concave corner surfaces.
  - PRO\_SHELL\_ALT\_CUT\_METHOD\_YES—Specifies the algorithm for convex corner surfaces.
- **PRO\_E\_ST\_SHELL\_LOCL\_LIST**—Specifies an array of local thickness of the type **PRO\_E\_ST\_SHELL\_LOCL\_CMPD** which consists of the following elements:
  - **PRO\_E\_ST\_SHELL\_SPEC\_SRF**—Specifies the surface selected for specifying the local thickness value. This surface cannot be one of the surfaces selected to be removed.
  - **PRO\_E\_ST\_SHELL\_SPEC\_THCK**—Specifies the local thickness value of the selected surface (initially equal to default shell thickness). It must be positive and greater than zero.

## Creating a Shell Feature

### Function Introduced

- **ProFeatureCreate()**

Use the function `ProFeatureCreate()` to create a Shell feature based on the element tree input. For more information about `ProFeatureCreate()`, refer to the section [References to Feature Creation Data on page 771](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

## Redefining a Shell Feature

### Function Introduced

---

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine a Shell feature based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer to the section [Feature Redefine on page 794](#) of section [Element Trees: Principles of Feature Creation on page 771](#).

## Accessing a Shell Feature

Function Introduced

- **ProFeatureElemtreeExtract()**

Use the function `ProFeatureElemtreeExtract()` to create a feature element tree that describes the contents of a Shell feature and to retrieve the element tree description of a Shell feature. For more information about `ProFeatureElemtreeExtract()` refer to the section [Feature Inquiry on page 792](#) of [Element Trees: Principles of Feature Creation on page 771](#).

## Element Trees: Patterns

This section describes the element tree structure required to create patterns of features. The on [Element Trees: Principles of Feature Creation on page 771](#) is a necessary background for this topic. Read that section before this one.

### Introduction

Using Creo TOOLKIT, you can create patterns of features, including those not supported by Creo TOOLKIT feature creation. Consequently, you can programmatically create patterns of any feature that can be patterned in Creo Parametric.

The creation and manipulation of patterns use the following Creo TOOLKIT objects:

- `ProPattern`—A structure that contains the type and owner of the pattern, and an opaque pattern handle
- `ProPatternClass`—An enumerated type that contains the pattern class, which specifies either a feature pattern (`PRO_FEAT_PATTERN`) or a group pattern (`PRO_GROUP_PATTERN`)

The procedure for creating a pattern is similar to creating features, in that you construct an element tree and pass this element tree to Creo Parametric. When you pass the tree to Creo Parametric, you also specify the feature to be patterned.

---

## The Element Tree for Pattern Creation

Unlike the element tree for features, the element tree for a pattern does not contain information about the construction of new features. Rather, the element tree contains information needed to make copies of existing features at specified locations on the model. For example, the element tree for a pattern of holes does not contain the geometry (such as edges) used to place the holes, but contains the dimensions and dimension variations used to pattern the specified hole.

You construct the element tree for a pattern by following the procedure described in section [Element Trees: Principles of Feature Creation on page 771](#):

1. Allocate tree elements using the function `ProElementAlloc()`.
2. Set values of the elements using the function `ProElementValueSet()`.
3. Add elements to the tree using `ProElementTreeElementAdd()`.

As with feature creation, the system cannot create your pattern unless the element tree is correct.

The element tree for a pattern is documented in the header file `ProPattern.h`. This tree contains the same information required when you create a pattern in an interactive session of Creo Parametric. Therefore, you should be familiar with how to create a pattern interactively before you try to understand the element tree.

---

### Note

It is highly recommended that you use the new element tree from `ProPattern.h`. The old element tree is only for your reference.

---

The following figure shows a part of the element tree for patterns. All elements are described in detail in the following sections.

## A Part of the Element Tree for Patterns

```
PRO_E_PATTERN_ROOT
|
|--- PRO_E_GENPAT_TYPE
|
|--- PRO_E_GENPAT_REGEN_METHOD
|
|--- PRO_E_STD_FEATURE_NAME
|
| * Dim Pattern *
|--- PRO_E_GENPAT_DIM
|
| * Table Pattern *
|--- PRO_E_GENPAT_TABLE
|
| * Ref Pattern *
|--- PRO_E_GENPAT_REF
|
| * Fill Pattern *
|--- PRO_E_GENPAT_FILL
|
| * Curve Pattern *
|--- PRO_E_GENPAT_CURVE
|
| * Dir Pattern *
|--- PRO_E_GENPAT_DIR
|
| * Axis Pattern *
|--- PRO_E_GENPAT_AXIS
|
| * Point Pattern *
|--- PRO_E_GENPAT_POINT
|
|--- PRO_E_STD_SECTION
|
|--- PRO_E_PAT_GEOM_REFS
|
|-- PRO_E_FLEX_OPTS_CMPND
|
|--- PRO_E_PAT_APPLICATIONS
```

---

The element with the identifier `PRO_E_GENPAT_TYPE` sets the type of the pattern to be created. The structure of the rest of the element tree depends strongly on the value of this element. Valid values for the `PRO_E_GENPAT_TYPE` element are as follows:

- `PRO_GENPAT_REF_DRIVEN`—Reference pattern
- `PRO_GENPAT_DIM_DRIVEN`—Dimension pattern
- `PRO_GENPAT_TABLE_DRIVEN`—Table pattern
- `PRO_GENPAT_FILL_DRIVEN`—Fill pattern
- `PRO_GENPAT_DIR_DRIVEN`—Direction pattern
- `PRO_GENPAT_AXIS_DRIVEN`—Axis pattern
- `PRO_GENPAT_POINT_DRIVEN`—Point pattern
- `PRO_GENPAT_CRV_DRIVEN`—Curve pattern

The element with the identifier `PRO_E_GENPAT_REGEN_METHOD` sets the regeneration method for the pattern. The regeneration method varies with the complexity of the pattern. Valid values for the `PRO_E_GENPAT_REGEN_METHOD` element are as follows:

- `PRO_PAT_GENERAL`—General pattern. This is the most complex type of pattern.
- `PRO_PAT_VARYING`—Varying pattern.
- `PRO_PAT_IDENTICAL`—Identical pattern. This is the least complex type of pattern.

For more information on regeneration methods, see the *Part Modeling User's Guide*.

You must populate the element `PRO_E_STD_SECTION` with a valid reference sketch and other related elements for the following pattern types:

- a point pattern that uses an element of type `PRO_GENPAT_REF_SKETCH`
- a fill pattern
- a curve pattern

For more information on how to populate the section elements with the valid sketched reference, refer to the [Element Trees: Sketched Features on page 1002](#) section.

The following sections describe the types of pattern in more detail.

---

## Reference Patterns

A reference pattern uses an existing pattern as a guide for the placement of the new pattern members. Consequently, if the pattern type is `PRO_GENPAT_REF_DRIVEN`, the element tree requires only that you specify the type of the reference pattern.

### Element Tree for a Reference Pattern

The element with identifier `PRO_E_GENPAT_REF` specifies the type of pattern to be created. The valid values are as follows:

- `PRO_PAT_FEATURE`—Use feature pattern references.
- `PRO_PAT_GROUP`—Use group pattern references.
- `PRO_PAT_BOTH`—Use feature and group pattern references.

## Dimension Patterns

If the pattern type is `PRO_GENPAT_DIM_DRIVEN`, the element tree must include information about the dimensions used to drive the pattern. You must specify this information for each direction in which the feature is to be patterned.

## Element Tree for a Dimension Pattern

The elements with identifiers `PRO_E_GENPAT_DIM_FIRST_DIR` and `PRO_E_GENPAT_DIM_SECOND_DIR` contain information about the pattern dimensions.

These elements are array elements that contain as many `PRO_E_GENPAT_DIM_DIR_COMPOUND` elements as are required to complete the pattern. The following table describes the contents of the `PRO_E_GENPAT_DIM_DIR_COMPOUND` element.

| Element ID Values                       | Element Name                | Data Type                                           | Valid Values                                                                    |
|-----------------------------------------|-----------------------------|-----------------------------------------------------|---------------------------------------------------------------------------------|
| <code>PRO_E_GENPAT_DIR_DIMENSION</code> | Dimension                   | <code>PRO_VALUE_TYPE_SELECTION</code>               |                                                                                 |
| <code>PRO_E_GENPAT_DIR_VAR_TYPE</code>  | Variation type              | <code>PRO_VALUE_TYPE_INT</code>                     | <code>PRO_PAT_RELATION_DRIVEN</code> ,<br><br><code>PRO_PAT_VALUE_DRIVEN</code> |
| <code>PRO_E_GENPAT_DIR_VAR_VALUE</code> | Variation value (increment) | <code>PRO_VALUE_TYPE_DOUBLE</code>                  |                                                                                 |
| <code>PRO_E_GENPAT_RELATION_EDIT</code> | Relation                    | Application ( <code>PRO_VALUE_TYPE_POINTER</code> ) |                                                                                 |

The element `PRO_E_GENPAT_DIR_VAR_TYPE` specifies whether the pattern increment is relation-driven or value-driven. If the increment is relation-driven, the element `PRO_E_GENPAT_RELATION_EDIT` contains an array of wide strings whose members are individual relations.

The elements `PRO_E_GENPAT_DIM_FIRST_DIR_NUM_INST` and `PRO_E_PAT_SECOND_DIR_NUM_INST` specify the number of instances in each of the pattern dimensions.

Even if the pattern extends in only one direction, you must specify elements for the second direction. In this case, add an empty `PRO_E_PAT_SECOND_DIR` element and set the value of the `PRO_E_PAT_SECOND_DIR_NUM_INST` element to 1 (not 0).

## Table Patterns

If the pattern type is `PRO_GENPAT_TABLE_DRIVEN`, your element tree must contain the table-driven dimensions and table information (variation in dimensions for each instance). The following figure shows the elements of the Table pattern:

### Element Tree for a Table Pattern

The `PRO_E_GENPAT_TABLE_DIMS` element is an array that contains one table dimension (`PRO_E_GENPAT_TABLE_DIM`) element for each dimension to be varied in the tables. The value of each `PRO_E_GENPAT_TABLE_DIM` element is a `ProSelection` object for the corresponding dimension.

The `PRO_E_GENPAT_TABLE_LIST` element is an array element that contains all the tables that control the pattern. This element should contain one `PRO_E_GENPAT_TABLE_ENTRY` element for each table.

Each `PRO_E_GENPAT_TABLE_ENTRY` element contains the name of the table (`PRO_E_GENPAT_TABLE_NAME`) and table instances (`PRO_E_GENPAT_TABLE_INSTANCES`).

Each PRO\_E\_GENPAT\_TABLE\_INSTANCE element contains an index number (PRO\_E\_GENPAT\_TABLE\_INSTANCE\_INDEX) element and a dimensions (PRO\_E\_GENPAT\_TABLE\_INSTANCE\_DIMS) element. The PRO\_E\_GENPAT\_TABLE\_INSTANCE\_DIMS element is an array element that must contain one dimension value (PRO\_E\_GENPAT\_TABLE\_INSTANCE\_DIM\_VALUE) element for each of the selected dimensions in the PRO\_E\_PAT\_MULT\_TABLE\_DIMS element. Note that the dimension value specifies the value of the selected dimension, not the dimension increment.

The following table lists the contents of each PRO\_E\_GENPAT\_TABLE\_ENTRY element.

| Element ID Values                     | Element Name         | Data Type              |
|---------------------------------------|----------------------|------------------------|
| PRO_E_GENPAT_TABLE_NAME               | Table name           | PRO_VALUE_TYPE_WSTRING |
| PRO_E_GENPAT_TABLE_INSTANCES          | Table instances      | Array                  |
| PRO_E_GENPAT_TABLE_INSTANCE           | Table instance       | Compound               |
| PRO_E_GENPAT_TABLE_INSTANCE_INDEX     | Instance index       | PRO_VALUE_TYPE_INT     |
| PRO_E_GENPAT_TABLE_INSTANCE_DIMS      | Dimension variations | Compound               |
| PRO_E_GENPAT_TABLE_INSTANCE_DIM_VALUE | Dimension value      | PRO_VALUE_TYPE_DOUBLE  |

The element PRO\_E\_GENPAT\_TABLE\_SET\_ACTIVE sets the active table for the pattern. Valid values are 0 (for the first table) through (num\_tables - 1), where num\_tables is the number of tables in the element tree.

## Fill Patterns

A fill pattern controls the pattern by filling an area with pattern members. You can select a grid to define this area.

If the pattern type in your element tree is PRO\_GENPAT\_FILL\_DRIVEN, the element tree must contain information about the grid and pattern members. The following figure shows the elements of the Fill pattern:

### Element Tree for a Fill Pattern

```

* Fill Pattern *
|
| --- PRO_E_GENPAT_FILL
| | --- PRO_E_GENPAT_FILL_TEMPLATE_TYPE
| | --- PRO_E_GENPAT_FILL_SPACING
| | --- PRO_E_GENPAT_FILL_BORDERING
| | --- PRO_E_GENPAT_FILL_ROT_ANG
| | --- PRO_E_GENPAT_FILL_RADIUS_INC
|
| --- PRO_E_STD_SECTION
|

```

The element `PRO_E_GENPAT_FILL_TEMPLATE_TYPE` specifies the type of grid template that you want to use to create a fill pattern.

The element `PRO_E_GENPAT_FILL_SPACING` specifies the spacing between the pattern members.

The element `PRO_E_GENPAT_FILL_BORDERING` specifies the minimum distance between the centers of the pattern members and the area boundary.

The element `PRO_E_GENPAT_FILL_ROT_ANG` specifies the rotation angle of the grid about the Csys origin.

The element `PRO_E_GENPAT_FILL_RADIUS_INC` specifies the radial spacing for circular and spiral grids.

The following table lists the contents of each `PRO_E_GENPAT_FILL` element.

| Element ID Values                            | Element Name          | Data Type                          | Valid Values                                                                                                                                                                                                                        |
|----------------------------------------------|-----------------------|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>PRO_E_GENPAT_FILL_TEMPLATE_TYPE</code> | Fill template         | <code>PRO_VALUE_TYPE_INT</code>    | <code>PRO_GENPAT_SQUARE_FILL</code> , <code>PRO_GENPAT_DIAMOND_FILL</code> , <code>PRO_GENPAT_TRIANGLE_FILL</code> , <code>PRO_GENPAT_CIRCLE_FILL</code> , <code>PRO_GENPAT_CURVE_FILL</code> , <code>PRO_GENPAT_SPIRAL_FILL</code> |
| <code>PRO_E_GENPAT_FILL_SPACING</code>       | Fill spacing          | <code>PRO_VALUE_TYPE_DOUBLE</code> |                                                                                                                                                                                                                                     |
| <code>PRO_E_GENPAT_FILL_BORDERING</code>     | Fill bordering        | <code>PRO_VALUE_TYPE_DOUBLE</code> |                                                                                                                                                                                                                                     |
| <code>PRO_E_GENPAT_FILL_ROT_ANG</code>       | Fill angle            | <code>PRO_VALUE_TYPE_DOUBLE</code> |                                                                                                                                                                                                                                     |
| <code>PRO_E_GENPAT_FILL_RADIUS_INC</code>    | Fill radius increment | <code>PRO_VALUE_TYPE_DOUBLE</code> |                                                                                                                                                                                                                                     |

## Direction Patterns

A direction pattern adds pattern members in one or two selected directions.

If the pattern type in the element tree is `PRO_GENPAT_DIR_DRIVEN`, the element tree must contain the information about the two directions and the pattern members.

The following figure shows the elements of a direction pattern:

## Element Tree for a Direction Pattern

For a direction patter, use the elements `PRO_E_DIR_PAT_DIR1_OPT` and `PRO_E_DIR_PAT_DIR2_OPT` to specify the pattern orientation in the first and second direction, respectively. The orientation options are translation, rotation, and coordinate system.

Depending on the selected orientation, choose references for the two directions using the element `PRO_E_DIRECTION_REFERENCE`. To flip the selected directions, use the elements `PRO_E_DIR_PAT_DIR1_FLIP` and `PRO_E_DIR_PAT_DIR2_FLIP`.

PAT\_DIR2\_FLIP. The values of the references and the choice to flip the direction are stored in the elements PRO\_E\_GENPAT\_DIR1 and PRO\_E\_GENPAT\_DIR2.

The elements PRO\_E\_GENPAT\_DIR1\_INC and PRO\_E\_GENPAT\_DIR2\_INC specify the spacing between the pattern members in the first and second directions, respectively.

The elements with identifiers PRO\_E\_GENPAT\_DIM\_FIRST\_DIR and PRO\_E\_GENPAT\_DIM\_SECOND\_DIR contain dimension information for the pattern members in the first and second direction, respectively. These elements are array elements that contain as many PRO\_E\_GENPAT\_DIM\_DIR\_COMPOUND elements as required to complete the pattern. For more information on the elements PRO\_E\_GENPAT\_DIR\_DIM\_COMPOUND, PRO\_E\_GENPAT\_FIRST\_DIR\_NUM\_INST, and PRO\_E\_GENPAT\_SECOND\_DIR\_NUM\_INST, refer to the section on [Dimension Patterns on page 968](#).

The following table lists the contents of each PRO\_E\_GENPAT\_DIR element.

| Element ID Values                                          | Element Name                                        | Data Type                | Valid Values                                         |
|------------------------------------------------------------|-----------------------------------------------------|--------------------------|------------------------------------------------------|
| PRO_E_DIR_PAT_DIR1_OPT                                     | Direction 1st option                                | PRO_VALUE_TYPE_INT       | PRO_GENPAT_TRANSLATIONAL, PRO_GENPAT_DIR1_ROTATIONAL |
| PRO_E_DIR_PAT_DIR2_OPT                                     | Direction 2nd option                                | PRO_VALUE_TYPE_INT       | PRO_GENPAT_TRANSLATIONAL, PRO_GENPAT_DIR2_ROTATIONAL |
| PRO_E_GENPAT_DIR1 and PRO_E_GENPAT_DIR2                    | 1st direction and 2nd direction                     | Compound                 |                                                      |
| PRO_E_DIRECTION_COMPOUND                                   | PRO_E_DIRECTION_COMPOUND                            | Compound                 |                                                      |
| PRO_E_DIRECTION_REFERENCE                                  | Direction reference                                 | PRO_VALUE_TYPE_SELECTION |                                                      |
| PRO_E_DIRECTION_FLIP                                       | Direction flip                                      | PRO_VALUE_TYPE_INT       | Value ignored                                        |
| PRO_E_DIR_PAT_DIR1_FLIP and PRO_E_DIR_PAT_DIR2_FLIP        | 1st direction flip and 2nd direction flip           | PRO_VALUE_TYPE_INT       | 0 or 1                                               |
| PRO_E_GENPAT_DIR1_INC and PRO_E_GENPAT_DIR2_INC            | 1st direction increment and 2nd direction increment | PRO_VALUE_TYPE_DOUBLE    |                                                      |
| PRO_E_GENPAT_DIM_FIRST_DIR and PRO_E_GENPAT_DIM_SECOND_DIR | 1st direction dimensions                            | Array                    |                                                      |

Use the axis pattern to create a pattern by revolving a feature around a selected axis. An axis pattern allows you to place members in the first direction or angular direction and in the second direction or radial direction.

## Element Tree for an Axis Pattern

The element `PRO_E_GENPAT_AXIS_REF` specifies the axis around which you want to create the pattern. The value of this element is `PRO_VALUE_TYPE_SELECTION`, which is of type `ProSelection`.

User's Guide

The element `PRO_E_GENPAT_AXIS2_INC` specifies the spacing between the pattern members in the second direction and is of type `PRO_VALUE_TYPE_DOUBLE`. The second direction being radial, this distance is the linear distance and the range is `-999999999.9999` through `+999999999.9999`.

The elements `PRO_E_AXIS_PAT_DIR1_FLIP` and `PRO_E_AXIS_PAT_DIR2_FLIP` flip the pattern members in the first and second direction, respectively, around the axis. These elements are of type `PRO_VALUE_TYPE_INT`.

The element `PRO_E_GENPAT_AXIS_ANG_WHOLE` specifies the angular extent of the pattern members and is of type `PRO_VALUE_TYPE_DOUBLE`. The range for this element is `0.0000` through `999999999.9999`.

The value of each `PRO_E_GENPAT_DIR_DIMENSION` element is a ProSelection object for the corresponding dimensions.

The elements with identifiers `PRO_E_GENPAT_DIM_FIRST_DIR` and `PRO_E_GENPAT_DIM_SECOND_DIR` contain dimension information for the pattern members in the first and second direction, respectively. For more information on these elements, refer to the section on [Dimension Patterns on page 968](#).

## Curve Patterns

A curve pattern creates instances of a feature along a sketched curve or a datum curve.

If the pattern type in your element tree is `PRO_GENPAT_CRV_DRIVEN`, the element tree must contain information about the curve and the pattern members.

### Element Tree for a Curve Pattern

```
* Curve Pattern *
|
| --- PRO_E_GENPAT_CURVE
| |
| | --- PRO_E_GENPAT_CRV_PNT_REF
| | --- PRO_E_GENPAT_CRV_PLC_TYPE
| | --- PRO_E_GENPAT_CRV_SPACING
| | --- PRO_E_GENPAT_CRV_NUMBER
| | --- PRO_E_GENPAT_CRV_FLIP
|
| --- PRO_E_STD_SECTION
```

The element `PRO_E_GENPAT_CRV_PNT_REF` specifies the curve to be used as a reference.

After you select the reference, you can either select a sketched curve or draw a curve using Sketcher. The element `PRO_E_GENPAT_CRV_PLC_TYPE` specifies the curve types.

The element `PRO_E_GENPAT_CRV_SPACING` specifies the separation between the pattern members.

The element `PRO_E_GENPAT_CRV_NUMBER` specifies the number of pattern members to be created.

The element `PRO_E_GENPAT_CRV_FLIP` specifies flipping the curve used in patterning.

The following table lists the contents of each `PRO_E_GENPAT_CRV` element.

| Element ID Values                      | Element Name    | Data Type                             | Valid Values           |
|----------------------------------------|-----------------|---------------------------------------|------------------------|
| <code>PRO_E_GENPAT_CRV_PNT_REF</code>  | Curve reference | <code>PRO_VALUE_TYPE_SELECTION</code> |                        |
| <code>PRO_E_GENPAT_CRV_PLC_TYPE</code> | Curve type      | <code>PRO_VALUE_TYPE_INT</code>       |                        |
| <code>PRO_E_GENPAT_CRV_SPACING</code>  | Curve spacing   | <code>PRO_VALUE_TYPE_DOUBLE</code>    | 0.0000 to 1000000.0000 |
| <code>PRO_E_GENPAT_CRV_NUMBER</code>   | Curve number    | <code>PRO_VALUE_TYPE_INT</code>       |                        |
| <code>PRO_E_GENPAT_CRV_FLIP</code>     | Curve flip      | <code>PRO_VALUE_TYPE_INT</code>       | 0 or 1                 |

## Point Patterns

A point pattern creates a pattern by placing a pattern member at a particular point.

The following figure shows the elements of a point pattern:

### Element Tree for a Point Pattern

|                                     |                                              |
|-------------------------------------|----------------------------------------------|
| * Point Pattern *                   |                                              |
| --- <code>PRO_E_GENPAT_POINT</code> |                                              |
|                                     | --- <code>PRO_E_GENPAT_POINT_REF_TYPE</code> |
|                                     | --- <code>PRO_E_GENPAT_POINT_REF</code>      |
| --- <code>PRO_E_STD_SECTION</code>  |                                              |

If the pattern type in the element tree is `PRO_GENPAT_POINT_DRIVEN`, the element tree must contain the information about the reference point and the actual point at which you want to draw the pattern.

Use the element `PRO_E_GENPAT_POINT_REF_TYPE` to select the type of the point at which you want to repeat the selected feature. This selected point is the reference point for creating the pattern. You can select a point from the following options:

- Internal or External sketch
- Datum point feature

After the type of the reference point is set, use the element `PRO_E_GENPAT_POINT_REF` to select the actual point.

The following table lists the contents of each `PRO_E_GENPAT_POINT` element.

| Element ID Values           | Element Name    | Data Type                | Valid Values                                |
|-----------------------------|-----------------|--------------------------|---------------------------------------------|
| PRO_E_GENPAT_POINT_REF_TYPE | Point type      | PRO_VALUE_TYPE_INT       | PRO_GENPAT_REF_SKETCH, PRO_GENPAT_REF_POINT |
| PRO_E_GENPAT_POINT_REF      | Point reference | PRO_VALUE_TYPE_SELECTION |                                             |

## Selecting References for Pattern

The compound element PRO\_E\_PAT\_GEOM\_REFS contains information about the references selected for the pattern leader.

The element PRO\_E\_PAT\_GEOM\_REFS allows you to only read the references selected for pattern leader. You cannot select the references in Creo TOOLKIT using these elements.

The following figure shows the element tree for selecting references for pattern leader:

The compound element PRO\_E\_PAT\_GEOM\_REFS contains the following elements:

- PRO\_E\_STD\_SURF\_COLLECTION\_APPL—Specifies the collection of surfaces that define the leader of the geometry pattern.
- PRO\_E\_PAT\_CRV\_DTM\_REFS—Specifies the collection of curves and datums that define the leader of the geometry pattern.

The following table lists the contents of PRO\_E\_PAT\_GEOM\_REFS element:

| Element ID Values              | Element Name                | Data Type                |
|--------------------------------|-----------------------------|--------------------------|
| PRO_E_STD_SURF_COLLECTION_APPL | Reference Surfaces          | PRO_VALUE_TYPE_SELECTION |
| PRO_E_PAT_CRV_DTM_REFS         | Reference Curves and Datums | PRO_VALUE_TYPE_SELECTION |

## Attachment Options for Pattern

The compound element PRO\_E\_FLEX\_OPTS\_CMPND contains information about the attachment options for the pattern.

The element `PRO_E_FLEX_OPTS_CMPND` allows you to only read the attachment options selected for a pattern. You cannot set the attachment option in Creo TOOLKIT using these elements.

The following figure shows the element tree for attachment options for the pattern:

The compound element `PRO_E_FLEX_OPTS_CMPND` contains the following elements:

- `PRO_E_FLEX_TRF_SEL_ATT_GEOM`—Specifies if the selected rounds and chamfers that attach the patterned geometry to the model must be patterned. 1 specifies that the rounds and chamfers are patterned. When you specify 0, the selected attaching rounds and chamfers are removed.
- `PRO_E_FLEX_ATTACH_GEOM`—Specifies if the geometry of the pattern members must be reattached to the model after patterning. 1 specifies that the pattern geometry is attached to the model.
- `PRO_E_FLEX_CR_RND_GEOM`—Specifies if the round or chamfer geometry of the pattern members must be recreated after patterning. 1 specifies that the pattern geometry is recreated with rounds or chamfers.

The following table lists the contents of `PRO_E_FLEX_OPTS_CMPND` element:

| Element ID Values                        | Element Name                           | Data Type                       | Valid Values |
|------------------------------------------|----------------------------------------|---------------------------------|--------------|
| <code>PRO_E_FLEX_TRF_SEL_ATT_GEOM</code> | Transform selected attachment geometry | <code>PRO_VALUE_TYPE_INT</code> | 0 or 1       |
| <code>PRO_E_FLEX_ATTACH_GEOM</code>      | Attachment option                      | <code>PRO_VALUE_TYPE_INT</code> | 0 or 1       |
| <code>PRO_E_FLEX_CR_RND_GEOM</code>      | Round option                           | <code>PRO_VALUE_TYPE_INT</code> | 0 or 1       |

## Pattern Features

The compound element `PRO_E_PAT_APPLICATIONS` contains elements for pattern applications. You can create a NC sequence using the elements under the compound element `PRO_E_PAT_MFG_TOOL_PATH`. You can view the various parameters of a pattern using the Pattern Recognition feature elements under the compound element `PRO_E_PAT_GPRF`.

## NC Sequence Pattern

You can create an NC sequence by using the element tree for pattern applications. The compound element `PRO_E_PAT_MFG_TOOL_PATH` described in this section allows you to set various options related to manufacturing order and fixtures used to pattern an NC sequence.

The following figure shows the element tree for pattern applications.

### Pattern Element Tree for NC Sequence

The compound element `PRO_E_PAT_MFG_TOOL_PATH` contains the following elements of type integer:

- `PRO_E_PAT_MFG_ORD_LEADER`—Specifies the number of the pattern member that you want to use as the manufacturing leader. The default value of this element is zero, which indicates that the pattern leader itself is the manufacturing leader.
- `PRO_E_PAT_MFG_ORDER_OPT`—Specifies the criteria for selecting the manufacturing order. The valid values are:
  - 1— Specifies the manufacturing order based on the pattern order. Set the values of the following elements as:
    - ◆ `PRO_E_PAT_MFG_ORD_REVERSE`—Specify 1 to reverse the order of the pattern for the CL output.

- 
- ◆ `PRO_E_PAT_MFG_ORD_ALT_ROWS`—Specify 1 to set the alternate rows of the pattern in the same direction for the CL output. Here the first and the second rows are in opposite directions with the first row being in the direction of the pattern. The manufacturing leader is the first tool path in the CL output.
  - ◆ `PRO_E_PAT_MFG_ORD_ALT_DIR`—Specify 1 to generate the CL output with the direction of the first row being treated as the direction of the second row and the direction of second row treated as the direction of the first row until the tool paths for all the pattern members are generated. The manufacturing leader is the first tool path in the CL output.
  - 2—Specifies the manufacturing order based on the shortest distance between the pattern members.
  - 3—Select the manufacturing order for each of the pattern member from the pattern UI.

---

 **Note**

The functionality to select the manufacturing order for each pattern member is currently not supported through Creo TOOLKIT.

---

- `PRO_E_PAT_MFG_ORD_SHARED`—Specify 1 to sequentially set the orders for the 4-axis or 5-axis tool paths with a common Z-axis orientation.
- `PRO_E_PAT_MFG_FIX_OFFSET`—Specifies the parameters for the fixture offset. Specify 1 to set the following fixture options:
  - `PRO_E_PAT_MFG_FIX_OFF_INIT`—Specifies the initial value of the fixture Offset.
  - `PRO_E_PAT_MFG_FIX_OFF_INCR`—Specifies the increment value for the fixture offset.
- `PRO_E_PAT_MFG_SUB_OUTPUT`—Specifies if subroutine pattern must be created. Subroutines enable you to create NC sequences, place them as macros at the beginning of the CL file, and then call them from the main body of the CL file as many times as needed.
- `PRO_E_PAT_MFG_SUB_OUT_MODE`—Specifies the output mode for the CL data for the subroutine. Pass the value 1 for absolute mode and 2 for incremental mode.
- `PRO_E_PAT_MFG_SUB_OUT_MULTAX`—Specifies if the Multax mode must be selected. Multax is related to cutter location output format where it puts the post-processor in the multi-axis output mode to process the i, j, k vector. When

in multi-axis output mode, Creo NC outputs the i, j, k vector even when the tool is in 0, 0, 1 orientation.

In Multax mode, the system will output transformed CL data rather than outputting rotate table commands.

- **PRO\_E\_PAT\_MFG\_SUB\_OUT\_COPYCL**—Specifies if the subroutine pattern definitions in CL output must be temporarily suppressed. The system will output CL data without the subroutine definitions and calls.

Refer to Creo NC online Help for more information on subroutines.

The following table lists the contents of each PRO\_E\_PAT\_MFG\_TOOL\_PATH element.

| Element ID Values            | Element Name              | Data Type          | Valid Values                                                                       |
|------------------------------|---------------------------|--------------------|------------------------------------------------------------------------------------|
| PRO_E_PAT_MFG_ORD_LEADER     | Number of the leader      | PRO_VALUE_TYPE_INT | 0 <= value < number of instances                                                   |
| PRO_E_PAT_MFG_ORDER_OPT      | Order options             | PRO_VALUE_TYPE_INT | 1, 2, 3 ( if you specify 3, order may be selected only through Creo Parametric UI) |
| PRO_E_PAT_MFG_ORD_REVERSE    | Reverse option            | PRO_VALUE_TYPE_INT | 0 or 1                                                                             |
| PRO_E_PAT_MFG_ORD_ALT_ROWS   | Alternate rows            | PRO_VALUE_TYPE_INT | 0 or 1                                                                             |
| PRO_E_PAT_MFG_ORD_ALT_DIR    | Alternate direction       | PRO_VALUE_TYPE_INT | 0 or 1                                                                             |
| PRO_E_PAT_MFG_ORD_SHARED     | Shared orientation        | PRO_VALUE_TYPE_INT | 0 or 1                                                                             |
| PRO_E_PAT_MFG_FIX_OFFSET     | Fixture offsets           | PRO_VALUE_TYPE_INT | 0 or 1                                                                             |
| PRO_E_PAT_MFG_FIX_OFF_INIT   | Initial fixture offsets   | PRO_VALUE_TYPE_INT | 1 <= value                                                                         |
| PRO_E_PAT_MFG_FIX_OFF_INCR   | Fixture offsets increment | PRO_VALUE_TYPE_INT | 1 <= value                                                                         |
| PRO_E_PAT_MFG_SUB_OUTPUT     | Subroutine option         | PRO_VALUE_TYPE_INT | 0 or 1                                                                             |
| PRO_E_PAT_MFG_SUB_OUT_MODE   | Subroutine mode           | PRO_VALUE_TYPE_INT | 1 or 2                                                                             |
| PRO_E_PAT_MFG_SUB_OUT_MULTAX | Subroutine multax         | PRO_VALUE_TYPE_INT | 0 or 1                                                                             |

For more information on the patterning options related to an NC sequence, refer to Manufacturing section of the Creo Parametric help.

## Geometry Pattern Recognition

You can read the Pattern Recognition feature parameters using the element PRO\_E\_PAT\_GPRF described in this section. You cannot create the Pattern Recognition feature in Creo TOOLKIT using these elements.

The following figure shows the element tree for Geometry Pattern Recognition application:

### Pattern Element Tree for Geometry Pattern Recognition

The pattern recognition compound element PRO\_E\_PAT\_GPRF contains the following elements:

- PRO\_E\_PAT\_GPRF\_TYPE—Specifies the type of geometry pattern to be recognized: **Identical** or **Similar**. It takes the integer values: 0 for **Identical** and 1 for **Similar**.
- PRO\_E\_PAT\_GPRF\_TRF\_TYPE—Specifies the recognized geometry patterns. It takes the integer value: 0 for **Direction**, 1 for **Axis** and 2 for **Spatial**.
- PRO\_E\_PAT\_GPRF\_DIR1\_TRF—Specifies the first direction of transformation. It takes the following integer values from the enumerated type ProGenPatternDirectionType:
  - PRO\_GENPAT\_TRANSLATIONAL—Specifies -1 for translational pattern.
  - PRO\_GENPAT\_DIR1\_ROTATIONAL—Specifies 58 for first direction for rotational pattern.

- **PRO\_E\_PAT\_GPRF\_DIR1\_NUM\_INST**—Specifies the number of members in the first direction or in the angular direction.
- **PRO\_E\_PAT\_GPRF\_DIR1\_SPACING**—Specifies the spacing between members in the first direction or the angle between members in the angular direction.
- **PRO\_E\_PAT\_GPRF\_DIR2\_TRF**—Specifies the second direction of transformation. It takes the following integer values from the enumerated type `ProGenPatternDirectionType`:
  - **PRO\_GENPAT\_TRANSLATIONAL**—Specifies –1 for translational pattern.
  - **PRO\_GENPAT\_DIR2\_ROTATIONAL**—Specifies 60 for second direction for rotational pattern.
- **PRO\_E\_PAT\_GPRF\_DIR2\_NUM\_INST**—Specifies the number of members in the second direction or in the angular direction.
- **PRO\_E\_PAT\_GPRF\_DIR2\_SPACING**—Specifies the spacing between members in the second direction or the angle between members in the angular direction.
- **PRO\_E\_DIR\_GPRF\_MOVE\_OPT**—Specifies if a pattern of copy-move features must be created by the geometry pattern recognition feature. Specify 1 if you want the number of pattern members and spacing to be modified.
- **PRO\_E\_PAT\_GPRF\_USE\_SRF**—Specifies 1 if the members in the geometry pattern recognition feature have been limited with surfaces. This element restricts the pattern recognition to a limited region on the model.
- **PRO\_E\_STD\_SURF\_COLLECTION\_APPL**—Specifies the collection of surfaces that define the leader of the geometry pattern to be recognized.
- **PRO\_E\_PAT\_GPRF\_USE\_SEC**—Specifies 1 if a sketch has been used to limit the members in the geometry pattern recognition feature.

The following table lists the contents of each **PRO\_E\_PAT\_GPRF** element.

| Element ID Values                   | Element Name                               | Data Type                          | Valid Values |
|-------------------------------------|--------------------------------------------|------------------------------------|--------------|
| <b>PRO_E_PAT_GPRF_TYPE</b>          | Type of recognized pattern                 | <code>PRO_VALUE_TYPE_INT</code>    | 0 or 1       |
| <b>PRO_E_PAT_GPRF_TRF_TYPE</b>      | Type of transformation                     | <code>PRO_VALUE_TYPE_INT</code>    | 0, 1 or 2    |
| <b>PRO_E_PAT_GPRF_DIR1_TRF</b>      | First transformation direction             | <code>PRO_VALUE_TYPE_INT</code>    | –1, 58 or 60 |
| <b>PRO_E_PAT_GPRF_DIR1_NUM_INST</b> | Number of instances in the first direction | <code>PRO_VALUE_TYPE_INT</code>    |              |
| <b>PRO_E_PAT_GPRF_DIR1_SPACING</b>  | Spacing in the first direction             | <code>PRO_VALUE_TYPE_DOUBLE</code> |              |
| <b>PRO_E_PAT_GPRF_DIR2_TRF</b>      | Second transformation direction            | <code>PRO_VALUE_TYPE_INT</code>    | –1, 58 or 60 |

| Element ID Values              | Element Name                                | Data Type                | Valid Values |
|--------------------------------|---------------------------------------------|--------------------------|--------------|
| PRO_E_PAT_GPRF_DIR2_NUM_INST   | Number of instances in the second direction | PRO_VALUE_TYPE_INT       |              |
| PRO_E_PAT_GPRF_DIR2_SPACING    | Spacing in the second direction             | PRO_VALUE_TYPE_DOUBLE    |              |
| PRO_E_DIR_GPRF_MOVE_OPT        | Create pattern of move features             | PRO_VALUE_TYPE_INT       | 0 or 1       |
| PRO_E_PAT_GPRF_USE_SRF         | Use surface for region definition           | PRO_VALUE_TYPE_INT       | 0 or 1       |
| PRO_E_STD_SURF_COLLECTION_APPL | Reference surfaces                          | PRO_VALUE_TYPE_SELECTION |              |
| PRO_E_PAT_GPRF_USE_SEC         | Sketch for region definition                | PRO_VALUE_TYPE_INT       | 0 or 1       |

For more information on the geometry pattern recognition, refer to the Creo Parametric help.

## Obtaining the Element Tree for a Pattern

Function Introduced:

- **ProPatternElemtreeCreate()**

To obtain the element tree for a pattern, call the function `ProPatternElemtreeCreate()`. You can then use the element tree read-access functions described in the sections [Feature Elements on page 780](#) (on page 29 - 13) and [Feature Element Paths on page 779](#) (on page 29 - 11), such as the functions `ProElement*Get()`, `ProElement*Visit()`, and `ProElementArrayGet()`.

### Note

Inspection of Fill, Axis, and Directional patterns is not supported via the element tree in Pro/ENGINEER Wildfire 2.0.

`ProPatternElemtreeCreate()` returns `PRO_TK_NOT_IMPLEMENTED` for fill patterns.

## Visiting and Creating a Pattern

Functions Introduced:

- **ProPatternMemberVisit()**
- **ProPatternMembersGet()**
- **ProPatternCreate()**
- **ProPatternInAssemblyCreate()**

---

The function `ProPatternMemberVisit()` visits the feature members in a pattern. This function takes the visit action function `ProFeatureVisitAction()` and the filter action function `ProFeatureFilterAction()` as its input arguments. The function `ProFeatureFilterAction()` is a generic action function for filtering features from a pattern. It returns the filter status of the features in the pattern. This status is used as an input argument by the function `ProFeatureVisitAction()`.

The function `ProPatternMembersGet()` returns the feature members in a pattern. For a group pattern, the output argument is a group pattern feature.

When your element tree is complete, create the pattern by calling the function `ProPatternCreate()`. This function requires as input the feature (`ProFeature`) to be patterned and the pattern class (feature or group) of the new pattern.

To obtain the `ProPattern` handle for the new pattern, call the function `ProFeaturePatternGet()` with the same input feature as `ProPatternCreate()`. For more information on the function `ProFeaturePatternGet()`, refer to the section [Manipulating Patterns on page 149](#) in the [Core: Features on page 137](#) section.

The function `ProPatternInAssemblyCreate()` creates a pattern in the assembly that is provided in the element tree. The input parameters are as follows:

- *p\_component\_path*—The component path specified using the structure `ProAsmcomppath`.
- *pattern\_feature*—Feature defined by the `ProFeature` object.
- *pat\_class*—Pattern class defined by the enumerated data type `ProPatternClass`.
- *elem\_tree*—The root element of the pattern element tree.

You must specify the pattern object for this function because a feature pattern can be a part of both a group pattern and a feature pattern.

The function returns the error `PRO_TK_ABORT` if the pattern feature creation failed. You must ensure that you use a new pattern name every time you create a new pattern.

## Element Trees: Sections

A section is a parametric two-dimensional cross section used to define the shape of three-dimensional features, such as extrusions. In Creo Parametric, you create a section interactively using Sketcher mode. In a Creo TOOLKIT application, you can create sections completely programmatically using the functions described in this section.

---

## Overview

A section is a parametric two-dimensional model used to define the shape of three-dimensional features in parts and assemblies. When using Creo Parametric interactively, you create a section using Sketcher mode. In a Creo TOOLKIT application, you can create sections completely programmatically using the functions described in this section.

Sections fall into two types: 2D and 3D. Both types are represented by the object `ProSection` (an opaque handle) and manipulated by the same functions.

The difference between the types arises out of the context in which the section is being used, and affects the requirements for the contents of the section and also of the feature element tree in which it is placed when creating a sketched feature.

Put simply, a 2D section is self-contained, whereas a 3D section contains references to 3D geometry in a parent part or assembly.

You can use Intent Datums such Intent Axis, Intent Point, Intent Plane, and Intent Coordinate System as references for sketcher dimensions. You can use Intent Point and Intent Axis to create sections using projections.

In a Creo TOOLKIT application, you can work with a section either in an Intent Manager or a non-Intent Manager mode. In the non-Intent Manager mode, if you make any changes to the section, you must solve and regenerate the section to apply the changes. On the other hand, in the Intent Manager mode, all the changes are applied immediately.

You can create section constraints programmatically using the Intent Manager property. This corresponds to creating sections within the Intent Manager mode in Creo Parametric.

This is concerned with 2D sections, which are the simplest. The extra steps required to construct a 3D section are described in the [Element Trees: Sketched Features on page 1002](#), which follows this one.

## Creating Section Models

A 2D section, because it is self-contained, may be stored as a Creo Parametric model file. It then has the extension `.sec`.

The steps required to create and save a section model using Creo TOOLKIT follow closely those used in creating a section interactively using Sketcher mode in Creo Parametric.

### To Create and Save a Section Model

1. Allocate the two-dimensional section and define its name.
2. Add section entities (lines, arcs, splines, and so on) to define the section geometry, in section coordinates.

3. Add section dimensions that parametrically drive the shape of the entities.
4. Solve and regenerate the section.
5. Save the section.

When you are creating a section that is to be used in a sketched feature, Steps 1 and 5 will be replaced by different techniques. these techniques are described fully in the section on [Element Trees: Sketched Features on page 1002](#).

The steps are described in more detail in the following sections.

## Allocating a Two-Dimensional Section

Functions Introduced:

- **ProSection2DAlloc()**
- **ProSectionFree()**
- **ProSectionNameSet()**
- **ProSectionNameGet()**

A two-dimensional section is identified in Creo TOOLKIT by an opaque pointer called `ProSection`. This type, and the functions in this section, are declared in the include file `ProSection.h`.

The function `ProSection2DAlloc()` allocates memory for a new, standalone section and outputs a `ProSection` handle to identify it. All the other Creo TOOLKIT functions that operate on sections take this `ProSection` as their first input argument.

The function `ProSectionNameSet()` enables you to set the name of a section. Calling this function places the section in the Creo Parametric namelist and enables it to be recognized by Creo Parametric as a section model in the database.

The following code fragment shows how to use these two functions.

```
ProSection section;
ProName wname;

ProSection2DAlloc (§ion);
ProStringToWstring (wname, "demo");
ProSectionNameSet (section, wname);
```

Such sections created programmatically are in the non-Intent Manager mode by default.

To free a section allocated with `ProSection2DAlloc()`, you must use `ProSectionFree()`.

---

## Setting the Mode of a Section

Functions Introduced:

- **ProSectionIntentManagerModeGet()**
- **ProSectionIntentManagerModeSet()**

Use the function `ProSectionIntentManagerModeGet()` to check if the Intent Manager property is ON or OFF for the specified section.

Use the function `ProSectionIntentManagerModeSet()` to set the Intent Manager property to ON or OFF for the specified section. This function must be called before using the other Creo TOOLKIT functions to access sections with the Intent Manager property set to ON.

## Copying the Current Section

Functions Introduced:

- **ProSectionActiveGet()**
- **ProSectionActiveSet()**

Use the function `ProSectionActiveGet()` to create a copy of the section that you are using currently; this copy is created within the same Sketcher session. The mode of such a section depends on the current Sketcher mode. Starting from Pro/ENGINEER Wildfire 5.0, the Intent Manager mode is the default sketcher mode. Use the function `ProSectionFree()` to free the memory allocated to the section obtained with the function `ProSectionActiveGet()`.

Use the function `ProSectionActiveSet()` to set the specified section as the current active Sketcher section.

### Note

The function call `ProSectionActiveSet()` makes the **Undo** and **Redo** menu options available in Creo Parametric.

---

## Section Constraints

Functions Introduced:

- **ProSectionConstraintsIdsGet()**
- **ProSectionConstraintsGet()**
- **ProSectionConstraintDeny()**
- **ProSectionConstraintCreate()**
- **ProSectionConstraintDelete()**

---

The function `ProSectionConstraintsIdsGet()` returns an array of section constraint identifiers that currently exist in the specified section.

---

 **Note**

You must solve the section first by calling the function `ProSectionSolve()` to get the section constraints. Because adding or deleting section entities might invalidate the current list of section constraint identifiers, you must solve the section again to get the up-to-date list.

---

If a section has not been fully dimensioned with dimensions created explicitly by the user, the Sketcher will make assumptions in order to solve the section. If the Sketcher can assume enough constraints to find a unique solution to the section, it solves the section successfully.

However, you might want to disable certain Sketcher constraints to have more control over the way the section is dimensioned and solved. To do this, use the function `ProSectionConstraintDeny()` to deny a certain section constraint.

---

 **Note**

The function `ProSectionConstraintDeny()` is not supported for sections that have the Intent Manager property set to ON.

---

The function `ProSectionConstraintsGet()` returns information about the specified section constraint. It takes as input the section handle and the constraint identifier for which the information is requested. The function returns details about the section constraint including its type, status, and references. The constraint types are defined in the include file `ProSecConstr.h`. The following table lists the possible constraint types.

| Constraint Type                             | Description                               |
|---------------------------------------------|-------------------------------------------|
| <code>PRO_CONSTRAINT_SAME_POINT</code>      | Make the points coincident.               |
| <code>PRO_CONSTRAINT_HORIZONTAL_ENT</code>  | Make the entity horizontal.               |
| <code>PRO_CONSTRAINT_VERTICAL_ENT</code>    | Make the entity vertical.                 |
| <code>PRO_CONSTRAINT_PNT_ON_ENT</code>      | Place the point on the entity.            |
| <code>PRO_CONSTRAINT_TANGENT_ENTS</code>    | Make the entities tangent.                |
| <code>PRO_CONSTRAINT_ORTHOG_ENTS</code>     | Make the entities perpendicular.          |
| <code>PRO_CONSTRAINT_EQUAL_RADII</code>     | Make the arcs or circles of equal radius. |
| <code>PRO_CONSTRAINT_PARALLEL_ENTS</code>   | Make the entities parallel.               |
| <code>PRO_CONSTRAINT_EQUAL_SEGMENTS</code>  | Make the segments of equal length.        |
| <code>PRO_CONSTRAINT_COLLINEAR_LINES</code> | Make lines co-linear.                     |

| Constraint Type               | Description                                                            |
|-------------------------------|------------------------------------------------------------------------|
| PRO_CONSTRAINT_90_ARC         | Make the arcs 90 degrees.                                              |
| PRO_CONSTRAINT_180_ARC        | Make the arcs 180 degrees.                                             |
| PRO_CONSTRAINT_HORIZONTAL_ARC | Make the arcs horizontal.                                              |
| PRO_CONSTRAINT_VERTICAL_ARC   | Make the arcs vertical.                                                |
| PRO_CONSTRAINT_SYMMETRY       | Impose symmetry.                                                       |
| PRO_CONSTRAINT_SAME_COORD     | Assume the endpoints and centers of arcs to have the same coordinates. |

The possible types of constraint status are as follows:

- PRO\_TK\_CONSTRAINT\_DENIED—The constraint is denied. This gives you more control over the section.
- PRO\_TK\_CONSTRAINT\_ENABLED—The constraint is enabled. The Sketcher uses the predefined assumption.

Use the function `ProSectionConstraintCreate()` to create constraints between entities in the specified section. Use the function `ProSectionConstraintDelete()` to delete the specified section constraint.

#### Note

The function `ProSectionConstrainCreate()` works only if the Intent Manager property of the specified section is set to ON.

## Solving and Regenerating a Section

Functions Introduced:

- **ProSectionEpsilonGet()**
- **ProSectionEpsilonSet()**
- **ProSectionSolve()**
- **ProSectionSolveRigid()**
- **ProSecdimValueGet()**
- **ProSecdimValueSet()**
- **ProSectionRegenerate()**

Although the action of the **Regenerate** command in Sketcher mode is seen as a single operation by the Creo Parametric user, it is in fact composed of two distinct actions. These two operations are invoked separately from a Creo TOOLKIT application. The two operations are as follows:

- 
- Solving—Calculating the way in which the geometry of the entities is driven by the dimensions. It is at this stage that Sketcher constraints are applied, under- or over-dimensioning is discovered and reported, and values are assigned to new dimensions.
  - Regenerating—Reconstructing the geometry of the section to obey the current dimension values.

You invoke these stages using the functions `ProSectionSolve()` and `ProSectionRegenerate()`, respectively.

---

 **Note**

The `ProSectionSolve()` and `ProSectionRegenerate()` are not supported for sections that have the Intent Manager property set to ON.

---

You must solve a programmatically-created section before using it to build three-dimensional geometry. You need to regenerate the section only if you have explicitly modified the dimension values since you solved the section.

When you create a section interactively using Sketcher mode, you normally adjust the values of dimensions after the first regeneration, because the initial values assigned to them correspond to the free-hand, initial sketch and are therefore not exact. When you create a section with Creo TOOLKIT, the entities are usually created with exactly the geometry needed in the finished section. Therefore, although solving is always necessary, it is not usually necessary to explicitly reset dimension values or regenerate the section.

Solving a section in Creo TOOLKIT involves applying the same constraints used in interactive Sketcher mode. Creo TOOLKIT, like the Sketcher, identifies situations of near symmetry in the section, assumes them to be intended as exact symmetry, and constrains them to be symmetrical in future regenerations. For example, lines that are nearly the same length are assumed to be intended to be the same length, and are therefore constrained to be so.

The function `ProSectionSolveRigid()` solves the specified section by fixing the coordinates of all the section entities with respect to a coordinate system. In this way, the section entities do not have to be solved individually. To use this function, a coordinate system within the section must exist; the function uses the first coordinate system found in the section.

---

 **Note**

You must ensure that the added section entities are correct because potential errors will not be solved and may show up only during later stages.

---

---

When there are a lot of section entities, this function dramatically reduces the amount of time required to solve a section.

---

 **Note**

The function `ProSectionSolveRigid()` is not supported for sections that have the Intent Manager property set to ON.

---

Epsilon is the tolerance value, which is used to set the proximity for automatic finding of constraints. Use the function `ProSectionEpsilonSet()` to set the value for epsilon. For example, if your section has two lines that differ in length by 0.5, set the epsilon to a value less than 0.5 to ensure that `ProSectionSolve()` does not constrain the lines to be the same length. To get the current epsilon value for the section, use the function `ProSectionEpsilonGet()`.

Please note the following important points related to epsilon:

- Epsilon determines the smallest possible entity in a section. If an entity is smaller than epsilon, then the entity is considered to be a degenerate entity. Degenerate entity is an entity which cannot be solved. It causes solving and regenerating of the section to fail. For example, a circle with radius 0 or line with length 0 are considered as degenerate entities.
- There are many types of constraints, and epsilon has a different meaning for each type. For example, consider two points. For the constraint `PRO_CONSTRAINT_SAME_POINT`, epsilon is the minimum distance between the two points beyond which the points will be treated as separate points. If the distance between the two points is within the epsilon value, the two points are treated as coincident points.
- Creo Parametric has a default value set for epsilon. This value is also used in the Sketcher user interface.
- If the input geometry is accurate and the user does not want the solver to change it by adding constraints, then set the value of epsilon to 1E-9.
- If the input geometry is nearly accurate and the user wants the solver to guess the intent by adding constraints and further aligning the geometry, then in this case epsilon should reflect the maximal proximity between geometry to be constrained.
- You cannot set the value of epsilon to zero.

The functions `ProSecdimValueGet()` and `ProSecdimValueSet()` enable you to access the value of a dimension. If you change dimension values, you must call `ProSectionRegenerate()` to recalculate the new section shape.

---

## Automatic Section Dimensioning

Function Introduced:

- **ProSectionAutodim()**

The function `ProSectionAutodim()` is used to automatically add needed dimensions to a section to make it fully constrained. It takes as input a `ProSection` handle and a pointer to the opaque structure called `ProWSecerror`. Before calling this function, be sure to allocate the pointer to `ProWSecerror` using `ProSecerrorAlloc()`. Any errors resulting from the call to the function `ProSectionAutodim()` are stored in the `ProWSecerror` structure. To free the allocated memory, call the function `ProSecerrorFree()`.

The `ProSectionAutodim()` function can be used on a section where no dimensions have been created yet, as well as on a partially dimensioned section.

If dimensions have been added successfully, the function `ProSectionAutodim()` also solves the input section.

### Note

The function `ProSectionAutodim()` is not supported for sections that have the Intent Manager property set to ON.

---

## Adding Section Entities

Functions Introduced:

- **ProSectionEntityAdd()**
- **ProSectionEntityDelete()**
- **ProSectionEntityReplace()**

The function `ProSectionEntityAdd()` takes as input the `ProSection` that identifies the section, and a pointer to a user-visible structure called `Pro2dEntdef`, which defines the entity.

The `Pro2dEntdef` structure is a generic structure that contains only a field indicating the type of entity. For each type of entity, there is a dedicated structure that has the entity type as its first field; these structures are named `Pro2dLinedef`, `Pro2dArcdef`, and so on. The Creo TOOLKIT application builds up the structure appropriate to the entity to be added, and inputs it to `ProSectionEntityAdd()` by casting its address to `(Pro2dEntdef*)`. The entity structures are declared in the include file `Pro2dEntdef.h`.

---

The function `ProSectionEntityAdd()` outputs an integer that is the identifier of the new entity within the section. The Creo TOOLKIT application needs these values because they are used to refer to entities when adding dimensions.

The following code fragment demonstrates how to add a single line entity.

```
Pro2dLinedef line;
int line_id;

line.type = PRO_2D_LINE;
line.end1[0] = 0.0;
line.end1[1] = 0.0;
line.end2[0] = 10.0;
line.end2[1] = 0.0;

ProSectionEntityAdd (section,
 (Pro2dEntdef*)&line, &line_id);
```

The function `ProSectionEntityDelete()` enables you to delete a section entity from the specified section.

The function `ProSectionEntityReplace()` enables you to replace an existing entity from the specified section with another entity in the same section. This functionality enables you to redefine an existing section programmatically.

To use the function `ProSectionEntityReplace()`, you must first add the new entity to the section (to get its identifier), then replace the old entity identifier with the new one.

## Accessing Selection Reference of the Entity

Functions Introduced:

- **ProSectionEntityGetSelected()**

The function `ProSectionEntityGetSelected()` provides the references of the selected entity. The input arguments of this function are:

- *handle*—The section handle.
- *entity\_id*—The identifier of the section entity.
- *pnt\_type*—Specifies the type of point selection on the entity. The valid values are:
  - `PRO_ENT_WHOLE`—Specifies the whole entity.
  - `PRO_ENT_START`—Specifies the start point of the entity.
  - `PRO_ENT_END`—Specifies the end point of the entity.
  - `PRO_ENT_CENTER`—Specifies the center of the entity.
  - `PRO_ENT_LEFT_TANGENT`—Specifies the point on the entity, where the normalized param value is 0.5.

- `PRO_ENT_RIGHT_TANGENT`—Specifies the point on the entity, where the normalized param value is 0.0.
- `PRO_ENT_TOP_TANGENT`—Specifies the point on the entity, where the normalized param value is 0.25.
- `PRO_ENT_BOTTOM_TANGENT`—Specifies the point on the entity, where the normalized param value is 0.75.
- *pnt*—Specifies the location of the point on the entity geometry.
- *idx\_pnt*—Specifies the index of interpolation point relative to *pnt\_type*, if the section entity is a spline. In this case the value of the argument *pnt* is ignored. Specify `PRO_VALUE_UNUSED` if the entity is not a spline.

This function creates the selection object programmatically for use in functions that require selection references of entities as the input.

## Construction Entities

Functions Introduced:

- **`ProSectionEntityIsConstruction()`**
- **`ProSectionEntityConstructionSet()`**

Use the function `ProSectionEntityIsConstruction()` to determine if the specified entity is a construction entity. Construction entities are used for reference and are not used to create feature geometry.

The function `ProSectionEntityConstructionSet()` sets the specified entity to be of type construction.

## Modifying Entities

Functions Introduced:

- **`ProSectionEntityIntersectionGet()`**
- **`ProSectionEntityParamEval()`**
- **`ProSectionEntityCorner()`**
- **`ProSectionEntityDivide()`**

The function `ProSectionEntityIntersectionGet()` returns the intersection points between the two section entities. Use the function `ProArrayFree()` to free the memory.

The function `ProSectionEntityParamEval()` to find the corresponding normalized parameter on the curve, given the XY point.

The function `ProSectionEntityCorner()` trims the selected entities to each other. The selected entities may not intersect with each other. The entities may be trimmed by either cutting them or extending them.

Use the function `ProSectionEntityDivide()` to divide a section entity into two or more new entities. If the entity is dimensioned then delete the dimensions before dividing it.

## Adding Section Dimensions

Functions Introduced:

- **ProSecdimCreate()**
- **ProSecdimDelete()**
- **ProSecdimDiameterSet()**
- **ProSecdimDiameterClear()**
- **ProSecdimDiameterInquire()**
- **ProSecdimStrengthen()**
- **ProSecdimLockSet()**
- **ProSecdimIsLocked()**

When you create a dimension interactively in Sketcher mode, you select entities and points on entities and Creo Parametric deduces from those picks what type of dimension is being added. When you add a dimension using the function `ProSecdimCreate()`, you must specify the dimension type. The dimension types are defined in the include file `ProSecdimTypes.h`. The following table lists the possible values.

| Constant                                  | Description                                                   |
|-------------------------------------------|---------------------------------------------------------------|
| <code>PRO_TK_DIM_LINE</code>              | Length of a line                                              |
| <code>PRO_TK_DIM_LINE_POINT</code>        | Distance between a line and a vertex                          |
| <code>PRO_TK_DIM_RAD</code>               | Radius of an arc or a circle                                  |
| <code>PRO_TK_DIM_DIA</code>               | Diameter of an arc or a circle                                |
| <code>PRO_TK_DIM_LINE_LINE</code>         | Distance between two lines                                    |
| <code>PRO_TK_DIM_PNT_PNT</code>           | Distance between two points                                   |
| <code>PRO_TK_DIM_PNT_PNT_HORIZ</code>     | Distance between two points (X coordinates)                   |
| <code>PRO_TK_DIM_PNT_PNT_VERT</code>      | Distance between two points (Y coordinates)                   |
| <code>PRO_TK_DIM_AOC_AOC_TAN_HORIZ</code> | Horizontal distance between two arcs or circles               |
| <code>PRO_TK_DIM_AOC_AOC_TAN_VERT</code>  | Vertical distance between two arcs or circles                 |
| <code>PRO_TK_DIM_ARC_ANGLE</code>         | Angle of an arc                                               |
| <code>PRO_TK_DIM_LINES_ANGLE</code>       | Angle between two lines                                       |
| <code>PRO_TK_DIM_LINE_AOC</code>          | Distance between a line and an arc or a circle                |
| <code>PRO_TK_DIM_LINE_CURVE_ANGLE</code>  | Angle between a spline and a line                             |
| <code>PRO_TK_DIM_3_PNT_ANGLE</code>       | Angular dimension defined by three points                     |
| <code>PRO_TK_DIM_DIA_LINEAR</code>        | Linear diameter dimension                                     |
| <code>PRO_TK_DIM_PNT_PNT_ORI</code>       | Distance between two points in specified orientation          |
| <code>PRO_TK_DIM_AOC_AOC_ORI</code>       | Distance between two arcs or circles in specified orientation |

| Constant               | Description                                                                |
|------------------------|----------------------------------------------------------------------------|
| PRO_TK_DIM_TOT_INC_ANG | Total included angle                                                       |
| PRO_TK_DIM_ANG_POLAR   | Angle between the x-axis and a vector. The vector is defined by two points |

The function `ProSecdimCreate()` takes several input arguments, including the following:

- `int entity_ids[]`—An array of integers that are the identifiers of the section entities to which the dimension refers.
- `ProSectionPointType point_types[]`—A dimension can reference a vertex (the end of an entity), the center of an arc or a circle, a line or circle itself (the whole entity), or tangent points on an arc or a circle. To specify these types of dimension reference points, specify the appropriate point type constant for each dimension in the `entity_ids` array. These constants are listed in the include file `ProSecdimType.h`.
- `int num_ids`—The number of section dimension identifiers in the `entity_ids` array. This is typically 1 or 2 (line length versus a point-to-point dimension).
- `ProSecdimType dim_type`—The type of section dimension to create, as listed in the `ProSecdimType.h` file.
- `Pro2dPnt place_pnt`—The two-dimensional location of the dimension label. This is equivalent to the middle mouse button pick when you are using Sketcher mode.

Note that the position of this label can sometimes determine the exact role of the dimension. For example, a dimension of type `PRO_TK_DIM_LINES_ANGLE` may refer to the acute or obtuse angle between two lines, depending on where the label is positioned.

The `ProSecdimCreate()` function outputs the identifier of the dimension, which is needed to identify the dimension if its value needs to be changed at a later time.

### Note

The dimensions do not need to be given values to create a complete and correct section of any form. See the section [Solving and Regenerating a Section on page 991](#) for a detailed explanation of the assignment of values.

The following code fragment shows how to create a dimension for the length of a line entity.

```
int line_id[1], width_dim;
Pro2dPnt point;
```

```

ProSectionPointType pnt_type[1];

line_id[0] = 1;
point[0] = 5.0;
point[1] = 1.0;
pnt_type[0] = PRO_ENT_WHOLE;

ProSecdimCreate (section, line_id, pnt_type, 1,
 PRO_TK_DIM_LINE, point,
 &width_dim);

```

The following code fragment shows how to create a dimension for the horizontal distance between two arc ends.

```

int arc1_id, arc2_id, arc1_end2, arc2_end1,
 dist_dim;
Pro2dPnt point;
int entities[2];
ProSectionPointType pnt_types[2];

pnt_types[0] = PRO_ENT_START;
pnt_types[1] = PRO_ENT_END;
entity[0] = arc1_end2;
entity[1] = arc2_end1;
point[0] = 5.0;
point[1] = 5.0;

ProSecdimCreate (section, entities, pnt_types, 2,
 PRO_TK_DIM_PNT_PNT_HORIZ, point, &dist_dim);

```

The `ProSecdimDiam...()` functions extend the dimension creation functionality to include diameters for sections used to create revolved features. Function `ProSecdimDiamSet()` converts a specified section dimension (between a centerline and another entity) into a diameter dimension. `ProSecdimDiamClear()` does the opposite, converting a diameter dimension into a regular one. Use function `ProSecdimDiamInquire()` to determine if a dimension is a diameter dimension.

The function `ProSecdimStrengthen()` converts a weak dimension to a strong dimension.

You can lock or unlock sketch dimensions. Locking of dimensions avoids modifications to the sections outside the sketcher mode. The function `ProSecdimIsLocked()` determines whether a sketch dimension is locked. Use the function `ProSecdimLockSet()` to lock or unlock a specified dimension.

---

## Example 1: Creating Spline Point Dimensions in Sections

The sample code in `Ug3DSectSplineDim.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a Section dimension between the first and last interpolation point of a Spline.

## Error Reporting

Functions Introduced:

- **ProSecerrorAlloc()**
- **ProSecerrorCount()**
- **ProSecerrorMsgGet()**
- **ProSecerrorItemGet()**
- **ProSecerrorAdd()**
- **ProSecerrorFree()**

Both `ProSectionSolve()` and `ProSectionRegenerate()` might result in a list of errors about the entities in the section. These errors are stored in an opaque structure called `ProWSecerror`. Before calling one of these functions, use `ProSecerrorAlloc()` to allocate memory for an error structure, then pass the pointer to the error structure to `ProSectionSolve()` or `ProSectionRegenerate()`.

You can add application-specific section errors to an error structure. To do this, call the function `ProSecerrorAdd()`.

The function `ProSecerrorCount()` tells you how many error messages are contained in the error structure. The errors themselves are identified by sequential integers, so you can step through the list. Use the function `ProSecerrorMsgGet()` to get the text of each message. Use the function `ProSecerrorItemGet()` to get the identifier of the problem entity that caused a specific error message. To free the allocated memory, call the function `ProSecerrorFree()`.

A Creo TOOLKIT application that builds sections generally aims to make them complete and correct without any interactive help from the Creo Parametric user. Therefore, the errors reported by the functions `ProSectionSolve()` and `ProSectionRegenerate()` are directed at the Creo TOOLKIT developer as a debugging aid, rather than at the final Creo Parametric user.

The following code fragment shows a call to `ProSectionSolve()` and an analysis of the errors produced.

```
ProWSecerror errors;
int n_errors, e;
ProError status;
ProMsg wmsg;
```

```

char msg[PRO_PATH_SIZE];
int ent_id;

ProSecerrorAlloc (&errors);
status = ProSectionSolve (section, &errors);
if (status != PRO_TK_NO_ERROR)
{
 ProSecerrorCount (&errors, &n_errors);
 for (e = 0; e < n_errors; e++)
 {
 ProSecerrorMsgGet (errors, e, wmsg);
 ProWstringToString (msg, wmsg);
 ProSecerrorItemGet (errors, e, &ent_id);
 printf ("%s: Problem ID, %d\n", msg, ent_id);
 }
 ProSecerrorFree (&errors);
 return (-1);
}

```

## Retrieving and Saving a Section

Functions Introduced:

- **ProFeatureNumSectionsGet()**
- **ProFeatureSectionCopy()**

To retrieve a section from disk, use the function `ProMdlnameRetrieve()` with the model type `PRO_2DSECTION`. You can save a section to a file using the function `ProMdlSave()`.

You can also retrieve or copy a section from a feature. The function `ProFeatureNumSectionsGet()` finds the number of sections in the specified feature. Given a feature handle and section index, `ProFeatureSectionCopy()` initializes and returns a section handle to a section copied from the specified feature. Memory for this section is controlled by the Creo TOOLKIT application and must therefore be freed by a call to `ProSectionFree()`.

## Example 1: Creating a Section Model

The sample code in `UgSectModelCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` illustrates how to use all the functions described in this to create a section model.

---

# Element Trees: Sketched Features

## Element Trees: Sketched Features

This section describes the Creo TOOLKIT functions that enable you to create and manipulate sketched features.

Sketched features are features that require one or more sections to completely define the feature, such as extruded and revolved protrusions.

This section outlines the necessary steps to programmatically create sketched features using Creo TOOLKIT.

## Overview

The section [Element Trees: Principles of Feature Creation on page 771](#) explains how to create a simple feature using the feature element tree, and the documentation in the section on [Element Trees: Sections on page 986](#) explains how to create a section. This section explains how to put these methods together, with a few additional techniques, to create features that contain sketched sections.

## Element Tree for Sketched Features

The element tree of any feature that contains a sketch contains a subtree that identifies the sketch object and describes how it is positioned in the model. As this subtree is the same for every sketched feature, it is documented in its own header file, called `ProStdSection.h`. The diagram below shows the structure of that subtree.

### Element Tree for Sketched Features

The subtree of the `PRO_E_STD_SEC_SETUP_PLANE` element defines the sketch plane, the location of the sketch plane, the orientation plane and the orientation direction, and the viewing direction. You can use Intent Planes as sketch orientation or placement references.

The element `PRO_E_SKETCHER` is of type `POINTER`, and its value is the object `ProSection`, introduced in the documentation in the topic on Sections.

The element `PRO_E_SEC_USE_SKETCH` refers to any valid selected 'Sketch' (sketched datum curve) suitable to the current Sketch Based Feature. When this element is used, the sketch will be stored in the feature as a reference to the sketch feature, and no internal section, sketch plane or orientation will be required. Using this element in the `PRO_E_STD_SECTION` element tree allows a feature to be created in one step, without creating the feature first as incomplete.

#### Note

The use of internal sections, and the process by which an internal-section based feature is created, remains unchanged in Pro/ENGINEER Wildfire 2.0.

The following table shows the sketched features that are supported by Creo TOOLKIT, the names of the corresponding header files which show their element trees, and the IDs of the elements in each tree which contain the standard sketch subtree as shown in the above figure Element Tree for Sketched Features

| Feature                   | Header                    | Element containing Subtree                                              |
|---------------------------|---------------------------|-------------------------------------------------------------------------|
| Extrude                   | <code>ProExtrude.h</code> | <code>PRO_E_STD_SECTION</code>                                          |
| Revolve                   | <code>ProRevolve.h</code> | <code>PRO_E_STD_SECTION</code>                                          |
| Rib                       | <code>ProRib.h</code>     | <code>PRO_E_STD_SECTION</code>                                          |
| Hole                      | <code>ProHole.h</code>    | <code>PRO_E_SKETCHER (2D)</code><br><code>PRO_E_STD_SECTION</code>      |
| Fill (Flat datum surface) | <code>ProFlatSrf.h</code> | <code>PRO_E_STD_SECTION</code>                                          |
| Draft                     | <code>ProDraft.h</code>   | <code>PRO_E_STD_SECTION</code>                                          |
| Sketched datum curve      | <code>ProDtmCrv.h</code>  | <code>PRO_E_STD_SECTION</code>                                          |
| Sketched datum point      | <code>ProDtmCrv.h</code>  | <code>PRO_E_STD_SECTION</code>                                          |
| Simple (constant) sweep   | <code>ProSweep.h</code>   | <code>PRO_E_SWEEP_SPINE</code><br><code>PRO_E_SWEEP_SECTION (2D)</code> |

---

## Creating Features Containing Sections

The section [Element Trees: Principles of Feature Creation on page 771](#) explained that to create a feature from an element tree, you build the tree of elements using `ProElementAlloc()`, `ProElementtreeElementAdd()`, and so on, and then call `ProFeatureCreate()` to create the feature using the tree. If the feature is to contain a sketch, the sequence is a little more complex.

As explained in the documentation in the section on [Element Trees: Sections on page 986](#), a 2D section stored in a model file can be allocated by calling `ProSection2dAlloc()`. Instead, Creo Parametric must allocate as part of the initial creation of the sketched feature, a section that will be part of a feature. The allocation is done by calling `ProFeatureCreate()` with an element tree which describes at minimum the feature type and form, in order to create an incomplete feature. In creating the feature, Creo Parametric calculates the location and orientation of the section, and allocates the `ProSection` object. This section is then retrieved from the value of the `PRO_E_SKETCHER` element that is found in the element tree extracted from the created feature. Fill the empty section using `ProSection` related functions.

After adding the section contents and the remaining elements in the tree, add the new information to the feature using `ProFeatureRedefine()`.

### To Create Sketched Features Element Trees

1. Build an element tree but do not include the element `PRO_E_SKETCHER`.
2. Call `ProFeatureCreate()` with the option `PRO_FEAT_CR_INCOMPLETE_FEAT`, so that the incomplete element tree is accepted.
3. Extract the value of the element `PRO_E_SKETCHER` created by Creo Parametric from an element tree extracted using `ProFeatureElementtreeExtract()` on the incomplete feature.
4. Using that value as the `ProSection` object, create the necessary section entities and dimensions, and solve the section.
5. Add any other elements not previously added to the tree, such as extrusion depth. The depth elements may also be added before the creation of incomplete feature (before step 2).
6. Call `ProFeatureRedefine()` with the completed element tree.

## Creating Features with 2D Sections

Sketched features using 2D sections do not require references to other geometry in the Creo Parametric model. Some examples of where 2D sections are used are:

- Base features, sometimes called first features. This type of feature must be the first feature created in the model, and be of type `PRO_FEAT_FIRST_FEAT`.

- Sketched hole features.
- The `PRO_E_SWEEP_SECTION` section of a simple sweep feature.

To create 2D sketched features, follow the steps outlined in the section [To Create Sketched Features Element Trees on page 1004](#).

### Note

For 2D sketched features, you need not specify section references or use projected 3D entities. Entities in a 2D section are dimensioned to themselves only. A 2D section does not require any elements in the tree to setup the sketch plane or the orientation of the sketch. Thus, the `PRO_E_STD_SEC_SETUP_PLANE` subtree is not included.

## Verifying Section Shapes

Function Introduced:

- **ProSectionShapeGet()**

Certain features may or may not be able to use a section due to the shape of the section. Different sketched feature tools such as extrude and revolve have different requirements for sections. For example, solid protrusions contain only closed and non-intersecting sections. Solid cuts or datum surfaces have open non-intersecting sections. Fill features must have closed sections.

After the section is regenerated, `ProSectionShapeGet()` obtains the shape of a given section. This information is used to determine if the section is acceptable for feature creation.

The section shapes are as follows:

| Constant                                   | Function                          | Description                                                                  |
|--------------------------------------------|-----------------------------------|------------------------------------------------------------------------------|
| <code>PRO_SECSHAPE_EMPTY</code>            | <code>ProSectionShapeGet()</code> | An empty section                                                             |
| <code>PRO_SECSHAPE_POINTS</code>           | <code>ProSectionShapeGet()</code> | Section contains only sketched datum points                                  |
| <code>PRO_SECSHAPE_1_OPEN_LOOP</code>      | <code>ProSectionShapeGet()</code> | Section contains a single open loop (and possibly points)                    |
| <code>PRO_SECSHAPE_1_CLOSED_LOOP</code>    | <code>ProSectionShapeGet()</code> | Section contains a single closed loop (and possibly points)                  |
| <code>PRO_SECSHAPE_MIXED_LOOPS</code>      | <code>ProSectionShapeGet()</code> | Section contains at least one open and one closed loop (and possibly points) |
| <code>PRO_SECSHAPE_MULTI_OPEN_LOOPS</code> | <code>ProSectionShapeGet()</code> | Section contains multiple open loops (and possibly points)                   |

| Constant                        | Function             | Description                                                            |
|---------------------------------|----------------------|------------------------------------------------------------------------|
| PRO_SECSHAPE_MULTI_CLOSED_LOOPS | ProSectionShapeGet() | Section contains multiple closed loops (and possibly points)           |
| PRO_SECSHAPE_INTERSECTING       | ProSectionShapeGet() | Section contains loops that intersect each other (and possibly points) |

### Note

Use geometry entities and not construction entities to define section shapes that are then used to create solid or surface geometry. To convert the construction entities to geometry entities, use the function `ProSectionEntityConstructionSet()` with the input argument *construction* set to `PRO_B_FALSE`.

## Creating Features with 3D Sections

A 3D section needs to define its location with respect to the existing geometrical features. The subtree contained in the element `PRO_STD_SEC_SETUP_PLANE` defines the location of the sketch planeEdge entities; any other 2D entities in the sketch must be dimensioned to those entities, so that their 3D location is fully defined.

### 3D Section Location in the Owning Model

Function Introduced:

- **ProSectionLocationGet()**

For a 2D section in a feature, Creo Parametric decides where the section will be positioned in 3D.

If the section is 3D, the feature tree elements below `PRO_E_STD_SEC_SETUP_PLANE` specify the sketch plane, the direction from which it is being viewed, an orientation reference, and a direction which that reference represents (TOP, BOTTOM, LEFT or RIGHT). When you call `ProFeatureCreate()`, this information is used to calculate the 3D plane in which the section lies, and its orientation in that plane.

The position of the section origin in the plane is not implied by the element tree, and cannot be specified by the Creo TOOLKIT application: position is chosen arbitrarily by Creo Parametric. This is because the interactive user of Creo Parametric never deals in absolute coordinates, and doesn't need to specify, or even know, the location of the origin of the section. In Creo TOOLKIT describe

---

all section entities in terms of their coordinate values, so you need to find out where Creo Parametric has put the origin of the section. This is the role of the function `ProSectionLocationGet()`.

`ProSectionLocationGet()` provides the transformation matrix that goes from 2D coordinates within the section to 3D coordinates of the owning part or assembly. This is equivalent to describing the position and orientation of the 2D section coordinate system with respect to the base coordinate system of the 3D model.

So `ProSectionLocationGet()` can be called in order to calculate where to position new section entities so that they are in the correct 3D position in the part or assembly.

## Reference Entities and Use Edge

Functions introduced:

- **`ProSectionEntityFromProjection()`**
- **`ProSectionEntityIsProjection()`**
- **`ProSectionEntityUseEdge()`**
- **`ProSectionEntityUseEdgeLoop()`**
- **`ProSectionEntityUseEdgeChain()`**
- **`ProSectionEntityReferenceGet()`**

The previous section explained how to set the correct 3D position of new section entities. You also need to make the entities parametric, that is, to ensure that Creo Parametric knows how to calculate their new positions during regeneration.

When sketching a section using Creo Parametric, entities are positioned parametrically by dimensioning them or aligning them to items in the 3D model. Creo TOOLKIT does not allow you to explicitly align section entities, but you can add dimensions which relate section entities to 3D entities in the owning model. You can do this using references. A reference entity represents a position in the section of an item in a 3D model that is used as a dimension reference. The reference entity itself does not give rise to 3D geometry in the owning feature. Reference entities are visible in interactive sketcher operations; they are shown as dashed and are used during autodimensioning and alignment operations.

In Creo TOOLKIT reference entities are created using `ProSectionEntityFromProjection()`. This function takes as input a `ProSelection` describing the 3D model entity being projected, and outputs the integer ID of the resulting known section entity. This ID is used to specify the attachment of a section dimension, as described in the documentation in the section [Element Trees: Sections on page 986](#). Reference entities are included in

---

the output of `ProSectionEntityIdsGet()`, but can be distinguished from regular section entities by calling the function `ProSectionEntityIsProjection()`.

To align a section entity with a 3D model entity, project the 3D entity to create a reference entity, and then either add a dimension between this reference entity and the one to be aligned or use `ProSectionAutodim()` to do this.

To create a regular section entity whose geometry is itself an exact projection of a 3D model entity, create it and align it in a single step using the function `ProSectionEntityUseEdge()`. This function has the same arguments as `ProSectionEntityFromProjection()`, and it creates a reference entity in the same way, but it requires an additional step of copying the reference entity to a regular entity with the same geometry. It outputs the ID of the regular entity it creates. The ID of the reference entity is always 1 less than the ID of the regular entity.

`ProSectionEntityUseEdge()` is equivalent to the Creo Parametric sketcher command **Use Edge**. The functions `ProSectionEntityUseEdgeLoop()` and `ProSectionEntityUseEdgeChain()` allow you to execute a **Use Edge** operation on multiple edges simultaneously.

---

#### **Note**

If you create the known and projected entities first, you need not call `ProSectionLocationGet()` as described above; instead you can look at the geometry of the known and projected entities, and then position the new entities relative to the projected entities.

---

The function `ProSectionEntityReferenceGet()` provides 3D geometry that is a reference for a projected entity in a given section.

## Creating Geometry by Offsetting

The functions described in this section enable you to create offset entities from edges and 3D curve segments from normal, chain and loop selection.

Functions Introduced:

- **`ProSectionEntityUseOffset()`**
- **`ProSectionEntityUseOffsetChain()`**
- **`ProSectionEntityUseOffsetLoop()`**

The function `ProSectionEntityUseOffset()` creates a sketched entity that is offset at a specified distance from a single edge. This function takes as input a `ProSelection` object describing the 3D model entity.

---

The function `ProSectionEntityUseOffsetChain()` creates sketched entities that are offset from a chain of edges or entities and the function `ProSectionEntityUseOffsetLoop()` creates sketched entities offset from a loop of edges or entities.

The behavior of the functions in this section is similar to the offset operation achieved using **Sketch ► Offset** in Creo Parametric.

## Reusing Existing Sketches

Functions introduced:

- **ProFeatureSketchAdd()**
- **ProFeatureSketchedWithOptionsCreate()**

Creo Parametric allows you to copy sections from previously created features into new sketched features.

The function `ProFeatureSketchAdd()` copies the selected section from one feature to another feature.

The function `ProFeatureSketchedWithOptionsCreate()` creates a feature from the element tree, and also copies the sketched sections to the new feature. This reduces the sketched feature creation effort to a single Creo TOOLKIT function call. The element tree must contain all of the required elements except the `PRO_E_STD_SECTION` subtree.

### Example 1: Creating an Extruded Protrusion Base Feature

The sample code in `UgSktExtrusionCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows the creation of an extruded protrusion as a base feature.

### Example 2: Creating a Sketched Datum Curve

The sample code in `UgSketchedCurveCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows the creation of a sketched datum curve using the conventional approach.

## Element Trees: Extrude and Revolve

### Element Trees: Extrude and Revolve

This section describes how to use the include files `ProExtrude.h`, and `ProRevolve.h` so that you can create extruded and revolved features programmatically. As Extrude and Revolve features are sketched features; we

---

recommend you to read the section [Element Trees: Principles of Feature Creation on page 771](#) and [Element Trees: Sketched Features on page 1002](#) before referring to this section.

## The Element Tree for Extruded Features

The element tree for extrude features is documented in the header file `ProExtrude.h`. The functions `ProFeatureTypeGet()` and `ProFeatureSubtypeGet()` return an Extrude feature. The types of Extrude features are:

- Protrusion
- Cut
- Surface
- Surface Trim
- Thin Protrusion
- Thin Cut
- Sheetmetal Cut
- Sheetmetal Unattached Wall

Refer to the section [Production Applications: Sheetmetal on page 1307](#) for element details on sheetmetal features.

The extrude element tree contains toggles to switch between different feature types. An extruded feature tree also contains subtrees supporting the section and depth parameters for the feature.

You can use Intent Datums such as Intent Point, Intent Axis, and Intent Plane for depth reference in extrude features.

The following figure shows the element tree for extruded features.

## The Element Tree for Extruded Feature

```

| PRO_E_STD_DIRECTION*          | Direction of creation.<br><br>Of type ProExtDirection<br><br>= PRO_EXT_CR_IN_SIDE_ONE<br><br>for depth in side one<br><br>= PRO_EXT_CR_IN_SIDE_TWO<br><br>for depth in side two |
| PRO_E_STD_MATRLSIDE*          | Direction of material affected with respect to the sketch. Required for all cuts, all thin features, and for solid protrusions with open sections.                              |
| PRO_E_STD_EXT_DEPTH           | Compound Element. Specifies the depth type and value for the extrude feature.                                                                                                   |
| PRO_E_EXT_DEPTH_TO            | Compound Element. Specifies the depth type and value for Side 1, that is, extrusion in the first direction from the sketch plane.                                               |

| Element ID                 | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_EXT_DEPTH_TO_TYPE    | <p>Mandatory element. Specifies the type of depth for Side 1. The depth type is specified using the enumerated data type <code>ProExtDepthToType</code>. The valid values are:</p> <ul style="list-style-type: none"> <li>• <code>PRO_EXT_DEPTH_TO_BLIND</code>—Extrudes a section from the sketching plane to the specified depth value.</li> <li>• <code>PRO_EXT_DEPTH_TO_NEXT</code>—Extrudes a section from the sketching plane to the first surface that it reaches.</li> <li>• <code>PRO_EXT_DEPTH_TO_ALL</code>—Extrudes a section from the sketching plane to the last surface it reaches.</li> <li>• <code>PRO_EXT_DEPTH_TO_UNTIL</code>—Extrudes a section to intersect with a selected surface.</li> <li>• <code>PRO_EXT_DEPTH_TO_REF</code>—Extrudes a section to a selected point, curve, plane, or surface.</li> <li>• <code>PRO_EXT_DEPTH_SYMMETRIC</code>—Extrudes a section on each side of the sketching plane by half of the specified depth value in each direction.</li> </ul> |
| PRO_E_EXT_DEPTH_TO_REF     | <p>Specifies the reference element for Side 1, when the depth type is <code>PRO_EXT_DEPTH_TO_REF</code> or <code>PRO_EXT_DEPTH_TO_UNTIL</code>. The valid reference types are:</p> <ul style="list-style-type: none"> <li>• <code>PRO_SURFACE</code></li> <li>• <code>PRO_AXIS</code></li> <li>• <code>PRO_EDGE</code></li> <li>• <code>PRO_CURVE</code></li> <li>• <code>PRO_POINT</code></li> <li>• <code>PRO_EDGE_START</code></li> <li>• <code>PRO_EDGE_END</code></li> <li>• <code>PRO_CRV_START</code></li> <li>• <code>PRO_CRV_END</code></li> <li>• <code>PRO_BODY</code></li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_EXT_DEPTH_TO_REF_TRF | <p>Specifies the options available for the depth type <code>PRO_EXT_DEPTH_TO_REF</code> for Side 1. The depth type is specified using the enumerated data type <code>ProExtDepthRefOpt</code>. The valid values are:</p> <ul style="list-style-type: none"> <li>• <code>PRO_EXT_DEPTH_REF_NONE</code>—Extrudes a section to a selected point, curve, plane, or surface.</li> <li>• <code>PRO_EXT_DEPTH_REF_OFFS</code>—Extrudes a section to an offset of the selected point, curve, plane, or surface.</li> <li>• <code>PRO_EXT_DEPTH_REF_TRNSLT</code>—Extrudes a section to a translation of the selected point, curve, plane, or surface.</li> </ul>                                                                                                                                                                                                                                                                                                                                            |

| Element ID                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_EXT_DEPTH_TO_REF_TRF_VAL | Specifies the offset or translation value for Side 1, when the depth type is PRO_EXT_DEPTH_TO_REF, and the option type is PRO_EXT_DEPTH_REF_OFFS or PRO_EXT_DEPTH_REF_TRNSLT.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_EXT_DEPTH_TO_VALUE       | Specifies the value of depth for Side 1, when the depth type is PRO_EXT_DEPTH_TO_BLIND or PRO_EXT_DEPTH_SYMMETRIC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| PRO_E_EXT_DEPTH_FROM           | Compound Element. Specifies the depth type and value for Side 2, that is, extrusion in the second direction from the sketch plane.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| PRO_E_EXT_DEPTH_FROM_TYPE      | Mandatory element. Specifies the type of depth for Side 2. The depth type is specified using the enumerated data type ProExtDepthFromType. The valid values are: <ul style="list-style-type: none"> <li>PRO_EXT_DEPTH_FROM_BLIND—Extrudes a section from the sketching plane to the specified depth value.</li> <li>PRO_EXT_DEPTH_FROM_NEXT—Extrudes a section from the sketching plane to the first surface that it reaches.</li> <li>PRO_EXT_DEPTH_FROM_ALL—Extrudes a section from the sketching plane to the last surface it reaches.</li> <li>PRO_EXT_DEPTH_FROM_UNTIL—Extrudes a section to intersect with a selected surface.</li> <li>PRO_EXT_DEPTH_FROM_REF—Extrudes a section to a selected point, curve, plane, or surface.</li> <li>PRO_EXT_DEPTH_FROM_NONE—Extrudes a section only on Side 1 from the sketch plane, no extrusion on Side 2.</li> </ul> |
| PRO_E_EXT_DEPTH_FROM_REF       | Specifies the reference element for Side 2, when the depth type is PRO_EXT_DEPTH_FROM_REF or PRO_EXT_DEPTH_FROM_UNTIL. The valid reference types are: <ul style="list-style-type: none"> <li>PRO_SURFACE</li> <li>PRO_AXIS</li> <li>PRO_EDGE</li> <li>PRO_CURVE</li> <li>PRO_POINT</li> <li>PRO_EDGE_START</li> <li>PRO_EDGE_END</li> <li>PRO_CRV_START</li> <li>PRO_CRV_END</li> <li>PRO_BODY</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| PRO_E_EXT_DEPTH_FROM_REF_TRF   | Specifies the options available for the depth type PRO_EXT_DEPTH_FROM_REF for Side 2. The depth type is specified using the enumerated data                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Element ID                                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                               | <p>type <code>ProExtDepthRefOpt</code>. The valid values are:</p> <ul style="list-style-type: none"> <li>• <code>PRO_EXT_DEPTH_REF_NONE</code>—Extrudes a section to a selected point, curve, plane, or surface.</li> <li>• <code>PRO_EXT_DEPTH_REF_OFFS</code>—Extrudes a section to an offset of the selected point, curve, plane, or surface.</li> <li>• <code>PRO_EXT_DEPTH_REF_TRNSLT</code>—Extrudes a section to a translation of the selected point, curve, plane, or surface.</li> </ul>                     |
| <code>PRO_E_EXT_DEPTH_FROM_REF_TRF_VAL</code> | Specifies the offset or translation value for Side 2, when the depth type is <code>PRO_EXT_DEPTH_FROM_REF</code> , and the option type is <code>PRO_EXT_DEPTH_REF_OFFS</code> or <code>PRO_EXT_DEPTH_REF_TRNSLT</code> .                                                                                                                                                                                                                                                                                              |
| <code>PRO_E_EXT_DEPTH_FROM_VALUE</code>       | Specifies the value of depth for Side 2, when the depth type is <code>PRO_EXT_DEPTH_FROM_BLIND</code> .                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>PRO_E_STD_FEATURE_NAME</code>           | Default given by application depending on the feature type. Can be modified by the user.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>PRO_E_EXT_COMP_DRFT_ANG</code>          | Draft Compound Element that allows you to add a draft on the extrude feature.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>PRO_E_EXT_DRFT_ANG</code>               | <p>Draft of type <code>ProExtDrftAng</code>.</p> <ul style="list-style-type: none"> <li>• <code>PRO_EXT_DRFT_ANG_NO_DRAFT</code>—To create extruded features without a draft.</li> <li>• <code>PRO_EXT_DRFT_ANG_DRAFT</code>—To create extruded features with a draft.</li> </ul>                                                                                                                                                                                                                                     |
| <code>PRO_E_EXT_DRFT_ANG_VAL</code>           | The draft angle. The draft angle can have value between [-89.9, 89.9].                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>PRO_E_FEAT_THIN</code>                  | Compound element. It specifies how to close a thin feature when one or more surfaces can be used to cap, that is, close the feature and attach it to the solid geometry. Here the sketch is an open sketch.                                                                                                                                                                                                                                                                                                           |
| <code>PRO_E_FEAT_THIN_STRT</code>             | Compound element. It specifies the options for the first end point of the thin feature.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>PRO_E_FEAT_THIN_STRT_OPT</code>         | <p>Specifies how to cap the first end point of the thin feature using the enumerated data type <code>ProFeatThinOpt</code>. The valid values are:</p> <ul style="list-style-type: none"> <li>• <code>PRO_FEAT_THIN_IGNORE</code>—Caps the feature as a free end. When you specify this value, the feature is created with a free end even if a reference edge or surface is available to cap the feature.</li> <li>• <code>PRO_FEAT_THIN_DEFAULT</code>—Caps the feature to the specified edge or surface.</li> </ul> |
| <code>PRO_E_FEAT_THIN_STRT_REF</code>         | Specifies the edge or surface that must be used to cap and attach the first end point of the feature to the solid geometry.                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>PRO_E_FEAT_THIN_END</code>              | Compound element. It specifies the options for the second end point of the feature.                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Element ID              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEAT_THIN_END_OPT | Specifies how to cap the second end point of the thin feature using the enumerated data type ProFeatThinOpt. The valid values are: <ul style="list-style-type: none"> <li>PRO_FEAT_THIN_IGNORE—Caps the feature as a free end. When you specify this value, the feature is created with a free end even if a reference edge or surface is available to cap the feature.</li> <li>PRO_FEAT_THIN_DEFAULT—Caps the feature to the specified edge or surface.</li> </ul> |
| PRO_E_FEAT_THIN_END_REF | Specifies the edge or surface that must be used to cap and attach the second end point to the solid geometry.                                                                                                                                                                                                                                                                                                                                                        |

Elements identified with ‘\*’ depend on the definition of the standard section. These elements are not assigned values until the standard section has been completely allocated (which typically happens during redefine of the feature). Values assigned to these elements while the section is not complete are ignored.

The following table lists the elements needed to create extruded features, in addition to those already discussed:

| Feature Type | Element ID              | Comment                                                                                                                                                                                                                                                                                                    |
|--------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Solid        | PRO_E_EXT_COMP_DRFT_ANG | Compound element to specify draft options.                                                                                                                                                                                                                                                                 |
|              | PRO_E_BODY              | Compound element                                                                                                                                                                                                                                                                                           |
|              | PRO_E_BODY_USE          | Mandatory. Specifies the body to add geometry to.<br><br>The valid values are: <ul style="list-style-type: none"> <li>PRO_BODY_USE_NEW—The geometry in the feature is stored in the new body.</li> <li>PRO_BODY_USE_SELECTED—The geometry in the feature is stored in the single selected body.</li> </ul> |
|              | PRO_E_BODY_SELECTED     | Specifies the reference to the selected body.<br><br>Mandatory if PRO_E_BODY_USE is set to PRO_BODY_USE_SELECTED<br><br> <b>Note</b><br><br>Only single reference is allowed.                                           |
| Thin         | PRO_E_THICKNESS         | Mandatory >= 0.0                                                                                                                                                                                                                                                                                           |

| Feature Type | Element ID              | Comment                                                                                                                                                                                                                                                                                                                    |

## Examples: Creating Extruded Features

The following examples demonstrate creation of extrude features of various forms. These examples are adapted from an example template file `UgSktExtrusionTemplate.c` available on the Creo Parametric load point under `protoolkit/protk_appls/pt_userguide/ptu_featcreat`.

- [Example 1: Creating an Extruded Feature on page 1020](#)
- [Example 2: To Create an Extruded Cut with Two-sided Thru-all Depth on page 1020](#)

- [Example 3: To Create an Extruded Thin Cut on page 1020](#)
- [Example 4: To Create an Extruded Datum Surface Feature on page 1020](#)
- [Example 5: To Create a Surface Trim Extruded Feature on page 1020](#)

## Conventional\_Approach

### Example 1: Creating an Extruded Feature

The sample code in the file `UserSktExtrusionProtrusion.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create an Extruded Protrusion by the conventional approach for sketched features. The example creates an incomplete feature using `ProFeatureCreate()`, extracts the section from the element tree of the incomplete feature, builds the section on the section handle obtained, and, completes the feature using `ProFeatureRedefine()`.

The user is prompted to select the sketching and the orientation planes and then the reference edges for the sketch. The user is also required to enter the X and Y offsets to be applied to the sketch from the projected edges.

### Example 2: To Create an Extruded Cut with Two-sided Thru-all Depth

The sample code in the file `UgSktExtrusionCut.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create an extruded cut with two-sided thru-all depth.

### Example 3: To Create an Extruded Thin Cut

The sample code in the file `UgSktExtrusionCut.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create an extruded thin cut. Its depth is two-sided, up to a selected reference.

### Example 4: To Create an Extruded Datum Surface Feature

The sample code in the file `UgSktExtrusionSurfaceCapped.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create an extruded datum surface feature. Its depth is one-side blind.

### Example 5: To Create a Surface Trim Extruded Feature

The sample code in the file `UgSktExtrusionSurfaceTrim.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create an extruded surface trim. Its depth is one-side blind.

---

## Direct Creation Approach

The sample code in the file `UgSktExtrusionCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create an extruded protrusion by the direct approach for sketched features introduced in Pro/ENGINEER Wildfire. The user is prompted to select a sketched datum curve feature that is used as a section for the created protrusion.

## The Element Tree for Revolved Features

The element tree for revolved features is documented in the header file `ProRevolve.h`, and has a fairly simple structure. It shows that, apart from the usual elements for the tree root and feature name, a revolved feature tree contains the elements to make the feature a solid protrusion, a thin protrusion, a solid cut, a thin cut, a surface, a surface trimmed feature, or a thin surface trimmed feature.

You can use Intent Datums such as Intent Axis, Intent Plane, and Intent Point for placement references.

The following figure shows the element tree for revolved features.

## Element Tree for Revolved Feature

|                                  |
|----------------------------------|
| PRO_E_FEATURE_TREE               |
| --PRO_E_STD_FEATURE_NAME         |
| --PRO_E_EXT_SURF_CUT_SOLID_TYPE  |
| --PRO_E_REMOVE_MATERIAL          |
| --PRO_E_BODY                     |
| --PRO_E_FEATURE_FORM             |
| --PRO_E_STD_SECTION              |
| --PRO_E_FEAT_FORM_IS_THIN        |
| --PRO_E_STD_MATRLSIDE            |
| --PRO_E_THICKNESS                |
| --PRO_E_SRF_END_ATTRIBUTES       |
| --PRO_E_TRIM_QLT_SIDE            |
| --PRO_E_TRIM_QUILT               |
| --PRO_E_STD_DIRECTION            |
| --PRO_E_REVOLVE_AXIS             |
| --PRO_E_REVOLVE_AXIS_OPT         |
| --PRO_E_REV_ANGLE                |
| --PRO_E_STD_SMT_THICKNESS        |
| --PRO_E_STD_SMT_SWAP_DRV_SIDE    |
| --PRO_E_SMT_WALL_SHARPS_TO_BENDS |
| --PRO_E_SMT_FILLETS              |
| --PRO_E_SMT_DEV_LEN_CALCULATION  |
| --PRO_E_SMT_MERGE_DATA           |
| --PRO_E_FEAT_THIN                |

The elements are assigned values depending on the type of revolved feature you want to create.

The following table lists the common elements for all types of revolved features and their permissible values:

| Element ID                    | Value                                                                                                                                                                     |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| PRO_E_STD_FEATURE_NAME    | Default given by application depending on the feature type. Can be modified by the user.                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_FEAT_THIN           | Compound element. It specifies how to close a thin feature when one or more surfaces can be used to cap, that is, close the feature and attach it to solid geometry. Here the sketch is an open sketch.                                                                                                                                                                                                                       |
| PRO_E_FEAT_THIN_STRT      | Compound element. It specifies the options for the first end point of the thin feature.                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_FEAT_THIN_STRT_OPT  | Specifies how to cap the first end point of the thin feature using the enumerated data type ProFeatThinOpt. The valid values are: <ul style="list-style-type: none"> <li>• PRO_FEAT_THIN_IGNORE—Caps the feature as a free end. When you specify this value, the feature is created with a free end even if a reference edge or surface is available to cap the feature.</li> <li>• PRO_FEAT_THIN_DEFAULT—Caps the</li> </ul> |

| Element ID               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | feature to the specified edge or surface.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| PRO_E_FEAT_THIN_STRT_REF | Specifies the edge or surface that must be used to cap and attach the first end point to the solid geometry.                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_FEAT_THIN_END      | Compound element. It specifies the options for the second end point of the thin feature.                                                                                                                                                                                                                                                                                                                                                                                           |
| PRO_E_FEAT_THIN_END_OPT  | Specifies how to cap the second end point of the thin feature using the enumerated data type <code>ProFeatThinOpt</code> . The valid values are: <ul style="list-style-type: none"> <li>PRO_FEAT_THIN_IGNORE—Caps the feature as a free end. When you specify this value, the feature is created with a free end even if a reference edge or surface is available to cap the feature.</li> <li>PRO_FEAT_THIN_DEFAULT—Caps the feature to the specified edge or surface.</li> </ul> |
| PRO_E_FEAT_THIN_END_REF  | Specifies the edge or surface that must be used to cap and attach the second end point to the solid geometry.                                                                                                                                                                                                                                                                                                                                                                      |

Elements identified with ‘\*’ depend on the definition of the standard section. These elements may not be assigned values until the standard section has been completely allocated (which typically happens during redefine of the feature). Values assigned to these elements while the section is not complete are ignored.

The following table lists the angle types for revolved features along with possible valid references:

| Angle Type             | Valid Reference Types                                                                     |
|------------------------|-------------------------------------------------------------------------------------------|
| PRO_REV_ANGLE_TO_REF   | PRO_POINT, PRO_EDGE_START, PRO_EDGE_END, PRO_CRV_START, PRO_CRV_END, PRO_SURFACE (Plane). |
| PRO_REV_ANGLE_FROM_REF | PRO_POINT, PRO_EDGE_START, PRO_EDGE_END, PRO_CRV_START, PRO_CRV_END, PRO_SURFACE (Plane). |

The following table lists the elements needed to create revolved features, in addition to those already discussed:

| Feature Type | Element ID     | Comment                                                                                                                                                                                                  |
|--------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Solid        | PRO_E_BODY     | Compound element                                                                                                                                                                                         |
|              | PRO_E_BODY_USE | Mandatory. Specifies the body to add geometry to.<br><br>The valid values are: <ul style="list-style-type: none"> <li>PRO_BODY_USE_NEW—The geometry in the feature is stored in the new body.</li> </ul> |

| Feature Type | Element ID              | Comment                                                                                                                                                                                                                                                                                                                           |
|--------------|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              |                         | <ul style="list-style-type: none"> <li>PRO_BODY_USE_SELECTED—The geometry in the feature is stored in the single selected body.</li> </ul>                                                                                                                                                                                        |
|              | PRO_E_BODY_SELECTED     | <p>Specifies the reference to the selected body.</p> <p>Mandatory if PRO_E_BODY_USE is set to PRO_BODY_USE_SELECTED</p> <p> <b>Note</b></p> <p>Only single reference is allowed.</p>                                                             |
| Thin         | PRO_E_STD_MATRLSIDE     | <p>Mandatory</p> <p>Of type ProRevMatlSide</p>                                                                                                                                                                                                                                                                                    |
|              | PRO_E_BODY              | Compound element                                                                                                                                                                                                                                                                                                                  |
|              | PRO_E_BODY_USE          | Same as Solid                                                                                                                                                                                                                                                                                                                     |

## Examples: Creating Revolved Features

The following examples demonstrate creation of revolved features of various forms. These examples are adapted from an example template file `UgSktRevolveTemplate.c` available on the Creo Parametric loadpoint under `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat`.

### Example 6: To Create a Revolved Protrusion

The sample code in the file `UgSktRevolveProtrusion.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a revolved protrusion feature with symmetric depth.

### Example 7: To Create a Revolved Thin Cut

The sample code in the file `UserSktRevolveThinCut.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a revolved thin cut, with independent angular dimensions for both sides.

### Example 8: To Create a Revolved Surface

The sample code in the file `UgSktRevolveSurface.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a revolved surface. It includes all possible element assignments. By following the instructions for the feature you want to create, it is possible to remove element settings not appropriate for your use.

## The Element Tree for First Features

First features (extrude and revolve solids created as the first feature in a part) require a subset of the standard element tree and some special handling for the section pointer.

The following table lists the elements applicable to first feature creation (extrude or revolve):

| Element ID              | Value                                                                                                                                                                                                                                                                                                       |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE      | Feature type: PRO_FEAT_FIRST                                                                                                                                                                                                                                                                                |
| PRO_E_FEATURE_FORM      | PRO_EXTRUDE / PRO_REVOLVE                                                                                                                                                                                                                                                                                   |
| PRO_E_FEAT_FORM_IS_THIN | Feature Form<br><br>Of Type ProRevFeatForm<br><br>= PRO_REV_FEAT_FORM_NO_THIN for a Solid feature<br>= PRO_REV_FEAT_FORM_THIN for a Thin feature                                                                                                                                                            |
| PRO_E_BODY_USE          | Mandatory. Specifies the body to add geometry to.<br><br>The valid values are: <ul style="list-style-type: none"><li>• PRO_BODY_USE_NEW—The geometry in the feature is stored in the new body.</li><li>• PRO_BODY_USE_SELECTED—The geometry in the feature is stored in the single selected body.</li></ul> |
| PRO_E_BODY_SELECT       | Specifies the reference to the selected body.                                                                                                                                                                                                                                                               |

| Element ID               | Value                                                                                                                                                                                             |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | Mandatory if PRO_E_BODY_USE is set to PRO_BODY_USE_SELECTED<br> <b>Note</b><br>Only single reference is allowed. |
| PRO_E_SKETCHER           | Sketcher pointer. Used because the standard section requires selected references not available in an empty model.                                                                                 |
| PRO_E_STD_MATRLSIDE*     | Mandatory if thin<br>Of type ProExtMatlSide (Extrude)<br>Of type ProRevMatlSide (Revolve)                                                                                                         |
| PRO_E_THICKNESS          | Mandatory $\geq 0.0$ if thin<br>Of type PRO_VALUE_TYPE_DOUBLE                                                                                                                                     |
| PRO_E_EXT_DEPTH_FROM     | Compound Element (Extrude only)                                                                                                                                                                   |
| PRO_E_EXT_DEPTH_FROM_VAL | Depth dimension (of type PRO_VALUE_TYPE_DOUBLE) (Extrude only)                                                                                                                                    |
| PRO_E_REV_ANGLE_FROM     | Compound Element (Revolve only)                                                                                                                                                                   |
| PRO_E_REV_ANGLE_FROM_VAL | Angular dimension (of type PRO_VALUE_TYPE_DOUBLE)<br>(Revolve only)                                                                                                                               |
| PRO_E_STD_FEATURE_NAME   | Default given by application depending on the feature type. Can be modified by the user.                                                                                                          |

Elements identified with ‘\*’ depend on the definition of the standard section. These elements may not be assigned values until the standard section has been completely allocated (which typically happens during redefine of the feature). Values assigned to these elements while the section is not complete are ignored.

## Example 9: Creating the First Extruded Protrusion Feature by Conventional Approach

The sample code in the file `UgSktFirstFeatureCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create the first extruded protrusion using the approach for the sketched features.

The following example:

- Creates an incomplete feature using `ProFeatureCreate()`,
- Extracts the section from the element tree of the incomplete feature,
- Builds the section on the section handle obtained, and,
- Completes the feature using `ProFeatureRedefine()`.

Following is the change in the approach for Pro/ENGINEER Wildfire release:

1. Level of PRO\_E\_SKETCHER in an element tree is changed.

For any Pro/ENGINEER release previous to Wildfire:

PRO\_E\_FEATURE\_TREE -> PRO\_E\_STD\_SECTION -> PRO\_E\_SKETCHER

For Pro/ENGINEER Wildfire release:

PRO\_E\_FEATURE\_TREE -> PRO\_E\_SKETCHER

2. Value of PRO\_E\_SKETCHER—A new ProValue is to be allocated and then assigned to the element (rather than the old approach of reusing the value extracted from the element tree).

## Example 10: Creating the First Thin Revolve Protrusion Feature by Conventional Approach

The sample code in the file `UgSktFirstFeatureRevCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a thin first revolve Protrusion using the approach for sketched features.

The following example:

- Creates an incomplete feature using `ProFeatureCreate()`,
- Extracts the section from the element tree of the incomplete feature,
- Builds the section on the section handle obtained, and,
- Completes the feature using `ProFeatureRedefine()`.

Following is the change in the approach for Pro/ENGINEER Wildfire release:

1. Level of PRO\_E\_SKETCHER in an element tree is changed.

For any Pro/ENGINEER release previous to Wildfire:

PRO\_E\_FEATURE\_TREE -> PRO\_E\_STD\_SECTION -> PRO\_E\_SKETCHER

For Pro/ENGINEER Wildfire release:

PRO\_E\_FEATURE\_TREE -> PRO\_E\_SKETCHER

2. Value of PRO\_E\_SKETCHER—A new ProValue is to be allocated and then assigned to the element (rather than the old approach of reusing the value extracted from the element tree).

# Element Trees: Ribs

## Element Trees: Ribs

This section describes how to use the include files `ProRib.h`, so that you can create ribs programmatically. As ribs are sketched features; we recommend you to read the sections [Element Trees: Principles of Feature Creation on page 771](#) and [Element Trees: Sketched Features on page 1002](#) before referring to this section.

## The Element Tree for Rib Features

The element tree for Rib features is documented in the Creo Parametric header file `ProRib.h`.

The following figure shows the element tree for rib features.

### The Element Tree for Rib Feature

```
PRO_E_FEATURE_TREE
|
|--PRO_E_FEATURE_TYPE
|
|--PRO_E_FEATURE_FORM
|
|-- PRO_E_STD_FEATURE_NAME
|
|--PRO_E_BODY
|
|-- PRO_E_RIB_SECTION_COMP
|
|-- PRO_E_RIB_THICKNESS
|
|-- PRO_E_RIB_SIDE_OPTS
```

The following table lists the data types for rib feature and their permissible values:

| Element ID             | Data Type              | Description                                                                                             |
|------------------------|------------------------|---------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE     | PRO_VALUE_TYPE_INT     | Feature type: PRO_FEAT_RIB                                                                              |
| PRO_E_FEATURE_FORM     | PRO_VALUE_TYPE_INT     | Mandatory= PRO_EXTRUDE                                                                                  |
| PRO_E_STD_FEATURE_NAME | PRO_VALUE_TYPE_WSTRING | Name of the rib feature. The default value is RIB.                                                      |
| PRO_E_BODY             | Compound               | Compound element that holds Body options. For more information, refer to the <code>ProBodyOpts.h</code> |

| Element ID             | Data Type                | Description                                                                                                                                                                               |
|------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        |                          | element tree.                                                                                                                                                                             |
| PRO_E_BODY_USE         | PRO_VALUE_TYPE_INT       | Holds Body use options. The valid value is PRO_BODY_USE_SELECTED.                                                                                                                         |
| PRO_E_BODY_SELECT      | PRO_VALUE_TYPE_SELECTION | Specifies the reference to the selected body.<br><br> <b>Note</b><br>Only single reference is allowed. |
| PRO_E_RIB_SECTION_COMP | Compound Element         | Holds section related elements.                                                                                                                                                           |
| PRO_E_RIB_THICKNESS    | PRO_VALUE_TYPE_DOUBLE    | Thickness of the rib. The value of the thickness should be positive and bigger than zero. The default value depends on part epsilon.                                                      |
| PRO_E_STD_SECTION      | PRO_VALUE_TYPE_INT       | Compound Element                                                                                                                                                                          |

| Element ID          | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_STD_MATRLSIDE | PRO_VALUE_TYPE_INT | <p>Material side options of the rib:</p> <ul style="list-style-type: none"> <li>PRO_RIB_SEC_SIDE_ONE—Rib will be on side one of the section</li> <li>PRO_RIB_SEC_SIDE_TWO—Rib will be on side two of the section</li> </ul> <p> <b>Note</b></p> <p>The element PRO_E_STD_MATRLSIDE is directly dependent upon the presence of a fully defined PRO_E_STD_SECTION element tree. Any value assigned to this element before fully defining the PRO_E_STD_SECTION, will be ignored. The default value depends on the sketch under the PRO_E_STD_SECTION element.</p> |
| PRO_E_RIB_SIDE_OPTS | PRO_VALUE_TYPE_INT | <p>Side options of the rib:</p> <ul style="list-style-type: none"> <li>PRO_RIB_SYMMETRIC— Rib will be symmetric to the sketch. This is the default value.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Element ID | Data Type | Description                                                                                                                                                                |
|------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            |           | <p>PRO_RIB_SIDE_ONE—Rib will be on Side One of the sketch.</p> <ul style="list-style-type: none"> <li>• PRO_RIB_SIDE_TWO—Rib will be on Side Two of the sketch.</li> </ul> |

## Element Trees: Sweep

### Sweeps in Creo Toolkit

This section describes the principles of creating a sweep feature. The sections [Element Trees: Principles of Feature Creation on page 771](#) and [Element Trees: Sketched Features on page 1002](#) provide the necessary background for this topic. Read those sections before this one.

Creo Parametric provides access and creates a constant section sweep feature. You can create a solid or surface feature. You can also add or remove material while sweeping a section along one or more selected trajectories by controlling the section's orientation, rotation, and geometry.

### Sweep Feature

The element tree for the sweep feature is documented in the header file `ProSweep.h`, and is shown in the following figure.

## Element Tree for Sweep Feature

The following table describes the elements in the element tree for sweeps:

| Element ID             | Data Type          | Description                                                                                                                                                                                                             |
|------------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_FORM     | PRO_VALUE_TYPE_INT | Specifies the feature form. The valid value is PRO_SWEEP defined in the enumerated data type ProFeatFormType in ProFeatForm.h.                                                                                          |
| PRO_E_SWEEP_TYPE       | PRO_VALUE_TYPE_INT | Specifies the type of sweep. The valid value is PRO_SWEEP_TYPE_MULTI_TRAJ defined in the enumerated data type ProSweepType.                                                                                             |
| PRO_E_SWEEP_FRAME_COMP | Compound           | This compound element specifies the trajectories and orientation of the section plane. For more information on this element, refer to the section <a href="#">Element Tree for PRO_E_SWEEP_FRAME_COMP</a> on page 1039. |
| PRO_E_SWEEP_PROF_COMP  | Compound           | This compound element defines the sweep type and holds the sketch related elements for the sweep cross section.                                                                                                         |

| Element ID                   | Data Type              | Description                                                                                                                                                                                                                                                                         |
|------------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_SWP_SEC_TYPE           | PRO_VALUE_TYPE_INT     | Specifies the type of sweep. The valid value is PRO_SWEEP_CONST_SECTION defined in the enumerated data type ProSweepSecType.<br><br>The option specifies a constant section sweep.                                                                                                  |
| PRO_E_SWEEP_SECTION          | Compound               | This compound element contains the sketch for the sweep cross section.                                                                                                                                                                                                              |
| PRO_E_SKETCHER               | PRO_VALUE_TYPE_POINTER | Specifies a sketcher pointer. The user defined sketch can be directly retrieved from this element.                                                                                                                                                                                  |
| PRO_E_SWP_ATTR               | Compound               | This compound element defines the sweep attributes. The element is available only for surface sweeps.                                                                                                                                                                               |
| PRO_E_END_SRF_ATTR           | PRO_VALUE_TYPE_INT     | Specifies the option to keep the end of sweep feature open or capped. The enumerated data type ProSweepEndSrfAttr contains the valid values for this element: <ul style="list-style-type: none"> <li>PRO_SWEEP_END_SRF_OPEN</li> <li>PRO_SWEEP_END_SRF_CAPPED</li> </ul>            |
| PRO_E_STD_FEATURE_NAME       | PRO_VALUE_TYPE_WSTRING | Specifies the name of the feature. The default value is SWEEP.                                                                                                                                                                                                                      |
| PRO_E_EXT_SRF_CUT_SOLID_TYPE | PRO_VALUE_TYPE_INT     | Specifies a solid or surface feature type. The enumerated data type ProSweepFeatType contains the following valid values for this element: <ul style="list-style-type: none"> <li>PRO_SWEEP_FEAT_TYPE_SOLID</li> <li>PRO_SWEEP_FEAT_TYPE_SURFACE</li> </ul>                         |
| PRO_E_REMOVE_MATERIAL        | PRO_VALUE_TYPE_INT     | Specifies whether to extrude or remove the material along the sweep. The enumerated data type ProSweepRemMaterial contains the following valid values for this element: <ul style="list-style-type: none"> <li>PRO_SWEEP_MATERIAL_ADD</li> <li>PRO_SWEEP_MATERIAL_REMOVE</li> </ul> |
| PRO_E_FEAT_FORM_IS_THIN      | PRO_VALUE_TYPE_INT     | Specifies whether to create a thin section. The enumerated data type ProSweepFeatForm contains                                                                                                                                                                                      |

| Element ID          | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     |                          | <p>the following valid values for this element:</p> <ul style="list-style-type: none"> <li>PRO_SWEEP_FEAT_FORM_NO_THIN</li> <li>PRO_SWEEP_FEAT_FORM_THIN</li> </ul>                                                                                                                                                                                                                                                                   |
| PRO_E_STD_MATRLSIDE | PRO_VALUE_TYPE_INT       | <p>Specifies the direction in which material will be added with respect to the sketch. This element is mandatory for all cuts and thin features. The enumerated data type <code>ProSweepMatlSide</code> contains the following valid values for this element:</p> <ul style="list-style-type: none"> <li>PRO_SWEEP_MATERIAL_SIDE_ONE</li> <li>PRO_SWEEP_MATERIAL_SIDE_TWO</li> <li>PRO_SWEEP_MATERIAL_BOTH_SIDES</li> </ul>           |
| PRO_E_THICKNESS     | PRO_VALUE_TYPE_DOUBLE    | Specifies the thickness for the thin feature. This element is mandatory for thin features.                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_TRIM_QUILT    | PRO_VALUE_TYPE_SELECTION | Specifies the selection of quilt to be trimmed.                                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_TRIM_QLT_SIDE | PRO_VALUE_TYPE_INT       | <p>Specifies the side of the quilt to be trimmed. This element is relevant when the element <code>PRO_E_STD_MATRLSIDE</code> has its value as <code>PRO_SWEEP_MATERIAL_BOTH_SIDES</code>.</p> <p>The enumerated data type <code>ProSweepTrimQltSide</code> contains the following valid values for this element:</p> <ul style="list-style-type: none"> <li>PRO_SWEEP_TRIMQLT_SIDE_ONE</li> <li>PRO_SWEEP_TRIMQLT_SIDE_TWO</li> </ul> |
| PRO_E_BODY          | Compound element         | Compound element for body options.                                                                                                                                                                                                                                                                                                                                                                                                    |

| Element ID        | Data Type                | Description                                                                                                                                                                                                                                                                                                                                       |
|-------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_BODY_USE    | PRO_VALUE_TYPE_INT       | <p>Mandatory. Specifies the body to add geometry to.</p> <p>Defined by the enumerated data type ProBodyUseOpts and the valid values follow:</p> <ul style="list-style-type: none"> <li>PRO_BODY_USE_NEW—Feature stores its geometry in the new body.</li> <li>PRO_BODY_USE_SELECTED—Feature adds its geometry to single selected body.</li> </ul> |
| PRO_E_BODY_SELECT | PRO_VALUE_TYPE_SELECTION | <p>Specifies the reference to the selected bodies.</p> <p>Mandatory if PRO_E_BODY_USE is set to PRO_BODY_USE_SELECTED.</p>                                                                                                                                                                                                                        |

For elements specific to sheetmetal, refer to the section [Production Applications: Sheetmetal on page 1307](#).

## Element Tree for PRO\_E\_SWEEP\_FRAME\_COMP

The element PRO\_E\_SWEEP\_FRAME\_COMP is a compound element, which defines the sweep type and holds the sketch related elements for the sweep cross section. The element tree for PRO\_E\_SWEEP\_FRAME\_COMP is as shown in the figure below:

```

|---PRO_E_SWEEP_FRAME_COMP

The following table describes the sub elements of the PRO\_E\_SWEEP\_FRAME\_COMP:

| Element ID           | Data Type          | Description                                                                                                                                       |
|----------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FRM_OPT_TRAJ   | Array              | Specifies an array of single trajectory that is only one element.                                                                                 |
| PRO_E_OPT_TRAJ       | Compound           | This compound element specifies the trajectory.                                                                                                   |
| PRO_E_STD_SEC_METHOD | PRO_VALUE_TYPE_INT | Specifies that the trajectory is selected. The valid value is PRO_SEC_SELECT defined in the enumerated data type ProSecMethod in ProStdSection.h. |
| PRO_E_STD_SEC_SELECT | Compound           | This compound element specifies the collection of trajectory.                                                                                     |
| PRO_E_STD_CURVE_     | PRO_VALUE_TYPE_    | Specifies the collection of curves                                                                                                                |

| Element ID               | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| COLLECTION_APPL          | SELECTION          | and edge chains for the trajectory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_FRAME_SETUP        | Compound           | This compound element specifies the orientation of the section plane.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_FRM_NORMAL         | PRO_VALUE_TYPE_INT | Specifies the orientation of the section plane normal. The enumerated data type <code>ProFrameNormal</code> contains the valid values for this element: <ul style="list-style-type: none"> <li>PRO_FRAME_NORM_ORIGIN—The section plane normal is perpendicular to the origin trajectory throughout the sweep.</li> <li>PRO_FRAME_PIVOT_DIR—The z-axis is tangent to the projection of the origin trajectory at the direction specified in the element <code>PRO_E_FRM_PIVOT_DIR</code>.</li> <li>PRO_FRAME_CONST_Z_DIR—The section plane remains parallel to the specified direction reference vector.</li> </ul> |
| PRO_E_FRM_PIVOT_DIR      | Compound           | This compound element for the direction reference is relevant when the element <code>PRO_E_FRM_NORMAL</code> has its value as <code>PRO_FRAME_PIVOT_DIR</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| PRO_E_DIRECTION_COMPOUND | Compound           | This compound element specifies the direction reference for <code>PRO_E_FRM_PIVOT_DIR</code> . The compound element is a standard Creo Parametric element subtree and is described in <code>ProDirection.h</code> .                                                                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_FRM_CONST_Z        | Compound           | This compound element for the direction reference is relevant when the element <code>PRO_E_FRM_NORMAL</code> has its value as <code>PRO_FRAME_CONST_Z_DIR</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| PRO_E_DIRECTION_COMPOUND | Compound           | This compound element specifies the direction reference for <code>PRO_FRAME_CONST_Z_DIR</code> . The compound element is a standard Creo Parametric element subtree and is described in <code>ProDirection.h</code> .                                                                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_FRM_ORIENT         | PRO_VALUE_TYPE_INT | Specifies how the rotation of the frame around the sketch plane's normal is oriented along the                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Element ID                              | Data Type                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                         |                                 | <p>sweep. The enumerated data type <code>ProFrameOrient</code> contains the valid vales for this element:</p> <ul style="list-style-type: none"> <li><code>PRO_FRAME_MIN</code>—Corresponds to the <b>Automatic</b> option in Creo Parametric user interface. The direction of the x-vector is calculated so that the swept geometry is minimally twisted.</li> <li><code>PRO_FRAME_NORM_SURF</code>—Orients the y-axis of the section plane to be normal to the surface on which the origin trajectory lies.</li> <li><code>PRO_FRAME_CONSTANT</code>—This option must be set when the element <code>PRO_E_FRM_NORMAL</code> has its value as <code>PRO_FRAME_PIVOT_DIR</code>.</li> <li><code>PRO_FRAME_X_TRAJ</code>—This option is not supported as Creo Parametric supports only single trajectory in sweep feature.</li> </ul> |
| <code>PRO_E_FRM_NORM_SURF</code>        | Compound                        | This compound element for the edge chains is relevant when the element <code>PRO_E_FRM_ORIENT</code> has its value as <code>PRO_E_FRAME_NORM_SURF</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>PRO_E_SURF_CHAIN_CMPND</code>     | Compound                        | This compound element specifies the surface edge collection and the collection method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>PRO_E_SURF_CHAIN_METHOD</code>    | <code>PRO_VALUE_TYPE_INT</code> | <p>Specifies the collection method for the surface edges. The valid values for this element are:</p> <ul style="list-style-type: none"> <li><code>PRO_SURF_CHAIN_METHOD_DEFAULT1</code></li> <li><code>PRO_SURF_CHAIN_METHOD_DEFAULT2</code></li> </ul> <p> <b>Note</b></p> <p>Both the options are available only if the trajectory is a two-sided edge of a surface. In case of one-sided edge, only one option is available.</p>                                                                                                                                                                                                                                                                                                               |
| <code>PRO_E_SURF_CHAIN_REF_SURFS</code> | Array                           | Specifies an array of surface edges.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| PRO_E_SURF_CHAIN_REF     | PRO_VALUE_TYPE_SELECTION | Specifies the collection of two-sided edge of a surface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_FRM_NORM_SURF_SIDE | PRO_VALUE_TYPE_INT       | <p>This element is relevant when the element PRO_E_FRM_ORIENT has its value as PRO_E_FRAME_NORM_SURF.</p> <p>Specifies the normal surface direction. The enumerated data type ProFrmNormSrfSide contains the valid vales for this element:</p> <ul style="list-style-type: none"> <li>PRO_FRAME_NORM_SRF_SIDE_INSIDE</li> <li>PRO_FRAME_NORM_SRF_SIDE_OUTSIDE</li> </ul>                                                                                                                                                                                                                                                                                                               |
| PRO_E_FRM_USER_X         | PRO_VALUE_TYPE_INT       | <p>This element is relevant when the element PRO_E_FRM_ORIENT has its value as PRO_FRAME_MIN.</p> <p>Specifies if the direction of x-axis at start is automatically computed or is user defined. The enumerated data type ProFrameStartX contains the valid values for this element:</p> <ul style="list-style-type: none"> <li>PRO_FRAME_DEFAULT_START_X</li> <li>PRO_FRAME_USER_START_X</li> </ul> <p> <b>Note</b></p> <p>It is sometimes necessary to specify the x-axis direction, for example, for straight line trajectories or trajectories that have a straight segment at the start.</p> |

| Element ID               | Data Type | Description                                                                                                                                                                                |
|--------------------------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FRM_START_X        | Compound  | This compound element for the direction reference is relevant when the element PRO_E_FRM_USER_X has its value as PRO_FRAME_USER_START_X.                                                   |
| PRO_E_DIRECTION_COMPOUND | Compound  | This compound element specifies the direction reference for PRO_FRAME_USER_START_X. The compound element is a standard Creo Parametric element subtree and is described in ProDirection.h. |

## Creating a Sweep Feature

### To Create a Sweep Feature

1. Create an incomplete feature without the PRO\_E\_SKETCHER element.
2. Call `ProFeatureElemtreeExtract()` with the feature handle to get the new feature tree. This results in an initialized PRO\_E\_SKETCHER element and sketch handle.
3. Create the section with the initialized sketch handle.
4. Call `ProFeatureWithoptionsRedefine()` to put the section in the Creo Parametric database to complete the sweep feature.

#### Note

If these elements PRO\_E\_FRAME\_SETUP and PRO\_E\_FRM\_ORIENT are not defined, you have to redefine the feature twice to get the valid initiated sketch handle.

### Example 1: Creating a Sweep Feature

The sample code in `UgCreoSweepCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a sweep feature.

## Simple Sweep Feature

The simple sweep element tree documented in the header file `ProSweep.h` is obsolete. Use the sweep element tree instead to create and access the SWEEP feature.

---

The element tree for the simple sweep feature is shown in the following figure.

### Element Tree for Simple Sweep Feature

The following table describes the elements in the element tree for simple sweeps:

| Element ID                       | Data Type                       | Description                                          |
|----------------------------------|---------------------------------|------------------------------------------------------|
| <code>PRO_E_FEATURE_TYPE</code>  | <code>PRO_VALUE_TYPE_INT</code> | Feature type                                         |
| <code>PRO_E_FEATURE_FORM</code>  | <code>PRO_VALUE_TYPE_INT</code> | Feature form ( <code>PRO_SWEEP</code> )              |
| <code>PRO_E_SWEEP_SPINE</code>   | Compound                        | Trajectory (like ( <code>PRO_E_STD_SECTION</code> )) |
| <code>PRO_E_SWEEP_SECTION</code> | Compound                        | Section (like <code>PRO_E_STD_SECTION</code> )       |

The element tree definitions of `PRO_E_SWEEP_SPINE` and `PRO_E_SWEEP_SECTION` take on the same form as the element `PRO_E_STD_SECTION` (documented in the header file `ProStdSection.h`).

---

#### Note

Release 20 of Pro/TOOLKIT supports only sketched, constant cross-sectional sweeps.

---

The following figure shows the valid elements within this subtree.

## Element Subtree for Simple Sweep

Swept, constant, cross-sectional feature forms are supported for the following feature types:

- `PRO_FEAT_FIRST_FEAT`
- `PRO_FEAT_PROTRUSION`
- `PRO_FEAT_CUT`
- `PRO_FEAT_DATUM_SURF`

## Creating a Simple Sweep Feature

To Create a Simple Sweep Feature

1. Create an incomplete feature with the `PRO_E_FEATURE_TYPE` and `PRO_E_FEATURE_FORM` elements defined. Also define the compound elements `PRO_E_SWEEP_SPINE` and `PRO_E_SWEEP_SECTION`, down to the `PRO_E_STD_SEC_METHOD` element (see the subtree for details).
2. Call `ProFeatureElemtreeExtract()` with the feature handle to get the new feature tree. This results in an initialized `PRO_E_SWEEP_SPINE` subtree and sketch handle.
3. Create the spine section with the initialized sketch handle.
4. Call `ProFeatureWithoptionsRedefine()` as an incomplete feature to put the spine section in the Creo Parametric database.

- 
5. Call `ProFeatureElemtreeExtract()` to get the new feature tree. This results in an initialized `PRO_E_SWEEP_SECTION` subtree and sketch handle. This step is necessary because the sweep section is dependent on the spine section.
  6. Create the sweep section with the initialized sketch handle. This section automatically contains the centerline cross hairs of the sweep section.  
The cross hairs can be used to locate and dimension the section.
  7. Call `ProFeatureWithoptionsRedefine()` with any option except incomplete to complete the simple sweep feature.

#### Example 1: Creating a Simple Sweep First Feature Protrusion

The sample code in `UgSweepCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a simple sweep first feature protrusion using the Creo Parametric functions.

#### Example 2: Creating a Simple Sweep Protrusion Feature by Conventional Approach

The sample code in `Ug3DSweepCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a simple sweep protrusion feature by the conventional approach for the sketched features.

The user is prompted to select the following:

- Sketching plane
- Orientation plane
- Orthogonal edge for the dimensioning of the spine (trajectory - `PRO_E_SWEEP_SPINE`) section
- Orthogonal edge for the sweep section (`PRO_E_SWEEP_SECTION`)

## Element Tree: Boundary Blend

### Overview about Boundary Blend

This section introduces and shows how to create, redefine and access boundary blend feature in Creo TOOLKIT.

Use the Boundary Blend tool to create a surface with boundary blend geometry. Create or reference an entity to define the surface in one or two directions. The first and last entity in each direction defines the surface boundaries. You can define more fully the shape of the boundary blend geometry by adding more reference entities.

## The Element Tree for Boundary Blend Feature

The element tree for boundary blend feature is documented in the header file `Probb1.h`.

The following figure shows the element tree for boundary blend feature.

### The Element Tree for Boundary Blend Feature

The following table lists the data types for boundary blend feature and their permissible values:

| Element ID         | Data Type          | Description                                                                    |
|--------------------|--------------------|--------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE | PRO_VALUE_TYPE_INT | Mandatory. Specifies the feature type. The valid value is PRO_FEAT_DATUM_SURF. |
| PRO_E_FEATURE_FORM | PRO_VALUE_TYPE_INT | Mandatory. Specifies the feature form. The valid value is PRO_USE_SURFS.       |
| PRO_E_DTM_SRF_     | PRO_VALUE_TYPE_    | Mandatory. Specifies the                                                       |

| Element ID                      | Data Type                | Description                                                                                                                                                                                                                             |
|---------------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TYPE                            | INT                      | datum surface type. The valid value is PRO_E_DTM_SRF_TYPE_BND_BLEND.                                                                                                                                                                    |
| PRO_E_BNBLN_CURVES              | PRO_ELEM_TYPE_COMPOUND   | Mandatory                                                                                                                                                                                                                               |
| PRO_E_BNBLN_1DIR                | PRO_ELEM_TYPE_COMPOUND   | Mandatory<br>Boundary Blend curves in first direction.<br> <b>Note</b><br>Specify at least 2 curves. Not required if PRO_E_BNBLN_2DIR is defined.    |
| PRO_E_BNBLN_2DIR                | PRO_ELEM_TYPE_COMPOUND   | Mandatory<br>Boundary Blend curves in second direction.<br> <b>Note</b><br>Specify at least 2 curves. Not required if PRO_E_BNBLN_1DIR is defined. |
| PRO_E_BNBLN_DIR_CURVES          | PRO_ELEM_TYPE_ARRAY      | Mandatory<br>Array of chain holders.                                                                                                                                                                                                    |
| PRO_E_STD_CHAIN_HOLDER          | PRO_ELEM_TYPE_COMPOUND   | Mandatory                                                                                                                                                                                                                               |
| PRO_E_STD_CURVE_COLLECTION_APPL | PRO_VALUE_TYPE_SELECTION | Mandatory<br>Curves to pass through. Curve can be composite.                                                                                                                                                                            |
| PRO_E_BBL_ADD_CLOSED            | PRO_VALUE_TYPE_INT       | Closes the surface in first or second direction.<br><br>Default value is PRO_B_FALSE. PRO_B_TRUE is applicable if there are at least 3 curves                                                                                           |

| Element ID                    | Data Type              | Description                                                                                                                                                 |
|-------------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_STD_FEATURE_NAME        | PRO_VALUE_TYPE_WSTRING | Specifies the feature name. The default name is given by the application depending on the feature type. You can modify the feature name as per requirement. |
| PRO_E_EXT_SURF_CUT_SOLID_TYPE | PRO_VALUE_TYPE_INT     | Mandatory<br>Valid value is PRO_FEAT_DATUM_SURF.                                                                                                            |

## Element Trees: Solid Body

### Introduction

This section describes the element tree structure for body options that can be selected while creating a feature. You can perform geometric operations such as splitting a body or merging with other bodies and boolean operations such as merge, intersect, and subtract.

The following sections describe the procedure for performing Boolean operations such as intersect, subtract, and, merge bodies in a model. This section also describes how to copy, remove, and split bodies.

Using Creo TOOLKIT, you can create bodies. The creation and manipulation of bodies use the following Creo TOOLKIT objects:

- ProSolid
- ProSolidBody

### The Element Tree for Body Options

The element tree for Body options is documented in the Creo Parametric header file `ProBodyOpts.h`.

The following figure shows the element tree for body options feature.

## The Element Tree for Body Options Feature

The following table describes the elements in the element tree:

| Element ID        | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_BODY        | Compound element         | Compound element for body options.                                                                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_BODY_USE    | PRO_VALUE_TYPE_INT       | <p>Mandatory. Specifies the body to add geometry to.</p> <p>Defined by the enumerated data type ProBodyUseOpts and the valid values follow:</p> <ul style="list-style-type: none"> <li>PRO_BODY_USE_NEW—Feature stores its geometry in the new body.</li> <li>PRO_BODY_USE_ALL—Feature cuts from all existing bodies.</li> <li>PRO_BODY_USE_SELECTED—Feature adds or removes its geometry to or from selected bodies.</li> </ul> |
| PRO_E_BODY_SELECT | PRO_VALUE_TYPE_SELECTION | <p>Specifies the reference to the selected bodies.</p> <p>Mandatory if PRO_E_BODY_USE is set to PRO_BODY_USE_SELECTED.</p>                                                                                                                                                                                                                                                                                                       |

## The Element Tree for Body Copy Feature

You can perform copy operation on bodies. When you copy bodies in a part, a new body is created for each source body. The element tree for the body copy feature is documented in the Creo Parametric header file ProBodyCopy.h.

## The Element Tree for Body Copy Feature

The following figure shows the element tree for the body copy feature.

The following table describes the elements in the element tree:

| Element ID             | Data Type                | Description                                                                                                                                                                                                                                                                                                        |
|------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE     | PRO_VALUE_TYPE_INT       | Specifies the feature type. Valid value is PRO_FEAT_BODY_COPY.                                                                                                                                                                                                                                                     |
| PRO_E_STD_FEATURE_NAME | PRO_VALUE_TYPE_WSTRING   | Specifies the feature name.                                                                                                                                                                                                                                                                                        |
| PRO_E_BODY_COPY_REFS   | PRO_VALUE_TYPE_SELECTION | Mandatory. Specifies the bodies to copy. Only bodies from the same model are allowed.<br><br> <b>Note</b><br>Use the function ProElementReferencesSet(), if you need to set multiple reference values for PRO_E_BODY_COPY_REFS. |

## The Element Tree for Body Split Feature

You can split a body into two bodies. The geometry of the original body is divided between the original body and the new body. The element tree for the body split feature is documented in the Creo Parametric header file ProSplitbody.h.

### The Element Tree for Body Split Feature

The following figure shows the element tree for the split body feature.

```

PRO_E_FEATURE_TREE
|
|--PRO_E_FEATURE_TYPE
|
|--PRO_E_STD_FEATURE_NAME
|
|--PRO_E_SPLIT_BY_OPTION
|
|--PRO_E_SPLIT_BODY_TYPE
|
|--PRO_E_SPLIT_BODY
| |--PRO_E_SPLIT_TARGET_BODY
| |--PRO_E_SPLIT_BODY_REF
| |--PRO_E_SPLIT_BODY_SLICE_OPT
| |--PRO_E_SPLIT_TOOL_EXTEND_OPT
|
|--PRO_E_SPLIT_OUT
| |--PRO_E_SPLIT_VOL_SRFS

```

The following table describes the elements in the element tree:

| Element ID             | Data Type              | Description                                                                                                                                                                                                                                          |
|------------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_STD_FEATURE_NAME | PRO_VALUE_TYPE_WSTRING | Name of the feature.                                                                                                                                                                                                                                 |
| PRO_E_SPLIT_BY_OPTION  | PRO_VALUE_TYPE_INT     | Mandatory element.<br>Split by option.                                                                                                                                                                                                               |
| PRO_E_SPLIT_BODY_TYPE  | PRO_VALUE_TYPE_INT     | Split Operation. The element is defined by the enumerated data type ProSplitOptions and the valid values are: <ul style="list-style-type: none"> <li>PRO_SPLIT_BODY—Split the body into two bodies.</li> <li>PRO_TRIM_BODY—Trim the body.</li> </ul> |
| PRO_E_SPLIT_BODY       | Compound element       | Split by object.                                                                                                                                                                                                                                     |

| Element ID                  | Data Type                | Description               |
|-----------------------------|--------------------------|---------------------------|
| PRO_E_SPLIT_TARGET_BODY     | PRO_VALUE_TYPE_SELECTION | Target body to be split.  |
| PRO_E_SPLIT_BODY_REF        | PRO_VALUE_TYPE_SELECTION | Split by body reference.  |
| PRO_E_SPLIT_BODY_SLICE_OPT  | PRO_VALUE_TYPE_INT       | Split by slice direction. |
| PRO_E_SPLIT_TOOL_EXTEND_OPT | PRO_VALUE_TYPE_INT       | Split by extended object. |
| PRO_E_SPLIT_OUT             | Compound element         | Split by volume.          |
| PRO_E_SPLIT_VOL_SRFS        | PRO_VALUE_TYPE_SELECTION | Split by surfaces.        |

### Splitting by Object

You can split one body into two bodies using a plane, surface, or quilt as the splitting object. The following table lists the mandatory element types for splitting a body by object:

| Element ID                  | Data Type                                                                                 |
|-----------------------------|-------------------------------------------------------------------------------------------|
| PRO_E_SPLIT_BY_OPTION       | The valid value is PRO_SPLIT_BY_SPLITTING_OBJ of the enumerated data type ProSplitByType. |
| PRO_E_SPLIT_TARGET_BODY     | Target bodies to be split.                                                                |
| PRO_E_SPLIT_BODY_REF        | Split by body reference.                                                                  |
| PRO_E_SPLIT_BODY_SLICE_OPT  | Side 1 / Side 2 of the enumerated data type ProSplitBodySliceOpt.                         |
| PRO_E_SPLIT_TOOL_EXTEND_OPT | Extend option of the enumerated data type ProSplitBodyToolExtendOpt.                      |

### Splitting by Volume type

When the geometry of the original body has disjoint volumes, you can split out one or more of these volumes into a new body. Select one or more body surfaces to define that volume as a new body. The following table lists the mandatory element types for splitting a body by volume type:

| Element ID            | Data Type                                                                          |
|-----------------------|------------------------------------------------------------------------------------|
| PRO_E_SPLIT_BY_OPTION | The valid value is PRO_SPLIT_BY_VOLUME of the enumerated data type ProSplitByType. |
| PRO_E_SPLIT_VOL_SRFS  | Split by surfaces or surface regions.                                              |

---

A body can be divided into two bodies by an intersecting object or by volume. The enumerated data type `ProSplitByType` defines the way the body is split and has the following valid values:

- `PRO_SPLIT_BY_SPLITTING_OBJ`—A body can be split by an intersecting object.
- `PRO_SPLIT_BY_VOLUME`—A body that has more than one disjoint volume can be split by picking up the surface or surface regions of the desired portion to split out as a new body.

The splitting side of the body is defined by the enumerated data type `ProSplitBodySliceOpt`. When a single body is split, an additional body is created. The valid values follow:

- `PRO_E_SPLIT_BODY_SLICE_FIRST_OPT`—Side 1 is the default option and the value is 0.
- `PRO_E_SPLIT_BODY_SLICE_SECOND_OPT`—Flips the default body creation and creates a body in the other side.

The extend object is available for splitting by object and is defined by the enumerated data type `ProSplitBodyToolExtendOpt` and has the following valid values:

- `PRO_E_SPLIT_TOOL_EXTEND_OPT_NO`—The splitting object intersects the body graphically.
- `PRO_E_SPLIT_TOOL_EXTEND_OPT_YES`—The splitting object is extended to intersect with the bodies. The extend option is available for the geometrically extendable objects such as a plane.

## The Element Tree for Body Remove Feature

As part of multibody design, there could be bodies that you want to remove from the model. For example, you created bodies as tools in the design process and you do not need them in the final model, or the system created bodies when you imported geometry from other models. You cannot delete these bodies, because they have contributing features. In such cases, you can remove the bodies.

---

### Note

Bodies that are removed do not contribute to mass properties.

---

The element tree for the body remove feature is documented in the Creo Parametric header file `ProRemoveBody.h`. Using this element tree you can remove bodies in a model.

## The Element Tree for Body Remove Feature

The following figure shows the element tree for the body remove feature.

The following table describes the elements in the element tree:

| Element ID             | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                  |
|------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE     | PRO_VALUE_TYPE_INT       | Specifies the feature type. The valid value is PRO_FEAT_REMOVEBODY.                                                                                                                                                                                                                                                                                          |
| PRO_E_STD_FEATURE_NAME | PRO_VALUE_TYPE_WSTRING   | Specifies the feature name. Default value is Remove body.                                                                                                                                                                                                                                                                                                    |
| PRO_E_BODY_SELECT      | PRO_VALUE_TYPE_SELECTION | Mandatory. Specifies the references for the bodies that needs to be removed. The valid selection reference is from PRO_BODY type only.<br> <b>Note</b><br>Use the function ProElementReferencesSet(), if you need to set multiple reference values for PRO_E_BODY_SELECT. |

## The Element Tree for Boolean Body Operations

When a part contains more than one body, you can use the Boolean Operations feature to perform geometric operations such as **Merge**, **Intersect**, and **Subtract**.

The element tree for Boolean body operations is documented in the Creo Parametric header file ProBooleanBodies.h. You can perform subtract, merge, and intersect operations on bodies.

## The Element Tree for The Element Tree for Boolean Body Operation

The following figure shows the element tree for Boolean body operation.

The following table describes the elements in the element tree:

| Element ID             | Data Type              | Description                                                                                                                                                                                                             |
|------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE     | PRO_VALUE_TYPE_INT     | Specifies the feature type. The valid value is PRO_FEAT_BOOLEANBODIES.                                                                                                                                                  |
| PRO_E_STD_FEATURE_NAME | PRO_VALUE_TYPE_WSTRING | Specifies the feature name for combined Boolean body.<br><br>Default value depends on the operation type: <ul style="list-style-type: none"><li>• Body Merge</li><li>• Body Intersect</li><li>• Body Subtract</li></ul> |
| PRO_E_BOOLEAN_TYPE     | PRO_VALUE_TYPE_INT     | Specifies the Boolean operation type that needs to be performed on the bodies and is defined by the enumerated data type ProBooleanbodies TypeOption. The valid values are:                                             |

| Element ID        | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   |                          | <ul style="list-style-type: none"> <li>MERGE_BOOL_TYPE—Body Merge</li> <li>INTERSECT_BOOL_TYPE—Body Intersect</li> <li>SUBTRACT_BOOL_TYPE—Body Subtract</li> </ul>                                                                                                                                                                                                                                                                                                                              |
| PRO_E_TARGET_BODY | PRO_VALUE_TYPE_SELECTION | <p>Specifies the reference to the modified bodies.</p> <p>Mandatory element and can be filled with single body MERGE_BOOL_TYPE or INTERSECT_BOOL_TYPE or multiple bodies SUBTRACT_BOOL_TYPE.</p> <p>The valid selection reference is from PRO_BODY type only.</p> <p> <b>Note</b></p> <p>Use the function ProElementReferencesSet(), if you need to set multiple reference values for PRO_E_TARGET_BODY.</p> |
| PRO_E_TOOL_BODIES | PRO_VALUE_TYPE_SELECTION | <p>Specifies the reference to the modifying bodies.</p> <p>Mandatory element and can be filled with single body SUBTRACT_BOOL_TYPE or multiple bodies MERGE_BOOL_TYPE or INTERSECT_BOOL_TYPE.</p> <p>The valid selection reference is from PRO_BODY type only.</p>                                                                                                                                                                                                                              |

| Element ID               | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_KEEP_TOOLS         | PRO_VALUE_TYPE_INT | <p>This element type is available only for SUBTRACT_BOOL_TYPE Boolean body operation. It specifies the body options that need to be kept. This element type is defined by the enumerated data type ProBooleanbodiesKeepBodyOption and the valid values are:</p> <ul style="list-style-type: none"> <li>KEEP_TOOL_NO—default value. Deletes the modifying bodies.</li> <li>KEEP_TOOL_YES—keeps the modifying bodies.</li> </ul> |
| PRO_E_IS_SMT_CUT         | PRO_VALUE_TYPE_INT | <p>This element is applicable in sheetmetal parts only and it controls the cut type as follows:</p> <ul style="list-style-type: none"> <li>PRO_B_TRUE—SMT cut type</li> <li>PRO_B_FALSE—Solid cut type</li> </ul>                                                                                                                                                                                                              |

## Element Trees: Creo Flexible Modeling Features

### Element Trees: Creo Flexible Modeling Features

This section describes how to construct and access the element tree for some Creo Flexible Modeling features in Creo TOOLKIT. It also shows how to redefine, create and access the properties of these features.

### Move and Move-Copy Features

This section describes how to construct and access the element tree for Move and Move-Copy features. It also shows how to create, redefine, and access the properties of these features.

#### Introduction

The Move and the Move-Copy features allow a rigid transformation to a geometry selection or its copy. The surfaces within the geometry selection must belong either to the solid geometry or to a single quilt. You can move the following the geometry selection:

- Any surface collection within the solid geometry or a single quilt.
- An intent surface within the solid geometry or a single quilt.
- Regular or intent datums (planes, axes, points and coordinate systems).
- Regular or intent curves.
- Any combination of the above geometries.

When you create a move feature at assembly level, the following types of references can be moved:

- Geometry of assembly components—Part level geometry only, that is, surfaces, quilts, curves, datums
- Assembly components—Parts and subassemblies

The moved entities are copies of the original entities and will have new IDs. The original entities can be removed (Move) or kept (Copy-Move).

A Move feature will act on a single set of objects. To move different geometry selections, multiple move features must be created.

## The Element Tree for Move and Move-Copy

The element tree for the Move and Move-Copy feature is documented in the header file `ProFlexMove.h`, and is shown in the following figure:

### Element Tree for Move and Move-Copy

The following table describes the elements in the element tree for the Move and Move-Copy features:

| Element ID             | Data Type              | Description                                                                         |
|------------------------|------------------------|-------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE     | PRO_VALUE_TYPE_INT     | Specifies the type of feature.                                                      |
| PRO_E_STD_FEATURE_NAME | PRO_VALUE_TYPE_WSTRING | Specifies the name of the feature.<br>The default value is <code>Flex_Move</code> . |

| Element ID                    | Data Type                                                                                                                                                                                                                                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FLEXMOVE_MOVED_GEOMETRY | Compound                                                                                                                                                                                                                                                                  | Specifies the geometry to be moved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| PRO_E_FLEXMOVE_MOVED_COMPS    | PRO_ELEM_TYPE_MULTI_VALUE<br><br> <b>Note</b><br><br>The data type PRO_ELEM_TYPE_MULTI_VALUE enables you to assign multiple values to the element, though the data type is not an array. | Optional element. This element is available only when you create the move feature at the assembly level. Specifies the collection of component references, that is, parts and subassemblies in an assembly, which are moved by the assembly level move feature.                                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_FLEXMOVE_DEFINE_METHOD  | PRO_VALUE_TYPE_INT                                                                                                                                                                                                                                                        | Mandatory element. Specifies the method to be used to move the entities. It takes the following values: <ul style="list-style-type: none"> <li>• PRO_FLEXMOVE_DEF_METHOD_3D_DRAG—You can use the 3D transformation sets (in Creo Parametric interface using 3D Dragger) to define the flexible move feature.</li> <li>• PRO_FLEXMOVE_DEF_METHOD_DIMENSIONS—You can specify up to three constraining nonparallel linear dimensions or angular dimensions to define the flexible move feature.</li> <li>• PRO_FLEXMOVE_DEF_METHOD_CONSTRAINTS—You can specify component-like (assembly-like) constraints to define the flexible move feature.</li> </ul> |
| PRO_E_D3ELEM_SETS             | Array holder                                                                                                                                                                                                                                                              | Mandatory element when the definition method is PRO_FLEXMOVE_DEF_METHOD_3D_DRAG. An array holder of PRO_E_D3ELEM_SET elements. The elements for 3D transformation sets are defined in ProD3Elem.h.<br><br>For more information, see the <a href="#">section 3D Transformation Set Feature on page 1066</a> .                                                                                                                                                                                                                                                                                                                                           |
| PRO_E_FLEXMOVE_DIMS_COMPOUND  | Compound                                                                                                                                                                                                                                                                  | Mandatory element when the definition method is PRO_FLEXMOVE_DEF_METHOD_                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Element ID                | Data Type    | Description                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                           |              | DIMENSIONS. Specifies the dimension references and arrays for the dimension definition method.                                                                                                                                                                                                                                                                                                             |
| PRO_E_FLEX_OPTS_CMPND     | Compound     | <p>Mandatory element that contains the flexible modeling geometry attachment options to attach the moved surfaces. Specifies the integer and chain collection type elements. The elements related to reattachment of geometry in flexible modeling are defined in <code>ProFlxmdlOpts.h</code>.</p> <p>For more information, see the section <a href="#">Attachment Geometry Feature on page 1073</a>.</p> |
| PRO_E_FLXSLV_PROP_CONSTRS | Array        | <p>Optional element. Specifies an array that contains the tangency conditions and the reference geometry elements for tangency propagation.</p> <p>The elements related to propagation of tangency in flexible modeling are defined in <code>ProFlexTanPropOpts.h</code>. For more information, see the section <a href="#">Tangency Propagation on page 1089</a>.</p>                                     |
| PRO_E_COMPONENT_SETS      | Array holder | <p>Mandatory element when the definition method is <code>PRO_FLEXMOVE_DEF_METHOD_CONSTRAINTS</code>. Specifies the constraint sets. The elements for constraint sets are defined in <code>ProAsmcomp.h</code>. For more information, see the section <a href="#">Constraint Sets and Mechanism Connections on page 1149</a> of section <a href="#">Assembly: Assembling Components on page 1141</a>.</p>   |

| Element ID                      | Data Type                    | Description                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_COMPONENT_<br>CONSTRAINTS | Array holder                 | Mandatory element when the definition method is PRO_FLEXMOVE_DEF_METHOD_CONSTRAINTS. Specifies the constraints. The elements for constraints are defined in ProAsmcomp.h. For more information, see the section <a href="#">Placement Constraints on page 1153</a> of section <a href="#">Assembly: Assembling Components on page 1141</a> . |
| PRO_E_STD_FLEX_<br>PROPAGATION  | PRO_VALUE_TYPE_<br>SELECTION | Optional element. Specifies a pattern or mirror recognition feature to propagate the move feature changes.                                                                                                                                                                                                                                   |

## Moved Geometry

The feature PRO\_E\_FLEXMOVE\_MOVED\_GEOMETRY is a compound element that allows you to select the geometries to be moved and the geometries to be excluded.

### PRO\_E\_FLEXMOVE\_MOVED\_GEOMETRY

```

PRO_E_FLEXMOVE_MOVED_GEOMETRY
|
|-- PRO_E_STD_SURF_COLLECTION_APPL
|
|-- PRO_E_FLEXMOVE_EXCLUDED_GEOMETRY
| |

|
|-- PRO_E_FLEXMOVE_DTM_REF

```

The following table lists the contents of PRO\_E\_FLEXMOVE\_MOVED\_GEOMETRY element.

| Element ID                           | Data Type                    | Description                                                                                                                     |
|--------------------------------------|------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_STD_SURF_<br>COLLECTION_APPL   | PRO_VALUE_TYPE_<br>SELECTION | Mandatory element. Specifies the collection of surface sets of the geometries to be moved. It may also include surface regions. |
| PRO_E_FLEXMOVE_<br>EXCLUDED_GEOMETRY | Compound                     | Optional element to exclude surfaces.                                                                                           |

| Element ID                     | Data Type                                                                                                                                                                                                                                                                | Description                                                                                                                               |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_STD_SURF_COLLECTION_APPL | PRO_VALUE_TYPE_SELECTION                                                                                                                                                                                                                                                 | Optional element. Specifies the collection of surfaces from the move surfaces collector which should be excluded from the move operation. |
| PRO_E_FLEXMOVE_DTM_REF         | PRO_ELEM_TYPE_MULTI_VALUE<br><br> <b>Note</b><br><br>The data type PRO_ELEM_TYPE_MULTI_VALUE allows you to assign multiple values to the element, though the data type is not an array. | Optional element. Specifies the collection of datum entities that should be moved with the moved geometry.                                |

## Dimension Elements

The element PRO\_E\_FLEXMOVE\_DIMS\_COMPOUND is a compound element that allows you to specify the dimensions to move the geometries.

### PRO\_E\_FLEXMOVE\_DIMS\_COMPOUND

```

PRO_E_FLEXMOVE_DIMS_COMPOUND
|
|-- PRO_E_FLEXMOVE_DIMS_ARRAY
| |
| |-- PRO_E_FLEXMOVE_DIM_COMPOUND
| |
| |-- PRO_E_FLEXMOVE_DIM_TYPE
| |
| |-- PRO_E_FLEXMOVE_DIM_REFS
| |
| |-- PRO_E_FLEXMOVE_DIM_VALUE

```

The following table lists the contents of PRO\_E\_FLEXMOVE\_DIMS\_COMPOUND element. All the elements are mandatory for the PRO\_FLEXMOVE\_DEF\_METHOD\_DIMENSIONS definition method type.

| Element ID                  | Data Type    | Description                                                                                                                                                                  |
|-----------------------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FLEXMOVE_DIMS_ARRAY   | Array holder | Mandatory element. The dimensions array can contain up to three dimensions of PRO_FLEXMOVE_DIM_TYPE_LINEAR type or a single dimension of PRO_FLEXMOVE_DIM_TYPE_ANGULAR type. |
| PRO_E_FLEXMOVE_DIM_COMPOUND | Compound     | Mandatory element. Specifies the constraining dimensions to move                                                                                                             |

| Element ID               | Data Type                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                           | the geometries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| PRO_E_FLEXMOVE_DIM_REFS  | PRO_ELEM_TYPE_MULTI_VALUE | <p>Mandatory element. Specifies two references for the given dimension. Out of the two selected references one must belong to the moved geometry and the other must belong to the geometry that is not affected by the move operation.</p> <p>The valid values for reference selections are as follows:</p> <ul style="list-style-type: none"> <li>• Surface—SEL_3D_SRF</li> <li>• Line—SEL_3D_EDG, SEL_3D_CURVE, SEL_3D_AXIS</li> <li>• Points—SEL_3D_VERT, SEL_3D_PNT, SEL_CURVE_END</li> </ul> <p>The valid combinations for reference selections are as follows:</p> <ul style="list-style-type: none"> <li>• Surface-Surface</li> <li>• Surface-Line</li> <li>• Surface-Point</li> <li>• Line-Line</li> <li>• Line-Point</li> </ul> |
| PRO_E_FLEXMOVE_DIM_VALUE | PRO_VALUE_TYPE_DOUBLE     | <p>Mandatory element. Specifies the value of the linear or angular dimension.</p> <p>The valid values are as follows:</p> <ul style="list-style-type: none"> <li>• Linear Dimensions—[-1e6, 1e6]</li> <li>• Angular Dimensions—[0, 360]</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## 3D\_Transformation\_Set\_Feature

### Introduction

This section describes how to construct and access the element tree for 3D Transformation Set features. It also shows how to create, redefine, and access the properties of these features.

The D3 element tree branch is used by features that use the 3D transformation steps, for example in the `PRO_FEAT_FLEXMOVE` feature type. See `ProFlexMove.h`. The 3D transformation steps are usually defined using the 3D Dragger in the Creo Parametric user interface.

Refer to the Creo Parametric Part Modeling Help for more information on placement and orientation references, and Degrees of Freedom.

## The Element Tree for 3D Transformation Sets

The element tree for the 3D Transformation Set feature is documented in the header file `ProD3Elem.h`, and is shown in the following figure:

### Element Tree for 3D Transformation Sets

```

PRO_E_D3ELEM_SETS
|
|-- PRO_E_D3ELEM_SET
| |
| |-- PRO_E_D3ELEM_PLACEMENT_REFERENCE
| |
| |-- PRO_E_D3ELEM_ORIENTATION_REFERENCE
| |
| |-- PRO_E_D3ELEM_LOCATION
| |
| |-- PRO_E_D3ELEM_MOVES
| |
| |-- PRO_E_D3ELEM_MOVE
| |
| |-- PRO_E_D3ELEM_MOVE_TYPE
| |
| |-- PRO_E_D3ELEM_MOVE_VALUE

```

The following table describes the elements in the element tree for the 3D Transformation Set feature:

| Element ID                                    | Data Type                             | Description                                                                                                                                                                                                                                     |
|-----------------------------------------------|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>PRO_E_D3ELEM_SETS</code>                | Array holder                          | An array holder of <code>PRO_E_D3ELEM_SET</code> elements.                                                                                                                                                                                      |
| <code>PRO_E_D3ELEM_SET</code>                 | Compound                              | A compound element representing a single transformations set.                                                                                                                                                                                   |
| <code>PRO_E_D3ELEM_PLACEMENT_REFERENCE</code> | <code>PRO_VALUE_TYPE_SELECTION</code> | Optional element. Specifies the placement reference for the 3D transformation sets.<br><br>The valid values for placement reference selection are as follows: <ul style="list-style-type: none"> <li>Surface—<code>SEL_3D_SRF</code></li> </ul> |

| Element ID                         | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                    |                          | <ul style="list-style-type: none"> <li>Line—SEL_3D_EDG, SEL_3D_CURVE, SEL_3D_AXIS</li> <li>Points—SEL_3D_VERT, SEL_3D_PNT, SEL_CURVE_END</li> <li>Coordinate System—SEL_3D_CSYS</li> </ul> <p> <b>Note</b></p> <p>In case of an empty value for the placement reference, the default placement reference will be used.</p>                                                                                                                                                                      |
| PRO_E_D3ELEM_ORIENTATION_REFERENCE | PRO_VALUE_TYPE_SELECTION | <p>Optional element. Specifies up to two references to define the orientation for the 3D transformation sets.</p> <p>The valid values for orientation reference selection are as follows:</p> <ul style="list-style-type: none"> <li>Surface—SEL_3D_SRF</li> <li>Line—SEL_3D_EDG, SEL_3D_CURVE, SEL_3D_AXIS</li> <li>Coordinate System—SEL_3D_CSYS</li> </ul> <p> <b>Note</b></p> <p>In case of an empty value for the placement reference, the default placement reference will be used.</p> |
| PRO_E_D3ELEM_LOCATION              | PRO_VALUE_TYPE_INT       | <p>Optional element. Specifies whether the transformation set moves with the geometry for every move. It takes the following values:</p> <ul style="list-style-type: none"> <li>PRO_D3_LOCATION_MOVING—This is the default value. The coordinate system of the transformation set moves with each move made in the set.</li> <li>PRO_D3_LOCATION_FIXED—This value can be set only if the placement reference and the orientation reference are both selected to be the</li> </ul>                                                                                                |

| Element ID             | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        |                    | <p>same coordinate system (SEL_3D_CSYS).</p> <p>When this value is set, the transformation set's coordinate system retains its position and orientation during the move, only the selected geometry moves. The move step is defined in reference to this fixed coordinate system.</p>                                                                                                                                                                                                                                                                                                                                                                         |
| PRO_E_D3ELEM_MOVES     | Array holder       | An array holder of PRO_E_D3ELEM_MOVE element.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_D3ELEM_MOVE      | Compound           | A compound element which represents a single move in the given set                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_D3ELEM_MOVE_TYPE | PRO_VALUE_TYPE_INT | <p>Mandatory element. ## Functions for the PRO\_E\_D3ELEM\_MOVE\_VALUE element

This section describes the functions to be used to set the move type for the element PRO\_E\_D3ELEM\_MOVE\_VALUE.

Functions Introduced:

- **ProFeatureD3elemUvGet()**
- **ProFeatureD3elemUvSet()**
- **ProFeatureD3elemRatioGet()**
- **ProFeatureD3elemRatioSet()**
- **ProFeatureD3elemMatrixGet()**
- **ProFeatureD3elemMatrixSet()**

The functions ProFeatureD3elemUvGet() and ProFeatureD3elemUvSet() get and set the position UV parameter for the PRO\_E\_D3ELEM\_MOVE\_VALUE element on a surface or plane.

### Note

The functions ProFeatureD3elemUvGet() and ProFeatureD3elemUvSet() are relevant only when the element PRO\_E\_D3ELEM\_MOVE\_TYPE has its move value as PRO\_D3\_MOVE\_TYPE\_SRF.

---

The functions `ProFeatureD3elemRatioGet()` and `ProFeatureD3elemRatioSet()` get and set the position ratio for the `PRO_E_D3ELEM_MOVE_VALUE` element on an edge or entity.

#### Note

The functions `ProFeatureD3elemRatioGet()` and `ProFeatureD3elemRatioSet()` are relevant only when the element `PRO_E_D3ELEM_MOVE_TYPE` has its move value as `PRO_D3_MOVE_TYPE_EDGE`.

The functions `ProFeatureD3elemMatrixGet()` and `ProFeatureD3elemMatrixSet()` get and set the position delta matrix for the `PRO_E_D3ELEM_MOVE_VALUE` element.

#### Note

The functions `ProFeatureD3elemMatrixGet()` and `ProFeatureD3elemMatrixSet()` are relevant only when the element `PRO_E_D3ELEM_MOVE_TYPE` has its move value as `PRO_D3_MOVE_TYPE_FREE`.

## Attachment Geometry Feature

This section describes how to construct and access the element tree for reattaching geometry when a flexible modeling feature modifies or transforms a geometry selection. It also shows how to create, redefine, and access the properties of the attachment features.

### Introduction

When a geometry selection is transformed by a flexible modeling feature, you can reattach the geometry to the model in one of the following ways:

- Extend the surfaces of the geometry selection and the neighboring geometry until they intersect each other, or until the hole where the geometry selection was originally located is closed and the transformed or modified geometry is reattached.
- Create the side surfaces to close the gap between the moved geometry and the hole left in the model.
- Recreate immediate neighboring surfaces maintaining tangency conditions, if the moved geometry and the immediate neighboring surfaces are tangent planes and circles.

---

The attachment element `PRO_E_FLEX_OPTS_CMPND` is seen in the following feature types:

- `PRO_FEAT_FLEXMOVE` (See `ProFlexMove.h`)
- `PRO_FEAT_FLX_OGF` (See `ProFlexOffset.h`)
- `PRO_FEAT_ANALYT_GEOM` (See `ProFlexMag.h`)
- `PRO_FEAT_FLXATTACH` (See `ProFlexAttach.h`)
- `PRO_FEAT_FLEXSUBST` (See `ProFlexSubstitute.h`)

## The Element Tree for Attachment Geometry Options

The element tree for the Attachment Geometry feature is documented in the header file `ProFlxmdlOpts.h`, and is shown in the following figure.

## Element Tree for Attachment Geometry Options

```

```

The following table describes the elements in the element tree for the Geometry Attachment feature:

| Element ID                  | Data Type              | Description                                                                                                                        |
|-----------------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FLEX_OPTS_CMPND       | Compound               | Specifies the flexible modeling geometry reattachment options.                                                                     |
| PRO_E_FLEX_TRF_SEL_ATT_GEOM | PRO_VALUE_TYPE_INTEGER | Mandatory element. Specifies whether the chamfers and rounds that attach the moved geometry to the model must also be transformed. |

| Element ID             | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        |                        | <p>This element is relevant in PRO_FEAT_FLEXMOVE, PRO_FEAT_FLX_OGF, PRO_FEAT_FLEXSUBST, mirror feature and in patterning.</p> <p>This element takes the following values:</p> <ul style="list-style-type: none"> <li>PRO_FLXMDL_OPT_YES</li> <li>PRO_FLXMDL_OPT_NO</li> </ul> <p>When the value PRO_FLXMDL_OPT_NO is specified, the chamfers and rounds are removed and optionally recreated.</p>                                                                  |
| PRO_E_FLEX_ATTACH_GEOM | PRO_VALUE_TYPE_INTEGER | <p>Mandatory element. Specifies whether to attach the moved geometry to the same quilt or solid it was detached from.</p> <p>This element is relevant in PRO_FEAT_FLEXMOVE, PRO_FEAT_FLX_OGF and PRO_FEAT_ANALYT_GEOM.</p> <p>This element takes the following values:</p> <ul style="list-style-type: none"> <li>PRO_FLEXMODEL_OPT_YES—Attaches the moved geometry to same quilt or solid.</li> <li>PRO_FLEXMODEL_OPT_NO—Creates a new separate quilt.</li> </ul> |
| PRO_E_FLEX_CR_RND_GEOM | PRO_VALUE_TYPE_INTEGER | <p>Mandatory element. Specifies whether to create a round geometry after the geometry selection is moved and reattached. This applicable for geometry selection that was originally attached by round geometry.</p> <p>This element is relevant in PRO_FEAT_FLEXMOVE, PRO_FEAT_FLX_OGF, PRO_FEAT_ANALYT_GEOM and PRO_FEAT_FLEXSUBST.</p>                                                                                                                           |

| Element ID                | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                           |                        | <p>This element takes the following values:</p> <ul style="list-style-type: none"> <li>PRO_FLEXMODEL_OPT_YES</li> <li>PRO_FLEXMODEL_OPT_NO</li> </ul> <p>There are two cases here:</p> <ul style="list-style-type: none"> <li>When PRO_E_FLEX_ATTACH_GEOM is set to PRO_FLEXMODEL_OPT_YES and PRO_E_FLEX_CR_RND_GEOM is set to following values: <ul style="list-style-type: none"> <li>PRO_FLEXMODEL_OPT_YES—The rounds are recreated.</li> <li>PRO_FLEXMODEL_OPT_NO—The rounds are not recreated.</li> </ul> </li> <li>When PRO_E_FLEX_ATTACH_GEOM is set to PRO_FLEXMODEL_OPT_NO the rounds are not reattached. However, in this case you can save the information about the attachment properties for the rounds. PRO_E_FLEX_CR_RND_GEOM is set to following values: <ul style="list-style-type: none"> <li>PRO_FLEXMODEL_OPT_YES—The attachment information of the rounds is stored in intent objects. This information can be used by some other features.</li> <li>PRO_FLEXMODEL_OPT_NO—The attachment information of the rounds is not stored.</li> </ul> </li> </ul> |
| PRO_E_FLEX_KEEP_ORIG_GEOM | PRO_VALUE_TYPE_INTEGER | Mandatory element. Specifies if the original geometry must be moved or a copy of the geometry should be moved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Element ID                    | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               |                        | <p>This element is relevant in PRO_FEAT_FLEXMOVE and PRO_FEAT_FLEXSUBST.</p> <p>This element takes the following values:</p> <ul style="list-style-type: none"> <li>PRO_FLEXMODEL_OPT_YES</li> <li>PRO_FLEXMODEL_OPT_NO</li> </ul>                                                                                                                                                                                                                                                                                                            |
| PRO_E_FLEX_PROPAGATE_TANGENCY | PRO_VALUE_TYPE_INTEGER | <p>Mandatory element. Specifies if tangency must be maintained between the modified geometry and the neighboring geometry.</p> <p>This element is relevant in PRO_FEAT_FLEXMOVE, PRO_FEAT_FLX_OGF and PRO_FEAT_ANALYT_GEOM.</p> <p>This element takes the following values:</p> <ul style="list-style-type: none"> <li>PRO_FLEXMODEL_OPT_YES</li> <li>PRO_FLEXMODEL_OPT_NO</li> </ul>                                                                                                                                                         |
| PRO_E_FLEX_DFLT_CONDITIONS    | PRO_VALUE_TYPE_INTEGER | <p>Mandatory element. Specifies if the default condition must be applied to the vertices of the dragged geometry. The vertices are selected by the system. The default condition is to fix the selected vertices. These vertices do not transform along with the dragged geometry.</p> <p>This element is relevant in PRO_FEAT_FLEXMOVE, PRO_FEAT_FLX_OGF and PRO_FEAT_ANALYT_GEOM.</p> <p>This element takes the following values:</p> <ul style="list-style-type: none"> <li>PRO_FLEXMODEL_OPT_YES</li> <li>PRO_FLEXMODEL_OPT_NO</li> </ul> |
| PRO_E_FLEX_BOUND_EDGES_CMP    | Compound               | This compound element collects the bounding edges.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_FLEX_MAINTAIN_TOPO      | PRO_VALUE_TYPE_INTEGER | Mandatory element. Specifies the option to maintain solution topology for generic flexible                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Element ID                      | Data Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 |           | <p>modeling features:</p> <ul style="list-style-type: none"> <li>PRO_FEAT_FLEXMOVE</li> <li>PRO_FEAT_FLX_OGF</li> <li>PRO_FEAT_ANALYT_GEOM</li> <li>PRO_FEAT_FLEXSUBST</li> <li>PRO_FEAT_FLEXATTACH</li> </ul> <p>This element has the following valid values:</p> <ul style="list-style-type: none"> <li>PRO_FLXMDL_OPT_YES—<br/>The application generates feature geometry that is topologically similar to the solution stored in the element PRO_E_FLEX_SOL_INDEX. If such a solution cannot be created, the feature will fail.</li> <li>PRO_FLXMDL_OPT_NO—<br/>The application generates geometry that is topologically similar to the solution stored in the element PRO_E_FLEX_SOL_INDEX. If such a solution cannot be created, the application tries to create other successful solution. If the application cannot create any other solution for the changed model, the feature fails.</li> </ul> <p> <b>Note</b></p> <p>You cannot select the solution interactively using Creo TOOLKIT applications.</p> |
| PRO_E_STD_CURVE_COLLECTION_APPL | Chain     | Optional element. Collects the bounding edges from the geometry list to which the primary feature geometry will be reattached. The bounding edges are used as the limiting edges for the feature reattachment solutions. The edges that belong to the primary feature references cannot be used as bounding edges.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Flips the side of the extending surfaces.</p> <p>This element is relevant in PRO_FEAT_FLEXMOVE, PRO_FEAT_FLX_OGF and PRO_FEAT_ANALYT_GEOM.</p> <p>This element takes the following values:</p> <ul style="list-style-type: none"> <li>PRO_FLEXMODEL_OPT_YES</li> <li>PRO_FLEXMODEL_OPT_NO</li> </ul> |

### Default Method for the Pull Option

When the value of the element PRO\_E\_FLEX\_PULL\_OPTION is set to PRO\_FLEXMODEL\_PULL\_NONE the moved geometry is attached using either of the following options:

- Default method
- According to the contents of the **Create side surfaces** and **Extend side surfaces** chain collectors

This section describes the default method for the Pull option in detail.

The geometry of the modified surface and the neighboring surface decides the default method by which the surfaces will be attached:

- If the modified surface and the neighboring surface are not tangential to each other, the surfaces are extended until they intersect, that is, they are attached using the **Extend and intersect** option.

- 
- If the modified surface and the neighboring surface are tangential to each other, the moved geometry is attached in one of the following ways:
    - If the modified surface is of any type and the neighboring surface is a round surface, the surfaces are attached in the following way:
      - ◆ The round is removed.
      - ◆ The surfaces are attached using the **Extend and intersect** option.
      - ◆ The round is recreated.
    - If the modified surface is of any type and the neighboring surface is not a round surface, the surfaces are attached in either of the following ways:
      - ◆ The surfaces are attached by creating side surfaces, that is, by using the **Create side surfaces** option.
      - ◆ If the side wall construction fails due to some geometrical reason, for example, self-intersection, then the default option is reset to **Extend and intersect**.
    - If modified surface and the neighboring surface are analytic, that is, cylindrical, planar, conical, toroidal, or tabulated cylinder and the tangency propagation is set to No, the surfaces are attached in either of the following ways:
      - ◆ If the neighboring surface is identified as a round, then the attachment is similar to the above mentioned round surface.
      - ◆ If the neighboring surface is not a round surface, then the surfaces are attached using the **Create side surfaces** option.
    - If modified surface and the neighboring surface are analytic, that is, cylindrical, planar, conical, toroidal, or tabulated cylinder, the tangency is along an isoline and the tangency propagation is set to Yes, the surfaces are attached in either of the following ways:
      - ◆ If the neighboring surface is identified as a round, then the attachment is similar to the above mentioned round surface.
      - ◆ If the neighboring surface is not a round surface, the neighboring surface is dragged to maintain the tangency between the surfaces.

Refer to the section [Tangency Propagation on page 1089](#) for more information on tangency propagation and dragged geometry.

## Offset Geometry Feature

This section describes how to construct and access the element tree for Offset Geometry feature. It also shows how to create, redefine, and access the properties of this feature.

## Introduction

The Offset Geometry feature allow you to offset a geometry selection that belongs to a solid geometry or to a quilt, and reattach it back to the solid or quilt. You can offset the following geometry selection:

- Any surface collection.
- An intent surface.
- Any combination of the above geometries.

A offset feature will act on a single geometry selection. To offset a different geometry selection, a new Offset Geometry feature must be created.

## The Element Tree for Offset Geometry

The element tree for the Offset Geometry feature is documented in the header file `ProFlexOffset.h`, and is shown in the following figure.

### Element Tree for Offset Geometry

```
PRO_E_FEATURE_TREE
|
|-- PRO_E_FEATURE_TYPE
|
|-- PRO_E_STD_FEATURE_NAME
|
|-- PRO_E_STD_SURF_COLLECTION_APPL
|
|-- PRO_E_OGF_OFFSET_VAL
|
|-- PRO_E_OGF_DIR_OPT
|
|-- PRO_E_FLEX_OPTS_CMPND (General FLX-MDL options branch,
| see ProFlxmdlOpts.h)
|
|-- PRO_E_FLXSLV_PROP_CONSTRS (General FLX-MDL tangency
| propagation branch,
| see ProFlexTanPropOpts.h)
|
|-- PRO_E_STD_FLEX_PROPAGATION
```

The following table describes the elements in the element tree for the Offset Geometry feature:

| Element ID                     | Data Type                | Description                                                                                                |
|--------------------------------|--------------------------|------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE             | PRO_VALUE_TYPE_INT       | Specifies the type of feature.                                                                             |
| PRO_E_STD_FEATURE_NAME         | PRO_VALUE_TYPE_WSTRING   | Specifies the name of the feature. The default value is <code>Offset_Geom</code> .                         |
| PRO_E_STD_SURF_COLLECTION_APPL | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the collection of surfaces to offset.                                         |
| PRO_E_OGF_OFFSET_VAL           | PRO_VALUE_TYPE_DOUBLE    | Mandatory element. Specifies the offset value. It takes value between <code>[-1.00e+06, 1.00e+06]</code> . |

| Element ID                 | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_OGF_DIR_OPT          | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the direction of offset. It takes the following values: <ul style="list-style-type: none"> <li>PRO_FLXOGF_DIR_NORMAL—Offsets the geometry normal to the selected surface.</li> <li>PRO_FLXOGF_DIR_FLIP—Flips the direction of offset.</li> </ul>                                                                                                                                                                                                                                                                               |
| PRO_E_FLEX_OPTS_CMPND      | Compound                 | Mandatory element that contains the flexible modeling geometry attachment options to attach the surfaces offset. Specifies the integer and chain collection type elements. The elements related to reattachment of geometry in flexible modeling are defined in <code>ProFlxmdlOpts.h</code> .<br><br>For more information, see the section <a href="#">Attachment Geometry Feature on page 1073</a> .                                                                                                                                                      |
| PRO_E_FLXSLV_PROP_CONSTRS  | Array                    | Optional element. Specifies an array that contains the tangency conditions and the reference geometry elements for tangency propagation. This element must be specified when the element <code>PRO_E_FLEX_PROPAGATE_TANGENCY</code> is set to <code>PRO_FLEXMODEL_OPT_YES</code> in the header file <code>ProFlxmdlOpts.h</code> .<br><br>The elements related to propagation of tangency in flexible modeling are defined in <code>ProFlexTanPropOpts.h</code> . For more information, see the section <a href="#">Tangency Propagation on page 1089</a> . |
| PRO_E_STD_FLEX_PROPAGATION | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies a pattern or mirror recognition feature to propagate the offset geometry feature changes.                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Modify Analytic Surface Feature

This section describes how to construct and access the element tree for Modify Analytic Surface feature for flexible modeling. It also shows how to create, redefine, and access the properties of this feature.

## Introduction

The Modify Analytic Surface feature allows you to modify the analytic surfaces. The modification is done by creating and modifying basic dimensions that define each surface type.

The following analytic surfaces can be modified:

- Cylinder—The axis remains fixed and the radius can be modified.
- Torus—The axis of revolution of the circle remains fixed. The radius of the circle and the distance (radius) from the center of the circle to the axis of revolution can be modified.
- Cone—The axis and vertex of the cone remain fixed, and the angle can be modified.

## The Element Tree for Modify Analytic Surface

The element tree for the Modify Analytic Surface feature is documented in the header file `ProFlexMag.h`, and is shown in the following figure.

### Element Tree for Modify Analytic Surface

```
PRO_E_FEATURE_TREE
|
|-- PRO_E_FEATURE_TYPE
|
|-- PRO_E_STD_FEATURE_NAME
|
|-- PRO_E_STD_SURF_COLLECTION_APPL
|
|-- PRO_E_STD_FLEX_PROPAGATION
|
|-- PRO_E_FLEX_OPTS_CMPND (General FLX-MDL options branch,
| see ProFlxmdlOpts.h)
|
|-- PRO_E_FLXSLV_PROP_CONSTRS (General FLX-MDL tangency
| propagation branch,
| see ProFlexTanPropOpts.h)
|
|-- PRO_E_MAG_ANGLE_VAL (Conic surface)
|
|-- PRO_E_MAG_RADII_VAL (Cylindric and toroidal surface)
|
|-- PRO_E_MAG_RADII2_VAL (Toroidal surface)
```

The following table describes the elements in the element tree for the Modify Analytic Surface feature:

| Element ID                     | Data Type                | Description                                                                                    |
|--------------------------------|--------------------------|------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE             | PRO_VALUE_TYPE_INT       | Specifies the type of feature.                                                                 |
| PRO_E_STD_FEATURE_NAME         | PRO_VALUE_TYPE_WSTRING   | Specifies the name of the feature. The default value is <code>MODIFY_ANALYTIC_SURFACE</code> . |
| PRO_E_STD_SURF_COLLECTION_APPL | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the                                                               |

| Element ID                 | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            |                          | <p>collection of analytical surface sets to be modified. The valid surface selections are: cylindrical, conical or toroidal surfaces.</p> <p> <b>Note</b></p> <p>You can specify only one reference surface or surface region at a time in this element.</p>                                                                                                                                                                                                                   |
| PRO_E_STD_FLEX_PROPAGATION | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies a pattern or mirror recognition feature to propagate the modified analytic surface feature changes.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_FLEX_OPTS_CMPND      | Compound                 | <p>Mandatory element that contains the flexible modeling geometry attachment options to attach the modified surfaces. Specifies the integer and chain collection type elements. The elements related to reattach of geometry in flexible modeling are defined in <code>ProFlxmdlOpts.h</code>.</p> <p>For more information, see the section <a href="#">Attachment Geometry Feature on page 1073</a>.</p>                                                                                                                                                       |
| PRO_E_FLXSLV_PROP_CONSTRS  | Array                    | <p>Optional element. Specifies an array that contains the tangency conditions and the reference geometry elements for tangency propagation. This element must be specified when the element <code>PRO_E_FLEX_PROPAGATE_TANGENCY</code> is set to <code>PRO_FLEXMODEL_OPT_YES</code> in the header file <code>ProFlxmdlOpts.h</code>.</p> <p>The elements related to propagation of tangency in flexible modeling are defined in <code>ProFlexTanPropOpts.h</code>. For more information, see the section <a href="#">Tangency Propagation on page 1089</a>.</p> |
| PRO_E_MAG_ANGLE_VAL        | PRO_VALUE_TYPE_DOUBLE    | <p>Mandatory element for conic surface. Specifies the angle of the conic surface.</p> <p>The element takes angular value between [0.5, 89] degrees.</p>                                                                                                                                                                                                                                                                                                                                                                                                         |

## Tangency Propagation

This section describes how to construct and access the elements for propagating tangency in a flexible modeling feature.

### Introduction

When geometry is modified with **Move**, **Offset**, or **Modify Analytic** command, you can maintain the tangency between the modified geometry and the neighboring geometry. To maintain the tangency, the neighboring geometry may be modified, though it was not selected for modification. The geometry that is included during tangency propagation is defined as dragged geometry. The dragged geometry is modified in such a way that it always remains tangential to the directly modified geometry. The tangency propagation stops when the application recognizes a surface that is round or chamfer. The chamfer or round surface, except variable rounds, is recreated after the geometry is modified. The round and chamfer geometry are called connecting geometry.

Depending on the type of round surface, the tangency may or may not be propagated. The rounds are of the following types:

- Rounds that can be propagated. Tangency propagation can be forced to be carried through and continue onto adjacent tangent geometry.
- Rounds that cannot be propagated. The tangency stops and cannot be forced to go further.
- Rounds that cannot be recreated. These are mainly the variable rounds. Variable rounds can be removed but cannot be recreated.

- Interfering rounds. These are rounds that do not connect transformed or dragged geometry to the rest of the model but have to be removed and recreated to accommodate the changes in the transformed geometry, dragged geometry, and other rounds.

The round or chamfer surfaces connect the directly modified geometry and the dragged surfaces to the background geometry. The background geometry is the base geometry that is not modified.

The modified, dragged, connecting, fixed, and background geometry are displayed in different colors during modification in the Creo Parametric user interface as shown in the figure below:

- 1—Default vertices are automatically created when you propagate tangency
- 2—Directly modified geometry
- 3—Dragged geometry
- 4—Rounds that cannot be propagated
- 5—Rounds that can be propagated
- 6—Rounds that cannot be recreated
- 7—Interfering rounds
- 8—Background geometry

You can control the changes in geometry during tangency propagation by specifying the tangency constraints. During tangency propagation the fixed vertex constraints are also considered. The tangency constraint is applied on a reference geometry that can either be the dragged geometry or the connecting geometry, or both. Refer to Creo Flexible Modeling Help for more information.

To work with tangency propagation, you must set the value of the element `PRO_E_FLEX_PROPAGATE_TANGENCY` to `PRO_FLEXMODEL_OPT_YES`. The element is defined in the header file `ProFlxmdlOpts.h`.

The element `PRO_E_FLXSLV_PROP_CONSTRS` is used to set the conditions that controls the changes in geometry during tangency propagation. It is seen in the following feature types:

- `PRO_FEAT_FLEXMOVE` (See `ProFlexMove.h`)
- `PRO_FEAT_FLX_OGF` (See `ProFlexOffset.h`)
- `PRO_FEAT_ANALYT_GEOM` (See `ProFlexMag.h`)

## The Element Tree for Tangency Propagation

The element tree for the Tangency Propagation is documented in the header file `ProFlexTanPropOpts.h`, and is shown in the following figure.

### Element Tree for Tangency Propagation

The following table describes the elements in the element tree for the Tangency Propagation:

| Element ID                             | Data Type | Description                                                                                     |
|----------------------------------------|-----------|-------------------------------------------------------------------------------------------------|
| <code>PRO_E_FLXSLV_PROP_CONSTRS</code> | Array     | Specifies an array of conditions that control the tangency propagation.                         |
| <code>PRO_E_FLXSLV_CONSTR</code>       | Compound  | Mandatory element. Specifies a single condition for tangency along with the reference geometry. |

| Element ID               | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FLXSLV_CONSTR_REFS | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the selection of reference geometry.                                                                                                                                                                                                                                                                                                 |
| PRO_E_FLXSLV_CONSTR_TYPE | PRO_VALUE_TYPE_INTEGER   | Mandatory element. Specifies a condition that sets constraint on the neighboring surfaces during the propagation of tangency. The valid values are defined in the enumerated data type <code>ProFlxmdlPropOptFlag</code> . Refer to section <a href="#">Setting Conditions for Tangency Propagation on page 1092</a> for more information on tangency conditions. |

## Setting Conditions for Tangency Propagation

You can set the conditions depending on geometry type that must be considered during tangency propagation. The conditions are specified using the enumerated data type `ProFlxmdlPropOptFlag`. The valid values are:

- `PRO_FLXSLV_CONSTR_TYPE_FIXED`—Specifies that the reference geometry must be fixed. Tangency is not maintained between the modified geometry and the neighboring geometry. You can set the value for following types of geometry:
  - Planar surface
  - Cylindrical surface
  - Conical surface
  - Toroidal surface
  - Spherical surface
  - Tabulated cylinder
  - Surface of revolution
  - Round surface
  - Edge (surface isoline) on the surface
  - Vertex on the surface

### Note

You can specify the condition `PRO_FLXSLV_CONSTR_TYPE_FIXED` while manipulating the geometry of parts, using the Creo Flexible Modeling commands, even if the value of `PRO_E_FLEX_PROPAGATE_TANGENCY` is set to `PRO_FLEXMODEL_OPT_NO`. Here the reference round and chamfer geometry are not considered as rounds and chamfers.

- 
- `PRO_FLXSLV_CONSTR_TYPE_FIX_AXIS`—Specifies that the axis of the reference geometry must be fixed. You can set the value for following types of geometry:
    - Cylindrical surface
    - Conical surface
    - Toroidal surface
    - Spherical surface
    - Surface of revolution
  - `PRO_FLXSLV_CONSTR_TYPE_FIX_CNTR`—Specifies that the center of the reference geometry must be fixed. You can set the value for following types of geometry:
    - Toroidal surface
    - Spherical surface
  - `PRO_FLXSLV_CONSTR_TYPE_FIX_NORM`—Specifies that the reference geometry must be normal to the directly modified geometry. You can set the value for following type of geometry:
    - Planar surface
  - `PRO_FLXSLV_CONSTR_TYPE_CONST_R1`—Specifies that the minor radius of reference geometry must be constant. You can set the value for following types of geometry:
    - Cylindrical surface
    - Toroidal surface—The minor diameter is kept constant.
    - Spherical surface
  - `PRO_FLXSLV_CONSTR_TYPE_CONST_R2`—Specifies that the major radius of reference geometry must be constant. You can set the value for following type of geometry:
    - Toroidal surface
  - `PRO_FLXSLV_CONSTR_TYPE_CONST_ANG`—Specifies that the angle between the reference geometry and directly modified geometry must be constant. You can set the value for following type of geometry:
    - Conical surface
  - `PRO_FLXSLV_CONSTR_TYPE_FIX_POLE`—Specifies that the position of the pole in the reference geometry must be fixed. You can set the value for following type of geometry:
    - Conical surface

- 
- `PRO_FLXSLV_CONSTR_TYPE_PRPG_THRU`—Specifies that the tangency must be propagated till the last available round surface or till the surface after which the tangency will break.
    - Round surface
    - Cylindrical surface
  - `PRO_FLXSLV_CONSTR_TYPE_FIX_RNDEDG_PNT`—Specifies that the endpoint (vertex) on the edge of the reference geometry must be fixed. You can set the value for following type of geometry:
    - Round surface
  - `PRO_FLXSLV_CONSTR_FIX_WITH_TNGCY`—Specifies that the tangency must be maintained between the modified geometry and the neighboring dragged geometry, and further between the neighboring dragged geometry and connecting geometry. You can set the value for following types of geometry:
    - Planar surface
    - Cylindrical surface
    - Conical surface
    - Toroidal surface
    - Spherical surface
    - Tabulated cylinder
    - Surface of revolution
    - Round surface
    - Edge (surface isoline) on the surface
    - Vertex on the surface
  - `PRO_FLXSLV_CONSTR_TYPE_CONST_R`—Specifies that the radius of reference geometry must be constant. You can set the value for following types of geometry:
    - Cylindrical surface
    - Spherical surface
  - `PRO_FLXSLV_CONSTR_TYPE_KEEP_SPHERICAL`—Specifies that the shape of the sphere does not change, though the radius can change. You can set the value for following types of geometry:
    - Spherical surface

## Mirror Feature

This section describes how to construct and access the element tree for Mirror feature for flexible modeling. It also shows how to create, redefine, and access the properties of this feature.

---

## Introduction

The Mirror feature allows you to mirror a selected set of geometry about a plane. You can either attach the mirrored geometry to the solid or quilt from which it was created or keep it detached.

If the geometry selection for the mirror feature includes or is attached by round geometry, then the round geometry can be recreated in the new mirrored location.

---

### Note

The group header of the Mirror feature behaves as a standard feature. You can extract the header element tree in Creo TOOLKIT.

---

## The Element Tree for Mirror

The element tree for the Mirror feature is documented in the header file `ProFlexMirror.h`, and is as shown in the following figure:

### Element Tree for Mirror

```
PRO_E_FEATURE_TREE
|
|--PRO_E_STD_FEATURE_NAME
|
|--PRO_E_MGF_REFS
| |
| |--PRO_E_STD_SURF_COLLECTION_APPL
| |
| |--PRO_E_MGF_MIRROR_PLANE
| |
| |--PRO_E_MGF_DATUMS
|
|--PRO_E_FLEX_OPTS_CMPND
 (General FLX-MDL options branch,
 see ProFlxmdlOpts.h)
```

The following table describes the elements in the element tree for the Mirror feature:

| Element ID             | Data Type              | Description                                                              |
|------------------------|------------------------|--------------------------------------------------------------------------|
| PRO_E_STD_FEATURE_NAME | PRO_VALUE_TYPE_WSTRING | Specifies the name of the feature. The default value is Mirror_Geometry. |
| PRO_E_MGF_REFS         | Compound               | Compound element that specifies                                          |

| Element ID                     | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                |                          | the geometry, curves, and datums to be mirrored.                                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_STD_SURF_COLLECTION_APPL | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the collection of surface sets of the geometry to be mirrored.                                                                                                                                                                                                                                                                                                           |
| PRO_E_MGF_MIRROR_PLANE         | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the datum plane or intent datum plane about which the geometry will be mirrored.                                                                                                                                                                                                                                                                                         |
| PRO_E_MGF_DATUMS               | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the collection of curves and datum entities to be mirrored.                                                                                                                                                                                                                                                                                                               |
| PRO_E_FLEX_OPTS_CMPND          | Compound                 | <p>Mandatory element that contains the Creo Flexible Modeling geometry attachment options to attach the mirrored surfaces. Specifies the integer and chain collection type elements. The elements related to reattachment of geometry in flexible modeling are defined in ProFlxmdlOpts.h.</p> <p>For more information, see the section <a href="#">Attachment Geometry Feature</a> on page 1073.</p> |

## Substitute Feature

This section describes how to construct and access the element tree for Substitute feature. It also shows how to create, redefine, and access the properties of this feature.

### Introduction

The Substitute feature allows you to replace a geometry selection that belongs to a solid geometry or a quilt with replacing surfaces. The replacing surfaces are attached to the solid or quilt, and any round geometry between the geometry selection. The model is recreated after the replacing geometry is attached.

You can substitute the following geometry selection:

- Any surface collection.
- An intent surface.
- Any combination of the above geometries.
- Any one-sided edges on surfaces or quilts.

---

All the surfaces and one-sided edges in the geometry selection must belong to the same solid geometry or to the same quilt. The geometry selection must not be tangential to the neighboring geometry, or should be attached to the neighboring geometry with round geometry.

The replacing surfaces must be large enough to attach to the extension of the neighboring geometry, without the need to extend the replacing surfaces.

After substitution, the replacing surfaces that define the one-sided edge loops are extended and trimmed so that the resulting edges lie on the substituting geometry.

Refer to the Creo Flexible Modeling Help for more information.

## The Element Tree for Substitute

The element tree for the Substitute feature is documented in the header file `ProFlexSubstitute.h`, and is shown in the following figure.

### Element Tree for Substitute

```

The following table describes the elements in the element tree for the Substitute feature:

| Element ID                     | Data Type                | Description                                                                                                                                                                                                                                                                                |
|--------------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE             | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of feature. The value of this feature must be PRO_FEAT_FLEXSUBST.                                                                                                                                                                                    |
| PRO_E_STD_FEATURE_NAME         | PRO_VALUE_TYPE_WSTRING   | Specifies the name of the feature. The default value is Substitute.                                                                                                                                                                                                                        |
| PRO_E_CMP_SUBSTITUTED          | Compound                 | Compound element for surfaces to be substituted.                                                                                                                                                                                                                                           |
| PRO_E_FLXSUBST_METHOD          | PRO_VALUE_TYPE_INT       | Specifies which kind of geometry must be substituted. The valid geometry types are: <ul style="list-style-type: none"> <li>PRO_FLEXSUBST_SURFACES—Specifies that surfaces must be substituted.</li> <li>PRO_FLEXSUBST_LOOPS—Specifies that one-sided edges must be substituted.</li> </ul> |
| PRO_E_STD_SURF_COLLECTION_APPL | PRO_VALUE_TYPE_SELECTION | Mandatory element for PRO_FLEXSUBST_SURFACES. Specifies the collection of surfaces that will be replaced by the substituting surfaces.                                                                                                                                                     |
| PRO_E_FLXSUBST_EDGELOOPS       | PRO_VALUE_TYPE_SELECTION | Mandatory element for PRO_FLEXSUBST_LOOPS. Specifies the collection of one-sided edges that will be replaced by the substituting surfaces.                                                                                                                                                 |
| PRO_E_CMP_SUBSTITUTING         | Compound                 | Compound element for substituting surfaces.                                                                                                                                                                                                                                                |
| PRO_E_STD_SURF_COLLECTION_APPL | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the collection of substituting surfaces.                                                                                                                                                                                                                      |

| Element ID                    | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_OPT_SUBST_SRF_NORM_SIDE | PRO_VALUE_TYPE_BOOLEAN | <p>Mandatory element. Specifies the direction of the normal vectors of the substituting surfaces.</p> <p>This element takes the following values:</p> <ul style="list-style-type: none"> <li>PRO_B_TRUE—Specifies that the side 1 is direction of normal vector.</li> <li>PRO_B_FALSE—Specifies that the side 2 is direction of normal vector.</li> </ul>                                                         |
| PRO_E_FLEX_OPTS_CMPND         | Compound               | <p>Mandatory element that contains the flexible modeling geometry attachment options to attach the substituting surfaces. Specifies the integer and chain collection type elements. The elements related to reattachment of geometry in flexible modeling are defined in <code>ProFlxmdlOpts.h</code>.</p> <p>For more information, see the section <a href="#">Attachment Geometry Feature</a> on page 1073.</p> |

## Planar Symmetry Recognition Feature

This section describes how to construct and access the element tree for Planar Symmetry Recognition feature. It also shows how to create, redefine, and access the properties of this feature.

### Introduction

The Planar Symmetry Recognition feature allows you to identify and modify geometry that is symmetric with respect to a plane. The modifications made to the geometry on one side are automatically propagated to the other side and the symmetry is kept.

The Planar Symmetry Recognition feature identifies symmetrical geometry in the following ways:

- You can collect two seed surfaces or surface regions that are symmetric. The feature computes the plane of symmetry, and finds all pairs of neighboring surfaces and surface regions which are symmetric with respect to the symmetry plane. The propagation ends when non-symmetric neighboring surfaces are found.

---

The two seed surfaces or regions must belong to:

- The solid geometry.
- A single quilt.
- Two quilts.
- You can collect a seed surface or surface region and a plane of symmetry. The feature finds the mirror image of the seed surface or surface region and, finds all the pairs of neighboring surfaces and surface regions which are symmetric with respect to the symmetry plane.

According to the correspondence between the geometry of the symmetrical members, the following variation of planar symmetry recognition are possible:

- **Identical**—There is exact correspondence between the surfaces of the symmetrical members as well as between the intersection edges defined by these members and the surrounding geometry.
- **Similar**—There is exact correspondence between the surfaces of the symmetrical members, but there is no exact correspondence between the intersection edges defined by these members and the surrounding geometry. The number of intersection loops must be the same, but the type of edges, number of edges in each intersection loop and the intersected model surfaces do not have to be the same.

---

 **Note**

The group header of the Planar Symmetry Recognition feature behaves as a standard feature. You can extract the header element tree in Creo TOOLKIT.

---

## The Element Tree for Planar Symmetry Recognition Feature

The element tree for the Planar Symmetry Recognition feature is documented in the header file `ProSymmetryRecognition.h`, and is shown in the following figure:

## Element Tree for Planar Symmetry Recognition Feature

```
PRO_E_FEATURE_TREE
|
|--PRO_E_STD_FEATURE_NAME
|
|--PRO_E_PSR_PLN_REF
|
|--PRO_E_PSR_DTM_REF
|
|--PRO_E_PSR_RCG_OPT
```

The following table describes the elements in the element tree for the Planar Symmetry Recognition feature:

| Element ID             | Data Type                | Description                                                                                                                                                                                                                                                    |
|------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_STD_FEATURE_NAME | PRO_VALUE_TYPE_WSTRING   | Specifies the name of the feature. The default value is Mirror_Recognition.                                                                                                                                                                                    |
| PRO_E_PSR_PLN_REF      | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the collection of two seed surfaces or one seed surface and the symmetry mirror plane.                                                                                                                                            |
| PRO_E_PSR_DTM_REF      | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the collection of datums and curve chains that will be included in the symmetry recognition.                                                                                                                                       |
| PRO_E_PSR_RCG_OPT      | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of symmetrical geometry to be recognized: <b>Identical</b> or <b>Similar</b> .<br><br>This element takes the following values: <ul style="list-style-type: none"><li>PRO_PSR_IDENTICAL</li><li>PRO_PSR_SIMILAR</li></ul> |

## Attach Feature

This section describes how to construct and access the element tree for Attach feature. It also shows how to create, redefine, and access the properties of this feature.

## Introduction

The Attach feature allows you to attach open quilts to solid or quilt geometry, if the open quilt does not intersect the solid or quilt geometry. You can select an open quilt and attach it to another quilt or solid geometry within the same model. You can also select two open quilts within the same model which do not intersect and attach them.

This feature is useful in case of UDF placement when the geometry of the UDF does not intersect the part.

## The Element Tree for Attach Feature

The element tree for the Attach feature is documented in the header file `ProFlexAttach.h`, and is shown in the following figure:

### Attach Feature Element Tree

The following table describes the elements in the element tree for the Attach feature:

| Element ID                | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE        | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of feature. The value of this feature must be PRO_FEAT_ATTACH.                                                                                                                                                                                                                                                                                       |
| PRO_E_STD_FEATURE_NAME    | PRO_VALUE_TYPE_WSTRING   | Specifies the name of the feature. The default value is Attach_1.                                                                                                                                                                                                                                                                                                                          |
| PRO_E_REF_ATTACH_PRIM_QLT | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the primary open quilt to be attached to another quilt. The primary quilt will be extended or trimmed during the attachment.                                                                                                                                                                                                                                  |
| PRO_E_REF_ATTACH_MERG_QLT | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the merge quilt or solid geometry upto which the primary quilt can be extended or trimmed.                                                                                                                                                                                                                                                                     |
| PRO_E_OPT_ATTACH_OPER     | PRO_VALUE_TYPE_BOOLEAN   | <p>Mandatory element. Specifies whether to attach the primary quilt to the merge quilt or solid geometry.</p> <p>This element takes the following values:</p> <ul style="list-style-type: none"> <li>PRO_B_TRUE—Specifies that the primary quilt must not be attached.</li> <li>PRO_B_FALSE—Specifies that the primary quilt must be attached.</li> </ul>                                  |
| PRO_E_OPT_ATTACH_RMV_MAT  | PRO_VALUE_TYPE_BOOLEAN   | <p>This element is available when the element PRO_E_REF_ATTACH_MERG_QLT has no reference geometry specified. Specifies if material must be added or removed.</p> <p>This element takes the following values:</p> <ul style="list-style-type: none"> <li>PRO_B_TRUE—Specifies that the material must be removed.</li> <li>PRO_B_FALSE—Specifies that the material must be added.</li> </ul> |
| PRO_E_OPT_ATTACH_PQ_DIR   | PRO_VALUE_TYPE_BOOLEAN   | <p>This element is available when the element PRO_E_OPT_ATTACH_OPER has its value as PRO_B_FALSE. Specifies the side of the quilt that must be included in the merged quilt</p> <p>This element takes the following values:</p>                                                                                                                                                            |

| Element ID               | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| PRO_E_OPT_ATTACH_MGQ_DIR | PRO_VALUE_TYPE_BOOLEAN | <p>This element is available when the element PRO_E_OPT_ATTACH_OPER has its value as PRO_B_TRUE and the element PRO_E_REF_ATTACH_MERG_QLT has reference geometry specified. Specifies the direction in which the material should be added or removed in the primary quilt.</p> <p>This element takes the following values:</p> <ul style="list-style-type: none"> <li>PRO_B_TRUE—Specifies that the material must be added or removed from the second side.</li> <li>PRO_B_FALSE—Specifies that the material must be added or removed from the first side.</li> </ul> |
| PRO_E_OPT_ATTACH_PIO     | PRO_VALUE_TYPE_BOOLEAN | Specifies if the quilt should be attached to the model geometry in the same way as it was attached previously by using the attachment information stored in the intent objects.                                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_OPT_ATTACH_RNDCH   | PRO_VALUE_TYPE_BOOLEAN | Specifies if the round or chamfer geometry of the quilt should be attached using the attachment information stored in the intent objects.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_FLEX_OPTS_CMPND    | Compound               | <p>Mandatory element that contains the flexible modeling geometry attachment options to attach the substituting surfaces. Specifies the integer and chain collection type elements. The elements related to reattachment of geometry in flexible modeling are defined in <code>ProFlxmdlOpts.h</code>.</p> <p>For more information, see the section <a href="#">Attachment Geometry Feature</a> on page 1073.</p>                                                                                                                                                     |

---

## Example 1: Creating a Flexible Model Feature

The sample code in `UgFlexModelCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` shows how to create a Creo Flexible Modeling feature.

## Element Trees: Bushing Load

### Introduction

This section describes how to construct and access the element tree for Bushing Load features in Creo TOOLKIT. It also shows how to redefine, create and access the properties of these features.

The bushing loads in the model are represented under the **Bushing Load** node in the product mechanism tree. As the bushing load is a regular Creo Parametric feature, it also has an appropriate node in the main model tree. You can create, edit, and redefine the bushing loads. To create new bushing loads select a weld connection or a 6DOF connection. You must specify six stiffnesses and six damping coefficients for all the degrees of freedom of the reference connection. Each coefficient is associated with one feature parameter.

#### Note

- The default units of the spring stiffnesses and the damping coefficients on the three rotational axes are degree-based.
  - If bushing load reference is a weld connection, any axis can be locked. In this case the spring stiffness on the locked axis should have a value of -1.0, regardless of the current units.
- 

### The Feature Element Tree for Bushing Loads

The element tree for the bushing load feature is documented in the header file `ProBushingLoadFeat.h`, and is shown in the following figure.

## Element Tree for Bushing Loads

## Element Trees: Cosmetic Thread

### Introduction

This section describes how to construct and access the element tree for Cosmetic Thread features. It also shows how to create, redefine, and access the properties of these features.

A cosmetic thread is a cosmetic feature that represents the diameter of a thread. It is displayed in purple. Unlike other cosmetic features, you cannot modify the line style of a cosmetic thread.

You can create cosmetic threads using cylinders, cones, splines, and non-normal planes as the references. The surface that you select determines whether a cosmetic thread is external or internal. If the surface is a shaft, the thread is external. If the surface is a hole, the thread is internal.

You can create a standard thread or a nonstandard thread. When you choose to create a standard thread, the standard thread series and diameter is used. You can create, edit, and redefine the cosmetic thread features.

### The Element Tree for Cosmetic Thread

The element tree for the cosmetic thread feature is documented in the header file `ProThread.h`, and is shown in the following figure.

## Element Tree for Cosmetic Thread

The following table describes the elements in the element tree for the cosmetic thread feature:

| Element ID         | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE | PRO_VALUE_TYPE_INT | Specifies the type of feature                                                                                                                                                                                                                                                                                                                                                   |
| PRO_E_FEATURE_FORM | PRO_VALUE_TYPE_INT | Optional element. Specifies the type of the feature form. Use the value PRO_EXTRUDE or PRO_REVOLVE from the enumerated type ProFeatFormType depending on the threaded surface. <ul style="list-style-type: none"> <li>Use PRO_EXTRUDE when the referenced threaded surface is cylindrical.</li> <li>Use PRO_REVOLVE when the referenced threaded surface is conical.</li> </ul> |

| Element ID               | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                          |  <b>Note</b><br>If the enumerated value and referenced threaded surface are incorrectly selected, the feature creation or redefinition will fail.                                                                                                                                          |
| PRO_E_STD_FEATURE_NAME   | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the cosmetic thread feature name. The default value is COSMETIC_THREAD.                                                                                                                                                                                                                                                                           |
| PRO_E_THRD_TYPE_OPT_NEW  | PRO_VALUE_TYPE_BOOLEAN   | Optional element. Specifies if a simple or a standard thread should be created. It has two values: FALSE for simple thread and TRUE for standard thread.                                                                                                                                                                                                                      |
| PRO_E_THRD_SERIES_NEW    | PRO_VALUE_TYPE_INT       | Specific the thread series for the standard threads. From the *.hol files information about different THREAD_SERIES is gathered and a list is generated. You can specify UNC, UNF, and ISO as the standard thread series. The current index to the list is stored in this element.                                                                                            |
| PRO_E_THRD_SCREWSIZE_NEW | PRO_VALUE_TYPE_INT       | Optional element. Specifies the screw size for the standard thread. The screw_size list is extracted from the *.hol files corresponding to the thread series. The index to the screw_size list is stored in this element.                                                                                                                                                     |
| PRO_E_THRD_SURF_NEW      | PRO_VALUE_TYPE_SELECTION | Specifies the surface to thread.                                                                                                                                                                                                                                                                                                                                              |
| PRO_E_THRD_DIAM_NEW      | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the diameter for a simple thread. If the reference threaded surface is conical, the thread diameter value can be between 0.0 and $diam/4$ , where $diam$ is the largest estimated diameter of the cone. For all other reference surfaces, the diameter can have values between 0.1 and MAX_DIM_VALUE, that is the maximum allowed diameter value. |
| PRO_E_THRD_START_REF_NEW | PRO_VALUE_TYPE_SELECTION | Specifies the starting location of the cosmetic thread.                                                                                                                                                                                                                                                                                                                       |
| PRO_E_THRD_DEP_COMP_NEW  | Compound                 | Specifies the depth and flip elements. It contains the following elements: <ul style="list-style-type: none"> <li>• PRO_E_THRD_DEP_OPT_</li> </ul>                                                                                                                                                                                                                            |

| Element ID                 | Data Type                | Description                                                                                                                                                                                                                                                                                                                                           |
|----------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            |                          | NEW <ul style="list-style-type: none"> <li>• PRO_E_THRD_FLIP_OPT_NEW</li> <li>• PRO_E_THRD_DEP_VAL_NEW</li> <li>• PRO_E_THRD_END_REF</li> </ul>                                                                                                                                                                                                       |
| PRO_E_THRD_DEP_OPT_NEW     | PRO_VALUE_TYPE_BOOLEAN   | Optional element. Specifies the depth option: FALSE for blind depth option and TRUE for the depth up to the selected entity.                                                                                                                                                                                                                          |
| PRO_E_THRD_FLIP_OPT_NEW    | PRO_VALUE_TYPE_INT       | Optional element. Specifies the flip direction of the thread with respect to the reference surface. The flip direction is specified by the enumerated type <code>ProThreadFlip</code> that takes the following values: <ul style="list-style-type: none"> <li>• PRO_COSTHREAD_THD_FLIP_OPT_FLIP</li> <li>• PRO_COSTHREAD_THD_FLIP_OPT_NORM</li> </ul> |
| PRO_E_THRD_DEP_VAL_NEW     | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the depth value when the element <code>PRO_E_THRD_DEP_OPT_NEW</code> is FALSE (Blind option). You can specify a minimum depth of 0.1. When the element <code>PRO_E_THRD_DEP_OPT_NEW</code> is TRUE, the node is invisible.                                                                                                |
| PRO_E_THRD_END_REF         | PRO_VALUE_TYPE_SELECTION | Mandatory element when <code>PRO_E_THRD_DEP_OPT_NEW</code> is TRUE. Specifies the reference surface up to which the thread depth should be created. This node is available only when the element <code>PRO_E_THRD_DEP_OPT_NEW</code> is TRUE. When the element <code>PRO_E_THRD_DEP_OPT_NEW</code> is FALSE, the node is invisible.                   |
| PRO_E_THRD_NOTE_PARAMS_NEW | PRO_VALUE_TYPE_POINTER   | Reserved for future use. Optional element. Displays the thread parameters in a data structure.                                                                                                                                                                                                                                                        |

## Element Trees: ECAD Area Feature

### Introduction to ECAD Area Feature

This section describes how to access ECAD Area feature through Creo TOOLKIT.

---

An ECAD Area specifies where you can place electrical components or cannot place them to avoid interference with other electric components or electrical routing. You can create an ECAD area as a sketched cosmetic feature of an electrical board part. However, since this area is sketched, you cannot dimension or regenerate it.

The ECAD area can have a closed 3D volume represented by a quilt. Use these quilts to perform a clearance and interference check on the neighboring electric components. You can access the geometry of the ECAD area feature by using standard Creo TOOLKIT functions such as `ProFeatureGeomitemVisit()` and `ProSolidQuiltVisit()`.

## Feature Element Tree for the ECAD Area

The element tree for the ECAD Area feature is documented in the header file `ProEcadArea.h`. The following figure demonstrates the element tree structure:

## Feature Element Tree for an ECAD Area

```
PRO_E_FEATURE_TREE
|
|--PRO_E_FEATURE_TYPE
|
|--PRO_E_IS_ECAD_AREA
|
|--PRO_E_STD_FEATURE_NAME
|
|--PRO_E_ECAD_AREA_TYPE
|
|--PRO_E_STD_SECTION
|
|--PRO_E_ECAD_AREA_3D_VOLUME
|
|--PRO_E_ECAD_AREA_DEPTH_TYPE
|
|--PRO_E_ECAD_AREA_DEPTH
|
|--PRO_E_ECAD_AREA_DEPTH2
|
|--PRO_E_ECAD_AREA_XHATCH
|
|--PRO_E_ECAD_AREA_TRIM_BNDRS
|
|--PRO_E_ECAD_AREA_COLOR
|
|--PRO_E_ECAD_AREA_USER_DEF_TYPE
```

The information about the elements in this tree is as follows:

- PRO\_E\_FEATURE\_TYPE—Specifies the feature type; should always have the value PRO\_FEAT\_COSMETIC.
- PRO\_E\_IS\_ECAD\_AREA—Specifies whether the created cosmetic feature is an ECAD area. This element must have the value PRO\_B\_TRUE to distinguish this feature from other cosmetic features.
- PRO\_E\_STD\_FEATURE\_NAME—Specifies the name of the ECAD area feature.

- 
- `PRO_E_ECAD_AREA_TYPE`—Specifies the type of ECAD area in the form of the enumerated type `ProEcadAreaType`. Specify the value of this element as one of the following:
    - `PRO_ECAD_AREA_TYPE_PLACE_KEEPPIN`—Specifies a keepin region. You can specify the depth of the area above and below the electric board while creating this region. The default depth value is zero.
    - `PRO_ECAD_AREA_TYPE_PLACE_KEEPOUT`—Specifies a keepout region. You can specify the depth of the area above and below the electric board while creating this region. The default depth value is zero.
    - `PRO_ECAD_AREA_TYPE_PLACE_REGION`—Specifies a group area section.
    - `PRO_ECAD_AREA_TYPE_ROUTE_KEEPPIN`—Specifies a routing keepin region where routing actions are permitted.
    - `PRO_ECAD_AREA_TYPE_ROUTE_KEEPOUT`—Specifies a routing keepout region where routing actions are not permitted.
    - `PRO_ECAD_AREA_TYPE_VIA_KEEPOUT`—Specifies an area where you cannot create vias.
    - `PRO_ECAD_AREA_TYPE_FLEX_REGION`—Specifies a region created using flexible modeling features.
    - `PRO_ECAD_AREA_TYPE_USER_DEFINED`—Specifies an user-defined area.
  - `PRO_E_STD_SECTION`—Specifies the sketched region for the ECAD area. For more information on how to populate the section elements of the sketched region, refer to the [Element Trees: Sketched Features on page 1002](#) section.
  - `PRO_E_ECAD_AREA_3D_VOLUME`—A `ProBoolean` element that specifies whether the ECAD area appears with a 3D quilt. Only `PRO_ECAD_AREA_TYPE_PLACE_KEEPPIN` and `PRO_ECAD_AREA_TYPE_PLACE_KEEPOUT` types of ECAD areas accept a 3D volume on one or two sides.
  - `PRO_E_ECAD_AREA_DEPTH_TYPE`—Specifies the depth type in the form of the enumerated type `ProEcadAreaDepthType`. The depth options are applicable only if the element `PRO_E_ECAD_AREA_3D_VOLUME` is set to `PRO_B_TRUE`. These options are as follows:
    - `PRO_ECAD_AREA_DEPTH_ONE_SIDE`—Creates the ECAD area with a 3D volume on one side of the electrical board.
    - `PRO_ECAD_AREA_DEPTH_TWO_SIDES_SYM`—Places the created ECAD area with a 3D volume at the top and bottom of the electrical board symmetrically.

- `PRO_ECAD_AREA_DEPTH_TWO_SIDES_NOT_SYM`—Places the created ECAD area with a 3D volume at the top and bottom of the electrical board asymmetrically.
- `PRO_E_ECAD_AREA_DEPTH`—Specifies the depth for the ECAD area.
- `PRO_E_ECAD_AREA_DEPTH2`—Specifies the other depth value, which is applicable only if the element `PRO_E_ECAD_AREA_DEPTH_TYPE` is set to `PRO_ECAD_AREA_DEPTH_TWO_SIDES_NOT_SYM`.
- `PRO_E_ECAD_AREA_XHATCH`—Specifies whether the ECAD area is created as a meshed region.
- `PRO_E_ECAD_AREA_TRIM_BNDRS`—Specifies whether to trim the boundary of an ECAD area, where the ECAD area exceeds the boundary of the electric board.
- `PRO_E_ECAD_AREA_COLOR`—Specifies the color of the ECAD area. The default color of the ECAD area is set in the **Creo Parametric Options** dialog box.

Use the function `ProElementEcadAreaProColorSet()` to set the color of the ECAD area. Specify a defined `ProColor` structure as input argument. The data from `ProColor` structure is copied to the element `PRO_E_ECAD_AREA_COLOR`. When you redefine the element tree, the data copied from `ProColor` structure is used to set the color of the ECAD area.

The function `ProElementEcadAreaProColorGet()` returns the color of the specified ECAD area.

- `PRO_E_ECAD_AREA_USER_DEF_TYPE`—Specifies the name of the user-defined area. Similar to the other types of ECAD areas, the color of the user-defined ECAD area is also set using the element `PRO_E_ECAD_AREA_COLOR`.

You can also set the name and color of user-defined area in a comma separated value (.csv) file. The .csv file contains 2 columns, the names of user-defined areas and the names of the colors associated with each area. The names of the colors set in the .csv file must be defined in the \*.dmt file.

Set the path to the .csv file using the configuration option `ecad_usrdef_area_type_file_path`.

If you specify the name of a user-defined area from the .csv file, then the ECAD area is created with the color specified for that area in the .csv file. For an user-defined area that was created from the .csv file, if you use the element `PRO_E_ECAD_AREA_COLOR` to set the area color, then the color set by the element overrides the color set by the \*.csv file.

Refer to the **Creo Parametric ECAD Help** for more information on how to create the .csv file and set colors in \*.dmt files.

---

# Assembly: Basic Assembly Access

## Assembly: Basic Assembly Access

This section describes the Creo TOOLKIT functions that access the contents of a Creo Parametric assembly. Before you read this section, you should be familiar with the following documentation:

- [User Interface: Selection on page 521](#)
- [Core: Coordinate Systems and Transformations on page 230](#)
- [Core: 3D Geometry on page 177](#)

## Structure of Assemblies and Assembly Objects

The object `ProAssembly` is an instance of `ProSolid` and shares the same declaration. The `ProAssembly` object can therefore be used as input to any of the `ProSolid` and `ProMdl` functions applicable to assemblies. In particular, because you can use the function `ProSolidFeatVisit()` to traverse features, you can extract the assembly datum features and their geometry in the same way as for parts (described in detail in the section on [Core: 3D Geometry on page 177](#)).

However, assemblies do not contain active geometry items other than those in datums—that is, no “solid” geometry as described in the [Core: 3D Geometry on page 177](#) and [Element Trees: Principles of Feature Creation on page 771](#) sections. Therefore, the function `ProSolidBodySurfaceVisit()` will not find any surfaces, and solid assembly features such as holes and slots will not contain active surfaces or edges.

The solid geometry of an assembly is contained entirely in its components. Each component is a feature of type `PRO_FEAT_COMPONENT`, which is a reference to a part or another assembly, plus a set of parametric constraints for determining its geometric location within the parent assembly.

Assembly features that are solid, such as holes and slots, and therefore affect the solid geometry of parts in the assembly hierarchy, do not themselves contain the geometry items that describe those modifications. These items are always contained in the parts whose geometry is modified, within local features created for that purpose of type `PRO_FEAT_ASSEM_CUT`.

The most important Creo TOOLKIT functions for assemblies are those that operate on the components of an assembly. The object `ProAsmcomp`, which is an instance of `ProFeature` and shares its `DHandle` declaration, is defined for that purpose. Each assembly component is treated as a variety of feature, and the integer identifier of the component is also the feature identifier.

An assembly component can be another assembly. In general, therefore, an assembly can contain a hierarchy of assemblies and parts at many levels, in which some assemblies and parts may appear more than once. To identify the role of any

---

database item in the context of the root assembly, it is not enough to have the integer identifier of the item and the handle to its owning part or assembly, as would be provided by its `ProFeature` or `ProGeomitem` description. It is also necessary to give the full path of the assembly-component references down from the root assembly to the part or assembly that owns the database item. The object `ProAsmcomppath`, which is used as the input to Creo TOOLKIT assembly functions, accomplishes this purpose.

The declaration of `ProAsmcomppath` is as follows:

```
typedef struct pro_comp_path
{
 ProSolid owner;
 ProIdTable comp_id_table;
 int table_num;
} ProAsmcomppath;
```

The data structure fields are as follows:

- `owner`—Identifies the root assembly
- `comp_id_table` (the component identifier table)—An integer array that contains the identifiers of the components that form the path from the root assembly down to the component part or assembly being referred to
- `table_num`—Specifies the number of component identifiers in the `comp_id_table` array

The following figure [Sample Assembly Hierarchy on page](#) shows an assembly hierarchy with two examples of the contents of a `ProAsmcomppath` object.

[illegible]

In the assembly shown in Figure 12-1, [Sample Assembly Hierarchy on page 1117](#) subassembly C is component identifier 11 within assembly A, Part B is component identifier 3 within assembly AB, and so on. The subassembly AB occurs twice. To refer to the two occurrences of part B, use the following:

| Component B'       | Component B''       |
|--------------------|---------------------|
| table_num = 5      | table_num = 4       |
| comp_id_tab[0] = 2 | comp_id_tab[0] = 11 |
| comp_id_tab[1] = 2 | comp_id_tab[1] = 6  |
| comp_id_tab[2] = 5 | comp_id_tab[2] = 12 |
| comp_id_tab[3] = 2 | comp_id_tab[3] = 3  |
| comp_id_tab[4] = 3 |                     |

A `ProAsmcomppath` structure in which `table_num` is set to 1 contains the same information as a `ProAsmcomp` object.

The object `ProAsmcomppath` is one of the main ingredients in the `ProSelection` object, as described in [The Selection Object on page 521](#).

## Visiting Assembly Components

### Functions Introduced:

- **ProSolidFeatVisit()**

---

- **ProFeatureTypeGet()**

Each component of an assembly is also a feature of that assembly. Therefore, to visit the components, visit the features using `ProSolidFeatVisit()` and find those features whose type is `PRO_FEAT_COMPONENT` using the function `ProFeatureTypeGet()`. You can convert the `ProFeature` object for each component to the `ProAsmcomp` object by casting.

## Properties Related to Component Purpose

Functions Introduced:

- **ProAsmcomppathInit()**
- **ProAsmcompMdlMdlnameGet()**
- **ProAsmcompMdlGet()**
- **ProAsmcomppathMdlGet()**
- **ProAsmcompTypeGet()**
- **ProAsmcompMdlldataGet()**

To create a `ProAsmcomppath` object for the component, use the function `ProAsmcomppathInit()` and set the component identifier table to contain only a single component identifier.

The function `ProAsmcompMdlMdlnameGet()` retrieves the model name and type for the component. If an assembly component is missing on retrieval, the function `ProAsmcompMdlMdlnameGet()` still provides information about the component while the function `ProAsmcompMdlGet()` fails to retrieve a valid model handle.

The function `ProAsmcompMdlGet()` provides the `ProMdl` handle to the part or assembly being referenced by the component. To traverse the components at all levels in the assembly hierarchy, make a recursive function to perform these steps:

1. Call `ProAsmcompMdlGet()` for each component of the root assembly to find the model for the component.
2. Call `ProMdlTypeGet()` to find out if the model is a part or an assembly.
3. If the model is an assembly, traverse each component by calling `ProSolidFeatVisit()` again.

The function `ProAsmcomppathMdlGet()` retrieves a model specified by `ProAsmcomppath` and is useful when analyzing a `ProSelection` object that refers to an assembly.

The function `ProAsmcompTypeGet()` yields the type of the assembly component. Examples of the possible types are as follows:

- `PRO_ASM_COMP_TYPE_WORKPIECE`—Workpiece

- `PRO_ASM_COMP_TYPE_REF_MODEL`—Reference model
- `PRO_ASM_COMP_TYPE_FIXTURE`—Fixture
- `PRO_ASM_COMP_TYPE_MOLD_BASE`—Mold base
- `PRO_ASM_COMP_TYPE_MOLD_COMP`—Mold component
- `PRO_ASM_COMP_TYPE_MOLD_ASSEM`—Mold assembly
- `PRO_ASM_COMP_TYPE_GEN_ASSEM`—General assembly
- `PRO_ASM_COMP_TYPE_CAST_ASSEM`—Cast assembly
- `PRO_ASM_COMP_TYPE_DIE_BLOCK`—Die block
- `PRO_ASM_COMP_TYPE_DIE_COMP`—Die component
- `PRO_ASM_COMP_TYPE_SAND_CORE`—Sand core
- `PRO_ASM_COMP_TYPE_CAST_RESULT`—Cast result
- `PRO_ASM_COMP_TYPE_FROM_MOTION`—Component for use by Creo Simulate.
- `PRO_ASM_COMP_TYPE_NO_DEF_ASSUM`—Component for which Creo Parametric cannot apply default assumptions.

The function `ProAsmcompMdldataGet()` takes the handle to the assembly component as its input argument and retrieves the following information:

- *r\_mdl\_type*—Specifies the type of the model using the enumerated data type `ProMdlType`.
- *r\_mdl\_filetype*—Specifies the file type of the component using the enumerated data type `ProMdlfileType`.
- *r\_mdl\_name*—Specifies the name of the component. You must free this argument using the function `ProWstringFree()`.

## Component Placement

- **`ProAsmcompIsBulkitem()`**
- **`ProAsmcompIsPackaged()`**

The function `ProAsmcompIsBulkitem()` reports whether an assembly component is a bulk item. A bulk item is a non-geometric assembly feature that should appear in an assembly bill of materials.

Use the function `ProAsmcompIsPackaged()` to determine whether the specified component is packaged.

## Simplified Representations

- **`ProAsmcompIsUnderconstrained()`**
- **`ProAsmcompIsFrozen()`**

- 
- **ProAsmcompIsUnplaced()**
  - **ProAsmcompIsPlaced()**
  - **ProAsmcompIsSubstitute()**
  - **ProAsmcompVisibilityGet()**

The function `ProAsmcompIsUnderconstrained()` determines whether the specified component is underconstrained, that is, it has one or more constraints but they are not sufficient to fully constraint the component location.

The function `ProAsmcompIsFrozen()` determines whether the specified component is frozen. The frozen component behaves similar to the packaged component and does not follow the constraints that you specify.

From Creo Parametric 3.0 onward, the frozen status in components is set only during the regeneration of the model. You cannot use the freeze commands in the Creo Parametric user interface, to set the frozen status on a component. By default, behavior of the configuration option `freeze_failed_assy_comp` is ignored. For the models created in releases prior to Creo Parametric 3.0, the frozen status of components is retained during model retrieval.

The configuration option `allow_freeze_failed_assy_comp` allows you to restore the behavior of the configuration option `freeze_failed_assy_comp` and freeze commands in the Creo Parametric user interface. The valid values are:

- `yes`—Specifies that the behavior of the configuration option `freeze_failed_assy_comp` is available. The freeze commands in the Creo Parametric user interface are also available. The valid values for the configuration option `freeze_failed_assy_comp` are:
  - `yes`—Automatically freezes any component that fails retrieval into the assembly at its last known location.
  - `no`—Requires you to perform specific actions to fix the assembly or freeze the component that fails retrieval.
- `no`—This is the default value. Specifies that the behavior of the configuration option `freeze_failed_assy_comp` is ignored.

The functions `ProAsmcompIsUnplaced()` and `ProAsmcompIsPlaced()` determine whether the specified component is unplaced or placed respectively. Unplaced components belong to an assembly without being assembled or packaged.

The function `ProAsmcompIsSubstitute()` determines whether the specified component is substituted. When you substitute a component in a simplified representation, you temporarily exclude the substituted component and superimpose the substituting component in its place.

---

The function `ProAsmcompVisibilityGet()` to skip components of the master representation that are not shown in the representation when you traverse the assembly components of a simplified representation.

## Modifying Component Properties

- **`ProAsmcompTypeSet()`**
- **`ProAsmcompFillFromMdl()`**
- **`ProAsmcompMakeUniqueSubasm()`**
- **`ProAsmcompRmvUniqueSubasm()`**
- **`ProAsmcompSetPlaced()`**

The function `ProAsmcompTypeSet()` enables you to set the type of a component.

The function `ProAsmcompFillFromMdl()` copies the template model into the model of the component.

### Note

The function returns the error `PRO_TK_UNSUPPORTED` when the model to which the template model is being copied is an unsupported model. For example, it is an embedded model.

---

Use the function `ProAsmcompMakeUniqueSubasm()` to create a unique instance of a sub-assembly by specifying the path of the sub-assembly. The function `ProAsmcompRmvUniqueSubasm()` removes the instance of the sub-assembly.

The function `ProAsmcompSetPlaced()` forces Creo Parametric to consider a particular component to be placed or unplaced.

### Example 1: Listing the Members of an Assembly

The sample code in the file `UgAsmCompVisit.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_asmt`, recursively lists the components of an assembly and writes the name of the solid for each component.

## Locations of Assembly Components

Functions Introduced:

- **`ProAsmcomppathTrfGet()`**
- **`ProAsmcomppathTrfSet()`**

- 
- **ProAssemblyDynPosGet()**
  - **ProAssemblyDynPosSet()**
  - **ProAsmpathProarrayFree()**

The function `ProAsmcomppathTrfGet()` provides the transformation matrix that describes the coordinate transformation between the coordinate system of an assembly component and that of the root assembly. As its name implies, its input is a `ProAsmcomppath` object, so it can be applied to a component at any level within an assembly hierarchy. It has an option to provide the transformation from bottom to top, or from top to bottom. (To apply the transformation, use the function `ProPntTrfEval()` or `ProVectorTrfEval()`, described in the section [Coordinate Systems on page 228](#).)

In effect, this function describes the current position and orientation of the assembly component in the root assembly.

Use the function `ProAsmpathProarrayFree()` to free the memory allocated to the `ProArray` of type `ProAsmpath`.

## Example 2: Finding the Position of a Component

The sample code in the file `UgAsmcompTransfGet.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_asm` shows a function that finds the matrix that describes the position of an assembly component in its parent assembly.

## Assembling Components

To assemble components into an assembly, use the methods of feature creation. These methods are described in detail in the section [Assembly: Assembling Components on page 1141](#).

## Redefining and Rerouting Components

The functions used to redefine and reroute components are described in the section [Assembly: Assembling Components on page 1141](#).

## Deleting Components

Function Introduced:

- **ProFeatureDelete()**

The function `ProFeatureDelete()` deletes components. It has the same options as described in the section [Core: Features on page 137](#).

---

## Flexible Components

A flexible component allows variance of items such as features, dimensions, annotations, and parameters of a model in the context of an assembly.

The object `ProAsmitem` describes the contents of a variant item in an assembly component. The declaration for this object is as follows:

```
typedef struct pro_asm_item
{
 ProModelitem item;
 ProName name; /* used for PRO_PARAMETER in
 this case item->type == PRO_PART or PRO_
ASSEMBLY */
 ProAsmcomppath path;
} ProAsmitem;
```

Refer to the section [Exploded State Objects on page 1126](#) for the declaration of the `ProModelitem` object. The field `name` in the `ProAsmitem` object is used only in case of `PRO_PARAMETER`; wherein the field `type` in the `ProModelitem` object is either `PRO_PART` or `PRO_ASSEMBLY`.

In case of parameter initialization, the field `name` specifies the parameter name and the fields `type` and `id` in the `ProModelitem` object initiate the model on which the parameter is defined. For non-parameter items such as features, dimensions, and annotations, the fields `owner`, `type` and `id` in the `ProModelitem` object have the same values as the values of the input arguments for the function `ProModelitemInit()`.

The field `path` specifies the path from the top-level component model. This field is empty if the variant items are defined on the top-level component model.

Functions Introduced:

- **ProAsmcompAsmitemInit()**
- **ProAsmcompFlexibleSet()**
- **ProAsmcompFlexibleUnset()**
- **ProAsmcompIsFlexible()**
- **ProAsmcompFlexiblemodelAdd()**
- **ProAsmcompVarieditemsToModelAdd()**
- **ProAsmcompFlexibleWithPredefineditemsSet()**

Use the function `ProAsmcompAsmitemInit()` to initialize the `ProAsmitem` object that describes the contents of a variant item in an assembly component.

The function `ProAsmcompFlexibleSet()` converts a specified assembly component to a flexible component based on an array of specified variant items.

Use the function `ProAsmcompFlexibleUnset()` to convert a flexible assembly component to a regular component.

---

Use the function `ProAsmcompIsFlexible()` to identify if the specified assembly component is a flexible component. The function returns `PRO_B_TRUE` if the component is a flexible component, otherwise it returns `PRO_B_FALSE`.

The function `ProAsmcompFlexiblemodelAdd()` creates a flexible model from the specified model of the flexible component.

---

 **Note**

The model is temporarily converted into a flexible model in order to allow you to define variant items on it using the existing Creo TOOLKIT functions for variant items. If no variant items are added, the temporary flexible model becomes a regular one upon regeneration. You can convert a model into a temporary flexible model only via Creo TOOLKIT. For information on the functions that can be used to access and modify the variant items in a flexible assembly component, refer to the section [Inheritance Feature and Flexible Component Variant Items](#) on page 1195.

---

The function `ProAsmcompVarieditemsToModelAdd()` adds an array of specified variant items to the predefined flexibility definition of the specified component model. All varied items are replaced by the provided ones.

The function `ProAsmcompFlexibleWithPredefineditemsSet()` converts a specified assembly component to a flexible component using the predefined flexibility definition of the variant items in the component model.

## Embedded Components and Inseparable Assemblies

An embedded component is a copy of the component model that becomes a part of its parent assembly. The parent assembly can be the top-level assembly or a subassembly.

In an inseparable assembly some components are embedded in the assembly. It is a single file that contains the embedded components in the assembly. The assembly structure is visible in the **Model Tree**.

The inseparable assembly is created in the open session of Creo Parametric and must be saved to be used again. When you embed a component in an assembly, you copy the model to the assembly file. The original model is not affected and continues to exist in your database. The new embedded copy is not dependent on the original model. If you no longer need the original model, you can erase it from the session and remove it from the database. When you embed a component, the name of the embedded copy is appended to include the name of the owner assembly.

Functions Introduced:

- **ProAsmcompEmbed()**
- **ProAsmcompExtract()**
- **ProAsmcompEmbeddedOwnerMdlGet()**

Use the function `ProAsmcompEmbed()` to embed selected components in its owner assembly. The input arguments follow:

- *comp\_sel*—Selection of components specified using the array of `ProSelection` object.
- *embed\_recursively*—`ProBoolean` that is used only when the input argument *comp\_sel* is a subassembly selection.
  - If the value of *embed\_recursively* is set to `PRO_B_FALSE` and *comp\_sel* is a subassembly selection, only the subassembly is embedded.
  - If the value of *embed\_recursively* is set to `PRO_B_TRUE` and *comp\_sel* is a subassembly selection, the subassembly and all the possible components are embedded.

The function `ProAsmcompExtract()` extracts the embedded component from the owner assembly. The input argument follow:

- *comp\_sel*—Selection of components specified using the array of `ProSelection` object.
- *newMdlName*—Name of the new model.

The extracted component becomes a standalone model and replaces the embedded component in the assembly. This name of the new model is specified using the input argument *newMdlName*.

The function returns the error `PRO_TK_NO_CHANGE` if the selected component is not embedded in the owner assembly.

The function `ProAsmcompEmbeddedOwnerMdlGet()` returns the handle of the nonembedded owner model for the specified embedded model.

Refer to the Creo Parametric online help, for more information about Inseparable Assemblies and Embedded Components.

## Exploded Assemblies

An exploded view of an assembly shows each component of the model separated from the other components. An exploded view affects the appearance of the assembly only. The design intent and the true distance between the assembly components do not change.

Functions Introduced:

- **ProAssemblyExplode()**
- **ProAssemblyUnexplode()**

---

- **ProAssemblyIsExploded()**

The functions `ProAssemblyExplode()` and `ProAssemblyUnexplode()` enable you to explode and unexplode an assembly. The function `ProAssemblyIsExploded()` identifies whether the specified assembly is exploded. Use this function in the assembly mode only.

The exploded status of an assembly depends on the mode. If an assembly is opened in the drawing mode, the state of the assembly in the drawing view is displayed. The drawing view does not represent the actual exploded state of the assembly. Use the function `ProDrawingViewExplodedGet()` to get the exploded state of an assembly for a specified drawing view.

#### **Note**

These functions explode the assembly using the default exploded state of the assembly. Creo Parametric defines the positions of an assembly component in the default exploded state.

---

## **Exploded State Objects**

The structure `ProExpldstate` describes the contents of an exploded state object. This object uses the same declaration as the `ProModelitem`, `ProGeomitem`, and `ProFeature` objects, which is as follows:

```
typedef struct pro_model_item
{
 ProType type;
 int id;
 ProMdl owner;
} ProExpldstate;
```

## **Visiting Exploded States**

Function Introduced:

- **ProSolidExpldstateVisit()**

The function `ProSolidExpldstateVisit()` enables you to visit all the exploded states in the specified solid, except for the default exploded state. For a detailed explanation of visiting functions, see the section [Visit Functions on page 67](#) in the [Fundamentals on page 30](#) section.

## **Accessing Exploded States**

Functions Introduced:

- **ProExpldstateInit()**

- **ProExpldstateActivate()**
- **ProExpldstateSelect()**
- **ProExpldstateActiveGet()**
- **ProExpldstateNameGet()**
- **ProExpldstateNameSet()**
- **ProExpldstateExplodedcomponentsGet()**
- **ProExpldStateExplodeLinesGet()**
- **ProExpldstateMovesGet()**
- **ProExpldstateMovesSet()**
- **ProExpldAnimDataTranslatemoveInit()**
- **ProExpldAnimDataRotatemoveInit()**
- **ProExpldanimmovedataProarrayFree()**

The function `ProExpldstateInit()` returns the handle to a specified exploded state representation of a solid. It takes the following input arguments:

- *expld\_name*—Specifies the name of the exploded state. If you specify this value, then the function ignores the next argument *expld\_id*.
- *expld\_id*—Specifies the identifier of the exploded state. This argument is applicable only if the argument *expld\_name* is NULL.
- *p\_solid*—Specifies the Creo Parametric solid that contains the exploded state. This argument cannot be NULL.

The function `ProExpldstateActivate()` activates a specified exploded state representation of a solid.

The function `ProExpldstateSelect()` enables you to select a specific exploded state from the list of defined exploded states.

The function `ProExpldstateActiveGet()` retrieves the current active exploded state for the specified solid.

The functions `ProExpldstateNameGet()` and `ProExpldstateNameSet()` return and set, respectively, the name of the exploded state.

The function `ProExpldstateExplodedcomponentsGet()` returns an array of assembly component paths that are included in the exploded state.

The function `ProExpldStateExplodeLinesGet()` returns an array of explode lines for the specified exploded state.

The functions `ProExpldstateMovesGet()` and `ProExpldstateMovesSet()` retrieve and assign, respectively, the array of moves of an exploded state.

---

In order to define an exploded position of an assembly component (or a set of assembly components), you need to perform a sequence of moves. For example, you can move the assembly component over the X-axis, rotate over a selected edge, and then move over the Y-axis. In this case, the final position of the assembly component (or a set of assembly components) is attained by three moves.

The `ProExpldAnimMoveData` object describes the moves of an exploded state. The fields in this object are as follows:

- `comp_set`—Specifies an array of paths of the assembly components, in the form of the `ProAsmcomppath` objects.
- `move`—Specifies the move of the exploded state. It is given by the `ProExpldAnimMove` object. This object contains the following fields:
  - `move_type`—Specifies the move type in terms of the enumerated type `ProExpldAnimMoveType`. The move can be one of the following types:
    - ◆ `PRO_EXPLDANIM_MOVE_TRANSLATE`
    - ◆ `PRO_EXPLDANIM_MOVE_ROTATE`
  - `direction`—Depending upon the selected move type, this field specifies the translation direction or the rotational axis.
  - `value`—Depending upon the selected move type, this field specifies the translational distance or the rotation angle.

The function `ProExpldAnimDataTranslatemoveInit()` creates a translational move based on the specified direction of the translation and the specified array of the assembly components to which this move is applied.

The function `ProExpldAnimDataRotatemoveInit()` creates a rotational move based on the specified rotational axis, rotation angle, and the specified array of the assembly components to which this move is applied.

The function `ProExpldanimmovedataProarrayFree()` clears the array of assigned `ProExpldAnimMoveData` objects.

## Manipulating Exploded States

Functions Introduced:

- **`ProExpldstateCreate()`**
- **`ProExpldstateDelete()`**

The function `ProExpldstateCreate()` creates a new exploded state based on the values of the following input arguments:

- `p_solid`—Specifies the assembly in which the exploded state is created. This argument cannot be `NULL`.

- 
- *name*—Specifies the name of the exploded state. This argument also cannot be NULL.
  - *p\_move\_arr*—Specifies an array of `ProExpldAnimMoveData` objects.

Use the function `ProExpldstatDelete()` to delete a specified exploded state.

## Merge and Cutout

The Merge and Cutout function has been deprecated. Use the Merge feature element tree to create merge or cutout feature. See the section [Merge Feature on page 867](#) in [Element Trees: Edit Menu Features on page 860](#) for more details.

## Automatic Interchange

Functions Introduced:

- **ProAssemblyAutointerchange()**

In Creo Parametric, it is possible to interchange an assembly component with another model that contains equivalent assembly constraints. The Creo TOOLKIT function that performs this action is `ProAssemblyAutointerchange()`. Depending on the type of component interchange, the assembly constraints may need to be respecified for the replacement model.

Instances in a family table share the same assembly constraints. Consequently, you can automatically replace an assembly component with another instance in the component's family table without respecifying any assembly constraints. Simply retrieve the handle for the replacement instance and pass this handle to `ProAssemblyAutointerchange()`.

If the assembly component and replacement model are not instances in the same family table, you can define the necessary relationships between them interactively and save them in an Interchange Assembly. (See the *Assembly Modeling User's Guide* for details.) To perform an interchange using models in an interchange assembly, first retrieve the interchange assembly (using the function `ProMdlnameRetrieve()`), and then pass the handle of the replacement model to function `ProAssemblyAutointerchange()`. Note that the interchange assembly must be in memory before the call to `ProAssemblyAutointerchange()`.

An interchange assembly is not the same as an interchange domain. Interchange domains (`.int` files) contain interchange information, but they can no longer be created using Creo Parametric. However, it is possible to use `ProAssemblyAutointerchange()` to interchange models using an existing interchange domain.

---

# Assembly: Top-down Design

## Overview

This section describes the Creo TOOLKIT Design Manager functions. For more information on Design Intent, Top-Down Design, and other Design Manager issues, refer to the Assembly portion of the Creo Parametric help data, or the Top-Down Design Task Guide.

Creo Parametric supports a design concept called Top-Down Design. Top-Down Design is a method of designing a product by specifying top-level design criteria and passing those criteria down from the top level of the product's structure to all affected subsystems. The Creo TOOLKIT Design Manager functions support this design concept. The next sections contain a brief summary of the six steps of Top-Down Design.

## Defining Design Intent

Before building parts and assemblies, it is important that you define the intent of your design. Doing this means defining:

- Purpose or function of the product
- Major systems and subsystems required
- Incorporation of subsystems into the overall product
- Dependence (if any) on any existing design or product

Design criteria and parameters you specify in this process can be shared globally among all components of the assembly, and can be used to drive design parts, assemblies, and skeleton models.

## Defining Preliminary Product Structure

The preliminary product structure consists of a list of components and their hierarchy within the assembly design. This structure allows creation of subassemblies and parts without requiring creation of geometry and without having to assemble parts. You can add existing subassemblies and parts to this structure. You can also define non-geometric information for the entire design and capture design parameters including description, part number, and part type. Creo TOOLKIT Design Manager manages the assembly structure with assembly component functions.

## Introducing Skeleton Models

Skeleton models are a 3-dimensional layout of the assembly. These models are holders or distributors of critical design information, and can represent space requirements, important mounting locations, and motion.

---

Skeleton models can contain the master definition of the design information, which can be propagated to specific design models. You can also use skeleton models to communicate design information between components. Creo TOOLKIT Design Manager uses skeleton model functions to manipulate these models.

## **Communicating Design Intent Throughout the Assembly Structure**

Designers can distribute top-level design information to dependent skeleton models in the assembly. Design modification becomes a matter of changing certain distributed properties. This propagation of information first occurs from skeleton to skeleton, and then from skeleton to part until all necessary part- or subassembly-specific references have been distributed. Designers can then work on a small subsystem without retrieving or regenerating the entire top-level assembly.

This distribution lets designers reference the same information instead of recreating it for each subassembly. Creo TOOLKIT Design Manager handles the assembly structure with functions for assembly components, features, and copy geometry features.

## **Continued Population of the Assembly**

Populate the assembly with detailed parts and subassemblies in one of two ways:

- Create new components in the context of the assembly
- Model components individually and then bring them into the assembly

Relate individual parts to each other with assembly relations, skeleton models, layouts, and merge features. Creo TOOLKIT Design Manager functions manage the assembly structure with functions for assembly components, features, and copy geometry features.

## **Managing Part Interdependencies**

Associativity allows you to modify design intent to cause automatic updating of the appropriate objects in your assembly. Associativity is accomplished through external relationships, also known as dependencies or references.

Part interdependencies allow for communication of design criteria from components on one level of the design to components on lower levels. Associativity and part dependencies provide a means for controlled changing or updating of an entire assembly design. Reference control manages part interdependencies by limiting undesirable ones or allowing desirable ones.

---

External references are dependencies between a Creo Parametric object (part or subassembly) and information from another object not owned by either the referencing object or its submodels. References to “out-of-model” information are external references. Design Manager handles these references with external reference control functions.

Scope is the range of objects to which a specified object can refer. Scope control functions allow you to define objects to which other objects under development can refer. You can establish global scope settings for all objects or specific settings for individual objects.

Design Manager handles scope issues with external reference control functions. The enumerated type `ProExtRefScope` defines possible scope settings as:

- **None**—Allows no external references.
- **Subassembly**—Allows external references only to components of the same subassembly
- **Skeleton Model**—Allows external references to higher-level skeleton models only
- **All**—Allows external references to any other object anywhere in the assembly

The enumerated type `ProInvalidRefBehavior` defines two methods of handling out-of-scope references. They are as follows:

- **Prohibit Out-of-Scope references**—Creo TOOLKIT reports the external reference as out of scope. You must select another reference.
- **Copy Out-of-Scope Reference**—Creo TOOLKIT warns that the reference is out of scope. You must do one of the following:
  - Cancel the selection and choose a different reference
  - Confirm that you do want to use the selected reference. Creo TOOLKIT then creates a “local backup” of the reference. The local backup reference automatically updates (only while the parent is in the current session).

## Skeleton Model Functions

Functions Introduced:

- **ProAsmSkeletonMdlnameCreate()**
- **ProAsmSkeletonAdd()**
- **ProAsmSkeletonGet()**
- **ProAsmSkeletonDelete()**
- **ProMdlIsSkeleton()**

---

Create skeleton models using function

`ProAsmSkeletonMdlnameCreate()`. This function creates a new skeleton model with the specified name, adds it to the specified assembly, and initializes the model handle. The input arguments are assembly handle, the skeleton model name, and the handle to the part or skeleton used as a template. If the template handle is `NULL`, an empty skeleton model is created.

By default, the absolute accuracy template is used to create a new model. After you create a new model using the initial value of absolute accuracy, the baseline of the outline is used to determine whether the absolute accuracy is still valid. The outline of the model is calculated after the creation of the first feature of the model or placing the first component in an assembly model. Refer to the Creo Parametric help for more information on Model Accuracy.

`ProAsmSkeletonAdd()` adds an existing skeleton model to the specified assembly. The input arguments are a handle for the assembly to which the skeleton model will be added, and a handle to the skeleton model.

`ProAsmSkeletonGet()` returns a skeleton model of the specified assembly that is currently in memory, then initializes the model handle. The input argument is a handle to the specified assembly.

`ProAsmSkeletonDelete()` deletes a skeleton model component from the specified assembly. The input argument is a handle to the specified assembly.

`ProMdlIsSkeleton()` determines if the specified model is a skeleton model. The input argument is a handle to the model to be checked.

## Assembly Component Functions

Functions Introduced:

- **`ProAsmcompMdlnameCreateCopy()`**
- **`ProAsmcompIsUnplaced()`**
- **`ProAsmcompFillFromMdl()`**

Create new components in the specified assembly by copying them from a specified model using `ProAsmcompMdlnameCreateCopy()`. This function creates a new component with the specified name, places it at a default location in the assembly, or leaves it unplaced. The input arguments are the assembly to copy from, the new component name, the new component type (either `PRO_MDL_ASSEMBLY` or `PRO_MODEL_PART`), the handle to the model used as a template, and specification of default or “unplaced” component placement. If the template handle is `NULL`, the component is created empty.

`ProAsmCompIsUnplaced()` determines whether the specified component is unplaced. The input argument is a handle to the component to be checked.

---

`ProAsmCompFillFromMdl()` copies the specified template model into a model of the specified component. The input arguments are the handle to the component, and the handle to the model used as a template for the copy.

## External Reference Control Functions

Functions Introduced:

- **ProRefCtrlSolidSet()**
- **ProRefCtrlSolidGet()**
- **ProRefCtrlEnvirSet()**
- **ProRefCtrlEnvirGet()**
- **ProRefCtrlCheckScope()**

Function `ProRefCtrlSolidSet()` sets a specified external reference control setting on a solid, that is, on a part or assembly. Use `ProRefCtrlSolidGet()` to retrieve the external reference control setting for a specified solid.

`ProRefCtrlEnvirSet()` establishes the run-time environment setting for external reference control. Function `ProRefCtrlEnvirGet()` retrieves this data.

Function `ProRefCtrlCheckScope()` checks whether object-specific reference control settings for a specified model (either an independent object or an assembly component) allow that model to reference information belonging to a different model. The top-level assembly for the component being modified and for the component being referenced must be the same.

If `ProRefCtrlCheckScope()` finds that the owner of the component being modified is `NULL` and the solid (part or assembly) being referenced is not a sub-model of the solid being modified, it reports the reference as out of assembly context. If the `ProMdl` returned is `NULL` but there is a scope violation, the environment scope has been violated.

The enumerated type `ProExtRefScope` defines allowed scope settings for external references as follows:

```
typedef enum{
 PRO_REFCTRL_ALLOW_ALL = 0, /* all external references
allowed*/
 PRO_REFCTRL_ALLOW_SUBASSEMBLY = 1, /* allow only external
references
 inside the same higher
level
 subassembly as that
 of the modified object
*/
 PRO_REFCTRL_ALLOW_SKELETON = 2, /* only external references
to
```

---

```

 skeleton models allowed
*/
 PRO_REFCTRL_ALLOW_NONE = 3 /* no external references
allowed */
} ProExtRefScope;

Enumerated type ProInvalidRefBehavior defines the supported methods
for handling Out-of-Scope external references as follows:
typedef enum
{ PRO_REFCTRL_BACKUP_REF = 0, /* create a local backup
for
 out-of-scope references
*/
 PRO_REFCTRL_PROHIBIT_REF = 1 /* prohibit out-of-scope
external
 references
*/
} ProInvalidRefBehavior;

```

## Feature and CopyGeom Feature Functions

Functions Introduced:

- **ProFeatureCopiedRefStateDetailsGet()**
- **ProFeatureHasBackup()**
- **ProFeatureDSFDependencyStateSet()**
- **ProFeatureDSFDependencyStateGet()**
- **ProFeatureDSFDependencyNotifySet()**
- **ProFeatureDSFDependencyNotifyGet()**

The function `ProFeatureCopiedRefStateDetailsGet()` retrieves the status of copied references for a specified feature. This function supports both CopyGeom features and features with local backup of references.

---

### Note

CopyGeom features have no local backup of reference data.

---

The enumerated type `ProCopiedRefStateDetails` defines possible states of local copies of external references in a CopyGeom feature or in a feature with a local backup.

`ProFeatureHasBackup()` determines if the specified feature has local backup of external references.

---

Use the function `ProFeatureDSFDependencyStateSet()` with dependency status `PRO_DS_F_UPDATE_AUTOMATICALLY`. Use the function `ProFeatureDSFDependencyStateSet()` with dependency status `PRO_DS_F_UPDATE_MANUALLY`.

The function `ProFeatureDSFDependencyStateSet()` sets the dependency status of data sharing feature (DSF). The dependency status governs the behavior of the data sharing feature if the items referenced by the feature have changed. The valid values for the dependency status are:

- `PRO_DS_F_UPDATE_AUTOMATICALLY`—Specifies that all the changes made to the parent model are automatically reflected in the DSF feature.
- `PRO_DS_F_UPDATE_MANUALLY`—Specifies that the feature must be updated manually to keep it up-to-date with the referenced model.
- `PRO_DS_F_NO_DEPENDENCY`—Specifies that there will be no dependency between the DSF feature and referenced model. This includes updating the geometry of the DSF, automatic retrieval of the referenced model and checking in the model to Windchill.

For more information on the dependency statuses, refer to the section [Feature Element Tree on page 1191](#) in *Assembly: Data Sharing Features*.

The function `ProFeatureDSFDependencyStateGet()` gets the current dependency status for the DSF feature.

Use the function `ProFeatureDSFDependencyNotifySet()` to set the notification status, to visually indicate the changes applied to the source geometry of the data sharing feature.

Use the function `ProFeatureDSFDependencyNotifyGet()` to get a visual indication of the current notification status of the DSF feature. If the notification status is set to on, then any change made in the source geometry is indicated in the form of a yellow triangle in the model tree of the DSF feature in the Creo Parametric user interface. Also, a general notification icon appears, adjacent to the regeneration icon on the status bar in the Creo Parametric user interface. This icon indicates the change in the source geometry of the DSF feature.

---

 **Note**

Use the functions `ProFeatureDSFDependencyNotifySet()` and `ProFeatureDSFDependencyNotifyGet()` only if the dependency status of the DSF feature is set to `PRO_DS_F_UPDATE_MANUALLY`.

---

---

## External Reference Data Gathering

An external reference or an external dependency is a relationship between an object, such as, a part or subassembly and some information from another object that is not inherently available to the referencing object all the time. While investigating object dependencies in an assembly, some features may exist that were created in the context of another assembly. All such dependencies are called external dependencies and they point to a component in another assembly. See the Creo Parametric help for more information on external references.

Functions Introduced:

- **ProFeatureExternChildrenGet()**
- **ProFeatureExternParentsGet()**
- **ProSolidExternChildrenGet()**
- **ProSolidExternParentsGet()**
- **ProExtRefInfoFree()**
- **ProExtRefStateGet()**
- **ProExtRefTypeGet()**
- **ProExtRefAsmcompsGet()**
- **ProExtRefOwnMdlGet()**
- **ProExtRefMdlGet()**
- **ProExtRefOwnFeatGet()**
- **ProExtRefFeatGet()**
- **ProExtRefModelitemGet()**
- **ProExtRefInfoExport()**
- **ProExtRefIsDependency()**
- **ProExtRefDependencyIsBreakable()**
- **ProExtRefBreakDependency()**

The function `ProFeatureExternChildrenGet()` retrieves information about external and local children of the specified feature according to the specified reference type. The function `ProFeatureExternParentsGet()` does the same for parents of the feature.

The function `ProSolidExternChildrenGet()` retrieves external and local children of the specified solid according to the specified reference type. The function `ProSolidExternParentsGet()` does the same for parents of the solid.

The function `ProExtRefInfoFree()` releases memory allocated to the external reference data for a feature or solid.

---

The function `ProExtRefStateGet()` returns the external reference status of the referenced item of the specified reference.

The enumerated type `ProRefState` defines the possible states of top-level solids, such as, part, assembly or component, to which a lower-level solid refers.

The function `ProExtRefTypeGet()` returns the type of the external reference.

The enumerated type `ProExtRefType` defines the supported external reference types as follows:

```
typedef enum
{
 PRO_EXT_GEOM_REF = 1, /* all out of solid references,
kept in created in assembly context,
 plins, sections, draft sections
 */
 PRO_LOC_GEOM_REF = 2, /* local for solid references,
kept in plins, sections, draft sections
 */
 PRO_MERGE_REF = 3, /* reference models of merge by
ref feats */
 PRO_EXT_REL_REF = 4, /* out of solid references, ,
kept in symbols used for relations.
 Can be "to solid" or feature,
 geometry references.
 */
 PRO_LOC_REL_REF = 5, /* local for solid references,
kept in symbols used for relations.
 Can be "to solid" or feature,
 geometry references.
 */
 PRO_PRGM_REF = 6, /* out of solid references, ,
kept in symbols used in Pro/Program.
 Always solid references
 */
 PRO_MOVE_COMP_REF = 7, /* Move Components external
references. Kept in components and always "to
 solid".
 This reference is not present in models
 created after Creo Elements/Pro 5.0 */
 PRO_SUBS_REF = 8, /* Substitute Component
references. Kept in components and always "to
 solid"*/
 PRO_MFG_INFO_REF = 9, /* Mfg Info references. Kept in
```

---

```

 mfg feat, always "to solid"
*/
 PRO_INTRCH_REF = 10, /* Interchange Assembly
references.
 Kept in the solid itself.
 Always "to solid"
*/
 PRO_HARN_REF = 11, /* Harness references.
 Kept in the solid itself.
 Always "to solid"
*/
 PRO_FEAT_PAT_REF = 12, /* Feature pattern references.
 Does not include pattern relation
 references. Always "to solid"
*/
 PRO_NON_ASSY_GEOM_REF = 13, /* Out of solid external geometry
refs,
 created not in assembly context,
 kept in plins. (used in external
geom
 copy feature).
*/
 PRO_DIM_BOUND_REF = 14, /* Dim. bound references.
 Kept in the solid itself.
 Always "to solid"
*/
 PRO_HIDDEN_FEM_REFS = 15, /* Hidden Simulate features
references.
 Kept in the solid itself.
 Always "to solid"
*/
 PRO_ANALYSIS_REF = 16, /* Hidden analysis features
references.
 Kept in the solid itself.
 Always "to solid"
*/
 PRO_FEAT_PAT_LOC_REF = 17, /* References between pat. leader
and member
 or between pat. group headers
*/
 PRO_DEPENDENCY_REFS = 18, /* All types of references
collected via
 collect dependencies mechanism. This
type
is not included in COLL_ALL_REFS_TYPE, it
should be invoked separately.
 */
 PRO_IN_CIRCLE_REFS = 19, /* References encountered in
assembly loops.
This is reserved for future use */
 PRO_MEMBER_REFS = 20, /* Component models of assembly
members.

```

---

```

This type is not included in
COLL_ALL_REFS_TYPE, it should be invoked
separately. */
 PRO_LOC_MERGE_REF = 21, /* Merge reference of mirror
geom.
 Always "to solid"
*/
 PRO_ALL_EXT_REF_TYPES = 100, /* Same as PRO_ALL_REF_TYPES
except for
PRO_LOC_GEOM_REF, PRO_LOC_REL_REF,
PRO_LOC_MERGE_REF, PRO_FEAT_PAT_LOC_REF */
 PRO_ALL_REF_TYPES = 101 /* All known types of references,
except for
PRO_DEPENDENCY_REFS, PRO_IN_CIRCLE_REFS and
PRO_MEMBER_REFS.
*/
} ProExtRefType; /* types of references */

```

The structures `ProExtFeatRef` and `ProExtRefInfo` provide pointers to a structure containing external references for a specified feature:

```

typedef struct ext_feat_ref *ProExtFeatRef;
typedef struct
{
 ProExtRefType type; ProExtFeatRef *ext_refs;
 int n_refs;
} ProExtRefInfo;

```

The function `ProExtRefAsmcompsGet()` retrieves from the specified external reference a path to the component from which the reference was created. It also returns a path to the component that owns the specified external reference.

The function `ProExtRefOwnMdlGet()` retrieves a solid that is active in the session and uses the provided reference. The function `ProExtRefMdlGet()` retrieves a solid, in a model that is active in the session. This returned solid is referred to by the specified external reference.

The function `ProExtRefOwnFeatGet()` retrieves from the specified external reference a feature that uses the reference. The function `ProExtRefFeatGet()` retrieves from the specified external reference a feature referred to by the external reference.

The function `ProExtRefModelitemGet()` retrieves from the specified external reference a model item that uses that reference.

The function `ProExtRefInfoExport()` prints out a dependency report for all references of type `PRO_DEPENDENCY_REFS` in the specified format. The input arguments of this function are:

- `info_arr`—Specify all the references of the type `PRO_DEPENDENCY_REFS` collected using the functions `ProSolidExternParentsGet()` and `ProFeatureExternParentsGet()`. All the references that are not dependencies will be ignored.

- 
- `w_fname`—Specify the name of the file to which the report is to be printed.
  - `n_rep_type`—Specify the type of report format. The valid values for this input argument are:
    - `PRO_REPORT_TYPE_CSV`—Specifies a comma separated value file.
    - `PRO_REPORT_TYPE_XML`—Specifies a XML file.

The function `ProExtRefIsDependency()` indicates if the specified reference is an external dependency.

The function `ProExtRefDependencyIsBreakable()` indicates if some of the specified dependencies can be broken or not, in case the corresponding external references are not required.

The function `ProExtRefBreakDependency()` breaks the external references from the specified array of references. Among all references in the specified array, this acts only on those external references that are breakable. As a result of break operation, the dependency associated with the external reference is broken, which prevents the formation of ghost objects in Product Development Management System. Refer the Creo Parametric Help for more information on breaking dependencies.

## Assembly: Assembling Components

### Assembling Components by Functions

This section describes how to use the concepts of feature creation to assemble components into an assembly. Read the section [Element Trees: Principles of Feature Creation on page 771](#) before this section.

Functions Introduced:

- **`ProAsmcompMdlnameCreateCopy()`**
- **`ProAsmcompAssemble()`**
- **`ProAsmcompPositionGet()`**
- **`ProAsmcompPositionSet()`**
- **`ProAsmcompConstraintsWithComppathGet()`**
- **`ProAsmcompConstraintsSet()`**
- **`ProAsmcompAllConstrRemove()`**
- **`ProAsmcompConstrRemove()`**
- **`ProAsmcompRegenerate()`**

Superseded Function:

- **`ProAsmcompConstraintsWithDtmOrientGet()`**

---

Use the function `ProAsmcompMdlnameCreateCopy()` to create a new component in the assembly by copying from an existing model. Specify the handle to the model to be used as a template for the copy. If a model is not specified, a component that does not have initial geometry is created. The function provides the `ProAsmcomp` handle to the new component.

The function `ProAsmcompAssemble()` assembles a component to the assembly or sub-assembly using the parametric constraints available when assembling a component in Creo Parametric. The initial position of the component is a `ProMatrix` object. Specify the orientation of the three axes and the position of the origin of the component coordinate system, with respect to the target assembly coordinate system. The function provides the `ProAsmcomp` feature handle to the newly created assembly.

---

 **Note**

If the transform matrix passed as the initial position of the component is incorrect and non-orthonormal, the function `ProAsmcompAssemble()` returns the error `PRO_TK_BAD_INPUTS`. In such scenario, you can use the function `ProMatrixMakeOrthonormal()` to convert this non-orthonormal matrix to an orthonormal matrix.

---

The function `ProAsmcompPositionGet()` retrieves the component's initial position before constraint are applied.

The function `ProAsmcompPositionSet()` specifies the initial position of the component before constraints are applied. This affects the position of the component only if the component is packaged or underconstrained.

The function `ProAsmcompConstraintsWithDtmOrientGet()` is deprecated in Creo Parametric 7.0.0.0. Use the function `ProAsmcompConstraintsWithCompPathGet()` instead. The function retrieves the specified constraints for the given assembly component and component path. The orientation of the constraints is returned as a value of enumerated data type `ProDatumside`. The input argument *component\_path* is the path to the owner assembly only if the constraints have references to the other members of the top-level assembly. If the constraints have references only to the owner assembly, then you need to pass this as `Null`.

The function `ProAsmcompConstraintsSet()` sets an array of constraints for a given assembly component. This function modifies the component feature data and regenerates the assembly component.

The function `ProAsmcompAllConstrRemove()` removes all types of constraints including interface constraints for the specified assembly component. Specify a `ProAsmcomp` handle to the assembly component in the input argument *p\_feat\_handle*.

---

The function `ProAsmcompConstrRemove()` removes one or all constraints for the specified assembly component. However, the function does not remove the interface constraint. The input arguments are as follows:

- *p\_feat\_handle*—Specifies a `ProAsmcomp` handle to the assembly component.
- *index*—Specifies the constraint index. Pass the value as `-1` to remove all the constraints. Use the function `ProAsmcompConstraintGet()` to determine the index of a particular constraint.

The function `ProAsmcompRegenerate()` regenerates the placement instructions for an assembly component, given the component handle. The function regenerates the placement instructions just as in an interactive Creo Parametric session. Alternatively, you can use the visit functionality to regenerate recursively some or all of the components in the assembly.

## Assembling a Component Parametrically

Functions Introduced:

- **`ProAsmcompconstraintAlloc()`**
- **`ProAsmcompconstraintTypeGet()`**
- **`ProAsmcompconstraintTypeSet()`**
- **`ProAsmcompconstraintAsmreferenceGet()`**
- **`ProAsmcompconstraintAsmreferenceSet()`**
- **`ProAsmcompconstraintCompreferenceGet()`**
- **`ProAsmcompconstraintCompreferenceSet()`**
- **`ProAsmcompconstraintOffsetGet()`**
- **`ProAsmcompconstraintOffsetSet()`**
- **`ProAsmcompconstraintAttributesGet()`**
- **`ProAsmcompconstraintAttributesSet()`**
- **`ProAsmcompconstraintUserdataGet()`**
- **`ProAsmcompconstraintUserdataSet()`**
- **`ProAsmcompconstraintFree()`**
- **`ProAsmcompconstraintArrayFree()`**

The function `ProAsmcompconstraintAlloc()` allocates memory for the constraint data structure. This data structure describes the types of constraints that can be applied to the assembly component.

The function `ProAsmcompconstraintTypeGet()` retrieves the constraint type of the specified constraint. The types of constraints are:

- 
- `PRO_ASM_UNDEF`—Use this option to initialize a variable. This option is never returned by the function `ProAsmcompconstraintTypeGet()` and can be ignored.
  - `PRO_ASM_MATE`—Use this option to make two surfaces coincident with one another and facing each other.
  - `PRO_ASM_MATE_OFF`—Use this option to make two planar surfaces parallel and facing each other.
  - `PRO_ASM_ALIGN`—Use this option to make two planes coplanar, two axes coaxial or two points coincident. You can also align revolved surfaces or edges.
  - `PRO_ASM_ALIGN_OFF`—Use this option to align two planar surfaces at an offset.
  - `PRO_ASM_INSERT`—Use this option to insert a "male" revolved surface into a "female" revolved surface, making their respective axes coaxial.
  - `PRO_ASM_ORIENT`—Use this option to make two planar surfaces to be parallel in the same direction.
  - `PRO_ASM_CSYS`—Use this option to place a component in an assembly by aligning the coordinate system of the component with the coordinate system of the assembly.
  - `PRO_ASM_TANGENT`—Use this option to force two surfaces to be tangent.
  - `PRO_ASM_PNT_ON_SRF`—Use this option to align a point with a of a surface.
  - `PRO_ASM_EDGE_ON_SRF`—Use this option to align a straight edge with a surface.
  - `PRO_ASM_DEF_PLACEMENT`—Use this option to align the default coordinate system of the component to the default coordinate system of the assembly.
  - `PRO_ASM_SUBSTITUTE`—This constraint type is used in simplified representations only when the component is replaced by a substitute component.
  - `PRO_ASM_PNT_ON_LINE`—Use this option to force the intersection of a line with a point.
  - `PRO_ASM_FIX`—Use this option to fix the current location of the component as a constraint.
  - `PRO_ASM_AUTO`—Not for use by Creo TOOLKIT.
  - `PRO_ASM_ALIGN_ANG_OFF`—This option can only be used in conjunction with another constraint. If you have two flat surfaces and create an align edge

---

or axis constraint where the edge or axis lies on the surface, then you can specify an angle offset constraint between the two surfaces.

- `PRO_ASM_MATE_ANG_OFF`—This option can only be used in conjunction with another constraint. If you have two flat surfaces and create a mate edge or axis constraint where the edge or axis lies on the surface, then you can specify an angle offset constraint between the two surfaces.
- `PRO_ASM_CSYS_PNT`—This option can be used in **User Defined**, **General**, and **Gimbal** connections. Use this option to place a component in an assembly by aligning the origins of the coordinate systems. Here the axes are not aligned, and thus, the component can be freely rotated along the three rotation axes. In **User Defined** and **Rigid** connections you can switch from **Coord Sys Point** to **Coord Sys** constraint and vice-versa.

Use the function `ProAsmcompconstraintTypeSet()` to set the constraints for the assembly component constraint.

The function `ProAsmcompconstraintAsmreferenceGet()` retrieves the `ProSelection` handle to a reference on the assembly and the orientation of the assembly for the specified assembly component constraint. The assembly orientation can have the following values:

- `PRO_DATUM_SIDE_YELLOW`—The primary side of the datum plane which is the default direction of the arrow.
- `PRO_DATUM_SIDE_RED`—The secondary side of the datum plane which is the direction opposite to that of the arrow.
- `PRO_DATUM_SIDE_NONE`—No orientation is specified.

The assembly orientation is applicable for legacy models prior to M260.

The function `ProAsmcompconstraintAsmreferenceSet()` selects a reference on the assembly and sets the orientation of the assembly for a specified assembly component constraint.

---

 **Note**

The assembly reference selection must be assigned an assembly component path, even if the reference geometry is in the top-level assembly. In that situation the `table_num` value of the `ProAsmcomppath` structure would be 0.

---

The function `ProAsmcompconstraintCompreferenceGet()` retrieves the `ProSelection` handle to a reference on the placed component and the orientation of the component for the specified assembly component constraint. The component orientation can have the following values:

- `PRO_DATUM_SIDE_YELLOW`—The primary side of the datum plane which is the default direction of the arrow.
- `PRO_DATUM_SIDE_RED`—The secondary side of the datum plane which is the direction opposite to that of the arrow.
- `PRO_DATUM_SIDE_NONE`—No orientation is specified.

The component orientation is applicable for legacy models prior to M260.

`ProAsmcompconstraintCompreferenceSet()` selects a reference on the placed component and sets the orientation of the component for a specified assembly component constraint.

`ProAsmcompconstraintOffsetGet()` retrieves the offset value from the reference for the Mate or Align constraint type and the function `ProAsmcompconstraintOffsetSet()` defines the offset value.

The function `ProAsmcompconstraintAttributesGet()` retrieves the constraint attributes for the specified assembly component constraint. The function `ProAsmcompconstraintAttributesSet()` sets the constraint attributes. The types of constraint attributes are:

- `PRO_ASM_CONSTR_ATTR_FORCE`—Force the constraint, causing strict alignment for axes, lines, and points. You can force a constraint only if the constraint type is Align.
- `PRO_ASM_CONSTR_ATTR_IGNORE`—Not for use by Creo TOOLKIT.
- `PRO_ASM_CONSTR_ATTR_NONE`—No constraint attributes are specified. This is the default value.
- `PRO_ASM_CONSTR_ATTR_INTFC_DEPENDENT`—When set in a component interface, the constraint cannot be changed by application of settings making it coincident, offset, or reoriented.
- `PRO_ASM_CONSTR_ATTR_INACTIVE`—The constraint should not be applied to the feature. This corresponds to the **Constraint Enabled** check box in the component feature user interface.

The function `ProAsmcompconstraintUserdataGet()` retrieves the user data for the given constraint while the function `ProAsmcompconstraintUserdataSet()` specifies the user data for the given constraint.

Use the function `ProAsmcompconstraintFree()` to free the constraint data structure from the memory.

The function `ProAsmcompconstraintArrayFree()` provides a single function to use to free an entire `ProArray` of `ProAsmcompconstraint` structures.

---

## Example 1: Component Constraints

The sample code in the file `UgAsmcompConstraint.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_asm` displays each constraint of the component visually on the screen, and includes a text explanation for each constraint.

## Example 2: Assembling Components

The sample code in the file `UgAsmcompConstraint.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_asm` demonstrates how to assemble a component into an assembly, and how to constrain the component by aligning datum planes. If the complete set of datum planes is not found, the function will show the component constraint dialog to the user to allow them to adjust the placement as they wish.

## Redefining Components Interactively

The functions described in this section enable you to reroute previously assembled components, as in an interactive session of Creo Parametric.

Functions Introduced:

- **ProAsmcompConstrRedefUI()**
- **ProAsmcompPackageMove()**

The function `ProAsmcompConstrRedefUI()` is intended for use in interactive Creo TOOLKIT applications. This function displays the Creo Parametric Component Placement dialog box, enabling you to redefine the constraints interactively. Control is given back to the Creo TOOLKIT application when you select **OK** or **Cancel** the dialog box is closed.

The function `ProAsmcompPackageMove()` supports interactive and programmatic packaging of components. The arguments to this function allow the user or the program to repackage an existing component. If the component is used for interactive purposes, the control is given back to the Creo TOOLKIT application when you select **OK** or **Cancel** the dialog box is closed.

## Assembling Components by Element Tree

Assembly components are treated as features in Creo Parametric, so it is logical to replace those dedicated functions by a feature element tree that provides the same functionality, but uses the existing Creo TOOLKIT functions `ProFeatureCreate()`, `ProFeatureRedefine()` and `ProFeatureElementtreeExtract()`.

---

## The Element Tree for an Assembly Component

The element tree for a component assembly is documented in the header file `ProAsmcomp.h` and is shown in the following figure.

### Top-level Feature Element tree for Component Assembly

```
PRO_E_FEATURE_TREE
|
|--PRO_E_FEATURE_TYPE
|
|--PRO_E_COMPONENT_MODEL
|
|--PRO_E_COMPONENT_MISC_ATTR
|
|--PRO_E_COMPONENT_INIT_POS
|
|--PRO_E_COMP_PLACE_INTERFACE
|
|--PRO_E_COMPONENT_SETS
|
|--PRO_E_COMPONENT_CONSTRAINTS
|
|--PRO_E_COMPONENT_MOVEMENTS
```

#### Model

The element `PRO_E_COMPONENT_MODEL` defines the model to be assembled into the assembly.

#### Attributes

The element `PRO_E_MISC_ATTR` defines the type of component being assembled. You can also access this property through `ProAsmcompTypeGet()` and `ProAsmcompTypeSet()`.

#### Initial Position

The element `PRO_E_COMPONENT_INIT_POS` defines the absolute position of the component in the absence of any parametric constraints. Its value is a `ProMatrix` object describing the component position. If you supply this element but no `PRO_E_COMPONENT_CONSTRAINT` elements, the component is assembled as packaged at this location.

If you under constrain the component, the value of this element is used in conjunction with the constraints to set the packaged position for the component.

## Constraint Sets and Mechanism Connections

The element `PRO_E_COMPONENT_SETS` is an array of elements of type `PRO_E_COMPONENT_SET`. Each of these elements is a predefined set of constraints.

Although you can define a user-defined type of constraint set containing any type and combination of constraints, the set element is also important when used to create predefined types of sets in Creo Parametric.

Mechanism uses predefined set types to represent connections. The connection can also contain elements describing mechanism motion axes stored for the connection.

### PRO\_E\_COMPONENT\_SET

```
PRO_E_COMPONENT_SET
|--PRO_E_COMPONENT_SET_ID
|--PRO_E_COMPONENT_SET_TYPE
|--PRO_E_COMPONENT_SET_NAME
|--PRO_E_COMPONENT_SET_MISC_ATTR
|--PRO_E_COMPONENT_SET_FLIP
|--PRO_E_COMPONENT_JAS_SETS
 |--PRO_E_COMPONENT_JAS_SET
 |--PRO_E_COMPONENT_JAS_ZERO_TYPE
 |--PRO_E_COMPONENT_JAS_REFS
 |--PRO_E_COMPONENT_JAS_ORANGE_REF
 |--PRO_E_COMPONENT_JAS_GREEN_REF
 |--PRO_E_COMPONENT_JAS_O_OFFSET_VAL
 |--PRO_E_COMPONENT_JAS_REGEN_VALUE_GROUP
 |--PRO_E_COMPONENT_JAS_REGEN_VALUE_FLAG
 |--PRO_E_COMPONENT_JAS_REGEN_VALUE
 |--PRO_E_COMPONENT_JAS_MIN_LIMIT
 |--PRO_E_COMPONENT_JAS_MIN_LIMIT_FLAG
 |--PRO_E_COMPONENT_JAS_MIN_LIMIT_VAL
 |--PRO_E_COMPONENT_JAS_MIN_LIMIT_REF
 |--PRO_E_COMPONENT_JAS_MAX_LIMIT
 |--PRO_E_COMPONENT_JAS_MAX_LIMIT_FLAG
 |--PRO_E_COMPONENT_JAS_MAX_LIMIT_VAL
 |--PRO_E_COMPONENT_JAS_MAX_LIMIT_REF
 |--PRO_E_COMPONENT_JAS_RESTITUTION
 |--PRO_E_COMPONENT_JAS_RESTITUTION_FLAG
 |--PRO_E_COMPONENT_JAS_RESTITUTION_COEF
 |--PRO_E_COMPONENT_JAS_FRICTION
 |--PRO_E_COMPONENT_JAS_FRICTION_FLAG
 |--PRO_E_COMPONENT_JAS_STATIC_FRIC_COEF
 |--PRO_E_COMPONENT_JAS_KINEM_FRIC_COEF
 |--PRO_E_COMPONENT_JAS_RADIUS_VALUE
```

Each component set contains the following elements:

- **PRO\_E\_COMPONENT\_SET\_ID**—Specifies the component set id. This value is generated automatically by Creo Parametric upon creation of the set. The set ids should remain the same when redefining the component.
- **PRO\_E\_COMPONENT\_SET\_TYPE**—Specifies the component set type. The following table describes the valid values in details.

| Component Set Type           | Description                                                                                                                                                                                                       |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_ASM_SET_TYPE_FIXED       | A "Rigid" Mechanism connection: Connects two components so that they do not move relatively to each other.                                                                                                        |
| PRO_ASM_SET_TYPE_PIN         | A "Pin" Mechanism connection: Connects a component to a referenced axis so that the component rotates or moves along this axis with one degree of freedom.                                                        |
| PRO_ASM_SET_TYPE_SLIDER      | A "Slider" Mechanism connection: Connects a component to a referenced axis so that the component moves along the axis with one degree of freedom.                                                                 |
| PRO_ASM_SET_TYPE_CYLINDRICAL | A "Slider" Mechanism connection: Connects a component so that it moves along and rotates about a specific axis with two degrees of freedom.                                                                       |
| PRO_ASM_SET_TYPE_PLANAR      | A "Planar" Mechanism connection: Connects components so that they move in a plane relatively to each other with two degrees of freedom in the plane and one degree of freedom around an axis perpendicular to it. |
| PRO_ASM_SET_TYPE_BALL        | A "Ball" Mechanism connection: Connects a component so that it can rotate in any direction with three degrees of freedom (360° rotation).                                                                         |
| PRO_ASM_SET_TYPE_WELD        | A "Weld" Mechanism connection: Connects a component to another so that they do not move relatively to each other.                                                                                                 |
| PRO_ASM_SET_TYPE_BEARING     | A "Bearing" Mechanism connection: A combination of Ball and Slider connections with four degrees of freedom.                                                                                                      |
| PRO_ASM_SET_TYPE_GENERAL     | A "General" Mechanism connection: Has one or two configurable constraints that are identical to those in a user-defined set.                                                                                      |
| PRO_ASM_SET_TYPE_6DOF        | A "Six Degrees of Freedom" Mechanism connection: Does not affect the motion of the component in relation to the assembly because no constraints are applied.                                                      |
| PRO_ASM_SET_TYPE_GIMBAL      | A "Gimbal" Mechanism connection: This connection behaves similar to the "Six Degrees of Freedom" connection except that in Gimbal connection the translational degrees of freedom are locked.                     |

| Component Set Type            | Description                                                                                                                                                                   |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_ASM_SET_TYPE_SLOT         | A "Slot" Mechanism connection: A point on a non straight trajectory. This connection has four degrees of freedom, where the point follows the trajectory in three directions. |
| PRO_ASM_SET_USER_DEFINED_TYPE | A user defined constraint set. Legacy components which do not have defined Mechanism connections will always use this type.                                                   |

- PRO\_E\_COMPONENT\_SET\_NAME—Specifies the name of the component set.
- PRO\_E\_COMPONENT\_SET\_MISC\_ATTR—Specifies the component set attributes. Currently, these attributes are limited to flags which enable or disable the set.
- PRO\_E\_COMPONENT\_JAS\_SETS is an array of compound elements of type PRO\_E\_COMPONENT\_JAS\_SET which indicate Joint Axis Set (JAS). It represents the motion axis settings for the Mechanism connection. It consists of the following elements—
  - PRO\_E\_COMPONENT\_JAS\_ZERO\_TYPE—Specifies the type of motion represented by this motion axis element and the value is drawn from the following types:
    - ◆ PRO\_AXIS\_ZERO\_TRANSLATE1
    - ◆ PRO\_AXIS\_ZERO\_TRANSLATE2
    - ◆ PRO\_AXIS\_ZERO\_TRANSLATE3
    - ◆ PRO\_AXIS\_ZERO\_ROTATION1
    - ◆ PRO\_AXIS\_ZERO\_ROTATION2
    - ◆ PRO\_AXIS\_ZERO\_ROTATION3
    - ◆ PRO\_AXIS\_ZERO\_SLOT
  - PRO\_E\_COMPONENT\_JAS\_REFS—Specifies initial position references for the motion axis.
    - ◆ PRO\_E\_COMPONENT\_JAS\_ORANGE\_REF—Specifies the component reference of the motion axis.
    - ◆ PRO\_E\_COMPONENT\_JAS\_GREEN\_REF—Specifies the assembly reference of the motion axis.
    - ◆ PRO\_E\_COMPONENT\_JAS\_0\_OFFSET\_VAL—Specifies the zero offset value for the motion axis.
  - PRO\_E\_COMPONENT\_JAS\_REGEN\_VALUE\_GROUP is a compound element specifying the motion axis regeneration options. The motion axis regeneration value is an offset value used when regenerating the model.

---

This value determines the offset of the component being placed in the assembly from the zero reference during regeneration.

- ◆ `PRO_E_COMPONENT_JAS_REGEN_VALUE_FLAG`—Specifies enabling or disabling the regeneration value. When you disable it, the motion axis becomes free of constraint.
- ◆ `PRO_E_COMPONENT_JAS_REGEN_VALUE`— Specifies the value along this motion axis that will be used for regeneration of the position and orientation of the component.
- `PRO_E_COMPONENT_JAS_MIN_LIMIT` specifies the minimum limit for regeneration value. It consists of the following elements:
  - ◆ `PRO_E_COMPONENT_JAS_MIN_LIMIT_FLAG`—A boolean element indicating whether the minimum limit is applied to the component.
  - ◆ `PRO_E_COMPONENT_JAS_MIN_LIMIT_VAL`—The value for the minimum limit.
  - ◆ `PRO_E_COMPONENT_JAS_MIN_LIMIT_REF`—A selected item which serves as the minimum limit instead of using an assigned value.
- `PRO_E_COMPONENT_JAS_MAX_LIMIT`—Specifies the maximum limit for regeneration value. It consists of the following elements:
  - ◆ `PRO_E_COMPONENT_JAS_MAX_LIMIT_FLAG`—A boolean element indicating if the maximum limit is applied to the component.
  - ◆ `PRO_E_COMPONENT_JAS_MAX_LIMIT_VAL`—The value for the maximum limit.
  - ◆ `PRO_E_COMPONENT_JAS_MAX_LIMIT_REF`—A selected item, which serves as the maximum limit instead of using an assigned value.
- `PRO_E_COMPONENT_JAS_RESTITUTION`—Specifies coefficient of restitution for the motion axis. It is a compound element and consists of the following elements:
  - ◆ `PRO_E_COMPONENT_JAS_RESTITUTION_FLAG`—A boolean element indicating if a coefficient of restitution is applied.
  - ◆ `PRO_E_COMPONENT_JAS_RESTITUTION_COEF`— Specifies the coefficient of restitution value.
- `PRO_E_COMPONENT_JAS_FRICTION`—Specifies coefficient of friction for the motion axis. It is a compound element and consists of the following elements:
  - ◆ `PRO_E_COMPONENT_JAS_FRICTION_FLAG`—A boolean element indicating if the coefficients of friction are applied.

- ◆ `PRO_E_COMPONENT_JAS_STATIC_FRIC_COEF`— Specifies the coefficient of static friction value.
- ◆ `PRO_E_COMPONENT_JAS_KINEM_FRIC_COEF`— Specifies the coefficient of kinetic friction value.
- ◆ `PRO_E_COMPONENT_JAS_RADIUS_VALUE`— Specifies the contact radius value.

## Placement Constraints

The element `PRO_E_COMPONENT_CONSTRAINTS` is an array of elements of type `PRO_E_COMPONENT_CONSTRAINT`, each representing a single component placement constraint.

### `PRO_E_COMPONENT_CONSTRAINT`

```
PRO_E_COMPONENT_CONSTRAINT
|--PRO_E_COMPONENT_CONSTR_TYPE
|--PRO_E_COMPONENT_COMP_CONSTR_REF
|--PRO_E_COMPONENT_ASSEM_CONSTR_REF
|--PRO_E_COMPONENT_CONSTR_REF_OFFSET
|--PRO_E_COMPONENT_USER_DATA
|--PRO_E_COMPONENT_CONSTR_ATTR
|--PRO_E_COMPONENT_COMP_ORIENT
|--PRO_E_COMPONENT_ASSM_ORIENT
|--PRO_E_COMPONENT_CONSTR_SET_ID
|--PRO_E_COMPONENT_SLOT_EXTRA_CRV_REF
```

Each constraint element contains the following elements:

- `PRO_E_COMPONENT_CONSTR_TYPE`—See discussion regarding [Assembling a Component Parametrically on page 1143](#).
- `PRO_E_COMPONENT_COMP_CONSTR_REF`—Identifies the geometry item in the component referenced by the constraint. This element is of type `Selection`.
- `PRO_E_COMPONENT_ASSEM_CONSTR_REF`—Identifies the constraint reference in the assembly.

#### Note

this reference must include a component path referencing the top level assembly, even if the reference belongs directly to the top level assembly.

- `PRO_E_COMPONENT_CONSTR_REF_OFFSET`—Gives the offset value, if the constraint type is an offset.

- `PRO_E_COMPONENT_USER_DATA`—Specifies user data.
- `PRO_E_COMPONENT_CONSTR_ATTR`—See discussion under [Assembling a Component Parametrically on page 1143](#).
- The elements `PRO_E_COMPONENT_COMP_ORIENT` and `PRO_E_COMPONENT_ASSM_ORIENT` indicate which side of a referenced surface to be used. These values have different meanings for user-defined constraint sets and mechanism connections. See discussion under `ProAsmcompconstraintAsmreferenceGet()` and `ProAsmcompconstraintCompreferenceGet()`.
- `PRO_E_COMPONENT_CONSTR_SET_ID`—Specifies the index of the member of the array of `PRO_E_COMPONENT_SET` elements that owns the constraint.
- `PRO_E_COMPONENT_SLOT_EXTRA_CRV_REF`—Specifies the extra curve references used by a Slot connection only. This is a multivalued element.

## Component Movement in Assembly

The element `PRO_E_COMPONENT_MOVEMENTS` is an array of elements of type `PRO_E_COMPONENT_MOVEMENT` which represent movements applied to the component being assembled.

### PRO\_E\_COMPONENT\_MOVEMENT

|                                                |
|------------------------------------------------|
| <code>PRO_E_COMPONENT_MOVEMENT</code>          |
| -- <code>PRO_E_COMPONENT_MOVEMENT_TYPE</code>  |
| -- <code>PRO_E_COMPONENT_MOVEMENT_REF</code>   |
| -- <code>PRO_E_COMPONENT_MOVEMENT_VALUE</code> |

Each movement element contains the following elements:

- `PRO_E_COMPONENT_MOVEMENT_TYPE` specifies allowed movement types

Use the following options to move the component parallel to the reference selected and are of the following values:

- `PRO_ASM_TRANSLATE_X`
- `PRO_ASM_TRANSLATE_Y`
- `PRO_ASM_TRANSLATE_Z`

Use the following options to rotate the component about the selected references.

- `PRO_ASM_ROTATE_X`
- `PRO_ASM_ROTATE_Y`
- `PRO_ASM_ROTATE_Z`
- `PRO_ASM_TWIST_FIT`

- `PRO_E_COMPONENT_MOVEMENT_REF` specifies the translational and rotational motion references.
- `PRO_E_COMPONENT_MOVEMENT_VALUE`

## Placement via Interface

The element `PRO_E_COMP_PLACE_INTERFACE` is a compound element that defines an alternative assembly technique: using component interfaces to define the placement instead of traditional constraints.

### `PRO_E_COMP_PLACE_INTERFACE`

```
PRO_E_COMP_PLACE_INTERFACE
|--PRO_E_COMP_PLACE_INTERFACE_TYPE
|--PRO_E_COMP_PLACE_INTERFACE_COMP
|--PRO_E_COMP_PLACE_INTERFACE_ASSEMS
 |--PRO_E_COMP_PLACE_INTERFACE_ASSEM
 |--PRO_E_COMP_PLACE_INTERFACE_ASSEM_REF
```

The element contains the following elements:

- `PRO_E_COMP_PLACE_INTERFACE_TYPE`—Specifies the interface types as follows:
  - `PRO_ASM_INTFC_TO_GEOM`—Assembly of the component by matching an interface on the component to referenced geometry in the assembly.
  - `PRO_ASM_INTFC_TO_INTFC`—Assembly of the component by matching an interface on the component to an interface defined in the assembly.

#### Note

If this value is not set (set to 0) then component interfaces are not used to define this component.

- `PRO_E_COMP_PLACE_INTERFACE_COMP`—Specifies the component model interface. This should contain the component interface feature.
- `PRO_E_COMP_PLACE_INTERFACE_ASSEMS`—Specifies an array of assembly references. If the placement type is `PRO_ASM_INTFC_TO_GEOM` this contains 1 or more geometric references from the assembly. If the placement type is `PRO_ASM_INTFC_TO_INTFC` this contains a single reference element containing the component interface feature.

---

## Assembling Components Using Intent Datums

You can use Intent Datums such as Intent Axis, Intent Point, Intent Plane, and Intent Coordinate System in assembly component placement and constraints.

### Example 3: Assembling Components Using Intent Datums

The sample code in the file `UgAsmcompConstraint.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_asm` demonstrates how to assemble a component into an assembly using intent point and intent plane, and how to set constraints after assembling a component using intents.

## Assembly: Kinematic Dragging and Creating Snapshots

### Assembly: Kinematic Dragging and Creating Snapshots

This section describes the Creo TOOLKIT functions for dragging assembly entities through an allowable range to see how your assembly works in a specific configuration. These functions provide the same result as obtained by using the **Drag** dialog box in the Creo Parametric user interface.

This section also describes the functions to create snapshots of the assembly in different positions and orientations.

### Connecting to a Kinematic Drag Session

Functions Introduced:

- **ProKinDragStart()**
- **ProKinDragStop()**
- **ProKinDragSessionInquire()**
- **ProKinDragEnvironmentSet()**
- **ProKinDragReconnect()**

The function `ProKinDragStart()` starts a drag session. This function should be called before any other function for Kinematic drag or snapshots. All subsequent functions work with the snapshots of the top-level assembly. This function can be called for design assemblies in the Standard Assembly and Mechanism modes only. It cannot be used in the following cases:

- If the assembly is in the exploded state

- If the Sketcher mode is active
- When component placement is active
- When the **Drag** dialog box is active

The function `ProKinDragStop()` stops the drag session. Use `ProWindowRefresh()` to view the change in the graphic window scale according to the updated outline.

The function `ProKinDragSessionInquire()` determines if the drag session is active. The drag session may exist automatically in some cases, such as redefine, regeneration, window switch, representation mode change.

The function `ProKinDragEnvironmentSet()` sets the environment for dragging and reconnect operations. It requires the following input arguments:

- *snap\_name*—Specifies the name of the active snapshot whose constraints are used for the drag operation. The snapshot is checked for statuses such as good, outdated, or incomplete. Pass NULL if not required.

The *outdated* status means some parts from the body have a relative transformation that is different from the current transformation. The *incomplete* status means that some parts from the body are missing in the active snapshot.

- *path*—Specifies the path in terms of the `ProAsmcomppath` object to the active snapshot of a subassembly contained within the top-level assembly. Pass NULL for a top-level assembly snapshot.
- *type*—Specifies the type of drag to be performed. It is given by the enumerated type `ProKinDragType` that takes the following values:
  - `PRO_KIN_POINT_DRAG`—Select a point to drag in a part within the top-level assembly. During the dragging operation, the point you selected follows the pointer's movement while maintaining connections.
  - `PRO_KIN_BODY_DRAG`—Select a part from the top-level assembly to drag. When you drag a part, its position in the graphics window changes, but its orientation remains fixed. If the assembly requires a part to be reoriented in conjunction with a change in position, the part does not move at all, as the assembly cannot reassemble in the new position.
  - `PRO_KIN_ADVANCED_TRANS_X`—Specifies the translation in the X direction of the selected coordinate system. This type is applicable only in case of an advanced drag operation. You can select a coordinate system by selecting the part to be dragged.
  - `PRO_KIN_ADVANCED_TRANS_Y`—Specifies the translation in the Y direction of the selected coordinate system. This type is applicable only in case of an advanced drag operation.

- `PRO_KIN_ADVANCED_TRANS_Z`—Specifies the translation in the Z direction of the selected coordinate system. This type is applicable only in case of an advanced drag operation.
- `PRO_KIN_ADVANCED_ROT_X`—Specifies the rotation around the X axis of the selected coordinate system. This type is applicable only in case of an advanced drag operation. You can select a coordinate system by selecting the part to be dragged.
- `PRO_KIN_ADVANCED_ROT_Y`—Specifies the rotation around the Y axis of the selected coordinate system. This type is applicable only in case of an advanced drag operation.
- `PRO_KIN_ADVANCED_ROT_Z`—Specifies the rotation around the Z axis of the selected coordinate system. This type is applicable only in case of an advanced drag operation.
- *refobject*—Specifies the selection reference in the form a coordinate system (`PRO_CSYS`), part (`PRO_PART`), or mechanism body (`PRO_MDO_BODY`) for an advanced drag operation. This argument is relevant only for advanced drag types. For all other drag types, it is ignored and `NULL` should be passed.

The function `ProKinDragReconnect()` reconnects to a drag session taking into account constraints but not transforms from the active snapshot specified in `ProKinDragEnvironmentSet()`. Use `ProWindowRefresh()` to view the changes in the positions of the assembly components. Refer to the sections [Snapshot Constraints on page 1159](#) and [Snapshot Transforms on page 1162](#) for more information.

## Performing Kinematic Drag

Function Introduced:

- **`ProKinDragPerformMove()`**

The function `ProKinDragPerformMove()` drags the selected geometric object to the specified X and Y screen coordinates given by `ProArray` of `Pro2dPnt` object. The geometric object can be `PRO_POINT`, `PRO_SURFACE_PNT`, `PRO_AXIS`, `PRO_EDGE`, `PRO_CURVE`, `PRO_DATUM_PLANE`, `PRO_SRF_PLANE_PNT`, or `PRO_SURFACE` in case of a point drag, and `PRO_PART` or `PRO_MDO_BODY` for all other drag types. A hook point is displayed on the object selected for drag, which is removed at the end of the drag operation. The dragging is performed according to the environment set by the function `ProKinDragEnvironmentSet()`. Use the constraints set for the active snapshot while dragging.

## Creating and Modifying Snapshots

Functions Introduced:

- **ProKinDragSnapshotsNamesGet()**
- **ProSnapshotCreate()**
- **ProSnapshotUpdate()**
- **ProSnapshotRename()**
- **ProSnapshotDelete()**
- **ProSnapshotApply()**

The function `ProKinDragSnapshotsNamesGet()` retrieves an array of names of the snapshots belonging to the top-level assembly and all its subassemblies.

The function `ProSnapshotCreate()` creates a new snapshot for the top-level assembly as per its current position in the Creo Parametric window. Constraints are copied from the active snapshot. The newly created snapshot becomes active.

The function `ProSnapshotUpdate()` updates the snapshot for the top-level assembly as per its current position in the Creo Parametric window. Constraints are copied from the active snapshot. The newly updated snapshot becomes active.

The function `ProSnapshotRename()` renames the active snapshot of the top-level assembly.

The function `ProSnapshotDelete()` deletes a specified snapshot. The snapshot can be of the top-level assembly or any of its subassemblies. Pass `NULL` for the argument *path* to specify the top-level assembly.

The function `ProSnapshotApply()` applies the transforms of the active snapshot. Unlike in the user interface, no attempt to reconnect is made. Call `ProKinDragReconnect()` if reconnect is necessary. Use `ProWindowRefresh()` to view the changes in the positions of the assembly components.

## Snapshot Constraints

The constraints that can be applied to a snapshot are contained by the structure `ProSnapshotConstraint`. The declaration for `ProSnapshotConstraint` is as follows:

```
typedef struct proSnapshotConstraint
{
 ProSnapshotConstraintType type;
 ProSelection *sel_array;
 double value;
 ProBool user_active;
 ProBool valid
} ProSnapshotConstraint;
```

The fields in the above structure are described as follows:

- `type`—Specifies the type of snapshot constraint. The type is represented by the enumerated type `ProSnapshotConstraintType` and can take one of the following values:
  - `PRO_SNAP_ALIGN`—Select two points, two lines, or two planes from the top-level assembly. The two entities remain aligned during the drag operation.
  - `PRO_SNAP_MATE`—Select two planes from the top-level assembly. The planes remain mated during the drag operation.
  - `PRO_SNAP_ORIENT`—Select two planes that orient at an angle with each other.
  - `PRO_SNAP_MOTION_AXIS_POS`—Select a motion axis to specify the motion axis position.
  - `PRO_SNAP_BODY_LOCK`—Select the bodies to be locked together while dragging.
  - `PRO_SNAP_CONNECTION_DISABLE`—Select a connection that will be disabled while dragging.
  - `PRO_SNAP_PARALLEL_VIEW_PLANE`—Select a body that will move parallel only to the view plane. This constraint type is the same as the `PRO_SNAP_ALIGN` or `PRO_SNAP_MATE` types, but the second reference in this case is the view plane. This constraint type is available only via Creo TOOLKIT. If set by the Creo TOOLKIT application, this constraint type becomes visible in the **Drag** dialog box in the Creo Parametric user interface, but it cannot be stored.
  - `PRO_SNAP_CAM_LIFTOFF_ENABLE`—Allows two cams with a cam-follower connection to separate and collide during a dragging operation.
  - `PRO_SNAP_CAM_LIFTOFF_DISABLE`—Requires two cams with a cam-follower connection to be in contact with each other during the dragging operation.

---

 **Note**

The constraint types `PRO_SNAP_CAM_LIFTOFF_ENABLE` and `PRO_SNAP_CAM_LIFTOFF_DISABLE` override the `Enable Liftoff` property that you set from the **Cam-Follower Connection Definition** dialog box in the Creo Parametric user interface.

---

- `*sel_array`—Specifies the `ProArray` of selections. The number of selections needed and the permitted selection types for each constraint type are specified in the following table:

| Constraint Type                | Number of Selections needed | Permitted Selection Types                                                                                                                                            |
|--------------------------------|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_SNAP_ALIGN                 | 2                           | PRO_POINT, PRO_SURFACE_PNT, PRO_AXIS, PRO_EDGE, PRO_CURVE, PRO_DATUM_PLANE, PRO_SRF_PLANE_PNT, PRO_SURFACE                                                           |
| PRO_SNAP_MATE, PRO_SNAP_ORIENT |                             | PRO_DATUM_PLANE, PRO_SRF_PLANE_PNT, PRO_SURFACE                                                                                                                      |
| PRO_SNAP_MOTION_AXIS_POS       | 1                           | PRO_MDO_CONN_AXIS_ROT_1/2/3, PRO_MDO_CONN_AXIS_TR_1/2/3, PRO_MDO_SLOT_AXIS                                                                                           |
| PRO_SNAP_CONNECTION_DISABLE    |                             | PRO_MDO_CONN, PRO_MDO_CAM_CONN, PRO_MDO_SLOT_CONN, PRO_MDO_GEAR_CONN                                                                                                 |
| PRO_SNAP_PARALLEL_VIEW_PLANE   |                             | PRO_POINT, PRO_SURFACE_PNT, PRO_EDGE_START, PRO_EDGE_END, PRO_CRV_START, PRO_CRV_END, PRO_AXIS, PRO_EDGE, PRO_CURVE, PRO_SRF_PLANE_PNT, PRO_SURFACE, PRO_DATUM_PLANE |
| PRO_SNAP_CAM_LIFTOFF_ENABLE    |                             | PRO_MDO_CAM_CONN                                                                                                                                                     |
| PRO_SNAP_CAM_LIFTOFF_DISABLE   |                             |                                                                                                                                                                      |
| PRO_SNAP_BODY_LOCK             | 2 or more                   | PRO_PART, PRO_MDO_BODY                                                                                                                                               |

- **value**—Depending upon the constraint type, this field takes the following values:
  - For the PRO\_SNAP\_ALIGN and PRO\_SNAP\_MATE constraint types, value specifies the linear distance between the references.
  - For the PRO\_SNAP\_ORIENT type, value specifies the angle between the references.
  - For the PRO\_SNAP\_MOTION\_AXIS\_POS type, value specifies the offset of the joint axis zero position. This value is angular for the rotation axis and linear for the translational axis. The references for the joint axis zero position may be default or as specified by the user.
- **active**—Specifies the ProBoolean option to enable or disable a constraint.
- **valid**—Specifies if the constraint is valid or invalid in the current model context. If this ProBoolean option is PRO\_B\_TRUE, the constraint is valid (active), and if it is PRO\_B\_FALSE, the constraint is invalid (suppressed).

Functions Introduced:

- **ProSnapshotConstraintsGet()**
- **ProSnapshotConstraintAdd()**
- **ProSnapshotConstraintDelete()**

- 
- **ProSnapshotConstraintUpdate()**
  - **ProSnapshotConstraintEvaluate()**

The function `ProSnapshotConstraintsGet()` retrieves all the constraints of a specified snapshot. The snapshot can be of the top-level assembly or any of its subassemblies. Pass `NULL` for the argument *path* to specify the top-level assembly.

The function `ProSnapshotConstraintAdd()` adds a constraint to the snapshot of the top-level assembly.

The function `ProSnapshotConstraintDelete()` deletes a constraint from the snapshot of the top-level assembly.

The function `ProSnapshotConstraintUpdate()` updates a constraint for the snapshot of the top-level assembly.

The function `ProSnapshotConstraintEvaluate()` calculates the position of the motion axis for the constraint type `PRO_SNAP_MOTION_AXIS_POS` for the active model in the Creo Parametric window. This value does not depend on the current snapshot and it is not necessary for the snapshot to contain the constraint.

## Snapshot Transforms

Functions Introduced:

- **ProSnapshotTrfsGet()**
- **ProSnapshotTrfsUpdate()**

The function `ProSnapshotTrfsGet()` retrieves the transformation paths and transformation matrices saved in the snapshots for the subassemblies and their components with respect to the top-level assembly snapshot.

The function `ProSnapshotTrfsUpdate()` updates the transformation matrices saved in the snapshots for the subassemblies and their components with respect to the top-level assembly snapshot.

## Snapshots in Drawing Views

Functions Introduced:

- **ProSnapshotAllowedInDrawingSet()**
- **ProSnapshotAllowedInDrawingGet()**

The function `ProSnapshotAllowedInDrawingSet()` assigns the active snapshot of the top-level assembly to be available or unavailable in drawings. Set the argument *allow* to `PRO_B_TRUE` to make the snapshot available in drawings.

---

The function `ProSnapshotAllowedInDrawingGet()` determines if the active snapshot is allowed in drawings. The argument *p\_is\_allowed* is `PRO_B_TRUE` if the snapshot is allowed in drawings.

## Manikin Edit

A Creo Manikin is a detailed model of a human being, used to test designs for ergonomic compatibility and other human-centric requirements. A manikin model is considered a standard Creo Parametric assembly. PTC provides an out-of-the-box library of manikins. The manikins represent different populations by nationality, size percentiles, and genders. You might want to represent a specific population, for instance, based on third-party statistics, or on specific measurements. For that reason, an editable manikin is provided to use as a basis for customization.

For more details about Creo Manikin user interface and how to configure this functionality, refer to the Creo Manikin module in the Creo online help.

In Creo TOOLKIT, you can customize a manikin by changing the dimensions and parameters of the manikin using the data structure `ProManikinEditVarPair` added in the header file `ProManikinCust.h`.

Functions Introduced:

- **ProManikinCustomize()**

Use the function `ProManikinCustomize()` to edit a manikin by changing the dimensions and setting the specified parameters for a manikin. This operation may perform a regeneration, if required. This function works with the custom manikin which has to be the top object in the current Creo work window. All the modifications that you make to the model will be applied to the model immediately. If you set a particular dimension, the other dimensions of the manikin will be impacted accordingly.

The input argument *\*vars\_array* is a `ProArray` of arrays specified using the structure `ProManikinEditVarPair`.

To customize a manikin the following list of parameters that can be modified:

- **Dimensions**—Manikin dimensions that you can edit.
  - **DESIRED\_HEIGHT**—Double value in meter and is directly dependent on the Model Height. When you edit any of the Height Proportion dimensions, editing one dimension can affect the other two dimensions.
  - **DESIRED\_WEIGHT**—Double value in kilogram and is directly dependent on the Model Weight. The chest, waist and thigh dimensions are dependent. The shoulder width is dependent if it is not set earlier.
  - **Anthropometric Dimensions—Part 1**. Only 2 parameters in this section can be modified. When you set parameter 1, the other 2 parameters

- 
- change. When you set the other 2 parameters, the parameter which was already set changes.
- ◆ DESIRED\_UPPER\_BODY\_LENGTH—Double value in meter and is dependent on the MODEL\_UPPER\_BODY\_LENGTH.
  - ◆ DESIRED\_UPPER\_LEG\_LENGTH\_SEATED—Double value in meter and is dependent on the MODEL\_UPPER\_LEG\_LENGTH.
  - ◆ DESIRED\_LOWER\_LEG\_LENGTH\_SEATED—Double value in meter and is dependent on the MODEL\_LOWER\_LEG\_LENGTH.
  - Anthropometric Dimensions—Part 2.
    - ◆ DESIRED\_ARM\_LENGTH—Double value in meter and dependent on the MODEL\_ARM\_LENGTH.
    - ◆ DESIRED\_SHOULDER\_WIDTH—Double value in meter and dependent on the MODEL\_SHOULDER\_WIDTH.
    - ◆ DESIRED\_HAND\_LENGTH—Double value in meter and dependent on the MODEL\_HAND\_LENGTH.
    - ◆ DESIRED\_HAND\_WIDTH—Double value in meter and dependent on the MODEL\_HAND\_WIDTH.
    - ◆ DESIRED\_SHOE\_LENGTH—Double value in meter and dependent on the MODEL\_SHOE\_LENGTH.
  - Circumferences—Optimization is used to achieve this value. As a result getting the desired value requires some time.
    - ◆ DESIRED\_CHEST\_CIRCUMFERENCE—Double value in meter and dependent on the MODEL\_CHEST\_CIRCUMFERENCE.
    - ◆ DESIRED\_WAIST\_CIRCUMFERENCE—Double value in meter and dependent on the MODEL\_WAIST\_CIRCUMFERENCE.
    - ◆ DESIRED\_THIGH\_CIRCUMFERENCE—Double value in meter and dependent on the MODEL\_THIGH\_CIRCUMFERENCE.
  - Attributes—Manikin attributes such as demographic, version, and descriptive information. You can edit these parameters according to your manikin specifications.
    - MANIKIN\_AGE\_GROUP—Age group specified using wchar\_t in ProLine.
    - MANIKIN\_COUNTRY—Name of the country specified using wchar\_t in ProLine.
    - MANIKIN\_DATABASE—Data base specified using wchar\_t in ProLine.
    - MANIKIN\_PERCENTILE—Size percentile specified as an integer.

- 
- `MANIKIN_VERSION`—Version specified as a double value.
  - `MODELED_BY`—Specified using `wchar_t` in `ProLine`.
  - `DESCRIPTION`—Specified using `wchar_t` in `ProLine`.

If the process of updating the dimensions and parameters failed, the function returns the output argument `failed_param_name` which is the name of the problematic parameter that could not be updated.

## Assembly: Simplified Representations

### Overview

Creo TOOLKIT gives programmatic access to all the simplified representation functionality of Creo Parametric. You can create simplified representations either permanently or at runtime, and you can save, retrieve, or modify them by adding or deleting items.

Using Creo TOOLKIT, you can create and manipulate assembly simplified representations just as you can using Creo Parametric interactively.

#### Note

Creo TOOLKIT supports retrieval and activation of both part and assembly simplified representations. In addition, Creo TOOLKIT supports creation and modification of assembly simplified representations. Functions not appropriate for part mode are identified in the description.

---

Simplified representations are identified by the `DHandle ProSimpRep`. As with other `DHandles` such as `ProFeature` and `ProGeomitem`, the `ProSimpRep` handle contains just enough information to uniquely identify the object in the database—the model owner, type, and identifier.

The information required to create and modify a simplified representation is stored in a series of `ProSimpRepdata` structures, which are visible data structures. The data structure contains the following fields:

- `ProName name`—The name of the simplified representation
- `ProBoolean temp`—Specifies whether it is a temporary, simplified representation
- `ProSimpRepActionType action_type`—The rule that controls the default treatment of items in the simplified representation
- `ProSimpRepitem *items`—An array of assembly components and features and the actions applied to them in the simplified representation

---

A `ProSimpRepItem` is identified by the `ProIdTable` that defines the assembly component path to that item. (Even if the ID table path is only one level, use the `ProIdTable` and not the feature id for assemblies). Each `ProSimpRepItem` has its own `ProSimpRepAction` assigned to it. `ProSimpRepAction` is a visible data structure that includes a variable of type `ProSimpRepActionType`.

`ProSimpRepActionType` is an enumerated type that specifies the possible treatment of items in a simplified representation. You can specify the following types of actions on the component:

- `PRO_SIMPREP_NONE`—Specifies that no action is specified.
- `PRO_SIMPREP_REVERSE`—Specifies that the reverse of the default rule must be applied to the component. For example consider that the default rule is to exclude a component. When you set the value `PRO_SIMPREP_REVERSE`, the component is included in the simplified representation.
- `PRO_SIMPREP_INCLUDE`—Specifies to include the component in the simplified representation.
- `PRO_SIMPREP_EXCLUDE`—Specifies to exclude the component in the simplified representation.
- `PRO_SIMPREP_SUBSTITUTE`—Specifies to substitute the component in the simplified representation.
- `PRO_SIMPREP_GEOM`—Specifies to use geometric representation.
- `PRO_SIMPREP_GRAPHICS`—Specifies to use graphical representation.
- `PRO_SIMPREP_SYMB`—Specifies to use symbolic representation.
- `PRO_SIMPREP_BOUNDBOX`—Specifies to use boundary box representation.
- `PRO_SIMPREP_DEFENV`—Specifies to use the default envelope representation.
- `PRO_SIMPREP_LIGHT_GRAPH`—Specifies to use light weight graphics representation.
- `PRO_SIMPREP_AUTO`—Specifies to use automatic representation.

## Simplified Representations in Session

Functions Introduced:

- **`ProSolidSimpRepVisit()`**
- **`ProSimpRepInit()`**
- **`ProSimpRepSelect()`**
- **`ProSimpRepActivate()`**
- **`ProSimpRepActiveGet()`**
- **`ProSimpRepTypeGet()`**

---

- **ProSimprepIsDefault()**

This section describes the utility functions that relate to simplified representations.

`ProSolidSimprepVisit()` is like the other visit functions, and visits all the simplified representations of a parent `ProSolid`. The function visits only user-defined representation.

As all other visit functions, it takes four arguments—a pointer to the parent `ProSolid`, a filter function, the visit function itself, and a `ProAppData` field.

The function `ProSimprepInit()` initializes a `ProSimprep` structure. The function takes the following arguments:

- `ProName`*rep\_name*—The name of the simplified representation in the solid. If you specify this argument, the function ignores the *rep\_id*.
- `int`*rep\_id*—The identifier of the simplified representation, if you did not specify *rep\_name* (you specified `NULL`).
- `ProSolid`*p\_solid*—The parent solid that contains the simplified representation.
- `ProSimprep`*p\_simp\_rep*—The handle to the newly initialized simplified representation.

The function `ProSimprepSelect()` creates a Creo Parametric menu to enable interactive selection. The function takes the parent solid as input, and outputs the handle to the selected simplified representation. If you choose the **Quit** menu button, the function returns the value `PRO_TK_USER_ABORT`. If the user selects the master representation, the returned simplified representation structure has an identifier of `-1`.

`ProSimprepActivate()` enables you to set the currently active simplified representation. To set a simplified representation to be the currently displayed model, you must also call `ProSolidDisplay()`. This function enables you to bring inactive submodels into memory, and use their handles without displaying them.

`ProSimprepActivate()` does not support activation of part simplified representations, because part simplified representation handles cannot be passed to this function. You can display the simplified representation in a window using `ProSolidDisplay()`.

`ProSimprepActiveGet()` enables you to find the currently active simplified representation. Given a model handle, `ProSimprepActiveGet()` returns the handle to the currently active simplified representation. If the current representation is the master representation, the identifier of the handle is set to `-1`.

---

The function `ProSimpRepTypeGet()` returns the type of a specified simplified representation using the enumerated data type `ProSimpRepType`:

- `PRO_SIMPREP_MASTER_REP`—Specifies a fully detailed assembly. The model tree lists all its components and identifies them as included, excluded, or substituted.
- `PRO_SIMPREP_USER_DEFINED`—Specifies a representation from the selected component.
- `PRO_SIMPREP_GRAPH_REP`—Specifies a representation that contains only information for display. You can quickly browse through a large assembly. Graphics representations cannot be modified or referenced.
- `PRO_SIMPREP_GEOM_REP`—Specifies a representations that contains complete component geometry information. As compared to graphics representations, geometry representations take longer to retrieve and require more memory.
- `PRO_SIMPREP_SYMB_REP`—Specifies a representation that allows you to represent components with a symbol.
- `PRO_SIMPREP_DEFENV_REP`—Specifies a representation that allows you to represent assembly components with an default envelope.
- `PRO_SIMPREP_LIGHT_GRAPH_REP`—Specifies a lightweight graphics representations of assemblies that contains assembly information and 3D thumbnail graphics representations of assembly components.
- `PRO_SIMPREP_AUTO_REP`—Specifies a representation for retrieving the minimum data that is required for presenting the assembly in the most accurate way. You can perform actions such as measuring distances between points on a light surface without retrieving the part geometry.

---

## Note

When two standard representations of the same model are retrieved, for better memory usage, only one representation is used in the memory. The lower detailed representation is integrated into higher detailed representation. This higher detailed representation is used to retrieve both the representations.

If you retrieve a lower detailed representation when a higher detailed representation is already in the memory, this higher detailed representation is used and actually no retrieval is done.

The hierarchy for the representations is as follows with Master Simplified Representation being the highest representation level:

- Boundary Box Simplified Representation
- Symbolic Simplified Representation
- Graphic Simplified Representation
- Geometry Simplified Representation
- Master Simplified Representation

Refer to the Creo Parametric help for more information on Assembly Design.

---

The function `ProSimpRepIsDefault()` determines if the specified simplified representation is the default representation for the owner model.

## Retrieving Simplified Representations

Function Introduced:

- **ProAssemblySimpRepMdlNameRetrieve()**
- **ProSimpRepMdlNameRetrieve()**
- **ProMdlRepresentationFiletypeLoad()**

You can retrieve a named simplified representation from an assembly using the function `ProAssemblySimpRepMdlNameRetrieve()`. This function retrieves the handle of an existing simplified representation from an assembly without getting the generic representation into memory.

The function takes as arguments—the names of the assembly and simplified representation, the representation data, the type of model to retrieve, and the handle to the assembly. Note that you must provide the name of the assembly. To retrieve an existing simplified representation, specify its name as one of the inputs to the argument of this function. The name of the simplified representation can be `NULL` if the representation data is provided. In this case, the instructions in the data are used to dynamically create a new simplified representation. The

---

representation data can also be `NULL` if the name of the simplified representation is provided. Creo Parametric retrieves the simplified representation and any active submodels, and returns the `ProAssembly` handle.

You can retrieve geometry, graphics, symbolic simplified, boundary box, and default envelope representations into session using the function `ProSimpMdlnameRetrieve()`. The input arguments to the function are:

- *model\_name*—Specifies the name of the model whose simplified representation is to be retrieved.
- *file\_type*—Specifies the type of model using the enumerated data type `ProMdlFileType`.
- *rep\_type*—Specifies the type of simplified representation using the enumerated data type `ProSimpMdlType`.
- *rep\_name*—Specifies the name of the simplified representation that must be retrieved.

Similar to `ProAssemblySimpMdlnameRetrieve()`, the function `ProSimpMdlnameRetrieve()` retrieves the simplified representation without bringing the master representation into memory. The function outputs the handle to the model. It does not display the simplified representation.

You can retrieve the simplified representation of a model into memory using the function `ProMdlRepresentationFileTypeLoad()`.

## Retrieving and Expanding Lightweight Graphics Simplified Representations

Functions Introduced:

- **`ProSimpMdlnameRetrieve()`**
- **`ProLightweightGraphicsSimpMdlExpand()`**

The function `ProSimpMdlnameRetrieve()` retrieves the light graphics simplified representation of an assembly. Light graphics representations of assemblies contain assembly information and 3D thumbnail graphics representations of assembly components. In the light graphics simplified representation mode, the graphics of a model is represented using the Creo View viewable. The Creo View files must be in the same directory as the model. If the Creo View files are not available in the model directory, then the model is represented with bounding boxes in the light graphics simplified representation mode. Using this function you can initially retrieve and display graphic objects of higher levels of the assembly and then retrieve more detailed information of the sub-assemblies as required. This function is similar to

---

`ProAssemblySimpRepMdlNameRetrieve()`, and retrieves the light graphics assembly in the same way as described in the section [Retrieving Simplified Representations on page 1169](#).

Use the function `ProLightweightGraphicsSimpRepExpand()` to expand the light graphics representation of an assembly in the Creo Parametric active window to the specified level using the enumerated type `ProLightweightGraphicsSimpRepLevel`.

You can expand the representation to the following levels:

- `PRO_LWG_SIMPREP_LEVEL_NEXT`—Expands thumbnails to the next level.
- `PRO_LWG_SIMPREP_LEVEL_ALL`—Expands thumbnails to all levels.

To expand the sub-assembly level, use the functions `ProModelItemInit()` and `ProSelectionAlloc()` to first initialize the `ProSelection` handle for the component part or sub-assembly. You can pass the `ProSelection` handle to the function `ProLightweightGraphicsSimpRepExpand()` and expand the component part or sub-assembly node to the required level.

## Retrieving User-Defined Simplified Representations

Functions Introduced:

- **`ProAutomaticSimpRepRetrieve()`**
- **`ProAutomaticSimpRepConvert()`**
- **`ProAutomaticSimpRepActivate()`**

The function `ProAutomaticSimpRepRetrieve()` retrieves a user-defined simplified representation as an automatic representation. If error occurs during regeneration, the assembly includes suppressed features. Use the function `ProSolidRetrievalErrorsGet()` to identify if any errors have occurred during retrieval of the simplified representation. The input arguments follow:

- *assem\_name*—Name of the assembly specified using the structure `ProFamilyMdlName`.
- *file\_type*—File type of the assembly specified using the enumerated data type `ProMdlFileType`.
- *simp\_rep\_name*—Name of the simplified representation.

The output argument `p_assem` is the handle to the assembly specified using the structure `ProAssembly`.

The function returns the error `PRO_TK_NO_PERMISSION` if the function does not have permission to operate on the specified assembly. The function returns the error `PRO_TK_E_NOT_FOUND` if the function did not find the specified simplified representation in the solid.

---

The function `ProAutomaticSimpRepConvert()` converts a user-defined representation to automatic simplified representation while maintaining the excluded or substituted components in the representation.

The function `ProAutomaticSimpRepActivate()` activates a user-defined representation as an automatic simplified representation. To display the correct simplified representation, you must also call the function `ProSolidDisplay()`.

---

 **Note**

The functions `ProAutomaticSimpRepRetrieve()`, `ProAutomaticSimpRepConvert()` and `ProAutomaticSimpRepActivate()` support only assemblies.

---

The function `ProAutomaticSimpRepActivate()` returns the error `PRO_TK_E_NOT_FOUND` if the function did not find the specified simplified representation in the model.

## Creating and Deleting Simplified Representations

Functions Introduced:

- **`ProSimpRepdataAlloc()`**
- **`ProSimpRepCreate()`**
- **`ProSimpRepDelete()`**

---

 **Note**

Creo TOOLKIT does not support creation of part simplified representations.

---

To create a simplified representation, you must allocate and fill a `ProSimpRepdata` structure by calling the function `ProSimpRepdataAlloc()`. As input, the function requires the name of the new simplified representation, the `temp` value, and the default rule. The specific structure is initialized by the function in the Creo Parametric database.

To generate the new simplified representation, call `ProSimpRepCreate()`. This function returns the `ProSimpRep` handle for the new representation.

The function `ProSimpRepDelete()` deletes a simplified representation from its model owner. The function requires only the `ProSimpRep` handle as input.

---

## Example 1: Creating a Simplified Representation

The example in the file `UgSimprepCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_simprep`, shows how to create a simplified representation.

## Extracting Information About Simplified Representations

Functions Introduced:

- **ProSimprepdataGet()**
- **ProSimprepdataFree()**
- **ProSimprepdataDefltGet()**
- **ProSimprepdataNameGet()**
- **ProSimprepdataTmpvalGet()**
- **ProSimprepdataitemsVisit()**
- **ProSimprepSubstitutionNameGet()**
- **ProAsmcompSubstitutionTypeGet()**
- **ProAsmcompSubstituteGet()**

### Note

Creo TOOLKIT supports simplified representation of Assemblies only, not Parts.

---

Given the handle to a simplified representation and the address of a pointer to a `ProSimprepdata` structure, `ProSimprepdataGet()` fills out the `ProSimprepdata` structure. This function dynamically allocates storage for the data structure. When the memory is no longer needed, free it using the function `ProSimprepdataFree()`.

The `ProSimprepdataDefltGet()`, `ProSimprepdataNameGet()`, and `ProSimprepdataTmpvalGet()` functions return the associated values contained in the `ProSimprepdata` structure. They all take two arguments—the data structure to be queried, and the appropriate data structure for the type to be retrieved. `ProSimprepdataTmpvalGet()` retrieves the value of the `temp` field from the specified `ProSimprepdata`.

The function `ProSimprepdataitemsVisit()` visits all the items that make up the simplified representation. The action and filter functions both have `ProSimprepitem*` as their first argument.

---

The function `ProSimpRepSubstitutionNameGet()` returns the name of the substituted representation at the given assembly path even when the substituted representation is deleted from the model at the given path.

The function `ProAsmCompSubstitutionTypeGet()` returns the substitution type performed on the simplified representation of an assembly component. It takes the path to the component representation that is being substituted, including the component ID, as one of its input arguments.

The function `ProAsmCompSubstituteGet()` returns the path to the substituted component representation in the form of and the handle to the substituted component representation in the form of `ProAsmComp`. It takes the path to the component representation that is being substituted, including the component ID, as one of its input arguments.

### Example 2: Visiting the Items in a Simplified Representation

The sample code in `UgSimpRepInfo.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_simprep` shows how to use the Creo TOOLKIT functions to visit the items in the specified simplified representation.

## Modifying Simplified Representations

Functions Introduced:

- **`ProSimpRepActionInit()`**
- **`ProSimpRepdataSet()`**
- **`ProSimpRepdataDefltSet()`**
- **`ProSimpRepdataNameSet()`**
- **`ProSimpRepdataTmpvalSet()`**

---

#### **Note**

Creo TOOLKIT supports simplified representation of Assemblies only, not Parts.

---

Using Creo TOOLKIT, you can modify the attributes of existing simplified representations. After you create or retrieve a simplified representation, you can make calls to the `ProSimpRepdata*Set()` functions listed in this section to designate new values for the fields in the `ProSimpRepdata` structure.

To modify an existing simplified representation, retrieve it, then get the handle to its `ProSimpRepdata` structure by calling the function `ProSimpRepdataGet()`. (If you created the representation programmatically

---

within the same application, the `ProSimpredata` handle is already available.) After modifying the data structure, reassign it to the corresponding simplified representation by calling the function `ProSimpredataset()`. Use the function `ProSimpredatampvalset` to specify whether the newly created representation is temporary. Pass the value `PRO_B_TRUE` to the input argument `temp` to make the newly created representation a temporary representation.

---

 **Note**

Use the function `ProSimpredatampvalset()` to set the value of the `temp` input argument in the specified `ProSimpredata` structure while creating new simplified representations only. Once the simplified representation is created, this attribute is controlled by Creo Parametric. For all the existing representations, Creo Parametric controls the `temp` input argument and sets its value automatically.

---

## Adding Items to and Deleting Items from a Simplified Representation

Functions Introduced:

- **`ProSimpredataitemAdd()`**
- **`ProSimpredataitemDelete()`**
- **`ProSimpredataitemInit()`**

---

 **Note**

Creo TOOLKIT supports simplified representation of Assemblies only, not Parts.

---

You can add and delete items from the list of components in a simplified representation using Creo TOOLKIT. If you created a simplified representation using the option `PRO_SIMPREP_EXCLUDE` as the default rule, you would generate a list containing the items you want to include. Similarly, if the default rule for a simplified representation is `PRO_SIMPREP_INCLUDE`, you can add the items that you want to be excluded from the simplified representation to the list, setting the value of the `ProSimpredactionType` to `PRO_SIMPREP_EXCLUDE`.

### To Add Items

1. Get the `ProSimpredata` structure, as described in the previous section.

- 
2. Specify the action to be applied to the item with a call to the function `ProSimprepActionInit()`.
  3. Initialize a `ProSimprepitem` structure for the item by calling the function `ProSimprepdataitemInit()`.
  4. Add the item to the `ProSimprepdata` structure using the function `ProSimprepdataitemAdd()`.
  5. Reassign the `ProSimprepdata` structure to the corresponding `ProSimprep` object by calling `ProSimprepdataSet()`.

#### To Remove Items

1. Get the `ProSimprepdata` structure handle.
2. Pass the `ProSimprepdata` handle and the `ProSimprepitem` handle for the item to be deleted to the function `ProSimprepdataitemDelete()`.
3. Reassign the `ProSimprepdata` structure to the corresponding `ProSimprep` object by calling the function `ProSimprepdataSet()`.

## Gathering Components by Rule

Function Introduced:

- **ProRuleEval()**

Creo Parametric provides large assembly management tools. This section describes the access to some of this functionality through Creo TOOLKIT.

You can specify different types of rules and use them to generate a list of components for which the rule applies. After initializing the rule, call the function `ProRuleEval()` to generate the list of components that follow this rule.

Note that the returned list of components is in the form of an expandable array (`ProArray`), which is allocated by this function. To release the allocated memory, call the function `ProArrayFree()`.

The components can be gathered using the following rules:

- By model name
- By parameters, using an expression
- By location with a zone
- By distance from a point
- By size
- By an existing simplified representation

See the *Assembly Modeling User's Guide* for more details on this functionality.

---

## Gathering by Model Name

Function Introduced:

- **ProRuleInitName()**

The function `ProRuleInitName()` initializes the rule for gathering by model name. The `name_mask` variable can be a wildcard. For more information, see the Creo Parametric help.

## Gathering by Parameters

Function Introduced:

- **ProRuleInitExpr()**

You can specify an expression in the relations format to search for components of a particular parameter value. For example, consider the following expression:

```
type == "electrical" | cost <= 10
```

When you supply this expression to the rule, it gathers the components that have a “cost” parameter of less than or equal to 10, or whose *type* parameter is set to “electrical.”

The *expr* variable is an array of `ProLine` structures. You allocate this array using the function `ProArrayAlloc()`. The `ProArray*` functions are used for all array manipulations.

## Gathering by Zone

Function Introduced:

- **ProRuleInitZone()**

When you specify this rule, all the components that belong to the supplied zone feature are gathered.

See the *Assembly Modeling User's Guide* for detailed information about setting up and working with zones.

When you create a zone, the function creates a feature of type `PRO_FEAT_ZONE` in the top-level assembly.

## Gathering by Distance from a Point

Function Introduced:

- **ProRuleInitDist()**

Using `ProRuleInitDist()` to set up a rule that specifies distance from a point, Creo TOOLKIT gathers all the components within the specified spherical region.

---

By filling the `ProRuleDist` data structure, you can specify the center and the distance from the center. This information is in the coordinates of the top-level assembly.

## Gathering by Size

Function Introduced:

- **ProRuleInitSize()**

By filling the `ProRuleSize` data structure, you can specify the size of components to be gathered.

If you want to gather the components greater than the specified size, set the field `greater` to `PRO_B_TRUE`. If you set the field to `PRO_B_FALSE`, the function gathers the components that are less than the specified size.

If you want the specified size to be in absolute terms, set the field `absolute` to `PRO_B_TRUE`. Note that in this case, the function uses the units of the top-level assembly.

If the information is relative, set the field `absolute` to `PRO_B_FALSE`. In this case, the only valid values that can be specified are in the range (0.0, 1.0). The function compares the component size to that of the top-level assembly, and uses this ratio to determine whether the component should be gathered.

## Gathering by Simplified Representation

Function Introduced:

- **ProRuleInitRep()**

You can gather components that belong to an existing simplified representation by calling the function `ProRuleInitRep()`, which initializes the rule.

## Component Display

Functions Introduced:

- **ProSolidCompdisplayVisit()**
- **ProCompdisplayInit()**
- **ProCompdisplayActivate()**
- **ProCompdisplayIsDefault()**
- **ProCompdisplayActiveGet()**

This section describes the utility functions that relate to component displays.

---

The function `ProSolidCompdisplayVisit()` is like the other visit functions, and visits all the component displays of a parent `ProSolid`. The function visits only user-defined displays.

As all other visit functions, it takes four arguments—a pointer to the parent `ProSolid`, a filter function, the visit function itself, and a `ProAppData` field.

The function `ProCompdisplayInit()` initializes a `ProName` structure. The input arguments are as follows:

- *rep\_name*—The name of the component display in the solid. If you specify this argument, the function ignores the *rep\_id*.
- *rep\_id*—The identifier of the component display, if you did not specify *rep\_name* (if you specified it as `NULL`).
- *p\_solid*—The parent solid that contains the component display.

`ProCompdisplayActivate()` enables you to set the currently active component display. The input arguments are as follows:

- *p\_solid*—A pointer to the parent `ProSolid`.
- *p\_compdisp*—A pointer to the component display `ProCompdisp`.
- *no\_redisp*—Flag to specify whether you need to redisplay assembly in the window inside this call. If you set it to `TRUE`, you need to call `ProWindowRefresh()`.

The function `ProCompdisplayIsDefault()` determines if the specified component display is the default display for the owner model.

The function `ProCompdisplayActiveGet()` enables you to find the currently active component display. Given a model handle, `ProCompdisplayActiveGet()` returns the handle to the currently active component display.

## Assembly: Data Sharing Features

### Assembly: Data Sharing Features

This section describes the Creo TOOLKIT functions access for Data Sharing Features (DSF). These types of features are used to transfer information (geometry, annotations, and other details) from one model to another. Data Sharing Features also help you to consolidate your design information in a central location, control change propagation which aid towards accomplishing top down design objectives. Data Sharing Features are of the following types:

- Copy Geometry / Publish Geometry
- Shrinkwrap

- 
- Merge / Cutout
  - Inheritance

It also explains how to access the properties of variant features and lists read and write functions supporting the Inheritance Features.

## Copy Geometry, Publish Geometry, and Shrinkwrap Features

Copy Geometry Features are used to pass any type of geometric reference information, user-defined parameters to and from parts, skeleton models, and assemblies. Copy Geometry features can only copy reference geometry such as surface, datum features and not solid geometry. They are used in a top-down design to reduce the amount of data in session, thus avoiding the retrieval of entire reference source models.

A Publish Geometry feature contains independent, local geometry references. Only local geometry can be referenced in a Publish Geometry feature and external references are not allowed. A Publish Geometry feature has no geometry and does not create local copies of the references selected for its definition. It simply consolidates multiple local references in a model so that they can be copied to other models.

A Shrinkwrap feature is a collection of surfaces and datum features of a model that represents the exterior of the model. You can use a part, skeleton, or top-level assembly as the source model for a Shrinkwrap feature. A Shrinkwrap feature is associative and automatically updates to reflect changes in the parent copied surfaces.

## Feature Element Tree for the Copy Geometry, Publish Geometry, and Shrinkwrap Features

The element tree for Copy Geometry, Publish Geometry, and Shrinkwrap features is documented in the header file `ProDataShareFeat.h`.

The following figure demonstrates the feature element tree structure:

## Feature Element Tree for Copy Geometry, Publish Geometry, and Shrinkwrap Features

### PRO\_E\_FEATURE\_TREE

```

The following list details special information about some of the elements in this tree:

- **PRO\_E\_FEATURE\_TYPE**—Specifies the feature type and should be **PRO\_FEAT\_GEOM\_COPY**, for Copy Geometry, Publish Geometry, and Shrinkwrap features.
- **PRO\_E\_CG\_FEAT\_SUB\_TYPE**—Specifies the sub feature type and is a mandatory element. It is visible for all copy geometry features. The valid sub types are as follows:

- 
- PRO\_CG\_COPY\_GEOM—Copy Geometry feature
  - PRO\_CG\_SHRINKWRAP—Shrinkwrap feature
  - PRO\_CG\_PUB\_GEOM—Publish Geometry feature
  - PRO\_CG\_CMPST\_LAYUP—Composite Layup
  - PRO\_E\_CG\_REFS\_TYPE—Specifies the type of references used in a copy geometry feature (a published geometry feature, or an selected array of surfaces, edges, curves and datums). It is visible for Copy Geometry features.
  - PRO\_E\_CG\_LOCATION—Specifies a compound element that indicates the method used for placement of the feature within the parent model. This is valid for Copy Geometry and Shrinkwrap features. See the section describing [Element Details of the Subtree PRO\\_E\\_CG\\_LOCATION on page 1188](#) for more information.
  - PRO\_E\_CG\_PG\_OR\_REFS—Specifies either a published geometry feature to copy or a collection of local geometry references to copy. It is visible for Copy Geometry features and has the following elements:
    - PRO\_E\_CG\_PUBD\_GEOM—Specifies the selected publish geometry feature to be copied.
    - PRO\_E\_CG\_REFS\_COLL—Specifies the collection of references. It is used for Copy Geometry and Publish Geometry features and has the following elements:
      - ◆ PRO\_E\_STD\_SURF\_COLLECTION\_APPL—Specifies a collection of selected surfaces to copy.
      - ◆ PRO\_E\_STD\_CURVE\_COLLECTION\_APPL—Specifies a collection of selected curves and / or edges to copy.
    - PRO\_E\_CG\_OBJS\_COLL—Specifies a multivalued element containing miscellaneous references such as datums, quilts, points etc.
    - PRO\_E\_CG\_BODY\_COLL—Specifies a multivalued element that contains body selections to copy.

---

## Note

The reference collection elements `PRO_E_STD_SURF_COLLECTION_APPL`, `PRO_E_STD_CURVE_COLLECTION_APPL`, `PRO_E.CG_OBJS_COLL` may return the item of type `PRO_QUERY`. If `PRO_QUERY` is encountered, the Creo TOOLKIT application cannot access or modify the rules of the query. However, the application can redefine the other properties of the DSF without affecting or removing the query. For more information refer to the section [Saved Queries for Copy Geometry and Publish Geometry Features](#) on page 1190.

---

- `PRO_E_SW_COLLECTION_TYPE`—Specifies the collection mode used while creating a Shrinkwrap feature. The values for this element, specified by the enumerated type `ProShrinkwrapCollectionType`, are as follows:
  - `PRO_SW_OUTER_SHELL`—Surfaces and datums that represent the exterior of the model are used. This is the default.
  - `PRO_SW_ALL_SOLID_SURFS`—All solid surfaces in the model are automatically collected.
  - `PRO_SW_MANUAL`—Surfaces, edges, curves, and datums that you select are used. You can copy geometry from more than one reference model.
- `PRO_E_SW_OPTIONS`—Specifies Shrinkwrap feature options. This element is visible for Shrinkwrap features and has the following elements:
  - `PRO_E_SW_QUALITY`—Specifies the shrinkwrap quality level used when identifying the contributing geometry to the Shrinkwrap feature. It can have valid values in the range of 1 to `PRO_MAX_SHRINKWRAP_QUALITY_LVL`.
  - `PRO_E_SW_FILL_HOLES`—Specifies whether or not to use the option to auto fill holes.
  - `PRO_E_SW_COLLECT_QUILTS`—Specifies whether or not to include external quilts in the Shrinkwrap feature.
  - `PRO_E_SW_SKIP_SURF_SIZE`—Specifies the shrinkwrap skip surfaces size. Creo Parametric will not include surfaces smaller than the specified percentage of the model's size in the Shrinkwrap model. It can have a value ranging from 0(default) to 100%, to specify the relative size of the surface to ignore.
  - `PRO_E_SW_COLLECT_ORDER`—Specifies how the system will handle the subcomponents in creating the feature. This value can be of the following types:

- ◆ `PRO_SW_SHRINKWRAP_AND_SELECT`—Specifies to first shrinkwrap and then select (selected by default). The system analyzes the entire assembly to identify the external surfaces to be included and only the appropriate surfaces that belong to the selected components are included in the resulting shrinkwrap feature.
- ◆ `PRO_SW_SELECT_AND_SHRINKWRAP`—Specifies select and shrinkwrap. The system builds a shrinkwrap based on selected components.
- `PRO_E_SW_RES_GEOM_OPT`—Specifies the options for the resultant Shrinkwrap geometry. This element is available only if the element `PRO_E_SW_COLLECTION_TYPE` is set to the value `PRO_SW_ALL_SOLID_SURFS`. The values for this element, specified by the enumerated type `ProShrinkwrapResGeomOpt`, are as follows:
  - ◆ `PRO_SW_RES_GEOM_QUILT`—The resulting Shrinkwrap feature is a quilt.
  - ◆ `PRO_SW_RES_GEOM_SOLID`—The resulting Shrinkwrap feature is a solid.
  - ◆ `PRO_SW_RES_GEOM_ASM_QUILT`—The resulting Shrinkwrap feature is a quilt that contains a merged geometry of a referenced assembly.
- `PRO_E_SW_FAILED_SLD_OPT`—Specifies the options to address the failed solidification subfeatures (external reference copy geometry features) of a Shrinkwrap feature. This element is available only if the element `PRO_E_SW_RES_GEOM_OPT` is set to the value `PRO_SW_RES_GEOM_SOLID`. The values for this element, specified by the enumerated type `ProShrinkwrapFailedSldOpt`, are as follows:
  - ◆ `PRO_SW_FAILED_SLD_FAIL`—Failed solidification subfeatures of the Shrinkwrap feature are not resolved. As a result, the Shrinkwrap feature also fails.
  - ◆ `PRO_SW_FAILED_SLD_TO_QUILT`—Failed solidification subfeatures of the Shrinkwrap feature are restored as quilts. As a result, the Shrinkwrap feature does not fail.
- `PRO_E_SW_FILL_CNTRS_ARR`—Specifies the contours of open spaces that need to be filled. This element consists of an array of compound elements of the type `PRO_E_SW_FILL_CNTRS` which consists of the following elements:
  - ◆ `PRO_E_SW_FILL_CNTRS_SRF_SEL`—Select the surface that defines the contour to be filled.

- ◆ `PRO_E_SW_FILL_CNTRS_DISP_CRV`—Displays a yellow curve instead of a filled contour.
- `PRO_E_SW_COMP_SUBSET`—Specifies components of the assembly to be considered when creating the Shrinkwrap. This array element consists of an array of Shrinkwrap component subset elements (`PRO_E_SW_COMPONENT`). That element includes the following elements:
  - `PRO_E_SW_INCLUDE_COMP` specifies whether or not to include the component in the shrinkwrap
  - `PRO_E_SW_SEL_COMPONENT` specifies the selected component.
- `PRO_E_SW_REFS_COLL`—Specifies the collection of surfaces and other references to be included or excluded from the Shrinkwrap feature. It has the following elements:
  - `PRO_E_STD_SURF_COLLECTION_APPL`—Specifies the collection of individual surfaces that must always be included in the Shrinkwrap feature.
  - `PRO_E_SW_EXCLUDE_SURF_COLL_APPL`—Specifies the collection of individual surfaces that must always be excluded from the Shrinkwrap feature.
  - `PRO_E_STD_CURVE_COLLECTION_APPL`—Specifies a collection of chains constructed by selection of edges or curves.
  - `PRO_E_CG_OBJS_COLL`—Specifies a multivalued element containing miscellaneous references such as datums, quilts, points etc.
- `PRO_E_DSF_PROPAGATE_ANNOTS`—Specifies rules about how to propagate annotations. See the section [Element Details of PRO\\_E\\_DSF\\_PROPAGATE\\_ANNOTS on page 1189](#) below for the structure and contents of this element.
- `PRO_E_CG_SRFS_COPY`—Specifies a compound element that specifies copied surfaces. It is visible for Copy Geometry features and has the following elements:
  - `PRO_E_SRF_COPY_TYPE`—Specifies the type of copied surface. It can have one of the following values:
    - ◆ `PRO_SRFCOPY_AS_IS`
    - ◆ `PRO_SRFCOPY_EXCLD_FILL`
    - ◆ `PRO_SRFCOPY_INSIDE_BNDRY`
    - ◆ `PRO_SRFCOPY_UNTRIM_TO_ENVLP`
    - ◆ `PRO_SRFCOPY_UNTRIM_TO_DOMAIN`
  - `PRO_E_SRF_COPY_EXCL`—Specifies excluded surfaces.

- 
- `PRO_E_SRF_COPY_FILL`—Specifies loops to fill.
  - `PRO_E_STD_CURVE_COLLECTION_APPL`—Specifies the boundary for the copied surfaces.
  - `PRO_E_DSF_DTMS_FITS`—Specifies a compound element that indicates the rules for fitting datums in the DSF feature. It is visible for all internal Copy Geometry features) and Shrinkwrap features. This compound element includes `PRO_E_DTMLN_FIT` and `PRO_E_DTMAXIS_FIT` subtrees for any or all of the copied datums. Refer to the section [Element Trees: Datum Features on page 811](#) for details on the datum fit subtrees.
  - `PRO_E_DSF_DEPENDENCY`—Specifies the dependency type of the Copy Geometry Feature. The values for this element are specified by the enumerated type `ProDSFDependency` defined in the header file `ProDataShareFeat.h`. For more information on the values, refer to the section [Feature Element Tree on page 1191](#).

The valid values for the dependency status are as follows:

- `PRO_DSF_UPDATE_AUTOMATICALLY`—Specifies that the geometry can be updated when its parent changes.
- `PRO_DSF_UPDATE_MANUALLY`—Suspends the relationship between the current feature and the original geometry. If you change the original part, the current feature does not update automatically. It has to be updated manually.
- `PRO_DSF_NO_DEPENDENCY`—There is no dependency between DSF feature and referenced model.

#### Note

From Creo Parametric 3.0 onward, the enumerated type `ProDsfDependency` has been deprecated. Use the enumerated type `ProDSFDependency` instead.

---

- `PRO_E_DSF_NOTIFY_UPDATE`—Specify the notification status for the specified feature using the enumerated value `ProDsfNotifyUpdate`. Use this element only if the element `PRO_E_DSF_DEPENDENCY` is set to the value `PRO_DSF_UPDATE_MANUALLY`. The valid values for this element are:
  - `PRO_DSF_NOTIFY_UPDATE_OFF`—Switches off the notification update. This is the default value.
  - `PRO_DSF_NOTIFY_UPDATE_ON`—Switches on the notification update.

---

Use the functions `ProFeatureDSFDependencyNotifySet()` and `ProFeatureDSFDependencyNotifyGet()` to set and get the notification status of a DSF feature. For more information on these functions, refer to the section [Feature and CopyGeom Feature Functions on page 1135](#) in the section Assembly: Top-down Design.

- `PRO_E_CMPST_DESIGN_SURF_DIR`—Specify the stacking direction for a layup surface and the valid value is `CMPST_LAYUP`.

## Element Details of the Subtree `PRO_E_CG_LOCATION`

The compound element `PRO_E_CG_LOCATION` has the following elements:

- `PRO_E_DSF_EXT_LOCAL_TYPE`—Specifies the DSF location type:
  - `PRO_DSF_PLACE_LOCAL` type is a local feature within the assembly. Therefore the references will be dependent upon the assembly structure and the feature does not need placement information.
  - `PRO_DSF_PLACE_EXTERNAL` type is set to externalize a Data Sharing Feature. An external data-sharing feature must be placed in its target model explicitly.

---

### Note

The purpose of External DSF's is to copy geometry from one model to another model without the need to copy the geometry in the context of the assembly. External DSF's reduce the dependency on the assembly and all models along the path between the two components. Once a feature has been made "External", it cannot be converted to become internal.

---

- `PRO_E_DSF_SEL_REF_MDL`—Specifies the model to use for the external DSF.
- `PRO_E_CG_PLACEMENT`—Specifies the placement of the external reference model in the target model. It has the following elements:
  - `PRO_E_CG_PLACE_TYPE`—The external placement reference for the copied geometry can be of the following types:
    - ◆ `PRO_CG_PLC_DEFAULT`—Locates the copied geometry in the current model using the default location.
    - ◆ `PRO_CG_PLC_CSYS_CSYS`—Locates the copied geometry in the current model by aligning coordinate systems.

- ◆ `PRO_CG_PLC_CURRENT`—Locates the copied geometry in the current using the current placement (applicable only during a conversion of a local DSF to an external DSF).
- ◆ `PRO_E_CG_CSYS_PLACE`—The two reference elements below this element specifies Csys-Csys alignment.
- `PRO_E_CG_FOLLOW_SRF_OPT`—Specifies the options for surface to be followed.

## Element Details of `PRO_E_DSF_PROPAGATE_ANNOTS`

The compound element describes the options available to propagate annotations in DSF's. It has the following subelements:

- `PRO_E_DSF_ANNOT_CPY_ALL`—Specifies a flag whether to copy all annotation elements.
- `PRO_E_DSF_ANNOT_DEPEND_ALL`—Specifies a flag whether to make the copied annotation elements as dependent on their originals.
- `PRO_E_DSF_ANNOT_AUTO_CPY_DTM`—Specifies a flag to propagate annotation planes and other datums referenced by annotation elements automatically. Annotation planes are propagated if the annotation reference comprising of the solid or surface geometry is copied.
- `PRO_E_DSF_ANNOT_SELECTIONS`—Instead of using the automatic flags for propagation, the DSF feature can specify a list of annotations to propagate. Each subelement representing an annotation has the following sub-elements:
  - `PRO_E_DSF_ANNOT_SEL_ANNOTS` specifies the manually selected annotation element.
  - `PRO_E_DSF_ANNOT_CPY_STATUS` specifies the copy status for this selected element.
  - `PRO_E_DSF_ANNOT_DEPENDENCY` specifies whether to make the annotation dependant in the DSF. It can have one of the following values:
    - ◆ `PRO_DSF_DEPENDENT` is set by default.
    - ◆ `PRO_DSF_INDEPENDENT` makes the annotations independent of changes made to the parent annotation.

## Shrinkwrap Features Created from Copy Geometry References

Functions Introduced:

- **`ProFeatureIsShrinkwrapRefCopyGeom()`**
- **`ProFeatureShrinkwrapGetRefCopyGeoms()`**

- 
- **ProFeatureIsShrinkwrap()**
  - **ProFeatureRefCopyGeomShrinkwrapGet()**

The function `ProFeatureIsShrinkwrapRefCopyGeom()` checks whether the specified feature is a reference copy geometry feature, which is created by the shrinkwrap feature. The shrinkwrap reference copy geometry features reference models, which are collected by shrinkwrap according to the type of shrinkwrap, user-defined options, and user selections.

Use the function `ProFeatureShrinkwrapGetRefCopyGeoms()` to get an array of reference copy geometry features, which are created by the shrinkwrap feature.

The function `ProFeatureIsShrinkwrap()` checks whether the specified feature is a shrinkwrap feature.

Use the function `ProFeatureRefCopyGeomShrinkwrapGet()` to get the shrinkwrap feature for the specified reference copy geometry feature.

## Saved Queries for Copy Geometry and Publish Geometry Features

Copy Geometry and Publish Geometry features have the ability to retain and reuse search tool queries defined from its collectors. The functions described in this section provide the ability to update these query-driven data sharing features using Creo TOOLKIT.

Functions Introduced:

- **ProDatasharingfeatureIsQuerydriven()**
- **ProDatasharingfeatureQueryUpdate()**

The function `ProDatasharingfeatureIsQuerydriven()` returns true if the specified data sharing feature is query driven.

The function `ProDatasharingfeatureQueryUpdate()` updates the items collected by the query within the Copy Geometry or Publish Geometry feature. This will regenerate the feature and may cause geometry to be added or removed.

## Retrieving a Copy of the Annotation Item

Functions Introduced:

- **ProDatasharingfeatCopiedAnnotFind()**

The function `ProDatasharingfeatCopiedAnnotFind()` retrieves the annotation item owned by the data sharing feature, which is a copy of specified annotation item. The function supports Inheritance, Merge, CopyGeom, ShrinkWrap, and Cutout features only. The input arguments are:

- *p\_datasharing\_feature*—Specifies the data sharing feature.

- *p\_orig\_path*—Specifies the component path from the top level assembly to the subcomponent that owns the annotation. Pass `NULL` if the annotation is owned by the top level model in the data sharing feature.
- *p\_orig\_item*—Specifies the annotation item in the original model.

## General\_Merge\_Merge\_Cutout\_and\_Inheritance\_Feature\_

### Feature Element Tree

The element tree for the general merge feature is documented in the header file `ProDataShareFeat.h`. The following figure demonstrates the feature element tree structure:

#### Feature Element tree for General Merge Feature

```

```

The following list details special information about some of the elements in this tree:

- PRO\_E\_FEATURE\_TYPE—Specifies the feature type and should be PRO\_FEAT\_GEN\_MERGE.
- PRO\_E\_GMRG\_FEAT\_TYPE—Specifies the type of General Merge Feature:
  - PRO\_GEN\_MERGE\_TYPE\_MERGE (Merge or cutout feature)
  - PRO\_GEN\_MERGE\_TYPE\_INHERITANCE (Inheritance feature)
  - PRO\_GEN\_MERGE\_TYPE\_REF\_LAMINATE (Laminate feature)
- PRO\_E\_DSF\_REF\_MDL—Specifies the reference model. It has the following elements:
  - PRO\_E\_DSF\_EXT\_LOCAL\_TYPE—Specifies the DSF location type and is of the following type:
    - ◆ PRO\_DSF\_PLACE\_LOCAL type is a local reference to the reference model
    - ◆ PRO\_DSF\_PLACE\_EXTERNAL indicates an external merge, cutout, or inheritance feature.
    - ◆ PRO\_E\_DSF\_SEL\_REF\_MDL—Specifies a selected reference model.
    - ◆ PRO\_E\_DSF\_PLACEMENT—Specifies the placement of the Data Sharing feature. It contains the following elements:
      - ? PRO\_E\_COMPONENT\_CONSTRAINTS

For more information on component constraint elements, refer to section [Assembly: Assembling Components on page 1141](#).

- `PRO_E_GMRG_MATERIAL_OPT`—Specifies the general material options. These are listed as follows:
  - `PRO_GEN_MERGE_RMV_MATERIAL`—It removes material from the modified (target) model . The material removed is equal to the modifying (source) model.
  - `PRO_GEN_MERGE_ADD_MATERIAL`—It adds material to the modified model from the modifying model. The material added is equal to the modifying model.
  - `PRO_GEN_MERGE_INT_MATERIAL`—It retains the intersecting material between the modified and modifying models.

Refer to Creo Parametric Assembly Help for more information.

- `PRO_E_GMRG_VARIED_ITEMS`—Specifies a pointer element that defines the inheritance feature varied items and their values. This handle cannot be directly read or modified by Creo TOOLKIT. Instead, use the Visit functions available in `ProVariantFeat.h` to read varied items. To set varied items (after the feature has been created), use the appropriate modification function on an item whose owner is the variant feature model handle (`ProVariantFeatMdlGet()`). For more information, refer to the section [Inheritance Feature and Flexible Component Variant Items on page 1195](#).
- `PRO_E_GMRG_COPY_DATUMS`—True to copy datums with this merge or inheritance feature, false to leave them uncopied.
- `PRO_E_DSF_PROPAGATE_ANNOTS`—Specifies rules about how to propagate annotations. Refer to the section [Feature Element Tree for the Copy Geometry, Publish Geometry, and Shrinkwrap Features on page 1180](#) for the details. A Shrinkwrap feature is a collection of surfaces and datum features of a model that represents the exterior of the model. You can use a part, skeleton, or top-level assembly as the source model for a Shrinkwrap feature. A Shrinkwrap feature is associative and automatically updates to reflect changes in the parent copied surfaces.
- `PRO_E_DSF_DTMS_FIT`—Specifies a compound element that indicates the rules for fitting datums in the DSF feature. It is visible for all internal Copy Geometry features) and Shrinkwrap features. This compound element includes `PRO_E_DTMLN_FIT` and `PRO_E_DTMAXIS_FIT` subtrees for any or all of the copied datums. Refer to the section [Element Trees: Datum Features on page 811](#) for details on the datum fit subtrees.

- 
- `PRO_E_DSF_DEPENDENCY`—Specifies the dependency type. The values for this element are specified by the enumerated type `ProDsFDependency`.

---

 **Note**

From Creo Parametric 3.0 onward, the enumerated type `ProDsFDependency` has been deprecated. Use the enumerated type `ProDSFDependency` instead.

---

The types of dependencies are:

- `PRO_DSF_UPDATE_AUTOMATICALLY`—Specifies that the geometry of the DSF feature depends upon the geometry of the parent model used during feature creation. The DSF feature reflects all the changes made in the parent model.

---

 **Note**

From Creo Parametric 3.0 onward, the value `PRO_DSF_DEPENDENT` has been deprecated. Use the enumerated value `PRO_DSF_UPDATE_AUTOMATICALLY` instead.

---

- `PRO_DSF_UPDATE_MANUALLY` —Specifies that the geometry of the DSF feature is independent of the geometry of the parent model used during feature creation. If you update the parent model, the DSF feature does not change.

---

 **Note**

From Creo Parametric 3.0 onward, the value `PRO_DSF_INDEPENDENT` has been deprecated. Use the enumerated value `PRO_DSF_UPDATE_MANUALLY` instead.

---

- `PRO_DSF_NO_DEPENDENCY`—Specifies that there is no dependency between the geometry of the DSF feature and the geometry of the parent model used during feature creation.

`PRO_E_DSF_NOTIFY_UPDATE`—Specifies the notify status in the specified feature using the enumerated value `ProDsFNotifyUpdate`. For more information on this element, refer to the section [Feature Element Tree for the Copy Geometry, Publish Geometry, and Shrinkwrap Features](#) on page 1180.

---

`PRO_E_IS_SMT_CUT`—Specifies whether the specified feature is a sheetmetal cut or a solid cut. If true this feature is a sheetmetal cut.

`PRO_E_SMT_CUT_NORMAL_DIR`—Specifies the surface to which the section projection will be normal.

---

 **Note**

For more information,, refer to the section [Sheetmetal Cut Features on page 1340](#) in the section Production Applications: Sheetmetal.

---

## Inheritance Feature and Flexible Component Variant Items

An Inheritance feature allows one-way associative propagation of geometry and feature data from a reference part to target part within an assembly. The reference part is the original part and the target part contains the inheritance features. Inheritance features are always created by referencing existing parts. An inheritance feature begins with all of its geometry and data identical to the reference part from which it is derived.

Users can vary the visibility and values of items in inheritance features. Creo TOOLKIT offers the ability to access these varied items and their properties using the regular Creo TOOLKIT function appropriate for the property. Creo TOOLKIT also provides the ability to locate and separate the varied properties from the non-varied ones.

A flexible component has similar capabilities for variance of dimensions and parameters of a model in the context of an assembly. Creo TOOLKIT supports access to the variant properties of flexible components through the regular Creo TOOLKIT functions as well.

This section refers collectively to inheritance features and flexible components as "variant features".

### Variant Feature Model

Functions Introduced:

- **ProVariantfeatMdlGet()**
- **ProMdlIsVariantfeatMdl()**
- **ProMdlVariantfeatAsmcomppathGet()**
- **ProModelitemVariantfeatAsmcomppathGet()**

---

Use the function `ProVariantfeatMdlGet()` to obtain the special model pointer from a variant feature. A special `ProMdl` handle represents the "inherited" or "flexible" model handle in functions which access variant features. This handle is called the "Variant Feature Model". Only certain functions will support inputs including the Variant Feature Model handle.

The function `ProMdlVariantfeatAsmcomppathGet()` returns a special pointer `ProAsmcomppath` from a variant feature. `ProAsmcomppath` is the pointer to the component path from the model owner of the top level inheritance feature or the top flexible component to the specified variant feature model.

Both these pointers can be used for accessing properties that can be modified by the presence of an inheritance feature or flexible component. Other functions will return an error `PRO_TK_INVALID_PTR` if provided with this pointer.

---

 **Note**

If you are using the variant feature model handle and you need to use an unsupported function on it, you can attempt to retrieve the actual model by extracting the model name and type from the model and using `ProMdlnameRetrieve()` to get the original model. This requires that the parent model be accessible in session. Remember that the parent model will not reflect variations applied by the variant feature.

---

Use the function `ProMdlIsVariantfeatMdl()` to identify if a model pointer is a variant feature model handle.

Use the function `ProModelitemVariantfeatAsmcomppathGet()` to obtain the component path from an inheritance feature or a flexible component model owner to the specified varied item model item.

## Accessing Properties of Variant Features

The following items are supported by functions that accept the variant feature model handle. Except where noted, both read and write access is supported

- Dimensions
  - Variant dimensions of the inheritance feature:
    - ◆ Value
    - ◆ Tolerance
    - ◆ Dimension bound
    - ◆ Nonvariant dimensions of the inheritance feature (Properties are read only)
- Parameters

- 
- Variant parameters of the inheritance feature:
    - ◆ Value
    - ◆ Nonvariant parameters of the inheritance feature (Properties are read only)
  - Feature (Inheritance feature only)
    - Variant member features:
      - ◆ Suppressed or resumed or erased status
      - ◆ Nonvariant member features (Properties are read only)
      - ◆ Replaced or alternate feature references
  - Annotation (Inheritance feature only)
    - Variant geometric tolerances:
      - ◆ Copy status
      - ◆ Value
      - ◆ Nonvariant geometric tolerances (Properties are read only)
      - ◆ Variant notes
      - ◆ Copy status
      - ◆ Shown or hidden property
      - ◆ Nonvariant notes (Properties are read only)
      - ◆ Variant symbols
      - ◆ Copy status
      - ◆ Nonvariant symbols (Properties are read only)
      - ◆ Variant surface finishes
      - ◆ Copy status
      - ◆ Value
      - ◆ Nonvariant surface finishes (Properties are read only)

## Read Functions Supporting Inheritance Features

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Write and Modification Functions Supporting Inheritance Features

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Dimensions  | ProDimensionValueSet ()<br>ProDimensionToleranceSet ()<br>ProDimensionBoundSet ()                                                                                                                                                                                                                                                                                                                                                                                  |

## Variant Model Items

Function Introduced:

- **ProVariantfeatItemsVisit()**
- **ProVariantfeatItemStandardize()**
- **ProVariantfeatItemCopyGet()**
- **ProVariantfeatItemCopySet()**

---

- **ProVariantfeatItemCopyUnset()**

Use the function `ProVariantfeatItemsVisit()` to visit the variant items (dimensions, features, and annotations) owned by an inheritance feature or flexible component. The item handles will contain the variant feature model pointer.

Use the function `ProVariantfeatItemStandardize()` to remove a varied item from the inheritance feature or flexible component.

Use the function `ProVariantfeatItemCopyGet()` to obtain the copy flag for a given item in the inheritance feature or flexible component. The input arguments of this function are:

- *feature*—Specifies the variant feature
- *item*—Specifies the item.

The output arguments of this function are:

- *copy*—Specifies whether or not to copy the item into the variant feature. If this argument returns true, the item is copied into the feature. If it is false, the item is not copied. This value overrides the value of the features *copy all* flag.

Use the function `ProVariantfeatItemCopySet()` to assign the copy flag for a given item in the inheritance feature or flexible component.

Use the function `ProVariantfeatItemCopyUnset()` to remove the copy flag for a given item in the inheritance feature or flexible component.

## Variant Parameters

Function Introduced:

- **ProVariantfeatParamsVisit()**
- **ProVariantfeatParamStandardize()**

Use the function `ProVariantfeatParamsVisit()` to visit only the variant parameters owned by an inheritance feature or flexible component. The parameter handles contain the variant feature model pointer.

Use the function `ProVariantfeatParamStandardize()` to remove a varied parameter from the inheritance feature or flexible component.

## Variant References

By using variant references, you can reroute or replace the references for features in the inheritance feature with new references located inside or outside the inheritance feature. In assemblies, references can be to models other than the target model, as long as the model is within the assembly.

---

In Creo TOOLKIT, a variant reference is represented by a `ProVariantRef` handle.

Function Introduced:

- **`ProVariantrefAlloc()`**
- **`ProVariantrefOriginalrefGet()`**
- **`ProVariantrefOriginalrefSet()`**
- **`ProVariantrefReplacementrefGet()`**
- **`ProVariantrefReplacementrefSet()`**
- **`ProVariantrefFeatidsGet()`**
- **`ProVariantrefFeatidsSet()`**
- **`ProVariantfeatVariantrefsGet()`**
- **`ProVariantfeatVariantrefsSet()`**
- **`ProVariantrefFree()`**
- **`ProVariantrefProarrayFree()`**

Use the function `ProVariantrefAlloc()` to allocate a handle used to describe a variant reference assigned to a variant feature (like inheritance features). The input arguments of this function are:

- *original\_ref*—Specifies the initial reference handle.
- *replacement\_ref*—Specifies the replacement reference handle.
- *feat\_ids*—Specifies a `ProArray` of feature ids (from the base model) which will be assigned to the reference replacement action.

Use the function `ProVariantrefOriginalrefGet()` to obtain the original reference that is replaced.

Use the function `ProVariantrefOriginalrefSet()` to assign the original reference that is to be replaced.

Use the function `ProVariantrefReplacementrefGet()` to obtain the replacement reference for replacing the original reference in this variant feature.

Use the function `ProVariantrefReplacementrefSet()` to assign the replacement reference for replacing the original reference in this variant feature.

Use the function `ProVariantrefFeatidsGet()` to obtain an array of the feature ids taken from the base model which are assigned the replacement reference.

Use the function `ProVariantrefFeatidsSet()` to assign an array of the feature ids taken from the base model which are assigned the reference replacement.

### Note

An assignment of a replacement reference to a feature applies only if the features actually use the replacement reference.

Use the function `ProVariantfeatVariantrefsGet()` to obtain the variant reference assignments (a `ProArray` of the variant reference) stored by this variant feature.

Use the function `ProVariantfeatVariantrefsSet()` to assign the variant reference assignments stored by this variant feature.

Use the function `ProVariantrefFree()` to free a handle used to describe a variant reference assigned to a variant feature and the function `ProVariantrefProarrayFree()` to free an array of handles used to describe a variant reference assigned to a variant feature.

## Appearance States

This chapter describes the Creo TOOLKIT functions that deal with appearance states.

### About Appearance States

An appearance state captures appearances defined in the top-level model. It contains the appearances defined and applied to the models in the top-level model.

There are 2 predefined appearances:

- **Master**—No appearances are defined in the top-level model. This state cannot be changed. When you make changes to component appearances, you have to save the changes under a new Appearance State.
- **Default**—This is the active Appearance State when the model is retrieved. You can define and change this state.

Functions Introduced:

- **ProApprnstateNameGet()**
- **ProSolidApprnstateVisit()**
- **ProApprnstateIsActive()**

The function `ProApprnstateNameGet()` gets the name of an appearance state. The input argument to this function is *apprn*, which is a handle to the appearance state, and it is defined using the `ProApprnstate` object. The output

---

argument *r\_name* returns a pointer to a `wchar` string with the name of the appearance state, and the caller must release the string using `ProWstringFree()`.

The function `ProSolidApprnstateVisit()` visits all the appearance states in the specified solid. The input arguments are:

- *p\_solid*—Specify the solid handle, which is defined using the `ProSolid` object.
- *visit\_action*—The visiting function is defined using the `ProModelitemVisitAction` object. If it returns any other value than `PRO_TK_NO_ERROR`, visiting stops.
- *filter\_action*—The filter function is defined using the `ProModelitemFilterAction` object. If `NULL`, all items are visited using the action function.
- *app\_data*—Specify the application data that pass to the filter and visit functions using the object `ProAppData`.

The function `ProApprnstateIsActive()` determines if the given appearance state is active. The input argument to this function is *apprn*, which is a handle to the appearance state, and it is defined using the `ProApprnstate` object. The output of the function *r\_is\_active* is `PRO_B_TRUE` if the appearance state is active and `PRO_B_FALSE` if it is not.

## Drawings

### Creating Drawings from Templates

Function Introduced:

- **`ProDrawingFromTmplCreate()`**
- **`ProDrawingFromTemplateCreate()`**

---

#### Note

The function `ProDrawingFromTmplCreate()` will be deprecated in a future release. Use the function `ProDrawingFromTemplateCreate()` instead.

---

Use of drawing templates simplifies drawing creation. Such templates contain drawing views with various properties such as:

- Cross section view

- Simplified representation
- Dimensions On or Off
- Repeat regions (tables based on BOM balloons)

Use the function `ProDrawingFromTemplateCreate()` to create a drawing from a template and to return a structure containing any errors encountered during drawing creation. This input arguments are:

- New drawing name
- Name of existing template to use
- Solid model to use when creating drawing

---

#### **Note**

In the function `ProDrawingFromTemplateCreate()`, the object `ProMdlnameShortdata` supports a file name of 31 characters or less for a model.

---

- Drawing output options that specify how you want to view drawings output. Chose any or all from the following list:
  - `PRODWGCREATE_DISPLAY_DRAWING`—display new drawing in a window
  - `PRODWGCREATE_SHOW_ERROR_DIALOG`—display the template error dialog to the user
  - `PRODWGCREATE_WRITE_ERRORS_TO_FILE`—write the errors to a disk file

The function returns an error structure if any errors occur. The error structure contains an array of errors. Each error message may have:

- Error type
- Name of view where error occurred
- Name of drawing sheet where error occurred
- Name of the invalid or missing object

If the template and/ or the model name of the drawing is an embedded model name, the function `ProDrawingFromTemplateCreate()` returns the error `PRO_TK_INVALID_NAME`.

If there are one or more errors while creating the drawing, the function returns the error `PRO_TK_DWGCREATE_ERRORS`.

---

## Example 1: Drawing Creation from a Template

The sample code in the file `UgDrawingFromTpltCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_drawing` shows how to create a drawing from a template.

## Diagnosing Drawing Creation Errors

Functions Introduced:

- **ProDwgcreateErrsFree()**
- **ProDwgcreateErrsCountGet()**
- **ProDwgcreateErrTypeGet()**
- **ProDwgcreateErrViewNameGet()**
- **ProDwgcreateErrSheetGet()**
- **ProDwgcreateErrViewGet()**
- **ProDwgcreateErrObjNameGet()**

The function `ProDwgcreateErrsFree()` frees an existing errors table.

Use the function `ProDwgcreateErrsCountGet()` to return the number of drawing creation errors in the table.

The function `ProDwgcreateErrTypeGet()` returns the type of a drawing creation error.

Use the function `ProDwgcreateErrViewNameGet()` returns the name of the template view where the error occurred.

The function `ProDwgcreateErrSheetGet()` returns the drawing sheet number where the error occurred.

Use the function `ProDwgcreateErrViewGet()` returns the drawing view where the error occurred. This function is valid for the following error types:

- `PRODWGCRTErr_EXPLODE_DOESNT_EXIST`
- `PRODWGCRTErr_MODEL_NOT_EXPLODABLE`
- `PRODWGCRTErr_SEC_NOT_PERP`
- `PRODWGCRTErr_NO_RPT_REGIONS`
- `PRODWGCRTErr_FIRST_REGION_USED`
- `PRODWGCRTErr_NOT_PROCESS_ASSEM`
- `PRODWGCRTErr_TEMPLATE_USED`
- `PRODWGCRTErr_SEC_NOT_PARALLEL`
- `PRODWGCRTErr_SIMP_REP_DOESNT_EXIST`

---

`ProDwgcreateErrObjNameGet()` returns the name of the model invalid. This function is valid for the following error types:

- `PRODWGCRTErr_SAVED_VIEW_DOESNT_EXIST`
- `PRODWGCRTErr_X_SEC_DOESNT_EXIST`
- `PRODWGCRTErr_EXPLODE_DOESNT_EXIST`
- `PRODWGCRTErr_SEC_NOT_PERP`
- `PRODWGCRTErr_SEC_NOT_PARALLEL`
- `PRODWGCRTErr_SIMP_REP_DOESNT_EXIST`

## Drawing Setup

Functions Introduced:

- **`ProInputFileRead()`**
- **`ProOutputFileMdlnameWrite()`**
- **`ProDrawingSetupOptionGet()`**
- **`ProDrawingSetupOptionSet()`**
- **`ProMdlDetailOptionGet()`**
- **`ProMdlDetailOptionSet()`**

You can set all drawing setup file options from a Creo TOOLKIT application. To do this, import a text file in the format of the drawing setup file using the function `ProInputFileRead()`, with the file type set to `PRO_DWG_SETUP_FILE`. You can create such a file from Creo TOOLKIT with function `ProOutputFileMdlnameWrite()`. See the [Interface: Data Exchange on page 674](#) section for information on these functions.

Use the functions `ProDrawingSetupOptionGet()` and `ProDrawingSetupOptionSet()` to return and assign a specific drawing setup file option.

Some of the 2D detail options of the drawings are also applicable to 3D models. The detail options are applied to the model in the same way as to the drawings. Further, the detail options for the model and their values are also stored in the model in the same way as in the drawings.

Use the function `ProMdlDetailOptionGet()` to get the value of the specified detail option for the model. The function `ProMdlDetailOptionSet()` sets the value for the specified detail option of the model.

## Context in Drawing Mode

Functions Introduced:

- 
- **ProRibbonContextGet()**
  - **ProRibbonContextSet()**

The functions `ProRibbonContextGet()` and `ProRibbonContextSet()` retrieve and set the context for the specified drawing window, respectively.

From Pro/ENGINEER Wildfire 5.0 onwards, you can specify a context for a drawing. A context presents a set of commands relevant to the type of task that you are currently performing on a drawing. The contexts in the Drawing mode are **Layout**, **Table**, **Annotate**, **Sketch**, **AutobuildZ**, **Legacy Migration**, **Analysis**, and **Review**.

---

 **Note**

To set the context to **AutobuildZ**, you must first set the configuration option `autobuildz_enabled` to `yes`.

---

One of the arguments to the `ProRibbonContextGet()` and `ProRibbonContextSet()` functions is *context*, which is of the type `ProRibbonContext`. `ProRibbonContext` is an enumerated type, which takes the following values:

- `PRO_RBNCONTEXT_DWG_NONE`
- `PRO_RBNCONTEXT_DWG_LAYOUT`
- `PRO_RBNCONTEXT_DWG_TABLE`
- `PRO_RBNCONTEXT_DWG_ANNOTATE`
- `PRO_RBNCONTEXT_DWG_SKETCH`
- `PRO_RBNCONTEXT_DWG_AUTOBUILDZ`
- `PRO_RBNCONTEXT_DWG_REVIEW`
- `PRO_RBNCONTEXT_DWG_PUBLISH`

---

 **Note**

If you set *context* to `PRO_RBNCONTEXT_DWG_NONE`, all actions for the selected object are available in all contexts, except the contexts in which selection is not allowed. For example, the publish context.

---

## Access Drawing Location in Grid

Function Introduced:

---

- **ProDrawingPosToLocgrid()**

Use the function `ProDrawingPosToLocgrid()` to find the grid coordinates of a location in the specified drawing. The function specifies the position of a point, expressed in screen coordinates. `ProDrawingPosToLocgrid()` returns strings representing the row and column containing the point.

## Drawing Tree

Pro/ENGINEER Wildfire 5.0 onward, you can view a hierarchical representation of drawing items in an active drawing sheet. This representation is called a **Drawing Tree**. A drawing tree facilitates selection and availability of drawing operations for the represented drawing items. For more information, see the Creo Parametric Help. Use the following functions to refresh, expand, and collapse the drawing tree:

Functions Introduced:

- **ProDrawingtreeRefresh()**
- **ProDrawingtreeExpand()**
- **ProDrawingtreeCollapse()**

Use the function `ProDrawingtreeRefresh()` to rebuild the drawing tree in the Creo Parametric window that contains the drawing. You can use this function after adding a single drawing item or multiple drawing items to a drawing.

Use the function `ProDrawingtreeExpand()` to expand the drawing tree in the Creo Parametric window and make all drawing sheets and drawing items in the active drawing sheet visible.

Use the function `ProDrawingtreeCollapse()` to collapse all nodes of the drawing tree in the Creo Parametric window and make its child nodes invisible.

The input arguments to these functions are:

- *drawing*—Handle to the drawing that contains the drawing tree.
- *window\_id*—ID of the Creo Parametric window in which you want to refresh, expand, or collapse the drawing tree.

---

### Note

Use `PRO_VALUE_UNUSED` to refresh, expand, or collapse the drawing tree in the active window.

---

---

## Example 2: Performing Operations on a Drawing Tree

The sample code in the file `UgDrwTree.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_dwg` shows how to expand, collapse, and refresh the drawing tree in the selected drawing.

## Merge Drawings

Function Introduced:

- **ProDrawingMerge()**

Use the function `ProDrawingMerge()` to merge two drawings.

## Drawing Sheets

Functions Introduced:

- **ProDrawingSheetNameGet()**
- **ProDrawingSheetNameSet()**
- **ProDrawingSheetsCount()**
- **ProDrawingSheetTrfGet()**
- **ProDrawingSheetSizeGet()**
- **ProDrawingSheetOrientationGet()**
- **ProDrawingSheetUnitsGet()**
- **ProDrawingCurrentSheetGet()**
- **ProDrawingCurrentSheetSet()**
- **ProDrawingSheetCreate()**
- **ProDrawingSheetDelete()**
- **ProDrawingSheetCopy()**
- **ProDrawingSheetsReorder()**
- **ProDrawingSheetFormatIsBlanked()**
- **ProDrawingFormatGet()**
- **ProDrawingFormatAdd()**
- **ProDrawingSheetFormatShow()**
- **ProDrawingSheetFormatHide()**
- **ProDrawingSheetFormatIsShown()**
- **ProDrawingSheetFromFormatGet()**
- **ProDrawingToleranceStandardGet()**

- 
- **ProDrawingToleranceStandardSet()**
  - **ProDrawingToleranceStandardVersionSet()**
  - **ProDrawingToleranceStandardVersionGet()**
  - **ProDrawingToleranceStandardUpdate()**
  - **ProDwgSheetRegenerate()**

Drawing sheets are identified in Creo TOOLKIT by the same sheet numbers the Creo Parametric user sees.

The function `ProDrawingSheetNameGet()` retrieves the name of the specified drawing sheet.

Use the function `ProDrawingSheetNameSet()` to set the name of the specified drawing sheet. The input arguments are:

- *drawing*—Handle to the `ProDrawing` object.
- *sheet*—Sheet number.
- *sheet\_name*—Name of the sheet. If this argument is passed as `NULL`, the default sheet name is used.

The function `ProDrawingSheetsCount()` outputs the current number of sheets in the specified drawing.

The function `ProDrawingSheetTrfGet()` provides the matrix that transforms from screen to drawing units or vice versa. (See the [Core: Coordinate Systems and Transformations on page 228](#) section for more details on transformations.)

The function `ProDrawingSheetSizeGet()` returns the size of the sheet used for the drawing. If the sheet is a standard paper size, this will be returned, along with the width and height of the sheet measured in the sheet units.

The function `ProDrawingSheetOrientationGet()` returns the orientation of the drawing sheet. The orientation can be either portrait or landscape.

The function `ProDrawingSheetUnitsGet()` retrieves the name of the length units used for measuring the drawing sheet.

The function `ProDrawingCurrentSheetGet()` returns the sheet number of the currently selected sheet in the specified drawing. It returns a positive integer for the retrieved sheet number and a zero for an invalid input argument.

The function `ProDrawingCurrentSheetSet()` sets the sheet number for the currently selected sheet in the specified drawing. One of the input arguments to this function is an integer, *current\_sheet*.

---

The function `ProDrawingSheetCreate()` adds a sheet to a drawing model of type Notebook, Format, Drawing, Diagram, or Report. The output argument to this function is an integer, *new\_sheet*. If the drawing sheet is successfully created, *new\_sheet* takes the value of the sheet number for the newly created drawing sheet. Otherwise it takes the value, -1.

The function `ProDrawingSheetDelete()` deletes a sheet from a drawing model of type Notebook, Format, Drawing, Diagram, or Report. You need to enter the type of the drawing model and the sheet number of the sheet to be deleted as input arguments.

The function `ProDrawingSheetCopy()` creates a copy of a specified drawing sheet. The input arguments to this function are:

- *drawing*—The drawing model handle. Set it to NULL to copy a sheet from the current drawing.
- *sheet\_to\_copy*—The sheet number of the sheet to be copied. Set it to a value less than 1 to create a copy of the currently selected sheet.

The output argument to this function is:

- *sheet\_copy* (optional)—The sheet number of the newly created sheet. Set it to NULL, if you do not want the new sheet number.

The function `ProDrawingSheetsReorder()` assigns a new sheet number to a specified sheet, and renumbers the remaining sheets accordingly.

The function `ProDrawingSheetFormatIsBlanked()` identifies whether the format of a specified drawing sheet is blank. In case of the current sheet, set the input arguments *drawing* and *sheet* to NULL and to a value less than 1, respectively.

The function `ProDrawingFormatGet()` returns the name of the drawing format that was used for the specified sheet. `ProDrawingFormatAdd()` adds or replaces a specified format into a specified drawing sheet.

The function `ProDrawingSheetFormatShow()` displays the drawing format for a specified drawing sheet. To display the drawing format of the current sheet, set the input arguments *drawing* and *sheet* to NULL and to a value less than 1, respectively.

Use the function `ProDrawingSheetFormatHide()` to hide the drawing format for a specified drawing sheet.

The function `ProDrawingSheetFormatIsShown()` identifies if the drawing format for a specified drawing sheet is shown. It returns `PRO_B_TRUE` if the drawing format is shown and returns `PRO_B_FALSE` if the drawing format is not shown.

The function `ProDrawingSheetFromFormatGet()` retrieves the sheet number of the drawing format for a specified drawing and sheet number within the drawing.

---

The function `ProDrawingToleranceStandardGet()` returns the tolerance standard that is assigned to the specified drawing. Use the function `ProDrawingToleranceStandardSet()` to set the tolerance standard for a drawing.

Use the function `ProDrawingToleranceStandardVersionSet()` to set the version for the assigned tolerance standard for the specified drawing.

---

 **Note**

In the Creo Parametric user interface, this operation requests to regenerate the drawing sheet. The function `ProDrawingToleranceStandardVersionSet()` does not perform the regeneration itself.

---

Use the function `ProDrawingToleranceStandardVersionGet()` to get the version for the assigned tolerance standard for the specified drawing.

Use the function `ProDrawingToleranceStandardUpdate()` to update the drawing to the most current version of its tolerance standard. The function does not regenerate the drawing sheet.

The function `ProDwgSheetRegenerate()` regenerates a specified drawing sheet.

### Example 3: Listing Drawing Sheets

The sample code in the file `UgDrawingFromTpltCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_drawing` shows how to list the sheets in the current drawing.

### Example 4: Creating a Copy of the Current Drawing Sheet

The sample code in the file `UgSheetCopy.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_dwg` shows how to Add a drawing sheet to the current drawing-type object.

## Drawing Format Files

The format of a drawing refers to the boundary lines, referencing marks and graphic elements that appear on every sheet before any drawing elements are shown or added. These usually include items such as tables for the company name, detailers name, revision number and date. In a Creo Parametric drawing, you can associate a format file (`.frm`) with the drawing. This file carries all the

---

format graphical information, and it can also carry some optional default attributes like text size and draft scale. The functions described in this section allow you to get and set the size of the drawing format.

Functions Introduced:

- **ProDrawingFormatSizeSet()**
- **ProDrawingFormatSizeGet()**

The function `ProDrawingFormatSizeSet()` sets the size of the drawing format in the specified drawing. You can add a standard or customize size format in the drawing. The input arguments are:

- *drawing*—Specifies the name of the drawing.
- *drawing\_sheet*—Specifies the number of the drawing sheet where the drawing format must be set.
- *size*—Specifies the size of the drawing using the enumerated data type `ProPlotPaperSize`.
- *width*—Specifies the width of the drawing in inches, when *size* is set to `VARIABLE_SIZE_PLOT`.

It specifies the width of the drawing in millimeters, when *size* is set to `VARIABLE_SIZE_IN_MM_PLOT`.

---

 **Note**

This argument is ignored for all the other sizes of the drawing except `VARIABLE_SIZE_PLOT` and `VARIABLE_SIZE_IN_MM_PLOT`. In such cases specify the argument as `PRO_VALUE_UNUSED`.

---

- *height*—Specifies the height of the drawing in inches, when the *size* is set to `VARIABLE_SIZE_PLOT`.

It specifies the width of the drawing in millimeters, when the *size* is set to `VARIABLE_SIZE_IN_MM_PLOT`.

---

 **Note**

This argument is ignored for all the other sizes of the drawing except `VARIABLE_SIZE_PLOT` and `VARIABLE_SIZE_IN_MM_PLOT`. In such cases specify the argument as `PRO_VALUE_UNUSED`.

---

Use the function `ProDrawingFormatSizeGet()` to get the size of the drawing format in the specified drawing. The function returns the size of the drawing, and the width and height of the drawing in inches.

---

## Drawing Views and Models

Drawing views are identified by the OHandle `ProView`. This is the same object handle used to reference 3D model views, accessed by the functions in `ProView.h`, but there are no cases where the same object can be accessed by both types of function. The general rule is that functions for 3D views are in `ProView.h`, and start with `ProView`; functions to manipulate drawing views are in `ProDrawing.h` and therefore always start with `ProDrawing`.

Each drawing view has a solid attached to it. The same solid can appear in more than one view. Some solids may be attached to the drawing, but not appear in any view, if the Creo Parametric user has deleted all views of it without also removing the solid itself from the drawing.

## Listing Drawing Views

Functions Introduced:

- **`ProDrawingViewsCollect()`**
- **`ProDrawingViewVisit()`**
- **`ProDrawingViewSheetGet()`**
- **`ProDrawingErasedviewSheetGet()`**
- **`ProDrawingViewOutlineGet()`**
- **`ProDrawingViewTypeGet()`**
- **`ProDrawingViewIdGet()`**
- **`ProDrawingViewInit()`**
- **`ProDrawingViewonlyOpen()`**
- **`ProDrawingViewParentGet()`**
- **`ProDrawingViewSegmentedLeaderGet()`**
- **`ProDrawingViewChildrenGet()`**
- **`ProDrawingViewOriginGet()`**
- **`ProDrawingViewAlignmentGet()`**
- **`ProDrawingViewScaleIsUserdefined()`**
- **`ProDrawingViewScaleGet()`**
- **`ProDrawingScaleGet()`**
- **`ProDrawingViewPerspectiveScaleGet()`**
- **`ProDrawingViewFlagGet()`**
- **`ProDrawingViewDisplayGet()`**
- **`ProDrawingViewColorSourceGet()`**

- **ProDrawingViewSolidGet()**
- **ProDrawingViewTransformGet()**
- **ProDrawingViewNameGet()**
- **ProDrawingViewZclippingGet()**
- **ProDrawingViewDatumdisplayGet()**
- **ProDrawingViewPipingdisplayGet()**
- **ProDrawingViewIsErased()**
- **ProDrawingViewNeedsRegen()**
- **ProDrawingViewXhatchDependentGet()**

`ProDrawingViewsCollect()` outputs an array of `ProView` handles to all the views in a drawing. `ProDrawingViewVisit()` is an alternative way to find the views, and conforms to the usual form of visit functions.

`ProDrawingViewSheetGet()` outputs the number of the sheet in which a specified view appears.

The function `ProDrawingErasedviewSheetGet()` outputs the number of the sheet, which contained the view that was erased. If the sheet that contained the erased view is deleted, the sheet ID is returned as `PRO_VALUE_UNUSED`.

The function `ProDrawingViewOutlineGet()` outputs the position of the view in the sheet.

The function `ProDrawingViewTypeGet()` returns the type of a specified drawing view. A drawing view can be of the following types:

- `PRO_VIEW_GENERAL`—Specifies a general drawing view.
- `PRO_VIEW_PROJECTION`—Specifies a projected drawing view.
- `PRO_VIEW_AUXILIARY`—Specifies an auxiliary drawing view.
- `PRO_VIEW_DETAIL`—Specifies a detailed drawing view.
- `PRO_VIEW_REVOLVE`—Specifies a revolved drawing view.
- `PRO_VIEW_COPY_AND_ALIGN`—Specifies a copy and align drawing view.
- `PRO_VIEW_OF_FLAT_TYPE`—Specifies a flat type drawing view.

The function `ProDrawingViewIdGet()` retrieves the ID of the drawing view specified by the drawing and the drawing view handles.

The function `ProDrawingViewInit()` retrieves the drawing view handle based on the specified drawing handle and the view ID.

The function `ProDrawingViewonlyOpen()` opens a drawing in the view only mode.

The function `ProDrawingViewParentGet()` returns the parent view of a specified drawing view.

---

The function `ProDrawingViewSegmentedLeaderGet()` returns the leader view of a segmented (total unfold) view.

The function `ProDrawingViewChildrenGet()` returns the child views of a drawing view and the total number of children.

`ProDrawingViewOriginGet()` returns the location of the origin in terms of the `ProPoint3d` object and the selection reference in terms of the `ProSelection` object for a specified drawing view.

`ProDrawingViewAlignmentGet()` returns the alignment of a drawing view with respect to another view. It returns the alignment style of the drawing view that can be either horizontal or vertical, the reference view to which the view is aligned, and the alignment references of both the aligned and reference views.

`ProDrawingViewScaleIsUserdefined()` returns a boolean value depending on whether the drawing has a user-assigned scale or not.

`ProDrawingViewScaleGet()` returns the scale factor applied, even if the view is not a scaled view. `ProDrawingScaleGet()` returns the overall drawing scale that is applied to all unscaled views.

The function `ProDrawingViewPerspectiveScaleGet()` returns the perspective scale applied to a drawing view. This scale option is available only for general views. The function returns the following output arguments:

- *eye\_dist*—Specifies the eye-point distance from model space.
- *view\_dia*—Specifies the view diameter in paper units such as mm.

The function `ProDrawingViewFlagGet()` identifies if the projection arrow flag has been set for a projected or detailed drawing view.

`ProDrawingViewDisplayGet()` outputs the `ProDrawingViewDisplay` structure that describes the display status of the drawing view. The fields in the structure, all either enums or booleans, are listed below:

- *style*—Whether wireframe, hidden line, or shaded.
- *quilt\_hlr*—Whether hidden-line-removal is applied to quilts.
- *tangent\_edge\_display*—Style of line used for tangent edges.
- *cable\_display*—Whether cables are shown by centerline, as thick, or using the current default.
- *concept\_model*—Whether the skeleton is displayed.
- *weld\_xsec*—Whether welds are included in the cross-section.

`ProDrawingViewColorSourceGet()` returns the color source of the drawing view representation. The color source can be of the following types:

- `PRO_VIEW_MODEL_COLOR`—Specifies that the drawing colors are determined by the model settings.

- `PRO_VIEW_DRAWING_COLOR`—Specifies that the drawing colors are determined by the drawings settings.

`ProDrawingViewSolidGet()` provides the handle to the solid that is being displayed in the drawing view. `ProDrawingViewTransformGet()` returns the matrix that describes the transform between 3D solid coordinates and 2D screen coordinates for a specified view.

`ProDrawingViewNameGet()` returns the name of a specified view in the drawing.

`ProDrawingViewZclippingGet()` returns the reference of the Z-clipping on the drawing view. The reference can be an edge, datum, or point on the surface that is parallel to the view. Geometry contained in the Z-clipping plane and in front of the plane appears, but geometry behind the plane does not appear. The system clips geometry that intersects the plane.

The function `ProDrawingViewDatumdisplayGet()` determines if a solid model datum has been explicitly shown in a particular drawing view.

The function `ProDrawingViewPipingdisplayGet()` returns the piping display option for a drawing view.

The function `ProDrawingViewIsErased()` identifies if the drawing view is erased or not.

The function `ProDrawingViewNeedsRegen()` identifies whether the drawing or the specified drawing view needs to be regenerated.

The function `ProDrawingViewXhatchDependentGet()` checks if the section hatching is dependent on the parent view. The input arguments are listed below:

- *drawing*—Specify the drawing using the `ProDrawing` handle.
- *view*—Specify the view using the `ProView` handle.

The output argument *is\_dep* returns `PRO_B_TRUE` if dependent on the parent view using the `ProBoolean` object.

### Example 5: Listing the Views in a Drawing

The sample code in the file `UgDrawingViews.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_drawing` shows a command that creates an information window reporting information about all the views in a drawing.

## Modifying Views

Functions Introduced:

- **`ProDrawingViewMove()`**

- 
- **ProDrawingViewDelete()**
  - **ProDrawingViewErase()**
  - **ProDrawingViewResume()**
  - **ProDrawingViewOriginSet()**
  - **ProDrawingViewAlignmentSet()**
  - **ProDrawingViewScaleSet()**
  - **ProDrawingScaleSet()**
  - **ProDrawingViewProjectionSet()**
  - **ProDrawingViewFlagSet()**
  - **ProDrawingViewDisplaySet()**
  - **ProDrawingViewNameSet()**
  - **ProDrawingViewZclippingSet()**
  - **ProDrawingViewPipingdisplaySet()**
  - **ProDrawingViewRegenerate()**
  - **ProDwgViewRegenerate()**
  - **ProDrawingViewXhatchDependentSet()**

The function `ProDrawingViewMove()` moves the specified drawing view and its child views by a vector to a new position in screen coordinates. This function performs the same operation as the Creo Parametric command **Sketch ► Edit ► Move Special**.

The function `ProDrawingViewDelete()` deletes the drawing view and any of its child views, or fails if the view has any children.

The function `ProDrawingViewErase()` erases a specified drawing view.

The function `ProDrawingViewResume()` resumes the specified drawing view.

`ProDrawingViewOriginSet()` assigns the location of the origin in terms of the `ProPoint3d` object and the selection reference in terms of the `ProSelection` object for a specified drawing view.

The function `ProDrawingViewAlignmentSet()` assigns the alignment of a drawing view with respect to another view. This function assigns the following input arguments related to alignment:

- *view\_reference*—Specifies the reference view to which the drawing view is aligned.
- *align\_style*—Specifies the alignment style in terms of the enumerated type `ProDrawingViewAlignStyle`. The alignment style can be either horizontal or vertical. In case of horizontal alignment, the drawing view and

---

the view it is aligned to lie on the same horizontal line. In case of vertical alignment, the drawing view and the view it is aligned to lie on the same vertical line.

- *align\_ref\_1*—Specifies the alignment reference of the referenced view. If this is set to NULL, the reference view is aligned according to its view origin.
- *align\_ref\_2*—Specifies the alignment reference of the aligned view. If this is set to NULL, the aligned view is aligned according to its view origin.

The function `ProDrawingViewScaleSet()` modifies the scale of a scaled view. If you want to set the drawing view to use the default scale, use `PRO_DRAWING_SCALE_DEFAULT`. The function `ProDrawingScaleSet()` modifies the overall drawing scale that is applied to all unscaled views.

The function `ProDrawingViewProjectionSet()` assigns the specified drawing view as a projection.

The function `ProDrawingViewFlagSet()` sets the projection arrow flag to TRUE for a projected or detailed drawing view.

The function `ProDrawingViewDisplaySet()` assigns the fields in the `ProDrawingViewDisplay` structure that describe the display status of the drawing view. This function does not repaint the drawing view, use the function `ProWindowRepaint()` to repaint the view.

---

 **Note**

In order to modify the `concept_model` field in the `ProDrawingViewDisplay` structure, you require an Assembly license.

---

The function `ProDrawingViewNameSet()` assigns a name to a specified drawing view.

---

 **Note**

The configuration option `allow_duplicate_view_names` enables you to set duplicate names for drawing views. When the configuration option is set to `no`, the function returns an error if another drawing view in the specified drawing exists with the same name.

---

The function `ProDrawingViewZclippingSet()` sets the Z-clipping on the drawing view to reference a given edge, datum, or point on the surface that is parallel to the view. Geometry contained in the Z-clipping plane and in front of the plane appears, but geometry behind the plane does not appear. The system clips geometry that intersects the plane.

---

The function `ProDrawingViewPipingdisplaySet()` assigns the piping display option for a drawing view. The piping display options are as follows:

- `PRO_PIPINGDISP_DEFAULT`—Displays the default appearance of pipes for the piping assembly.
- `PRO_PIPINGDISP_CENTERLINE`—Displays pipes as centerlines without insulation.
- `PRO_PIPINGDISP_THICK_PIPES`—Displays thick pipes without insulation.
- `PRO_PIPINGDISP_THICK_PIPES_AND_INSULATION`—Displays thick pipes and insulation.

The function `ProDrawingViewRegenerate()` regenerates the drawing view specified by the `ProView` view handle.

The function `ProDwgViewRegenerate()` erases the displayed view of the current object, regenerates the view from the current drawing, then redisplay the view.

The function `ProDrawingViewXhatchDependentSet()` sets the section hatching dependency on the parent view. The input arguments are:

- *drawing*—Specify the drawing using the `ProDrawing` handle.
- *view*—Specify the view using the `ProView` handle.

The output argument is *dependent*—Pass the `PRO_B_TRUE` value to make it dependent or pass the `PRO_B_FALSE` value to make it independent from the parent view using the `ProBoolean` object.

## Creating Views

Function Introduced:

- **`ProDrawingGeneralviewCreate()`**
- **`ProDrawingProjectedviewCreate()`**

A general view is usually the first view placed on a drawing sheet. It is the most versatile view, that is, it can be scaled or rotated to any setting.

A projected view is an orthographic projection of another view's geometry along a horizontal or vertical direction.

The above functions create general and projected drawing views.

### Example 6: Creating General and Projected Drawing Views

The sample code in the file `UgDrawingViews.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_drawing` adds a new sheet to a drawing, and creates one general and two projected views of a selected model.

---

## Background Views

Functions Introduced:

- **ProDrawingViewIsBackground()**
- **ProDrawingBackgroundViewGet()**

Views can be assigned not only to the solid views that the user creates, but also to each sheet. The view assigned to a drawing sheet is called a background view.

Function `ProDrawingViewIsBackground()` determines whether the specified view is a background view.

If you use `ProSelect()` for an item in a drawing that is not inside a solid view, such as a detail item, the `ProView` view handle output by `ProSelectionViewGet()` is the background view.

### Note

These functions supersede the functions `ProDrawingViewIsOverlay()` and `ProDrawingOverlayviewGet()`, which previously served the same purpose.

---

## Detailed Views

Functions Introduced:

- **ProDrawingViewDetailCreate()**
- **ProDrawingViewDetailReferenceGet()**
- **ProDrawingViewDetailReferenceSet()**
- **ProDrawingViewDetailCurvedataGet()**
- **ProDrawingViewDetailCurvedataSet()**
- **ProDrawingViewDetailBoundaryGet()**
- **ProDrawingViewDetailBoundarySet()**

A detailed view is a small portion of a model shown enlarged in another view.

The function `ProDrawingViewDetailCreate()` creates a detailed view given the reference point on the parent view, the spline curve data, and location of the new view. A note with the detailed view name and the spline curve border are included in the parent view for the created detailed view.

The functions `ProDrawingViewDetailReferenceGet()` and `ProDrawingViewDetailReferenceSet()` return and assign, respectively, the reference point on the parent view for a specified detailed view.

---

The functions `ProDrawingViewDetailCurvedataGet()` and `ProDrawingViewDetailCurvedataSet()` retrieve and assign, respectively, the spline curve data in terms of the `ProCurvedata` handle for a specified detailed view. The output argument, `curve_data` specifies the following:

- The X, Y, and Z coordinate directions match the world space.
- The coordinate point (0,0,0) maps to the reference point.
- The scaling unit is of one inch relative to the top model of the view. If two points in the spline are at a distance of '1' from each other, then in the actual view, the points will be one inch distant from each other, if measured in the scale of the top model. For example, if one of the points in the spline definition has coordinates (0.5, 0.0, 0.0), then the position of that point is not half an inch to the right of the reference point on the paper. Instead, when projected as a point in the space of the top model of the view, it is half an inch to the right of the reference point when measured in the space of that model.

Use the function `ProCurvedataAlloc()` to allocate memory for the curve data structure.

The function `ProDrawingViewDetailBoundaryGet()` retrieves the type of spline curve used to define the boundary of the detailed view and also identifies whether the boundary is displayed on the parent view.

The function `ProDrawingViewDetailBoundarySet()` assigns the boundary type for a detailed view in terms of the enumerated type `ProViewDetailBoundaryType`. The types of boundaries are:

- `PRO_DETAIL_BOUNDARY_CIRCLE`—Draws a circle in the parent view.
- `PRO_DETAIL_BOUNDARY_ELLIPSE`—Draws an ellipse in the parent view.
- `PRO_DETAIL_BOUNDARY_HORZ_VER_ELLIPSE`—Draws an ellipse with a horizontal or vertical major axis.
- `PRO_DETAIL_BOUNDARY_SPLINE`—Displays the spline boundary drawn by the user in the parent view.
- `PRO_DETAIL_BOUNDARY_ASME_CIRCLE`—Displays an ASME standard-compliant circle as an arc with arrows and the detailed view name.

This function also sets the `ProBoolean` argument *show* to display the boundary of the detailed view in the parent view.

## Auxiliary Views

Functions Introduced:

- **`ProDrawingViewAuxiliaryCreate()`**
- **`ProDrawingViewAuxiliarySet()`**

---

- **ProDrawingViewAuxiliaryInfoGet()**

An auxiliary view is a type of projected view that projects at right angles to a selected surface or axis. The selected surface or axis in the parent view must be perpendicular to the plane of the screen.

The function `ProDrawingViewAuxiliaryCreate()` creates an auxiliary view given the selection reference and the point location.

The function `ProDrawingViewAuxiliarySet()` sets a specified drawing view as the auxiliary view.

The function `ProDrawingViewAuxiliaryInfoGet()` retrieves information such as the selection reference in terms of the `ProSelection` object and the point location in terms of the `ProPoint3d` object for a specified auxiliary view.

## Revolved Views

Functions Introduced:

- **ProDrawingViewRevolveCreate()**
- **ProDrawingViewRevolveInfoGet()**

A revolved view is a cross section of a drawing view revolved 90 degrees around a cutting plane projection.

The function `ProDrawingViewRevolveCreate()` creates a revolved view given a cross section, the selection reference, and the point location.

The function `ProDrawingViewRevolveInfoGet()` retrieves information such as the cross section in terms of the `ProXsec` object, the selection reference in terms of the `ProSelection` object, and the point location in terms of the `ProPoint3d` object for a specified revolved view.

## Draft Views

Functions Introduced:

- **ProDrawingDraftViewsCollect()**
- **ProDrawingViewIsDraft()**
- **ProDrawingDraftViewCreate()**

Draft views are created from the **Sketch** tab in a drawing using the selected draft entities. The draft entities added to the view are automatically related to the view. Any pre-existing relationship will be removed, and the entity will be related to the draft view.

---

The function `ProDrawingDraftViewsCollect()` collects all draft views in the specified drawing. The output argument `views` is the list of draft views. The function `ProDrawingDraftViewsCollect()` allocates memory to the `ProView` handle. To free the memory call the function `ProArrayFree()`.

The function `ProDrawingViewIsDraft()` determines whether the specified view is a draft view. The input arguments follow:

- *drawing*—Specify the drawing in which the draft view exists.
- *view*—Specify the view using the `ProView` handle.

If the specified view is a draft view, the function returns a `ProBoolean` output argument with the value `PRO_B_TRUE`. Otherwise, the function returns `PRO_B_FALSE`.

The function `ProDrawingDraftViewCreate()` creates a draft view in the specified drawing sheet. The input arguments follow:

- *drawing*—Specify the drawing in which draft view is to be created.
- *entities*—Specify at least one draft entity using the `ProDtIentity` object. Entities might or might not be related to any view.

The function outputs a pointer to the `ProView` handle.

## View Orientation

Functions Introduced:

- **`ProDrawingViewOrientationFromNameSet()`**
- **`ProDrawingViewOrientationFromReferenceSet()`**
- **`ProDrawingViewOrientationFromAngleSet()`**

The orientation type for a drawing view is given by the enumerated type `ProDrawingViewOrientationType`. The view orientation can be of the following types:

- `PRO_VIEW_ORIENT_NAME`—The drawing view is oriented using saved views from the model.
- `PRO_VIEW_ORIENT_GEOM_REF`—The drawing view is oriented using geometric references from the model.
- `PRO_VIEW_ORIENT_ANGLE`—The drawing view is oriented using angles of selected references or custom angles.

---

### Note

The drawing view must be displayed before applying any orientation to it.

---

---

The function `ProDrawingViewOrientationFromNameSet()` assigns the orientation of a specified drawing view according to the following input arguments:

- *mdl\_view\_name*—Specifies the name of the saved view in the model.
- *orientation\_name*—Specifies the name of the user-defined orientation for the saved view.
- *x\_angle*—Specifies the X angle in degrees for the user-defined orientation.
- *y\_angle*—Specifies the Y angle in degrees for the user-defined orientation.

The function `ProDrawingViewOrientationFromReferenceSet()` assigns the orientation of a specified drawing view according to the following input arguments:

- *ref\_name\_1*—Specifies the name of the first geometric reference.
- *ref\_sel\_1*—Specifies the first reference selection on the model in terms of the `ProSelection` object.
- *ref\_name\_2*—Specifies the name of the second geometric reference.
- *ref\_sel\_2*—Specifies the second reference selection on the model in terms of the `ProSelection` object.

The function `ProDrawingViewOrientationFromAngleSet()` assigns the orientation of a specified drawing view according to the following input arguments:

- *sel*—Specifies the reference selection in terms of the `ProSelection` object. It can be an axis or `NULL` for other type.
- *angle*—Specifies the angle in degrees with the selected reference.
- *rot\_ref\_name*—Specifies the name of the rotational angle.
- *index*—Specifies the index of the angle setting.

## Visible Areas of Views

Functions Introduced:

- **`ProDrawingViewVisibleareaTypeGet()`**
- **`ProDrawingViewFullVisibleAreaSet()`**
- **`ProDrawingViewHalfVisibleAreaGet()`**
- **`ProDrawingViewHalfVisibleAreaSet()`**
- **`ProDrawingViewPartialVisibleAreaSet()`**
- **`ProDrawingViewPartialVisibleAreaGet()`**
- **`ProDrawingViewBrokenVisibleAreaGet()`**

- **ProDrawingViewBrokenVisibleAreaSet()**
- **ProDrawingViewBrokenNumberGet()**

As you detail your model, certain portions of the model may be more relevant than others or may be clearer if displayed from a different view point.

The function `ProDrawingViewVisibleareaTypeGet()` retrieves the type of visible area for a specified drawing view in terms of the enumerated type `ProDrawingViewVisibleareaType`. The visible area can be of the following types:

- `PRO_VIEW_FULL_AREA`—The complete drawing view is retained as the visible area.
- `PRO_VIEW_HALF_AREA`—A portion of the model from the view on one side of a cutting plane is removed.
- `PRO_VIEW_PARTIAL_AREA`—A portion of the model in a view within a closed boundary is displayed.
- `PRO_VIEW_BROKEN_AREA`—A portion of the model view from between two or more selected points is removed, and the gap between the remaining two portions is closed within a specified distance.

The function `ProDrawingViewFullVisibleAreaSet()` retains the specified drawing view as the full visible area.

The function `ProDrawingViewHalfVisibleAreaGet()`

The function `ProDrawingViewHalfVisibleAreaSet()`

- *plane\_ref*—Specifies the selection reference in terms of the `ProSelection` object that divides the drawing view. The cutting plane can be a planar surface or a datum, but it must be perpendicular to the screen in the new view.
- *keep\_side*—Specifies the half side of the model that is to be retained.
- *line\_standard* `ProDrawingLineStandardType`
  - `PRO_HVL_NONE`—Specifies no line
  - `PRO_HVL_SOLID`—Specifies a solid line.
  - `PRO_HVL_SYMMETRY`—Specifies a symmetry line.
  - `PRO_HVL_SYMMETRY_ISO`—Specifies an ISO-standard symmetry line.
  - `PRO_HVL_SYMMETRY_ASME`—Specifies an ASME-standard symmetry line

The function `ProDrawingViewPartialVisibleAreaGet()` gets the partial visible area of a drawing view.

The function `ProDrawingViewPartialVisibleAreaSet()` assigns the following arguments to define the partial visible area for a specified drawing view:

- *ref\_point*—ProSelection
- *curve\_data*—ProCurvedata
- *show\_boundary*ProBooleanPRO\_B\_TRUE

The function ProDrawingViewBrokenVisibleAreaGet () retrieves the broken visible area for a specified drawing view.

The function ProDrawingViewBrokenVisibleAreaSet () assigns the following arguments to define the broken visible area for a specified drawing view:

- *dir*—Specifies the direction of the broken lines that define the broken area to be removed. The direction is given by the enumerated type ProViewBrokenDir and takes the following values:
  - PRO\_VIEW\_BROKEN\_DIR\_HORIZONTAL—Specifies the horizontal direction.
  - PRO\_VIEW\_BROKEN\_DIR\_VERTICAL—Specifies the vertical direction.
- *first\_sel*—Specifies the selection point in terms of the ProSelection object for the first break line.
- *second\_sel*—Specifies the selection point in terms of the ProSelection object for the second break line.
- *line\_style*—Specifies the line style for the broken lines in terms of the enumerated type ProViewBrokenLineStyle. It can be one of the following types:
  - PRO\_VIEW\_BROKEN\_LINE\_STRAIGHT—Specifies a straight broken line.
  - PRO\_VIEW\_BROKEN\_LINE\_SKETCH—Specifies a random sketch drawn by the user that defines the broken line.
  - PRO\_VIEW\_BROKEN\_LINE\_S\_CURVE\_OUTLINE—Specifies a S-curve on the view outline.
  - PRO\_VIEW\_BROKEN\_LINE\_S\_CURVE\_GEOMETRY—Specifies a S-curve on geometry.
  - PRO\_VIEW\_BROKEN\_LINE\_HEART\_BEAT\_OUTLINE—Specifies a heartbeat type of curve on the view outline.
  - PRO\_VIEW\_BROKEN\_LINE\_HEART\_BEAT\_GEOMETRY—Specifies a heartbeat type of curve on the geometry.
- *curve\_data*—Specifies the spline curve data in terms of the ProCurvedata object when the *line\_style* is of the type PRO\_VIEW\_BROKEN\_LINE\_SKETCH.

---

The function `ProDrawingViewBrokenNumberGet()` returns the number of breaks defined for the broken visible area. Two broken lines define one break.

### Note

A broken visible area can be created only for general and projected view types.

---

For the functions `ProDrawingViewPartialVisibleAreaSet()`, `ProDrawingView2DSectionGet()`, `ProDrawingViewBrokenVisibleAreaGet()`, `ProDrawingViewPartialVisibleAreaGet()`, `ProDrawingViewDetailCurvedataGet()`, and `ProDrawingViewDetailCurvedataSet()`, the output argument `curve_data` specifies the following::

- X, Y, and Z coordinate directions match the X, Y and Z of the world space.
- The coordinate points (0,0,0) maps to the detail view's reference point
- The scaling unit is of one inch relative to the top model of the view.

To map the curve data to world space:

- Scale the spline by inch to top model unit.
- Scale the spline by top model unit to world unit, which is the scale of the transform from `ProDrawingViewTransformGet()` (`view_to_drawing = TRUE`),
- Translate the curve to place (0,0) at the reference point.

To map a spline in world space for use here, perform the inverse actions:

- Translate the spline by the reference point to place that point at (0,0).
- Scale by world-to-model (inverse of the scale of the view's transformation matrix)
- Scale by top-model-unit-to-inch.

## Sections of a View

Functions Introduced:

- **`ProDrawingViewSectionTypeGet()`**
- **`ProDrawingView2DSectionGet()`**
- **`ProDrawingView2DSectionSet()`**
- **`ProDrawingView2DSectionNumberGet()`**
- **`ProDrawingView2DSectionFlip()`**

- **ProDrawingView2DSectionFlipGet()**
- **ProDrawingView3DSectionGet()**
- **ProDrawingView3DSectionSet()**
- **ProDrawingViewSinglepartSectionGet()**
- **ProDrawingViewSinglepartSectionSet()**
- **ProDrawingView2DSectionTotalSet()**
- **ProDrawingView2DSectionAreaSet()**

The function `ProDrawingViewSectionTypeGet()` retrieves the section type for a specified drawing view in terms of the enumerated type `ProDrawingViewSectionType`. A section can be of the following types:

- `PRO_VIEW_NO_SECTION`—Specifies no section.
- `PRO_VIEW_TOTAL_SECTION`—Specifies the complete drawing view.
- `PRO_VIEW_AREA_SECTION`—Specifies a 2D cross section.
- `PRO_VIEW_3D_SECTION`—Specifies a 3D cross section.
- `PRO_VIEW_PART_SURF_SECTION`—Specifies a section created out of a solid surface or a datum quilt in the model.

A drawing can have many 2D cross sections defined in it. These cross sections are indexed. The first cross section has its index number set to 0. Depending on which 2D cross section you want to work with, specify the index number.

The function `ProDrawingView2DSectionGet()` retrieves the 2D cross section for a specified drawing view.

The function `ProDrawingView2DSectionSet()` assigns the following arguments to define the 2D cross section for a drawing view:

- *sec\_name*—Specifies the name of the 2D cross section.
- *sec\_area\_type*—Specifies the type of section area. The section area is given by the enumerated type `ProDrawingViewSectionAreaType` and can be of the following types:
  - `PRO_VIEW_SECTION_AREA_FULL`—Sectioning is applied to full drawing view.
  - `PRO_VIEW_SECTION_AREA_HALF`—Sectioning is applied to half drawing view depending upon the inputs for half side.
  - `PRO_VIEW_SECTION_AREA_LOCAL`—Specifies local sectioning.
  - `PRO_VIEW_SECTION_AREA_UNFOLD`—Unfold the drawing view and section it.
  - `PRO_VIEW_SECTION_AREA_ALIGNED`—Sectioning is as per the aligned views.

- 
- *ref\_sel*—Specifies the selection reference in terms of the ProSelection object.
  - *curve\_data*—Specifies the spline curve data in terms of the ProCurvedata handle.
  - *arrow\_display\_view*—Specifies the drawing view, that is, either the parent or child view, where the section arrow is to be displayed.

---

 **Note**

For a section area of type `PRO_VIEW_SECTION_AREA_FULL` in the above function, you can pass the input arguments *ref\_sel*, *curve\_data*, and *arrow\_display\_view* as NULL.

---

The function `ProDrawingView2DSectionNumberGet()` retrieves the number of 2D cross sections defined for a drawing view.

The function `ProDrawingView2DSectionFlip()` flips the direction of 2D cross section in a drawing view. Specify the index of the 2D cross section that you want to flip.

Use the function `ProDrawingView2DSectionFlipGet()` returns a boolean value that indicates the direction in which the 2D cross section has been clipped. Depending on the type of cross section, the boolean value indicates different direction of clipping as below:

- Planar cross section—The boolean value:
  - `PRO_B_FALSE` indicates that the cross section has been clipped in the direction of the positive normal to the cross section plane.
  - `PRO_B_TRUE` indicates that the cross section has been clipped in the opposite direction of the positive normal.
- Offset cross section—The integer value:
  - `PRO_B_FALSE` indicates that material has been removed from the left of the cross section entities if the viewing direction is from the positive side of the entity plane.
  - `PRO_B_TRUE` indicates that the material has been retained from the left of the cross section entities and rest of the material has been removed.

The function `ProDrawingView3DSectionGet()` retrieves the 3D cross section for a specified drawing view.

The function `ProDrawingView3DSectionSet()` assigns the following arguments to define a 3D cross section for a view:

- *sec\_name* —Specifies the name of the 3D cross section.

- 
- *show\_x\_hatch*—Specifies a `ProBoolean` value that determines whether X-hatching is displayed in the 3D cross-sectional view. Set this argument to `PRO_B_TRUE` to display X-hatching.

The function `ProDrawingViewSinglepartSectionGet()` retrieves the section created out of a solid surface or a datum quilt in the model for a specified drawing view.

The function `ProDrawingViewSinglepartSectionSet()` assigns the reference selection in terms of the `ProSelection` object for the solid surface or datum quilt that is used to create the section in the view.

The functions `ProDrawingView2DSectionTotalSet()` and `ProDrawingView2DSectionAreaSet()` enable you to set the visibility of model edges in a 2D cross section view of a drawing.

The function `ProDrawingView2DSectionTotalSet()` sets the visibility of model edges to **Total**. A total cross section shows not only the cross-sectioned area, but also the edges of the model that become visible when a cross section is made. Here model edges behind the section planes as well as section edges are displayed.

The function `ProDrawingView2DSectionAreaSet()` sets the visibility of model edges to **Area**. An area cross section displays only the cross section without the geometry, that is, only section edges are displayed.

## View States

Functions Introduced:

- **`ProDrawingViewSimplifiedGet()`**
- **`ProDrawingViewSimplifiedSet()`**
- **`ProDrawingViewExplodedGet()`**
- **`ProDrawingViewExplodedSet()`**

The functions `ProDrawingViewSimplifiedGet()` and `ProDrawingViewSimplifiedSet()` retrieve and set the simplified representation for a specified drawing view.

The functions `ProDrawingViewExplodedGet()` and `ProDrawingViewExplodedSet()` retrieve and set the exploded state for a specified drawing view.

---

## Example 7: Creating Drawing Views and Accessing their Properties

The sample code in the file `UgNotesColor.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_dwg` creates both general and projection types of drawing views and accesses the view scale, orientation, exploded state, and visible areas of the created drawing views.

### Drawing Models

Functions Introduced:

- **ProDrawingSolidsCollect()**
- **ProDrawingSolidsVisit()**
- **ProDrawingSolidAdd()**
- **ProDrawingSolidDelete()**
- **ProDrawingSimpregsCollect()**
- **ProDrawingAsmsimpregAdd()**
- **ProDrawingAsmsimpregDelete()**
- **ProDrawingSolidReplace()**
- **ProDrawingCurrentsolidGet()**
- **ProDrawingCurrentsolidSet()**

The function `ProDrawingSolidsCollect()` outputs an array of the solids attached to the drawing, including those not currently displayed in a view.

Function `ProDrawingSolidsVisit()` is a visit function of the usual form which visits the same solids.

The function `ProDrawingSolidAdd()` adds a new solid to a drawing, but does not display it. (To create a drawing view, refer to the [Creating Views on page 1223](#) section.)

`ProDrawingSolidDelete()` deletes a solid from a drawing, provided that solid is not currently displayed in a view.

#### Functions

`ProDrawingSimpregsCollect()`, `ProDrawingAsmsimpregAdd()`, and `ProDrawingAsmsimpregDelete()` are the equivalents to the above functions but take a handle to a simplified rep.

The function `ProDrawingSolidReplace()` replaces a drawing model solid with another solid. The old and new solids must be members of the same family table. The following example code describes this function.

---

The functions `ProDrawingCurrentSolidGet()` and `ProDrawingCurrentSolidSet()` provide access to the current solid model for a given drawing.

### Example 8: Replace Drawing Model Solid with a Solid

The sample code in the file `UgDrawingSolidReplace.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_drawing` shows how to replace a drawing model solid with a solid.

## Detail Items

The functions described in this section operate on detail items. Detail items are those drawing items that you create in Creo Parametric in the drawings.

In Creo TOOLKIT, you have the ability to create, delete, and modify detail items, control their display, and examine what detail items are present in the drawing.

There types of detail items available in Creo TOOLKIT are:

- Draft entities—Contain the graphical items created in Creo Parametric using the options under the **Sketch** tab, in the **Sketching** group. Some of the items are as follows:
  - Arc
  - Ellipse
  - Line
  - Point
  - Polygon
  - Spline
- Notes—Textual annotations created in Creo Parametric using the command **Annotate ► Note**. They can also contain special symbols.
- Symbol definitions—Named groups of other detail items that the Creo Parametric user can save to disk. You create them in Creo Parametric using the options in the **Annotate ► Symbol** command.
- Symbol instances—Instances of a symbol.
- Draft groups—Groups of detail items such as draft entities, notes, symbol instances, and drawing dimensions. You create them in Creo Parametric using the command **Sketch ► Draft Group**.
- OLE objects—Object Linking and Embedding (OLE) objects embedded in the Creo Parametric drawing file from the **Insert Object** dialog box that opens when you click **Layout ► Object**.

---

All detail items are identified by DHandles which are equivalent to `ProModelitem`, and inherit from `ProModelitem`. This implies that functions such as `ProSelectionModelitemGet()`, `ProSelectionAlloc()`, and `ProModelitemInit()`, can be used for detail items. The values of the type field for the types of detail item are:

- `PRO_DRAFT_ENTITY`—This type is used for draft entities and OLE objects. Special functions exist to distinguish OLE objects from other detail entities.
- `PRO_NOTE`
- `PRO_SYMBOL_DEFINITION`
- `PRO_SYMBOL_INSTANCE`
- `PRO_DRAFT_GROUP`

There is generic detail object called `ProDtItem`, whose type field can take any of these values, and is used for arguments to functions that can represent any detail item. The following object handles are used in the more specific cases:

- `ProDtEntity`
- `ProDtNote`
- `ProDtSymDef`
- `ProDtSymInst`
- `ProDtGroup`

## Listing Detail Items

Functions Introduced:

- **`ProDrawingDtEntitiesCollect()`**
- **`ProDrawingDtEntityVisit()`**
- **`ProDrawingDtNotesCollect()`**
- **`ProDrawingDtNoteVisit()`**
- **`ProDrawingDtSymDefsCollect()`**
- **`ProDrawingDtSymDefVisit()`**
- **`ProDrawingDtSymInstsCollect()`**
- **`ProDrawingDtSymInstVisit()`**
- **`ProDrawingDtGroupsCollect()`**
- **`ProDrawingDtGroupVisit()`**
- **`ProDrawingOLEObjectsVisit()`**

---

The function `ProDrawingDtlentitiesCollect()` collects all the detail entities in the specified drawing and sheet. Set the input argument *symbol* to `NULL` if you are collecting a detail item in the drawing. If you are collecting a draft entity in a symbol definition, set *symbol* to specify the owning symbol definition.

---

 **Note**

The function `ProDrawingDtlentitiesCollect()` will not collect entities with special symbol definition, such as, datum targets or parametric connector symbols.

---

The function `ProDrawingDtlentityVisit()` visits all the draft entities stored in the specified drawing and sheet.

---

 **Note**

The function `ProDrawingDtlentityVisit()` will not visit entities with special symbol definition, such as, datum targets or parametric connector symbols.

---

The function `ProDrawingDtlnotesCollect()` collects all the notes in the specified drawing. Set the input argument *symbol* to `NULL` if you are collecting a note from the drawing. If you are collecting a note from a symbol definition, set *symbol* to specify the owning symbol definition.

The function `ProDrawingDtlnoteVisit()` visits the notes in the specified drawing.

The function `ProDrawingDtlsymdefsCollect()` collects the symbol definitions in the specified drawing.

The function `ProDrawingDtlsymdefVisit()` visits the symbol definitions in the drawing.

The function `ProDrawingDtlsyminstsCollect()` collects symbol instances in the specified drawing.

The function `ProDrawingDtlsyminstVisit()` visits symbol instances in the specified drawing.

The function `ProDrawingDtlgroupsCollect()` collects groups in the specified drawing.

The function `ProDrawingDtlgroupVisit()` visits groups in the specified drawing.

The function `ProDrawingOLEobjectsVisit()` visits the OLE objects embedded in the model. Specify the visit action and visit filter functions.

---

## Displaying Detail Items

Functions Introduced:

- **ProDtIentityDraw()**
- **ProDtIentityErase()**
- **ProDtInoteDraw()**
- **ProDtInoteErase()**
- **ProDtInoteShow()**
- **ProDtInoteRemove()**
- **ProDtIsyminstDraw()**
- **ProDtIsyminstErase()**
- **ProDtIsyminstShow()**
- **ProDtIsyminstRemove()**
- **ProDtIgroupDraw()**
- **ProDtIgroupErase()**

Each of the displayable item types has four display functions.

The Show function displays the detail item, such that it is repainted on the next draft regeneration.

The Remove function undraws the detail item permanently, so that it is not redrawn on the next draft regeneration.

The Draw function draws the detail item temporarily, so that it is removed on the next draft regeneration.

The Erase function undraws the detail item temporarily, so that it is redrawn on the next draft regeneration, if it was previously “shown”.

Use the Show function after creating an item, and the Remove function before deleting it. Use the Erase function before modifying an item, and the Draw function afterwards.

### Note

These functions require that the drawing must be the currently displayed model. To create or modify detail items in a model that is not currently displayed, use the attributes in the data structures related to Display. For example use `ProDtInotedataDisplayedSet()` to set the item to be saved with the displayed status turned on, so that the next retrieval of the model will display the item.

---

---

## Creating, Modifying and Reading Detail Items

Functions Introduced:

- **ProDtIentityCreate()**
- **ProDtIentityDataGet()**
- **ProDtIentityDelete()**
- **ProDtIentityModify()**
- **ProDtIentityErase()**
- **ProDtIentityIsOLEObject()**
- **ProDtIlnoteCreate()**
- **ProDtIlnoteDataGet()**
- **ProDtIlnoteDelete()**
- **ProDtIlnoteLineEnvelopeGet()**
- **ProDtIlnoteModify()**
- **ProDtIlsymdefCreate()**
- **ProDtIlsymdefDataGet()**
- **ProDtIlsymdefDelete()**
- **ProDtIlsymdefModify()**
- **ProDtIlsymdefToModelCopy()**
- **ProDtIlsyminstCreate()**
- **ProDtIlsyminstDataGet()**
- **ProDtIlsyminstDelete()**
- **ProDtIlsyminstModify()**
- **ProDtIlgrouPCreate()**
- **ProDtIlgrouPDataGet()**
- **ProDtIlgrouPDelete()**
- **ProDtIlgrouPModify()**

For each of the five detail item types there is an opaque data structure which describes the contents of the detail item. You build the appropriate data structure first, using functions provided for that purpose, and then pass it as input to the appropriate `Create()` function. The `*DataGet()` functions output a filled structure describing an existing detail item. The data structures are built and unpacked by their own functions for that purpose described in the following sections.

---

The function `ProDtlentityDataGet()` returns a structure that contains information about the specified detail item, in a drawing or in a symbol definition.

---

 **Note**

The functions `ProDtlentityDataGet()`, `ProDtlentityCreate()`, `ProDtlentityDelete()`, and `ProDtlentityModify` cannot access symbol definitions for special symbols, such as, datum targets or parametric connector symbols. For such symbols, the functions return the error `PRO_TK_GENERAL_ERROR`.

---

The functions `ProDtlnoteDataGet()` and `ProDtlsyminstDataGet()` have an argument for the display mode. Both notes and symbols may contain parameterized text, and the display mode specifies whether the data structure output by the `*DataGet()` function must contain the text before substitution of the parameters (SYMBOLIC mode), or after the displayed text (NUMERIC mode). If using `ProDtlnoteDataGet()` as a first step in note modification, always set *mode* to SYMBOLIC or the modification removes the parameterization. Refer to section [Detail Note Line Data on page 1248](#) for more information.

Some data structures contain arrays of, or pointers to, deeper structures which have their own manipulation functions, also described in later sections. Lower level data structures should be built before the upper level ones when creating detail items. The data structures and their member structures are listed below.

- `ProDtlentitydata`—A draft entity
- `ProCurvedata`—The 2D geometry of the entity (described in the [Core: 3D Geometry on page 177](#) section)
- `ProDtlnotedata`—A detail note
- `ProDtlnoteline`—A line of text in a note
- `ProDtlnotetext`—A segment of text in a line that may have it's own cosmetic properties, such as font, height, and so on
- `ProDtlattach`—One structure for the attachment of the note itself, and one per leader on the note
- `ProDtlsymdefdata`—A symbol definition
- `ProDtlsymdefattach`—The types of attachment support for an instance of this symbol
- `ProDtlsyminstdata`—A symbol instance
- `ProDtlvartext`—A variable text substitution

The sequence of calls to create a draft entity containing, for example, a line would be:

- 
1. `ProDtIentitydataAlloc()`—Allocate the entity data (see the section on [Draft Entity Data on page 1243](#)).
  2. `ProCurvedataAlloc()`—Allocate memory for a curve structure
  3. `ProLinedataInit()`—Set the curve structure to describe the required line by initializing a line data structure.
  4. `ProDtIentitydataCurveSet()`—Add the curve data to the entity data (see the section on [Draft Entity Data on page 1243](#)).
  5. `ProDtIentityCreate()`—Create the entity (see the section on [Creating, Modifying and Reading Detail Items on page 1240](#)).

---

 **Note**

You must set the drawing view before attempting to create a detail entity, unless you are creating entities in a symbol definition. The view can be a traditional drawing view obtained through `ProDrawingViewsCollect()`, or the drawing sheet background view obtained from `ProDrawingBackgroundViewGet()`.

---

The other detail items follow the same principles, although for symbol definitions there are added complexities; these are explained in section [Creating a Symbol Definition on page 1259](#).

The function `ProDtIentityIsOLEObject()` identifies if the specified detail entity is actually an OLE object. For more information on OLE objects refer to [Accessing OLE Objects on page 1245](#).

Each entity item has its own `Delete()` function which removes it permanently from the Creo Parametric drawing.

Each entity item also has its own `Modify()` function which passes a new Data structure.

Use the function `ProDtIlnoteErase()` to temporarily undraw the note (see the section on [Displaying Detail Items on page 1239](#)).

The function `ProDtIlnoteDataGet()` returns the data for the note.

The function `ProDtIlnoteModify()` uses the modified data to modify the note itself.

The function `ProDtIlnoteDraw()` redraws the note (see the section on [Displaying Detail Items on page 1239](#)).

The function `ProDtIlnoteLineEnvelopeGet()` determines the screen coordinates of the envelope around a detail note. This envelope is defined by four points. See figure Detail Note Envelope Point Order for how point order is determined.

---

## Detail Note Envelope Point Order

The function `ProDtlSymdefToModelCopy()` copies a specified symbol definition from one model to another.

The function `ProDtlSymdefDelete()` deletes a symbol definition. This function returns the error `PRO_TK_GENERAL_ERROR` when the deletion of a symbol definition from a part fails.

The function `ProDtlSymdefModify()` modifies a symbol definition. The input arguments are listed below:

- *symdef*—Specifies the symbol definition.
- *data*—Specifies the symbol definition data.

## Draft Entity Data

Functions Introduced:

- **`ProDtlEntitydataAlloc()`**
- **`ProDtlEntitydataFree()`**
- **`ProDtlEntitydataIdGet()`**
- **`ProDtlEntitydataCurveGet()`**
- **`ProDtlEntitydataCurveSet()`**
- **`ProDtlEntitydataColorGet()`**
- **`ProDtlEntitydataColorSet()`**
- **`ProDtlEntitydataFontGet()`**
- **`ProDtlEntitydataFontSet()`**
- **`ProDtlEntitydataWidthGet()`**
- **`ProDtlEntitydataWidthSet()`**
- **`ProDtlEntitydataViewGet()`**
- **`ProDtlEntitydataViewSet()`**
- **`ProDtlEntitydataIsConstruction()`**
- **`ProDtlEntitydataConstructionSet()`**

- **ProDtEntitydataIsPeriodic()**
- **ProDtEntitydataPeriodicSet()**
- **ProDrawingDraftToDraftent()**

The opaque data structure which describes the contents of a draft entity is called `ProDtEntitydata`.

The only lower-level opaque data structure contained by `ProEntitydata` is `ProCurvdata` which is also used for other 2D and 3D geometry, especially Import Features, and is described elsewhere.

The functions `ProDtEntitydataAlloc()` and `ProDtEntitydataFree()` allocate and free an opaque entity data structure.

Functions `ProDtEntitydataCurveGet()` and `ProDtEntitydataCurveSet()` get and set the geometry of the entity in the form of a `ProCurvdata` object.

`ProDtEntitydataColorGet()` and `ProDtEntitydataColorSet()` get and set the color of the draft entity. The visible data structure `ProColor`, declared in `ProDtItem.h`, can specify the color in three ways:

- By color index, that is, by choosing one of colors predefined in Creo Parametric, represented by the values of `ProColorType` in `ProToolkit.h`.
- By choosing the default color for this type of detail item. (For entities, the default is `PRO_COLOR_DRAWING` and for notes the default is `PRO_COLOR_LETTER`.)
- By specifying the three RGB color values.

If do you do not call `ProDtEntitydataColorSet()` when creating a new entity, the color will be set to be the default color for draft entities.

`ProDtEntitydataFontGet()` and `ProDtEntitydataFontSet()` get and set the line style font which determines the line style used to display the entity. The values are those which appear in the **Line Font** selector in the **Modify Line Style** dialog in Creo Parametric. If you do not call `ProDtEntitydataFontSet()` when creating an entity, the font will be `SOLIDFONT`.

`ProDtEntitydataWidthGet()` and `ProDtEntitydataWidthSet()` get and set the line width of the draft entity. The value -1.0 indicates that the entity should have the default width for entities currently set for the drawing. If you do not call `ProDtEntitydataWidthSet()` when creating a new entity, the width is -1.0.

---

`ProDtIentitydataViewGet()` and `ProDtIentitydataViewSet()` get and set the drawing view to which the entity will be attached. If an entity is attached to a view, it moves whenever the Creo Parametric user moves that view. Entities not attached to a model view must be assigned to the drawing sheet background view instead.

`ProDtIentitydataIsConstruction()` and `ProDtIentitydataConstructionSet()` get and set the flag that controls whether the entity is created normal or as a construction entity.

The function `ProDtIentitydataIsPeriodic()` checks if the draft identity is marked as periodic. The output argument `is_periodic` is a Boolean. The value `PRO_B_TRUE` indicates that the draft entity is periodic.

The function `ProDtIentitydataPeriodicSet()` marks the draft entity to be periodic. The input arguments are as follows:

- *data*—The draft entity data.
- *periodic*—Specify the value `PRO_B_TRUE` if the draft entity is to be periodic.

Use the function `ProDrawingDraftToDraftent()` to convert a selection of type draft to draft entity in the specified drawing. The input arguments follow:

- *p\_draw*—Specifies the drawing that owns the draft entity.
- *p\_sel\_draft*—A `ProSelection` object that represents the selection of type as draft.

The output argument `r_p_sel_draft_ent` returns the handle to the converted selection using the `ProSelection` object. The converted selection is managed by the function that calls the function `ProDrawingDraftToDraftent()`.

### Example 9: Create a Draft Line with Predefined Color

The sample code in the file `UgDtIentityExamples.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_drawing` shows a utility that creates a draft line in one of the colors predefined in Creo Parametric.

## Accessing OLE Objects

An object linking and embedding (OLE) object is an external file, such as a document, graphics file, or video file that is created using an external application and which can be inserted into another application, such as Creo Parametric. You can create and insert supported OLE objects into a two-dimensional Creo Parametric file, such as a drawing, report, format file, Notebook, or diagram. The functions described in this section enable you to identify and access OLE objects embedded in drawings.

### Function Description

- **ProDrawingOLEobjectSheetGet()**

- 
- **ProDrawingOLEobjectOutlineGet()**
  - **ProDrawingOLEobjectApplicationtypeGet()**
  - **ProDrawingOLEobjectPathGet()**

The function `ProDrawingOLEobjectSheetGet()` returns the sheet number for the OLE object.

The function `ProDrawingOLEobjectOutlineGet()` returns the extent of the OLE object embedded in the drawing.

The function `ProDrawingOLEobjectApplicationtypeGet()` returns the type of the OLE object as a string, for example, "Microsoft Word Document".

The function `ProDrawingOLEobjectPathGet()` returns the path to the external file for each OLE object, if it is linked to an external file.

## Detail Note Text Data

Functions Introduced:

- **ProDtlnotetextAlloc()**
- **ProDtlnotetextFree()**
- **ProTextStyleHeightGet()**
- **ProTextStyleHeightSet()**
- **ProTextStyleWidthGet()**
- **ProTextStyleWidthSet()**
- **ProTextStyleSlantAngleGet()**
- **ProTextStyleSlantAngleSet()**
- **ProTextStyleThicknessGet()**
- **ProTextStyleThicknessSet()**
- **ProTextStyleFontGet()**
- **ProTextStyleFontSet()**
- **ProDtlnotetextUlineGet()**
- **ProDtlnotetextUlineSet()**
- **ProDtlnotetextStringGet()**
- **ProDtlnotetextStringSet()**
- **ProDtlnotetextStyleGet()**
- **ProDtlnotetextStyleSet()**
- **ProDtlnoteWrapTextGet()**

---

- **ProDtlnoteWrapTextSet**

Each line of a drawing note may contain text in several different fonts, heights, and so on. So each line is described in terms of an array of text items, whose contents are described by the data structure `ProDtlnotetext`.

`ProDtlnotetextAlloc()` and `ProDtlnotetextFree()` allocate and free a `ProDtlnotetext` data structure.

`ProTextStyleHeightGet()` and `ProTextStyleHeightSet()` get and set the height of the text. The value -1.0 means that the text has the default height for text currently specified for the drawing.

`ProTextStyleWidthGet()` and `ProTextStyleWidthSet()` get and set the width factor of the text. The width factor is the ratio of the width of each character to the height. The value -1.0 means that the width factor has the default value for text currently specified for the drawing.

`ProTextStyleSlantAngleGet()` and `ProTextStyleSlantAngleSet()` get and set the slant angle of the text.

`ProTextStyleThicknessGet()` and `ProTextStyleThicknessSet()` get and set the line thickness of the text. The value -1.0 means that the text has the default thickness for text currently specified for the drawing.

`ProTextStyleFontGet()` and `ProTextStyleFontSet()` get and set the font used to display the text.

`ProDtlnotetextUlineGet()` and `ProDtlnotetextUlineSet()` get and set whether the text item is underlined. The default is no underline.

`ProDtlnotetextStringGet()` and `ProDtlnotetextStringSet()` get and set the string of characters contained in the text item.

The functions `ProDtlnotetextStyleGet()` and `ProDtlnotetextStyleSet()` retrieve and set the text style for the specified text as a `ProTextStyle` structure. It takes as input the `ProDtlnotetext` object.

The function `ProTextStyleFree()` frees the allocated data structure.

`ProDtlnoteWrapTextGet()` and `ProDtlnoteWrapTextSet()` get and set the wrap status of the text for a specified note in a drawing.

The function `ProDtlnoteWrapTextSet()` sets the text wrapping status to ON or OFF. The input arguments are listed below:

- *note*—Specifies the note for which the wrap status is to be set.
- *wrap*—Specifies if the text is wrapped. To wrap the text, specify the value as `Pro_B_True`.
- *wrapwidth*—Specifies the width of the wrapped text line, if the input argument *wrap* is set to `Pro_B_True`.

---

## Detail Note Line Data

Functions Introduced:

- **ProDtlnotelineAlloc()**
- **ProDtlnotelineFree()**
- **ProDtlnotelineTextAdd()**
- **ProDtlnotelineTextsSet()**
- **ProDtlnotelineTextsCollect()**

The `ProDtlnoteline` data structure describes the contents of a single line of text in a detail note.

`ProDtlnotelineAlloc()` and `ProDtlnotelineFree()` allocate and free a `ProDtlnoteline` structure.

`ProDtlnotelineTextAdd()` adds a text item, described by a `ProDtlnotetext` data structure, to a note line. If the line already contained text items, the new one is added at the end of the array.

`ProDtlnotelineTextsSet()` sets the contents of a whole text line, by providing a new array of `ProDtlnotetext` items. If the note line already contained text items, they are replaced by the new ones.

`ProDtlnotelineTextsCollect()` outputs an array of the text items contained in a specified text line.

Points to note about Text Lines and parameterization:

- If the string in a Text Line you put in a note contains one or more parameters, Creo Parametric will divide the Text Line into several Text Items to ensure that each parameter has its own Text Item.
- When you look at the text in an existing note by using the function `ProDtlnoteDataGet()` with the *mode* option set to `SYMBOLIC` (that is, to see the text before substitution of the parameters), you will see the text bracketing and text item identifiers that you also see when you edit a text line in Creo Parametric.

For example, if you make a text line containing a single text item with the text  
`"model = &model_name"`

Creo Parametric will put the `&model_name` into a separate text item when the note is created. If you then use `ProDtlnoteDataGet()` on the created note with the *mode* option set to `SYMBOLIC`, you will see the following two text items in the relevant text line

```
"model = " "&model_name"
```

If you set *mode* to `NUMERIC`, you see these text items:

```
"model = " "MODEL"
```

---

where `MODEL` is the name of the model.

---

 **Note**

Creo Parametric does not resolve and replace symbolic callouts for notes which are not displayed. Therefore, if the note is not displayed or is hidden in a layer, the text retrieved may contain symbolic callouts, even when the *mode* is set to `NUMERIC`.

Note that `ProDtlnotetextStringGet()` does not return the brackets and numbers for each individual text entity. In addition, the function does not return the special escape characters (such as `\}`) to represent characters previously provided.

Refer to the section [Creating a Symbol Definition on page 1259](#) for a description of how to find which Creo Parametric model owns the parameter referred to by parameterized text.

---

## Detail Attachments and Leaders

Functions Introduced:

- **`ProDtlattachAlloc()`**
- **`ProDtlattachGet()`**
- **`ProDtlattachSet()`**
- **`ProDtlattachFree()`**
- **`ProDtlattachArrowtypeGet()`**
- **`ProDtlattachArrowtypeSet()`**
- **`ProDtlattachIsSuppressedGet()`**

The opaque data structure `ProDtlattach` is used for two tasks:

- The way in which a drawing note or a symbol instance is attached to the drawing.
- The way in which a leader on a drawing note or symbol instance is attached.

Each note and symbol instance must contain one `ProDtlattach` to describe its attachment in the drawing, and may contain any number of `ProDtlattach` objects describing the leaders.

`ProDtlattachAlloc()` allocates and initializes the memory for a detail attachment. The inputs are:

- 
- *type*—The type of attachment to the drawing view. The detail attachment types are as follows:
    - `FREE`—The attachment is to a 2D location in the drawing view.
    - `PARAMETRIC`—The attachment is to a point on a surface or an edge of a solid.
    - `OFFSET`—The attachment is offset to another drawing view, to a model item, or to a 3D model annotation.

---

 **Note**

You cannot attach a symbol to 3D model annotation using the `OFFSET` attachment type.

---

- *view*—The drawing view. If the type is `FREE`, the attachment is relative to the drawing view, that is the attachment moves when the drawing view is moved. This is `NULL`, if the detail attachment is not related to the drawing view, but is placed at a specified location in the drawing sheet, or if the attachment is offset to a model item or to a 3D model annotation.
- *location*—If the type is `FREE` or `OFFSET`, this argument provides the location of the attachment. This location is in screen coordinates for drawing items, symbol instances and surface finishes on flat-to-screen annotation planes, and in model coordinates for symbols and surface finishes on 3D model annotation planes. The distance from this location to the location of the item to which the detail item is attached (given by the argument *attach\_point*) is saved as the offset distance for an `OFFSET` attachment.
- *attach\_point*—If the type is `PARAMETRIC` or `OFFSET`, this `ProSelection` structure provides the location of the item to which the detail item is attached. This includes the drawing view in which the attachment is made. If you are building this structure using `ProSelectionAlloc()`, set the location using `ProSelectionUvParamSet()`, and the drawing view using `ProSelectionViewSet()`.

Use the function `ProDtlattachSet()` to set the above `ProDtlattach` information for an existing attachment.

The function `ProDtlattachGet()` unpacks the above information for an existing attachment. The output arguments are:

- *type*—The type of attachment to the drawing view. The detail attachment types are as follows:
  - `FREE`—The attachment is to a 2D location in the drawing view.

- 
- **PARAMETRIC**—The attachment is to a point on a surface or an edge of a solid in a drawing view.
  - **OFFSET**—The attachment is offset to another drawing view, to a model item, or to a 3D model annotation.
  - **UNIMPLEMENTED**—The attachment is to an item that is not currently supported in Creo TOOLKIT. However, you can still retrieve the location and the view to which the attachment is connected.
  - **SUPPRESSED**—The attachment is to an item, which is missing from the drawing or part.
  - **view**—If the type is **FREE** or **UNIMPLEMENTED**, this argument specifies the drawing view. This is **NULL**, if the detail attachment is not related to the drawing view, but is placed at a specified location in the drawing sheet, or if the attachment is offset to a model item or to a 3D model annotation.
  - **location**—If the type is **FREE**, **OFFSET**, or **UNIMPLEMENTED**, this argument specifies the location of the attachment. This location is in screen coordinates for drawing items, symbol instances and surface finishes on flat-to-screen annotation planes, and in model coordinates for symbols and surface finishes on 3D model annotation planes. The distance from this location to the location of the item to which the detail item is attached (given by the argument *attach\_point*) is saved as the offset distance for an **OFFSET** attachment.
  - **attach\_point** —If the type is **PARAMETRIC** or **OFFSET**, this argument provides the location of the item to which the detail item is attached. This includes the drawing view in which the attachment is made.

`ProDtlattachFree()` frees an attachment that was allocated with `ProDtlattachAlloc()`.

The function `ProDtlattachArrowtypeGet()` returns the type of arrowhead used for the leaders attached to a drawing note or symbol instance. Use the function `ProDtlattachArrowtypeSet()` to assign the type of arrowhead.

---

### **Note**

The functions `ProDtlattachArrowtypeGet()` and `ProDtlattachArrowtypeSet()` are applicable only for `ProDtlattach` leader attachment objects obtained using the functions `ProDtlslminstdataLeadersCollect()` and `ProDtlnoteddataLeadersCollect()`.

---

The function `ProDtlattachIsSuppressedGet()` returns whether the attachment is suppressed. The input argument to this function is *attach*, which specifies the leader attachment structure.

---

The output argument to this function *is\_supp* is set to `true` if the attachment is suppressed.

## Detail Note Data

Functions Introduced:

- **ProDtlnotedataAlloc()**
- **ProDtlnotedataFree()**
- **ProDtlnotedataIdGet()**
- **ProDtlnotedataLineAdd()**
- **ProDtlnotedataLinesSet()**
- **ProDtlnotedataLinesCollect()**
- **ProTextStyleMirrorGet()**
- **ProTextStyleMirrorSet()**
- **ProTextStyleColorGetWithDef()**
- **ProTextStyleColorSetWithDef()**
- **ProDtlnotedataAttachmentGet()**
- **ProDtlnotedataAttachmentSet()**
- **ProDtlnotedataLeadersCollect()**
- **ProDtlnotedataLeadersSet()**
- **ProDtlnotedataLeaderAdd()**
- **ProDtlnotedataElbowlengthGet()**
- **ProDtlnotedataElbowlengthSet()**
- **ProTextStyleAngleGet()**
- **ProTextStyleAngleSet()**
- **ProTextStyleJustificationGet()**
- **ProTextStyleJustificationSet()**
- **ProTextStyleVertJustificationGet()**
- **ProTextStyleVertJustificationSet()**
- **ProDtlnotedataIsDisplayed()**
- **ProDtlnotedataDisplayedSet()**
- **ProDtlnoteDtlsyminstsCollect()**
- **ProDtlnotedataTextStyleGet()**
- **ProDtlnotedataTextStyleSet()**

---

- **ProDtlnoteTableCellGet()**

The object `ProDtlnotedata` is an opaque pointer to a data structure that describes the contents of a drawing note.

`ProDtlnotedataAlloc()` and `ProDtlnotedataFree()` allocate and free memory for the data.

`ProDtlnotedataIdGet()` gives you the integer id of the note in Creo Parametric that the data describes. This will be set if the `ProDtlnotedata` has been acquired using `ProDtlnoteDataGet()`. It is not necessary to set this when creating a note; the function `ProDtlnoteCreate()` will assign an id to the new note.

`ProDtlnotedataLineAdd()` adds a `ProDtlnoteline` object to a `ProDtlnotedata` description. If the note already contains lines of text, the new line will be added at the end.

`ProDtlnotedataLinesSet()` sets an array of `ProDtlnoteline` objects as the lines in a `ProDtlnotedata` description. If the note already contains text lines, they will be replaced by the new lines.

`ProDtlnotedataLinesCollect()` outputs an array of `ProDtlnoteline` objects describing the lines in a given `ProDtlnotedata` description.

`ProTextStyleMirrorSet()` specifies the option to mirror the note. Specify the input argument *mirror* to true to mirror the note.

`ProTextStyleMirrorGet()` returns the mirroring option specified for the note.

`ProTextStyleColorGetWithDef()` and `ProTextStyleColorSetWithDef()` get and set the color for the note. If you do not call `ProTextStyleColorSetWithDef()` when creating a note, the note will have the default color defined by `PRO_COLOR_METHOD_DEFAULT`. Refer to the [Draft Entity Data on page 1243](#) section for a fuller description of the `ProColor` object.

`ProDtlnotedataAttachmentGet()` and `ProDtlnotedataAttachmentSet()` get and set the `ProDtlattach` object which describes the attachment of the note, that is, where and how it is positioned on the drawing.

`ProDtlnotedataLeadersCollect()` outputs an array of `ProDtlattach` objects which described the attachment points of the leaders on the note. `ProDtlnotedataLeadersSet()` adds an array of leaders to a note, replacing existing leaders. `ProDtlnotedataLeaderAdd()` adds a new leader to the end of the array of current leaders on a note.

---

`ProDtlnotedataElbowlengthGet()` and `ProDtlnotedataElbowlengthSet()` get and set the length of the elbow that connects each leader to the note. If you do not call `ProDtlnotedataElbowlengthSet()` when creating a note, there will be no elbow.

The functions `ProTextStyleAngleGet()` and `PProTextStyleAngleSet()` get and set the angle of rotation of the note. If you do not call `ProTextStyleAngleSet()` when creating the note, the rotation defaults to 0.0.

The functions `ProTextStyleJustificationGet()` and `ProTextStyleJustificationSet()` return and set the horizontal justification for the text style object. The functions `ProTextStyleVertJustificationGet()` and `ProTextStyleVertJustificationSet()` return and set the vertical justification for the text style object. Vertical justification applies only to notes in drawing tables and `OnItem` notes.

`ProDtlnotedataIsDisplayed()` and `ProDtlnotedataDisplayedSet()` retrieve and set the flag that controls whether the note is visible or not. If the note is created with this flag set to true, regenerate the drawing using `ProDwgDraftRegenerate()` to see the displayed note.

`ProDtlnotedataSymInstsCollect()` returns a list of all the symbol instances that are declared in a detail note via the “sym()” callout format. The symbol instances are returned in the order they are encountered in the note text.

The functions `ProDtlnotedataTextStyleGet()` and `ProDtlnotedataTextStyleSet()` retrieve and set the text style for the specified note as a `ProTextStyle` structure. It takes as input the `ProDtlnotedata` object.

If the note has texts with different styles, the style returned by the function `ProDtlnotedataTextStyleGet()` will have mixed state for attributes. The attributes are not the same for all texts. In such a case of mixed attribute, if function such as `ProTextStyleFontGet()` is called, the error `PRO_TK_GENERAL_ERROR` is returned.

The function `ProTextStyleFree()` frees the allocated data structure.

The function `ProDtlnoteTableCellGet()` returns the information on the rows and columns within a table for the specified table note. The information is given by the following output arguments:

- *table*—Specifies the table.
- *p\_row*—Specifies the indexed row that starts at 0.
- *p\_col*—Specifies the indexed column that starts at 0.

---

## Example 10: Create Drawing Note at Specified Location with Leader to Surface and Surface Name

The sample code in the file `UgDtlnoteExamples.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_drawing`, shows a function which creates a drawing note with a text style at a specified location, with a leader attached to a solid surface, and which shows the name of the surface.

## Example 11: Create Drawing Note

The sample code in the file `UgNoteCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_dwg`, shows a function which creates a drawing note with a text style that gives the default text height for the specified drawing.

## Read-Only Notes

Functions Introduced:

- **ProDtlnotedataReadonlySet()**
- **ProDtlnotedataReadonlyGet()**
- **ProDrawingReadonlyselectionAllow()**

You can make an existing drawing note unselectable by Creo Parametric users if you wish to protect it from modification. The functions `ProDtlnotedataReadonlySet()` and `ProDtlnotedataReadonlyGet()` set and get this property on `ProDtlnotedata` objects. Use function `ProDtlnotedataReadonlySet()` in conjunction with `ProDtlnoteDataGet()` and `ProDtlnoteModify()` to change the setting.

The function `ProDrawingReadonlyselectionAllow()` will temporarily allow the selection of read-only notes.

## Parameterized Note Text

Function introduced:

- **ProDtlnoteModelrefGet()**

A note in a drawing, or in a symbol definition, can be parameterized. This means that it contains the name of a parameter from a Creo Parametric model, preceded by a '&'. The '&' and the parameter name are replaced by the value of the parameter when the note is displayed, or when the symbol is instantiated.

---

The parameterizations in different notes and symbols in a single drawing may refer to parameters on different Creo Parametric models, depending upon the history of the drawing. The function `ProDtlnoteModelrefGet()` allows you to find out which model is referred to by a specific parameter.

## Cross-referencing Gtols and Drawing Annotations

The functions described in this section provide the drawing object that represents a shown gtol (if the gtol is shown in the drawing), or vice-versa.

Functions Introduced:

- **ProGtolDtlnoteGet()**
- **ProDtlnoteGtolGet()**

The function `ProGtolDtlnoteGet()` returns the detail note that represents a shown geometric tolerance.

---

### Note

This function returns the first detail note that calls out the geometric tolerance. Creo Parametric does not restrict users to showing only a single version of a geometric tolerance callout.

---

The function `ProDtlnoteGtolGet()` returns the geometric tolerance shown in a detail note, if applicable.

## Cross-referencing 3D Notes and Drawing Annotations

The functions described in this section provide access to the drawing object that represents a shown 3D note, (if the 3D note is shown in the drawing), or vice-versa.

Functions Introduced:

- **ProNoteDtlnoteGet()**
- **ProDtlnoteNoteGet()**

The function `ProNoteDtlnoteGet()` returns a detail note that represents a shown model tree.

### Note

This function returns the first detail note that calls out the solid model note. Creo Parametric does not restrict users to showing only a single version of a solid model note callout.

The function `ProDtlNoteNoteGet()` returns the solid model note that is displayed as a detail note, if applicable.

## Symbol Definition Attachments

Functions Introduced:

- **ProDtlSymDefAttachAlloc()**
- **ProDtlSymDefAttachGet()**
- **ProDtlSymDefAttachFree()**
- **ProDtlSymDefDataAttachAdd()**
- **ProDtlSymDefDataAttachSet()**
- **ProDtlSymDefDataAttachGet()**

A symbol definition has several different ways in which instances of that symbol can be attached to the drawing. In Creo Parametric users set these attachments from the **General** tab on the **Symbol Definition Attributes** dialog. Each attachment type is described in Creo TOOLKIT by an opaque data structure called `ProDtlSymDefAttach`. This is allocated and filled by the function `ProDtlSymDefAttachAlloc()`. The types of attachment are:

- **FREE**—The symbol will have no leaders, and will be attached by a specified location.
- **ON\_ITEM**—The symbol will be attached to an entity in the drawing.
- **NORM\_ITEM**—The symbol will be attached to an entity, and be rotated to be normal to that entity.
- **LEFT\_LEADER**—The attachment is by a leader to a point on an entity at the left of the symbol.
- **RIGHT\_LEADER**—The attachment is by a leader to a point on an entity at the right of the symbol.
- **RADIAL\_LEADER**—The attachment is by a leader attached to a circular entity in the symbol.

The input arguments to the function are these

- *type*—The type of attachment

- *entity\_id*—The id of the entity in the symbol definition which has the attachment point, if the attachment type is \*\_LEADER.entity\_parameter The “t” value of the location on the entity which forms the attachment point, if the attachment type is \*\_LEADER.
- *position*—The location in the symbol coordinate system which forms the attachment point, if the attachment type is FREE, ON\_ITEM, or NORM\_ITEM.

## Symbol Definition Data

Functions Introduced:

- **ProDtlsymdefdataAlloc()**
- **ProDtlsymdefdataFree()**
- **ProDtlsymdefdataIdGet()**
- **ProDtlsymdefdataHeighttypeGet()**
- **ProDtlsymdefdataHeighttypeSet()**
- **ProDtlsymdefdataTextrefSet()**
- **ProDtlsymdefdataTextrefGet()**
- **ProDtlsymdefdataElbowGet()**
- **ProDtlsymdefdataElbowSet()**
- **ProDtlsymdefdataTextangfixedGet()**
- **ProDtlsymdefdataTextangfixedSet()**
- **ProDtlsymdefdataScaledheightGet()**
- **ProDtlsymdefdataPathSet()**
- **ProDtlsymdefdataPathGet()**
- **ProDtlsymdefdataNameGet()**

The opaque object `ProDtlsymdefdata` describes the contents of a symbol definition. The functions `ProDtlsymdefdataAlloc()` and `ProDtlsymdefdataFree()` allocate and free this data.

`ProDtlsymdefdataIdGet()` gives you the integer id of the symbol definition in Creo Parametric that the data describes. This will be set if the `ProDtlsymdefdata` has been acquired using `ProDtlsymdefDataGet()`. It is not necessary to set this when creating a symbol definition; the function `ProDtlsymdefCreate()` will assign an id to the new note.

`ProDtlsymdefdataHeighttypeGet()` and `ProDtlsymdefdataHeighttypeSet()` get and set the way in which the size of an instance of this symbol definition is set. The three types are:

- **FIXED**—The symbol instance height is fixed.

- **VARIABLE**—The symbol instance height may be modified by the Creo Parametric user.
- **TEXTRELATED**—The symbol instance height is related to the height of a text item in the definition.

If the height type is **TEXTRELATED** the functions

`ProDtlSymDefDataTextrefSet()` and

`ProDtlSymDefDataTextrefGet()` set and get the text item in the symbol definition which determines the symbol instance height. The reference is by note id, line index, and text item index.

`ProDtlSymDefDataElbowGet()` and

`ProDtlSymDefDataElbowSet()` get and set the bit flag representing the elbow of the symbol definition.

`ProDtlSymDefDataTextangfixedGet()` and

`ProDtlSymDefDataTextangfixedSet()` get and set whether the angle of text in the symbol is fixed.

`ProDtlSymDefDataScaledheightGet()` returns the height of the symbol definition in inches.

`ProDtlSymDefDataPathSet()` and `ProDtlSymDefDataPathGet()` set and get the path and file name of the file in which the symbol definition may be saved. This is used to give the symbol its name.

`ProDtlSymDefDataNameGet()` gets the name of the symbol definition.

## Creating a Symbol Definition

The notes and draft entities that are contained by a symbol definition are created using `ProDtlEntityCreate()` and `ProDtlNoteCreate()`, using the `ProDtlSymDef` handle as the *symbol* argument. So you need to create the empty symbol definition first, and then add the notes and entities.

If you want to add parametric leader attachments, using `ProDtlSymDefDataAttachAdd()` and so on, these identify the entities to which the leaders should attach using the object handles output by the calls to `ProDtlNoteCreate()` and `ProDtlEntityCreate()` that created them. So these attachment types should also be added after the symbol is created.

So the steps in creating a symbol definition are:

- Allocate a description — `ProDtlSymDefDataAlloc()`
- Add a FREE attachment — `ProDtlSymDefAttachAlloc()`,  
`ProDtlSymDefDataAttachAdd()`
- Create the symbol—`ProDtlSymDefCreate()`
- Add the notes and entities (as for creating notes and entities in the drawing)

- 
- Add any leader attachments—`ProDtlSymDefAttachAlloc()`, `ProDtlSymDefDataAttachAdd()`

### Example 12: Create Symbol Definition

The sample code in the file `UgDtlSymDefExamples.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_drawing`, shows a function which creates a symbol definition which contains four line entities forming a box, a note with text style at the middle of the box, and a free attachment.

## Retrieving a Symbol Definition from Disk

Function introduced:

- **`ProDrawingDtlSymDefRetrieve()`**
- **`ProDrawingSystemDtlSymDefRetrieve()`**

Creo Parametric symbols exist in two different areas: the user-defined area and the system symbols area.

The function `ProDrawingDtlSymDefRetrieve()` enables you to retrieve a symbol definition from the user-defined location designated by the configuration option `pro_symbol_dir`. The symbol definition should have been previously saved to a file using Creo Parametric.

The function `ProDrawingSystemDtlSymDefRetrieve()` retrieves a symbol definition from the system directory. The system area contains symbols provided by Creo Parametric with the Detail module (such as the Welding Symbols Library).

## Symbol Instance Variable Text

Functions Introduced:

- **`ProDtlVartextAlloc()`**
- **`ProDtlVartextFree()`**
- **`ProDtlVartextDataGet()`**

A symbol instance may replace any text inside a note in the symbol definition that is enclosed in back slash characters. The opaque data structure `ProDtlVartext` describes such a substitution. It describes the “prompt” string, that is, the string in the symbol definition which it is replacing, and the “value”, that is, the new text string.

The function `ProDtlVartextAlloc()` allocates and initializes a `ProDtlVartext` object. `ProDtlVartextFree()` frees the memory, and `ProDtlVartextDataGet()` unpacks the information in a `ProDtlVartext`.

---

## Symbol Instance Data

Functions Introduced:

- **ProDtlsyminstdataAlloc()**
- **ProDtlsyminstdataFree()**
- **ProDtlsyminstdataColorSet()**
- **ProDtlsyminstdataColorGet()**
- **ProDtlsyminstdataDefSet()**
- **ProDtlsyminstdataDefGet()**
- **ProDtlsyminstdataAttachtypeSet()**
- **ProDtlsyminstdataAttachtypeGet()**
- **ProDtlsyminstdataDefattachSet()**
- **ProDtlsyminstdataDefattachGet()**
- **ProDtlsyminstdataAttachmentGet()**
- **ProDtlsyminstdataAttachmentSet()**
- **ProDtlsyminstdataDimattachGet()**
- **ProDtlsyminstdataLeadersCollect()**
- **ProDtlsyminstdataLeadersSet()**
- **ProDtlsyminstdataLeaderAdd()**
- **ProDtlsyminstdataElbowlengthGet()**
- **ProDtlsyminstdataElbowlengthGet()**
- **ProDtlsyminstdataElbowlengthSet()**
- **ProDtlsyminstdataAngleSet()**
- **ProDtlsyminstdataAngleGet()**
- **ProDtlsyminstdataScaledheightSet()**
- **ProDtlsyminstdataScaledheightGet()**
- **ProDtlsymInstnoteDataGet()**
- **ProDtlsymInstentityDataGet()**
- **ProDtlsyminstdataDisplayedSet()**
- **ProDtlsyminstdataIsDisplayed()**
- **ProDtlsyminstdataIsInvisible()**
- **ProDtlsyminstdataVartextAdd()**
- **ProDtlsyminstdataVartextsSet()**
- **ProDtlsyminstdataVartextsCollect()**

- **ProDtlsyminstdataTransformGet()**
- **ProDtlsyminstdataGroupoptionsSet()**
- **ProDtlsyminstEntitiesVisibleGet()**
- **ProDtlsyminstIsDatumTarget()**
- **ProDtlsyminstEnvelopeGet()**
- **ProDtlsyminstReferencesAdd()**
- **ProDtlsyminstReferencesGet()**
- **ProDtlsyminstReferenceDelete()**
- **ProDtlsyminstSurffinGet()**

**ProDtlsyminstdataAlloc()** and **ProDtlsyminstdataFree()** allocate and free a **ProDtlsyminstdata** description.

**ProDtlsyminstdataDefSet()** and **ProDtlsyminstdataDefGet()** set and get the reference to the symbol definition that this instance instantiates.

**ProDtlsyminstdataAttachtypeSet()** and **ProDtlsyminstdataAttachtypeGet()** set and get the type of attachment being chosen for the symbol instance. The corresponding attachment types much exist in the symbol definition.

If you want to make an attachment to a symbol instance of a type that was not specified in the symbol definition, you can add you own symbol definition attachment to the symbol instances. **ProDtlsyminstdataDefattachSet()** and **ProDtlsyminstdataDefattachGet()** set and get a **ProDtlsymdefattach** object on a symbol instance with this purpose.

**ProDtlsyminstdataAttachmentGet()** and **ProDtlsyminstdataAttachmentSet()** get and set the actual attachment for the symbol instance, that is, where it is positioned on the drawing, in the form of a **ProDtlattach** object. Refer to the section on [Detail Attachments and Leaders on page 1249](#) for more information about this object. In Creo Parametric 10.0.0.0 and later, you can use the functions **ProDtlsyminstdataAttachmentGet()** and **ProDtlsyminstdataAttachmentSet()** to place 3D symbols as offset to other symbol, dimension, note or a datum target.

The function **ProDtlsyminstDimattachGet()** returns the dimension to which the specified symbol instance is attached. The function returns the error of type **PRO\_TK\_BAD\_CONTEXT** when the dimension to which the specified symbol instance is attached is not available. In this case, the model containing the dimension was either deleted or suppressed in the assembly.

**ProDtlsyminstElbowlengthGet()** gets the elbow properties of the symbol in 3D. The input argument *p\_sym\_inst* is the symbol instance that is defined by **ProDtlsyminst**. The output arguments are:

- 
- *op\_elbow\_length*—Specifies the elbow length in model units for annotation plane symbols.
  - *elbow\_direction*—Specifies the elbow direction in the model's coordinate system. This is the direction from the symbol text to the symbol leaders that is defined by *ProVector*.

`ProDtlSymInstDataLeaderAdd()` adds a leader to a symbol instance description.

`ProDtlSymInstDataLeadersSet()` sets an array of leaders in a symbol instance, replacing any existing leaders.

### Note

To remove all the leaders from the symbol instance data, pass `NULL` as the value for the input argument *leaders* and set the attachment type to `PROSYMDEFATTACHTYPE_FREE`.

---

`ProDtlSymInstDataLeadersCollect()` outputs an array of the leaders on a `ProDtlSymInstData` description.

`ProDtlSymInstDataElbowlengthGet()` and `ProDtlSymInstDataElbowlengthSet()` get and set the length of the elbow that connects each leader to the symbol instance. If you do not call `ProDtlNotedDataElbowlengthSet()` when creating a symbol instance, there will be no elbow.

`ProDtlSymInstDataAngleSet()` and `ProDtlSymInstDataAngleGet()` get and set the rotation angle of the symbol, if the symbol definition allows rotation. (See also the function `ProDtlSymDefDataTextangfixedSet()` in the section on [Symbol Definition Data on page 1258](#).)

`ProDtlSymInstDataScaledheightSet()` and `ProDtlSymInstDataScaledheightGet()` assign and return the height of a symbol instance in the units of the owner drawing or model, respectively. This value is consistent with the height value shown for a symbol instance in the **Properties** dialog box in the Creo Parametric user interface.

### Note

The scaled height obtained using the above functions is partially based on the properties of the symbol definition assigned using the function `ProDtlSymInstDataDefSet()`. Changing the symbol definition may change the calculated value for the scaled height.

---

---

`ProDtlSymInstNoteDataGet()` and

`ProDtlSymInstEntityDataGet()` retrieve the data of a note and an entity, respectively, in the symbol instance.

The function `ProDtlSymInstDataIsDisplayed()` checks if the specified instance is not marked as erased. The function

`ProDtlSymInstDataDisplayedSet()` sets the flag which controls whether or not the instance is marked as displayed.

The function `ProDtlSymInstDataIsInvisible()` checks if the specified instance is invisible. An invisible symbol instance will not appear in the drawing even if it marked as displayed. For example:

- if the symbol is in a draft group, which is marked as suppressed
- if the symbol is a BOM balloon, and the repeat region cannot find an appropriate model
- if the symbol is a weld symbol, and its feature is suppressed
- if the symbol is a datum target symbol, and its feature is suppressed

`ProDtlSymInstDataVartextAdd()`,

`ProDtlSymInstDataVartextsSet()`,

`ProDtlSymInstDataVartextsCollect()` manipulate

`ProDtlVartext` objects in the symbol instance, which provide for substitution of text in the symbol definition. See section [Symbol Instance Variable Text on page 1260](#) for more information about the `ProDtlVartext` object.

The function `ProDtlSymInstDataTransformGet()` provides a matrix that describes the transformation between symbol definition coordinates and screen coordinates for this instances, that is, it describes the location and orientation of the symbol. The symbol coordinates are specified in inches.

The function `ProDtlSymInstDataGroupOptionsSet()` sets the option for displaying groups in the symbol instance. The possible options are:

- Interactive—prompt the user to select the groups to activate
- All—activate all groups
- None—do not activate any group
- Custom—activate only those groups included in the array of `ProDtlSymGroup` handles passed to this function.

See the section [Drawing Symbol Groups on page 1267](#) to learn more about accessing groups during symbol placement.

The function `ProDtlSymInstEntitiesVisibleGet()` returns the visible entities in the symbol instance data. The input argument *sym\_inst* is the symbol instance that displays the symbol added to the drawing.

---

The function `ProDtlsyminstIsDatumTarget()` checks if the specified symbol instance is a datum target. This function returns `PRO_B_TRUE` if the specified symbol instance is a datum target and returns `PRO_B_FALSE` if it is not.

The function `ProDtlsyminstEnvelopeGet()` returns the envelope of the symbol. While retrieving coordinates of the symbol in a specified solid, if the symbol is displayed in the solid as well as in the drawing, the drawing must not be active. The input arguments follow:

- *syminst*—Symbol.
- *drawing*—Drawing. The value for this input argument must be passed only if the solid symbol is shown in the drawing. Else, pass it as `NULL`.
- *path*—If the value of the input argument *drawing* is not `NULL`, then the path points to a part in an assembly whose drawing is passed here. This part is the owner of the symbol instance.

The output argument *envelope* is the envelope surrounding the symbol in the model coordinate system. For drawing, the envelope surrounding the symbol is in the screen coordinates.

The function `ProDtlsyminstReferencesAdd()` adds semantic references to a specified symbol. The input arguments follow:

- *syminst*—Specifies the symbol to which the semantic references are to be added.
- *refs*—Specifies the array of semantic references using the enumerated data type `ProAnnotationReference`.

---

 **Note**

When a reference includes more than one collection, the function `ProDtlsyminstReferencesAdd()` returns the error `PRO_TK_MAX_LIMIT_REACHED` and no reference is added.

---

The function `ProDtlsyminstReferencesGet()` returns a `ProArray` of additional semantic references for a symbol.

Use the function `ProAnnotationreferencearrayFree()` to free the `ProArray`.

The function `ProDtlsyminstReferenceDelete()` deletes the additional semantic references. The input arguments are as follows:

- *syminst*—Symbol from which the additional semantic references are to be deleted.

- *index\_ref*—Specifies the index of the references that need to be deleted. Indices start from 0. Get the existing references from `ProDtlSymInstReferencesGet()`.

The function `ProDtlSymInstSurffinGet()` gets the owner surface finish from the symbol instance cosmetic. The input arguments are:

- *syminst*—Symbol to which the semantic references are to be added using the `ProDtlSymInst` object.

The output argument *surf\_fin* is the owner surface finish item using the `ProSurfFinish` object.

## Cross-referencing Weld Symbols and Drawing Annotations

The functions described in this section provide a drawing object that represents a shown weld symbol (if the weld symbol is shown in the drawing), or the weld feature that owns a shown weld symbol.

Functions Introduced:

- **ProFeatureDtlSymInstGet()**
- **ProDtlSymInstFeatureGet()**

The function `ProFeatureDtlSymInstGet()` returns the detail symbol instance that represents a shown model symbol.

The function `ProDtlSymInstFeatureGet()` returns the weld feature that owns the shown weld symbol.

### Example 13: Create Free Instance of Symbol Definition

The sample code in the file `UgDtlSymInstExamples.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_drawing`, shows a function which creates a free instance of a symbol definition.

## Detail Group Data

Functions Introduced:

- **ProDtlGroupDataAlloc()**
- **ProDtlGroupDataFree()**
- **ProDtlGroupDataIdGet()**
- **ProDtlGroupDataNameGet()**
- **ProDtlGroupDataIsDisplayed()**
- **ProDtlGroupDataDisplayedSet()**

- **ProDtlgroupdataItemAdd()**
- **ProDtlgroupdataItemsSet()**
- **ProDtlgroupdataItemsCollect()**

`ProDtlgroupdataAlloc()` and `ProDtlgroupdataFree()` allocate and free a detail group structure in the form of a `ProDtlgroup` object.

`ProDtlgroupdataAlloc()` also sets the name of the group.

`ProDtlgroupdataIdGet()` returns the internal ID of an existing group.

`ProDtlgroupdataNameGet()` gets the name of the group.

`ProDtlgroupdataDisplayedSet()` and `ProDtlgroupdataIsDisplayed()` set and get the flag that controls whether or not the group is visible.

`ProDtlgroupdataItemAdd()` adds an item to the group contents. Items supported in the groups include entities, notes, symbol instances, and draft drawing dimensions.

`ProDtlgroupdataItemsSet()` sets the array of items into a group structure, replacing any existing items that may have been assigned.

`ProDtlgroupdataItemsCollect()` returns an array of the items in the group structure.

### Example 14: Create New Group of Items

The sample code in the file `UgDtlgroupExamples.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_drawing`, shows a command which creates a group from a set of selected detail items.

## Drawing Symbol Groups

This section describes Creo TOOLKIT functions that give access to user-defined groups contained in drawing symbols.

User-defined groups in symbol definitions are represented by the following handle in Creo TOOLKIT:

```
typedef struct pro_dtlvargroup
{
 ProDtlsymdef symbol_def;
 int var_group_id;
} ProDtlsymgroup;
```

The group handle contains the definition handle and an identifier that is unique in the group definition.

---

Creo Parametric allows a hierarchical relationship between the groups in a symbol definition. Thus, some groups contain groups, or are parents of other groups. To transmit the “level” in which a group resides to Creo TOOLKIT functions, pass the `ProDtlSymgroup` handle of the parent group. To look at the groups at the top level, pass a `ProDtlSymgroup` handle with an identifier of -1.

## Identifying Symbol Groups in an Instance

Function introduced:

- **`ProDtlSymInstSymgroupsCollect()`**

The function `ProDtlSymInstSymgroupsCollect()` indicates which groups are included in the symbol instance. You can collect the groups based on their status:

- All—retrieve all groups in the definition of the symbol instance
- Active—retrieve only those groups which are actively shown in this symbol instance
- Inactive—retrieve only those groups which are not shown in this symbol instance

## Identifying Symbol Groups in a Definition

Functions Introduced:

- **`ProDtlSymgroupSubgroupsCollect()`**
- **`ProDtlSymgroupDataGet()`**
- **`ProDtlSymgroupdataNameGet()`**
- **`ProDtlSymgroupdataItemsCollect()`**
- **`ProDtlSymgroupParentGet()`**
- **`ProDtlSymgroupLevelIsExclusive()`**

The function `ProDtlSymgroupSubgroupsCollect()` returns the names of all subgroups stored in the symbol definition at the indicated level.

Use the function `ProDtlSymgroupDataGet()` to get the data for the group stored in the symbol definition.

The function `ProDtlSymgroupdataNameGet()` returns the name of the group using the symbol group data as input, while the function `ProDtlSymgroupdataItemsCollect()` returns the names of all the group members using symbol data as input. Note that all these group members are entities or notes contained only within the symbol definition.

The function `ProDtlSymgroupParentGet()` returns the parent group to which the current group belongs.

---

The function `ProDtlsymgroupLevelIsExclusive()` indicates if the subgroups stored in the symbol definition at the current level are exclusive or independent. If groups are exclusive, only one of the groups at this level may be active in the model at any time. If groups are independent, any number of groups may be active.

## Manipulating Symbol Groups

Functions Introduced:

- **`ProDtlsymgroupdataAlloc()`**
- **`ProDtlsymgroupdataNameSet()`**
- **`ProDtlsymgroupdataItemsSet()`**
- **`ProDtlsymgroupdataItemAdd()`**
- **`ProDtlsymgroupdataFree()`**
- **`ProDtlsymgroupSubgroupCreate()`**
- **`ProDtlsymgroupModify()`**
- **`ProDtlsymgroupDelete()`**
- **`ProDtlsymgroupLevelExclusiveSet()`**

The opaque handle `ProDtlsymgroupdata` contains the information needed to define or redefine a group.

The function `ProDtlsymgroupdataAlloc()` allocates the data structure.

The function `ProDtlsymgroupdataNameSet()` sets the name of the symbol group while the function `ProDtlsymgroupdataItemsSet()` sets the specified items to be contained in the symbol group, provided such items belong to the symbol definition. The items to be included can be detail entities and notes.

The function `ProDtlsymgroupdataItemAdd()` adds a single item to the symbol group, provided such an item belongs to the symbol definition. The item to be added can be a detail entity or a note.

The function `ProDtlsymgroupdataFree()` frees the data structure.

The function `ProDtlsymgroupSubgroupCreate()` creates a new group in the symbol definition at the specified level below the parent group.

The function `ProDtlsymgroupModify()` modifies the symbol group definition.

The function `ProDtlsymgroupDelete()` deletes a group from the symbol definition. This function does not delete the entities contained in the group.

The function `ProDtlsymgroupLevelExclusiveSet()` makes the groups at the indicated level, exclusive or independent, in the symbol definition.

---

## Drawing Edges

The functions described in this section provide access to the display properties such as color, line font, and thickness of model edges in drawing views. Model edges can be regular edges, silhouette edges, or non-analytical silhouette edges.

The opaque handle `ProDrawingEdgeDisplay` provides access to the display properties of model edges.

### Note

You can select model edges from detailed views for modification, but no change will be applied. To modify the display of a model edge in a detailed view, you must select the edge in the parent view.

---

Functions Introduced:

- **`ProDrawingEdgeDisplayGet()`**
- **`ProDrawingEdgeDisplaySet()`**
- **`ProDrawingedgedisplayFree()`**
- **`ProDrawingedgedisplayColorGet()`**
- **`ProDrawingedgedisplayColorSet()`**
- **`ProDrawingedgedisplayFontGet()`**
- **`ProDrawingedgedisplayFontSet()`**
- **`ProDrawingedgedisplayWidthGet()`**
- **`ProDrawingedgedisplayWidthSet()`**
- **`ProDrawingedgedisplayIsGlobal()`**
- **`ProDrawingedgedisplayGlobalSet()`**

The function `ProDrawingEdgeDisplayGet()` obtains the display properties of a specified model edge in a drawing view. It allocates the `ProDrawingEdgeDisplay` object for storing the display properties.

The function `ProDrawingEdgeDisplaySet()` assigns the display properties of a specified model edge in a drawing view. After assigning the properties, you must repaint the drawing view to update the display.

The function `ProDrawingedgedisplayFree()` frees the memory allocated for the `ProDrawingEdgeDisplay` object.

The functions `ProDrawingedgedisplayColorGet()` and `ProDrawingedgedisplayColorSet()` obtain and assign the color to be used for the display of a specified model edge.

---

The functions `ProDrawingedgedisplayFontGet()` and `ProDrawingedgedisplayFontSet()` obtain and assign the line font to be used for the display of a specified model edge.

The functions `ProDrawingedgedisplayWidthGet()` and `ProDrawingedgedisplayWidthSet()` obtain and assign the width to be used for the display of a specified model edge. You must pass a value less than zero to use the default width.

#### **Note**

The width obtained is in screen coordinates. To convert the width value into drawing coordinates, use the sheet transformation matrix obtained using `ProDrawingSheetTrfGet()`.

---

The function `ProDrawingedgedisplayIsGlobal()` determines if the model edge display properties such as color, line font, and width have been applied globally to all the drawing views in the drawing sheet.

The function `ProDrawingedgedisplayGlobalSet()` sets the flag that assigns the model edge display properties such as color, line font, and width globally to all the drawing views in the drawing sheet.

## **Creating BOM Balloons**

BOM balloons are circular callouts created in an assembly drawing. They show the Bill of Materials information for each component. You can add the BOM balloons in the drawing using the functions described in this section.

Before you can add BOM balloons, you must create a table, add the repeat region, enter the desired report symbols, and designate the BOM balloon region. After this you can show BOM balloons on a selected assembly view.

Functions Introduced:

- **`ProDwgtableCellRegionGet()`**
- **`ProBomballoonCreate()`**
- **`ProBomballoonAllCreate()`**
- **`ProBomballoonByComponentCreate()`**
- **`ProBomballoonByRecordCreate()`**
- **`ProBomballoonClean()`**

The function `ProDwgtableCellRegionGet()` returns the ID of the repeat region. You must specify the name of the table, the column and row ID as input parameters.

---

The function `ProBomBalloonCreate()` creates the BOM balloons at the specified view. The input arguments are:

- *pro\_drawing*—Specifies the name of the drawing.
- *pro\_table*—Specifies the name of the table that contains the repeat region and the bill of material.
- *region\_id*—Specifies the ID of the repeat region that contains the bill of material. If the ID of the repeat region in the table is -1, use the repeat region with ID as 0 in the table.
- *pro\_view*—Specifies the view where the balloons must be added.

The function `ProBomBalloonAllCreate()` creates the BOM balloons to the first view of the drawing.

The function `ProBomBalloonByComponentCreate()` creates the balloons at the specified view and on the specified component. If the view is specified as NULL, the balloons are added to the first view of the drawing. Specify the path to the component as *component\_memb\_id\_tab*.

The function `ProBomBalloonByRecordCreate()` creates the balloons for the specified record in the BOM table. The input arguments are:

- *pro\_drawing*—Specifies the name of the drawing.
- *pro\_table*—Specifies the name of the table that contains the repeat region and the bill of material.
- *region\_id*—Specifies the ID of the repeat region that contains the bill of material. If the ID of the repeat region in the table is -1, use the repeat region with ID as 0 in the table.
- *pro\_view*—Specifies the view where the balloons must be added. Specify this argument to create the balloons without a leader.
- *table\_record\_index*—Specifies the record in the BOM table. The balloons are created at the first component that matches the specified record.
- *reference\_memb\_id\_tab*—Specifies the path to the component. This path is used as reference for the leader of the balloon.
- *reference\_id*—Specifies the ID of the component. When the ID is set to K\_NOT\_USED, the balloons are attached without leaders.
- *reference\_type*—Specifies the type of component using the enumerated data type `ProType`.
- *attach\_note\_location*—Specifies a `ProArray` of the attachment point for the balloons on the component.

The function `ProBomBalloonClean()` cleans up the location and display of BOM balloons in the specified view. The input arguments are:

- *pro\_drawing*—Specifies the name of the drawing.
- *pro\_view*—Specifies the view where BOM balloons have been added.

- 
- *clean\_pos*—Specifies a boolean value to indicate if the balloon must be cleaned.
  - *existing\_snap\_lines*—Specifies a boolean value to indicate if the existing snap lines must be used for the clean up.
  - *offset\_from\_view\_outline*—Specifies the offset distance for the balloon placement from the view outline.
  - *stagger*—Specifies a boolean value to indicate if the balloons must be staggered at different offset distance from the view outline.
  - *create\_stagger\_snap\_lines*—Specifies the incremental value for the stagger distance between the snap lines.
  - *interballoons\_distance*—Specifies the distance between the BOM balloons.
  - *attach\_to\_surface*—Specifies if the leaders of the balloon must point to edges or surfaces. To attach the leader to a surface specify the value as `PRO_B_TRUE`.

## Drawing Dimensions

This section describes Creo TOOLKIT functions that give access to the types of dimension that can be created in drawing mode. They do not apply to dimensions which are created in solid mode, either those created automatically as a result of feature creation, or reference dimensions created in a solid.

The `ProDimension` object is introduced in the section on [Dimensions on page 579](#); read the explanation of `ProDimension` at the start of that section before reading further.

Dimensions created in drawing mode are stored either in the solid or in the drawing, depending upon the setting of the `config.pro` option `CREATE_DRAWING_DIMS_ONLY`. The default is `NO`, meaning that the dimensions will be stored in the solid. Refer to the Creo Parametric Detailed Drawings Help for more information on the various types of created dimension, and their behavior.

The `owner` field in the `ProDimension` object always refers to the model in which the dimension is stored.

The function `ProDrawingDimensionVisit()`, described in the section on [Dimensions on page 579](#), can be used to find all the dimensions stored in a drawing.

## Drawing Dimension Attachments and Dimension Creation

Functions Introduced:

- **`ProDrawingDimAttachpointsGet()`**
- **`ProDrawingDimensionAttachmentsSet()`**
- **`ProDrawingDimAttachpointsViewGet()`**

---

- **ProDrawingDimensionCreate()**

The function `ProDrawingDimAttachpointsGet()` retrieves the entities to which a dimension is attached and the type of attachments. This is applicable only for dimensions created in the drawing mode.

---

 **Note**

Dimensions created in solid mode are stored in a different way from those created in a drawing, because of their different role, and their attachments are not accessible to this function. If the function is called for a function created in solid mode, it will return an error.

---

The information about the entities to which the dimension is attached is given by the following output arguments:

- *attachments\_arr*—Specifies a `ProArray` of entities to which a dimension is attached. Each attachment point is described by two consecutive array elements, of which the second one may be `NULL`. If both elements are not `NULL`, then the attachment point refers to the intersection of the elements. If the second element is `NULL`, then the attachment point refers to the first one.
- *dsense\_arr*—Specifies a `ProArray` of `ProDimSense` that gives more information about how the dimension attaches to the entities.

`ProDimSense` is declared in header file `ProDimension.h`. This is the declaration:

```
typedef struct pro_dim_sense {
 ProDimSenseType type;
 int sense;
 ProDimAngleSense angle_sense;
 ProDimOrient orient_hint;
} ProDimSense;
```

The `type` field indicates what type of information is being provided by the `sense` and/or `angle_sense` fields. The following sections list the values of `ProDimSenseType` with an explanation of the value of `sense` and `angle_sense` needed in each case.

---

 **Note**

Some of the explanations below refer to the direction of an entity. Each entity (which includes 3D edges and curves, and 2D draft entities) has an inherent direction which is the direction in which its parameter “t” increases. In the data structure description of the entity, `ProCurvedata`, the first end specified is always the end at which  $t=0$ . For example, the direction of a line entity is from field `end1` to `end2` in `ProLinedata`.

- `PRO_DIM_SNS_TYP_NONE` — In this case, no other information is needed to describe the attachment points. For example, if there is a single attachment which is a straight line, the dimension is the length of the line; if the attachments are two parallel lines, the dimension is the distance between them.
- `PRO_DIM_SNS_TYP_PNT` — In this case the `sense` field is set to a value of the enum `ProPointType` (declared in the header), which specifies the part of the entity to which the dimension is attached. The possible values are these:

- 
- `PRO_POINT_TYP_END1` — The first end (that is, where “t” = 0)
  - `PRO_POINT_TYP_END2` — The second end (that is, where “t” = 1.0)
  - `PRO_POINT_TYP_CENTER` — The center, if entity is an arc or a circle
  - `PRO_POINT_TYP_NONE` — This is equivalent to setting `type` to `PRO_DIM_SNS_TYP_NONE`
  - `PRO_POINT_TYP_MIDPT` — The midpoint of the entity (where “t” = 0.5)
  - `PRO_DIM_SNS_TYP_SPLN_PNT` — This means that the attachment is to a point of a spline. The `sense` field is set to the index of the spline point.
  - `PRO_DIM_SNS_TYP_TGT_IDX` — The dimension attaches to a tangent of the entity, which is an arc or circle. The `sense` field is set to the index of the tangent in a list of all possible tangents ordered by the “t” value at which they touch the entity.
  - `PRO_DIM_SNS_TYP_LIN_AOC_TGT` — The dimension is the perpendicular distance between a line and a tangent to an arc or a circle which is parallel to the line. The value of `sense` is one of the values of the enum `ProDimLinAocTgtSense`. If the two possible tangents are on different sides of the line entity (because the distance from the line to the center is less than the radius) then the two tangents are distinguished as left or right of the line (with respect to its natural direction). If the two tangents are on the same side of the line (because the distance from the line to the center is more than the radius), the two tangents are distinguished as on the same side of the arc/circle center (0) or on the opposite side (1). There is an enum value for each of the four possible combinations of ways to identify a tangent, though of course only two are possible for a particular line and arc/circle pair.
- 

The four values of `ProDimLinAocTgtSense` are:

- `PRO_DIM_LIN_AOC_TGT_LEFT0`—The tangent is to the left of the line, and on the same side of the center of the arc/circle as the line.
- `PRO_DIM_LIN_AOC_TGT_RIGHT0`—The tangent is to the right of the line, and on the same side of the center of the arc/circle as the line.
- `PRO_DIM_LIN_AOC_TGT_LEFT1`—The tangent is to the left of the line, and on the opposite side of the center of the arc/circle to the line.
- `PRO_DIM_LIN_AOC_TGT_RIGHT1`—The tangent is to the right of the line, and on the opposite side of the center of the arc/circle to the line.
- `PRO_DIM_SNS_TYP_ANGLE` — The dimension is the angle between two straight entities. The field `angle_sense` is given by the structure

---

`ProDimAngleSense` which contains three boolean fields. They have the following meaning:

- `is_first`—Is set to `TRUE` if the angle dimension starts from this entity in a counterclockwise direction; `FALSE` if the dimension ends at this entity. The value must be `TRUE` for one entity, and `FALSE` for the other.
- `should_flip`—If `should_flip` is `FALSE`, and the entity's inherent direction is away from the angle vertex, then the dimension attaches directly to the entity. If the entity's direction is towards the angle vertex, the dimension is attached to a witness line which is in line with the entity but on the opposite side of the angle vertex—If `should_flip` is `TRUE`, then these cases are interchanged.
- `pic_vec_dir`—Reserved for future use.
- `PRO_DIM_SNS_TYP_PNT_ANGLE`—The dimension is the angle between a line entity and the tangent to a curved entity at one of its ends. The curve attachment is of this type. (The line attachment is of the type `PRO_DIM_SNS_TYP_PNT` described above.) In this case both the angle and `angle_sense` fields must be set: `sense` shows which end of the curve the dimension is attached to; `angle_sense` shows the direction in which the dimension rotates and in which side of the tangent it attaches.

The field `orient_hint` describes the orientation of the dimension in cases where this cannot be deduced from the attachments themselves. (When such a dimension is created interactively in Creo Parametric, the user is prompted for the extra information.) For example, if the attachments are datum points that are not vertically or horizontally aligned, Creo Parametric needs to know whether the dimension is to be horizontal, vertical, or slanted. The hint refers to the dimension itself, not the attachment, although it is a field in `ProDimSense`. Creo Parametric looks at the value of `orient_hint` in the first item in the `ProDimSense` array you provide.

The values of `ProDimOrient` are:

- `PRO_DIM_ORNT_NONE`—No orientation information is needed or provided.
- `PRO_DIM_ORNT_HORIZ`—The dimension is horizontal
- `PRO_DIM_ORNT_VERT`—The dimension is vertical
- `PRO_DIM_ORNT_SLANTED`—The dimension is slanted
- `PRO_DIM_ORNT_ELPS_RAD1`—The major diameter of an ellipse
- `PRO_DIM_ORNT_ELPS_RAD2`—The minor diameter of an ellipse
- `PRO_DIM_ORNT_ARC_ANG`—The angle of an arc
- `PRO_DIM_ORNT_ARC_LENGTH`—The length of an arc

- `PRO_DIM_ORNT_LIN_TANCRV_ANG`—If the dimension is attached to a line and an end point of a curve, the default dimension will be a linear dimension showing the distance between the line and the curve point. If you want the dimension to show instead the angle between the line and the tangent at the curve point, set “`orient_hint`” to this value.

This function `ProDrawingDimensionAttachmentsSet()` modifies the attachment information for a reference or driven dimension created in a drawing.

The input arguments are as follows:

- *drawing*—Handle to the drawing in which the dimension was created.
- *dimension*— The dimension type `PRO_REF_DIMENSION` or `PRO_DIMENSION`.
- *attachments\_arr*—`ProArray` of entities to which a dimension is attached.
- *dsense\_arr*—`ProArray` of a dimension sense.
- *orient\_hint*—The orientation hint for the dimension.

The function `ProDrawingDimAttachpointsViewGet()` retrieves the attachments and sense of the specified drawing dimension. This is applicable only for dimensions that are created in the drawing mode. This function fetches and interprets the attachment in the context of the view in which the dimension is placed. The function `ProDrawingDimAttachpointsViewGet()` supports drawing dimensions that are created from intersections of geometric entities.

The information about the entities to which the dimension is attached is given by the following output arguments:

- *attachments\_arr*—Specifies a `ProArray` of entities to which a dimension is attached. Each attachment point is described by two consecutive array elements, out of which the second one may be a `NULL`. If both elements are not `NULL`, the attachment point refers to the intersection of the elements. If the second element is `NULL`, the attachment point refers to the first one.
- *dsense\_arr*—Specifies a `ProArray` of `ProDimSense` that provides more information on how the dimension attaches to the entities.

. The function `ProDrawingDimensionCreate()` creates a dimension in a drawing. It takes as input an array of `ProSelection` objects and an array of `ProDimSense` structures that describe the required attachments. It will store the new dimension in the solid or the drawing depending upon the setting of the `config.pro` option `CREATE_DRAWING_DIMS_ONLY`. Specify the orientation of the dimension in the input argument *orient\_hint*. You can create dimensions that have intersection type of reference. The intersection type of reference is a reference that is derived from the intersection of two entities. Refer to the Creo Parametric Detailed Drawings Help for more information on intersection type of reference.

---

The dimension will be added to the drawing view specified in the `ProSelection` object. If you want to build the attachment `ProSelection` object programmatically by calling `ProSelectionAlloc()`, rather than interactively using `ProSelect()`, call the function `ProSelectionViewSet()` to ensure that your `ProSelection` specifies the drawing view.

The function outputs a `ProDimension` object to identify the new dimension.

## Ordinate Dimensions

Functions Introduced:

- **`ProDrawingDimIsOrdinate()`**
- **`ProDrawingOrdbaselineCreate()`**
- **`ProDrawingDimToOrdinate()`**
- **`ProDrawingDimToLinear()`**

The function `ProDrawingDimIsOrdinate()` tells you whether a particular dimension is an ordinate dimension. If so, it also outputs a `ProDimension` object to identify the baseline dimension being referenced.

The function `ProDrawingOrdbaselineCreate()` converts a specified dimension to an ordinate baseline dimension. The choice of which end of the dimension becomes the baseline is made by an input of type `ProVector` which should be close to the appropriate attachment entity, and be in 3D solid coordinates. The function outputs a new `ProDimension` object which is used to identify the baseline dimension when converting to ordinate other dimensions which should share that baseline.

The function `ProDrawingDimToOrdinate()` converts an existing linear dimension to ordinate. It requires as one of its inputs a `ProDimension` object that was output from `ProDrawingOrdbaselineCreate()` as input to identify the baseline.

The function `ProDrawingDimToLinear()` converts an existing ordinate dimension to linear.

The last three functions in this section all update the display of the dimension if it is currently displayed.

### Example 16: Command Creation of Datum Point Table

The sample code in the file `UgDrawingDimensions.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_drawing`, shows a command which creates vertical and horizontal ordinate dimensions from each datum point in a model in a drawing view to a selected coordinate system datum.

---

## Other Drawing Dimension Properties

Functions Introduced:

- **ProDrawingDimIsAssociative()**
- **ProDrawingDimensionIsDisplayed()**
- **ProDrawingDimensionIsToleranceDisplayed()**
- **ProDrawingDimensionViewGet()**
- **ProDrawingDimSwitchView()**
- **ProDrawingDimensionPosGet()**
- **ProDrawingDimensionMove()**
- **ProDrawingDualDimensionGet()**
- **ProDimensionDualOptionsGet()**
- **ProDimensionDualOptionsSet()**
- **ProDrawingDimensionPathGet()**

If you create a dimension which attaches only to draft entities in the drawing, the dimension may be associative or non-associative. This setting depends on the setting of the drawing setup option `associative_dimensioning`. The associative status of a dimension remains even when the setup option changes, so a drawing may contain dimensions of both types. The function `ProDrawingDimIsAssociative()` tells you whether or not a particular dimension is associative. Refer to the *Drawing User's Guide* for a fuller description of associative draft dimensions.

The function `ProDrawingDimensionIsDisplayed()` identifies whether a drawing dimension is displayed in the drawing.

The function `ProDrawingDimensionIsToleranceDisplayed()` identifies whether the tolerance value is displayed on the drawing dimension.

The function `ProDrawingDimensionViewGet()` tells you what drawing view a dimension is being displayed in. `ProDrawingDimSwitchView()` allows you to switch it's display to another view. Note that not all views will support the display of particular dimension.

The function `ProDrawingDimensionPosGet()` returns the position of the center of the text box for the specified dimension. The coordinates returned by this function cannot be used in the function `ProDrawingDimensionMove()`. Use the function `ProDimlocationTextGet()` instead of the function `ProDrawingDimensionPosGet()`.

The function `ProDrawingDimensionMove()` allows you to move the dimension text to a new position on the drawing. Use the function `ProDimlocationTextGet()` to get the position before and after the move.

---

The function `ProDrawingDualDimensionGet()` identifies whether a drawing is using dual dimensioning, and also specifies the properties of the dual dimensioning.

The function `ProDimensionDualOptionsGet()` gets information about the display options for the specified dual dimension. In the input argument *drawing*, specify the drawing in which the dimension is displayed. To specify a dimension in owner model, specify the argument value as `NULL`. The output arguments are:

- *type*—From Creo Parametric 5.0.0.0 onward, this argument is no longer supported. Specifies the type of display for primary and secondary dimension using the enumerated data type `ProDualDimensionDisplayType`. The valid values are:
  - `PRO_SECONDARY_DIM_DISPLAY_OFF`—Specifies that secondary dimension is not displayed in a dual dimension.
  - `PRO_SECONDARY_DIM_DISPLAY_BOTTOM`—Specifies that the secondary dimension must be placed below the primary dimension.
  - `PRO_SECONDARY_DIM_DISPLAY_RIGHT`—Specifies that the secondary dimension on the same line as the primary dimension, on the right side.
- *secondary\_unit*—From Creo Parametric 5.0.0.0 onward, this argument is no longer supported. Specifies the name of the unit for secondary dimension.
- *dim\_decimals*—Specifies the number of decimal places for the secondary dimension.
- *tol\_decimals*—Specifies the number of decimal places for tolerance in the secondary dimension.

Use the function `ProDimensionDualOptionsSet()` to set the display options for dual dimensions. From Creo Parametric 5.0.0.0 onward, the arguments *type* and *secondary\_unit* are no longer supported for the function `ProDimensionDualOptionsSet()`.

The function `ProDrawingDimensionPathGet()` extracts the component path for a dimension displayed in a drawing.

## Creating Drawing Tables

Functions Introduced:

- **`ProDwgtabledataAlloc()`**
- **`ProDwgtabledataOriginSet()`**
- **`ProDwgtabledataSizetypeSet()`**
- **`ProDwgtabledataColumnsSet()`**
- **`ProDwgtabledataRowsSet()`**

- **ProDrawingTableCreate()**
- **ProDwgtableTextEnter()**
- **ProDwgtableDisplay()**
- **ProDwgtableGrowthdirectionSet()**

The information required to build a table is contained in an opaque data structure, `ProDwgtabledata` that has to be allocated and filled before the table can be created. The function `ProDwgtabledataAlloc()` allocates the data.

`ProDwgtabledataOriginSet()` sets the position of the top left corner of a table in the `ProDwgtabledata` description.

`ProDwgtabledataSizetypeSet()` specifies whether the size of the columns and rows will be in screen coordinates, or as the number of text characters. It is usually more convenient to specify as numbers of characters.

`ProDwgtabledataColumnsSet()` sets the width of the columns as well as the default justifications of text in the columns.

`ProDwgtabledataRowsSet()` sets the height of the rows.

`ProDwgtableTextEnter()`

`ProDrawingTableCreate()` creates the table in the Creo Parametric drawing and optionally displays it. If your program is about to add rows, columns, or text to the table, it is usually better not to draw it immediately. It can be drawn later using `ProDwgtableDisplay()` and this will avoid multiple redrawing.

The growth direction of a drawing table determines how a drawing table will expand in terms of rows and columns when repeat regions are added to the table. Use the function `ProDwgtableGrowthdirectionSet()` to set the growth direction of the table. The growth direction argument, `ProDwgtableGrowthdirType` takes the following values:

- `PRODWGTABLEGROWTHDIR_DOWNRIGHT`
- `PRODWGTABLEGROWTHDIR_DOWNLEFT`
- `PRODWGTABLEGROWTHDIR_UPRIGHT`
- `PRODWGTABLEGROWTHDIR_UPLEFT`

For more information on the growth direction, see the Creo Parametric Help.

## Notification Functions

Creo TOOLKIT notifications are available when a drawing table or a row from a drawing table is deleted. The notification functions are established in a session using the function `ProNotificationSet()`.

- **ProDwgtableDeletePreAction()**
- **ProDwgtableDeletePostAction()**

- 
- **ProDwgtableRowDeletePreAction()**
  - **ProDwgtableRowDeletePostAction()**

The notification function `ProDwgtableDeletePreAction()` is called before deletion of a drawing table. This function is available by calling `ProNotificationSet()` with the value of the notify type as `PRO_DWGTABLE_DELETE_PRE`.

The notification function `ProDwgtableDeletePostAction()` is called after deletion of a drawing table. This function is available by calling `ProNotificationSet()` with the value of the notify type as `PRO_DWGTABLE_DELETE_POST`.

The notification function `ProDwgtableRowDeletePreAction()` is called before the deletion of a row from the selected drawing table. The input arguments for this function are as follows:

- *table*—The table containing the row to be deleted.
- *i\_row*—The index of the row to be deleted.

---

 **Note**

The index of the first row is 1.

---

This function is available by calling `ProNotificationSet()` with the value of the notify type as `PRO_DWGTABLE_ROW_DELETE_PRE`. The specified row is not deleted if the application returns an error from this callback. If the user cancels the deletion, an appropriate message should be displayed, if required.

The notification function `ProDwgtableRowDeletePostAction()` is called after the deletion of a row from the selected drawing table. This function is available by calling `ProNotificationSet()` with the value of the notify type as `PRO_DWGTABLE_ROW_DELETE_POST`.

## Modifying Drawing Tables

Functions Introduced:

- **ProDwgtableRowAdd()**
- **ProDwgtableColumnAdd()**
- **ProDwgtableRowDelete()**
- **ProDwgtableColumnDelete()**
- **ProDwgtableColumnWidthSet()**
- **ProDwgtableRowHeightSet()**

- **ProDwgtableRowheightAutoadjustGet()**
- **ProDwgtableRowheightAutoadjustSet()**
- **ProDwgtableCellsMerge()**
- **ProDwgtableCellsRemesh()**
- **ProDwgtableCelltextWrap()**
- **ProDwgtableSave()**
- **ProDwgtableRotate()**
- **ProDwgtableErase()**
- **ProDwgtableDelete()**

ProDwgtableRowAdd() and ProDwgtableColumnAdd() can add a row or a column before or after an existing row or column. The input arguments *height\_in\_chars* and *width\_in\_chars* specify the row height and column width in characters, respectively. Another input argument *display* specifies whether the updated table should be displayed. When making many changes to a table, it is advisable not to display them immediately, but to use ProDwgtableDisplay() to update the display later.

ProDwgtableRowDelete() and ProDwgtableColumnDelete() delete any specified row or column, including removing the text from the affected cells.

ProDwgtableColumnWidthSet() and ProDwgtableRowHeightSet() assign the width of a specified column and the height of a specified row, respectively, depending upon the size of the drawing table. The drawing table size given by the enumerated data type ProDwgtableSizetype can be of the following types:

- PRODWGTABLESIZE\_CHARACTER—Specifies the size in characters. If the specified value for width of a column or height of a row is a fraction, PRODWGTABLESIZE\_CHARACTER rounds down the fractional value to the nearest whole number.
- PRODWGTABLESIZE\_SCREEN—Specifies the size in screen coordinates.
- PRODWGTABLESIZE\_CHARS\_TRUE—Specifies the size in characters. It enables you to specify a fractional value for the width of a column and height of a row.

To accommodate a wrapped text in a table row, you can use the Creo TOOLKIT functions to automatically adjust the height of the row to accommodate the entire text content. The functions ProDwgtableRowheightAutoadjustGet() and ProDwgtableRowheightAutoadjustSet() get and set the automatic

---

row height adjustment property for a row of a drawing table. These functions use the enumerated type `ProDwgtableRowheightAutoadjusttype`, which has the following values:

- `PRODWGTBLROWHEIGHT_AUTOADJUST_FALSE`—Specifies that the automatic row height adjustment property is not set.
- `PRODWGTBLROWHEIGHT_AUTOADJUST_TRUE`—Specifies that the automatic row height adjustment property is set.
- `PRODWGTBLROWHEIGHT_AUTOADJUST_TRUE_LEGACY`—Specifies a pre-Creo Parametric 1.0 release behavior. In this behavior, sometimes the row height may be automatically adjusting and sometimes may not be automatically adjusting. To set an explicit row adjustment status use the function `ProDwgtableRowheightAutoadjustSet()`.

---

 **Note**

- The value `PRODWGTBLROWHEIGHT_AUTOADJUST_TRUE_LEGACY` is not applicable to the function `ProDwgtableRowheightAutoadjustSet()`.
  - When using the function `ProDwgtableRowheightAutoadjustSet()` any changes in the height of a row will be seen only after the next regeneration, or a call to the function `ProDrawingTablesUpdate()`.
- 

`ProDwgtableCellsMerge()` allows the merging of cells within a specified range of rows and columns, to form a single cell. The new cell can be addressed (for example, when using `ProDwgtableTextEnter()`, or other calls to `ProDwgtableCellsMerge()`) by the row and column number of the original top left cell. Rows below, and columns to the right, retain their original numbers. The function `ProDwgtableCellsRemesh()` unmerges all the merged cells in a specified range of rows and columns.

`ProDwgtableCelltextWrap()` wraps the text in a cell.

`ProDwgtableSave()` saves a drawing table in one of the formats listed below. The formats given by the enumerated type `ProDwgtableFormattype` can be of the following types:

- `PRODWGTABLEFORMAT_TBL`—Specifies the tabular format.
- `PRODWGTABLEFORMAT_TXT`—Specifies the text format.
- `PRODWGTABLEFORMAT_CSV`—Specifies the CSV format.

`ProDwgtableRotate()` rotates a table 90 degrees clockwise.

`ProDwgtableErase()` erases a drawing table.

`ProDwgtableDelete()` deletes a drawing table.

---

## Example 15: Creation of Table Listing Datum Points

The sample code in the file `UgDwgtableExamples.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_drawing`, shows a command that creates a drawing table listing the datum points in a model shown in a drawing view.

## Drawing Table Segments

Functions Introduced:

- **ProDwgtableSegMove()**
- **ProDwgtableSegCount()**
- **ProDwgtableSegSheetGet()**
- **ProDwgtableSegmentOriginSet()**

Drawing tables can be constructed with one or more segments. Each segment can be independently placed.

---

### Note

For these functions, pass -1 to refer to the only segment of a one-segment table.

---

Move a drawing table segment to new screen coordinates with the function `ProDwgtableSegMove()`. Pass the coordinates of the target position in format `x, y, z=0` to this the function. It moves the table segment to the target position.

Determine the number of segments in a table with the function `ProDwgtableSegCount()`. Pass the name of the table to the function and it returns the number of table segments.

Use the function `ProDwgtableSegSheetGet()` to determine which sheet contains a specified drawing table segment.

Use the function `ProDwgtableSegmentOriginSet()` to assign the origin for a specified drawing table segment.

## Repeat Regions

Functions Introduced:

- **ProDwgtableCellComponentGet()**
- **ProDwgtableCellRefmodelGet()**
- **ProDrawingTablesUpdate()**

---

## Superseded Functions

- **ProDwgtableCellIsComment()**

The functions `ProDwgtableCellIsComment()`, `ProDwgtableCellComponentGet()`, `ProDwgtableCellRefmodelGet()`, and `ProDrawingTablesUpdate()` apply to repeat regions in drawing tables.

`ProDwgtableCellIsComment()` indicates whether a cell in a repeat region contains a comment. `ProDwgtableCellIsComment()` is deprecated. Use the function `ProTableCellIsComment()` instead.

`ProDwgtableCellComponentGet()` returns the full path to the component referenced in a cell in a repeat region of a drawing table. However, this function does not return a valid path if the cell has the attribute `NO DUPLICATE` or `NO DUPLICATE/LEVEL` since there is no unique path available. In this case, use `ProDwgtableCellRefmodelGet()` to return the reference assembly and component referred to by the cell in a repeat region. This function differs from `ProDwgtableCellComponentGet()` such that it returns reference objects, even if the cell attribute is set to `NO DUPLICATE` or `NO DUPLICATE/LEVEL`.

The function `ProDrawingTablesUpdate()` updates repeat regions in all tables to account for changes to the model or models. It is equivalent to the Creo Parametric command `Table, Repeat Region, or Update`. The drawing must be displayed in the current window.

### Note

You must call the function `ProMdlDisplay()` to display the drawing before using the function `ProDrawingTablesUpdate()`.

---

## Drawing Tables

A drawing table is identified by the `DHandle ProDwgtable` which is typedef'd to and inherited from `ProModelitem`. The `type` field in `ProDwgtable` has the value `PRO_DRAW_TABLE`.

## Drawings

This section describes the Creo TOOLKIT functions that deal with drawings. Unless otherwise specified, functions that operate on drawings use screen coordinates. See the [Core: 3D Geometry on page 177](#) section to find out more about screen coordinates and how to convert to drawing coordinates (or paper coordinates).

---

# Model-Based Definition and Drawing Tables

## Model-Based Definition and Drawing Tables

This section describes the Creo TOOLKIT functions that can be used to create model-based definition tables and drawing tables.

In Model-Based Definition (MBD) you can create and manage annotations directly in the context of 3D models. Fully annotate your 3D models so that they can be used directly by downstream functions such as manufacturing and inspection, eliminating the need for 2D detailed drawings as an engineering deliverable.

## MBD and Drawing Tables

A drawing table is identified by the DHandle `ProDwgtable` which is typedef to `ProModelitem` and inherited from `ProModelitem`. The `type` field in `ProDwgtable` has the value `PRO_DRAW_TABLE`.

A drawing table and model-based definition table is identified by the DHandle `ProTable` which is typedef to `ProModelitem` and inherited from `ProModelitem`. The `type` field in `ProTable` has the value `PRO_TABLE`.

The information required to build a mbd table is contained in an opaque data structure, `pro_table_data` that has to be allocated and filled before the table can be created.

## Selecting Drawing Tables and Cells

Function Introduced:

- **ProSelectionDwgtblcellGet()**

In order to ask the user to select a table cell, use the option `dwg_table` as input to `ProSelect()`, and then use `ProSelectionModelitemGet()` to acquire the `ProDwgtable` handle to the table.

To select a table cell, use the option `table_cell` and call `ProSelectionModelitemGet()` to get the table handle, and the special function `ProSelectionDwgtblcellGet()` that returns the IDs of the selected table segment, column and row. The function `ProSelectionDwgtblcellGet()` returns row and column values starting from 0. To get the actual values of the rows and the columns, add 1 to the result, so that these can be used in other Creo TOOLKIT functions.

---

## Creating MBD and Drawing Tables

Functions Introduced:

- **ProTableDataAlloc()**
- **ProDwgtabledataFree()**
- **ProTableDataOriginSet()**
- **ProTableDataRowsSet()**
- **ProTableDataColumnsSet()**
- **ProTableDataFreeAttachSet()**
- **ProTableDataSizetypeSet()**
- **ProTableDataAnnotationPlaneSet()**
- **ProTableTextEnter()**
- **ProTableCreate()**
- **ProTableDisplay()**
- **ProDwgtableGrowthdirectionSet()**

Superseded Functions:

- **ProDwgtabledataAlloc()**
- **ProDwgtabledataOriginSet()**
- **ProDwgtabledataRowsSet()**
- **ProDwgtabledataColumnsSet()**
- **ProDwgtabledataSizetypeSet()**
- **ProDrawingTableCreate()**
- **ProDwgtableTextEnter()**
- **ProDwgtableDisplay()**

The information required to build a table is contained in an opaque data structure, `ProDwgtabledata` that has to be allocated and filled before the table can be created.

`ProDwgtabledataAlloc()` is deprecated. Use the function `ProTableDataAlloc()` instead. `ProTableDataAlloc()` allocates memory for `ProTableData` structure.

Use the function `ProDwgtabledataFree()` to free the memory allocated for the `ProDwgtabledata` structure. The output argument *data* is a pointer to the `ProDwgtabledata` structure.

`ProDwgtabledataOriginSet()` is deprecated. Use the function `ProTableDataOriginSet()` instead.

---

Use the function `ProTableDataOriginSet()` to set the origin in the specified `ProTableData` structure.

The function `ProDwgtabledataRowsSet()` is deprecated. Use the function `ProTableDataRowsSet()` instead.

The function `ProDwgtabledataColumnsSet()` is deprecated. Use the function `ProTableDataColumnsSet()` instead.

Use the function `ProTableDataFreeAttachSet()` to set the free attachment in the specified `ProTableData` structure. The input arguments are:

- *data*
- *plane*
- *origin*

`ProDwgtabledataSizetypeSet()` is deprecated. Use the function `ProTableDataSizetypeSet()` instead.

Use the function `ProTableDataAnnotationPlaneSet()` to set the annotation plane for the specified solid table. The input argument *data* is specified using the `ProTableData` structure.

`ProDwgtableTextEnter()` is deprecated. Use the function `ProTableTextEnter()` instead.

The function `ProTableTextEnter()` adds the specified lines of text into the appropriate row and column of the table. The input arguments are as follows:

- *table*—Specify the table using the `ProTable` object.
- *column*—column number of the cell.
- *row*—row number of the cell.
- *lines*—`ProArray` of text lines assigned to the table cell.

---

 **Note**

One or more lines of text can be written in a cell. If a line of text is too wide for a cell, the text overlaps the neighboring cells.

---

`ProDrawingTableCreate()` is deprecated.

Use the function `ProTableCreate()` instead, to create a table on the current sheet or active combination state. The input arguments are as follows:

- *mdl*—model using `ProMdl` typedef.
- *table\_data*—Specify the table data using the `ProTableData` structure.
- *display*—flag that indicates if the table is to be displayed after creation. If `TRUE`, the table is displayed, if `FALSE`, the table is not displayed.

---

Use the function `ProTableDataSizetypeSet()` to set up the size type in the specified `ProTableData` structure. The input argument *size\_type* is specified using the enumerated data type `ProTableSizetype`.

The function `ProDwgtableDisplay()` is deprecated. Use the function `ProTableDisplay()` instead.

The function `ProTableDisplay()` displays the specified table. The input arguments are as follows:

- *table*—table to be displayed.
- *state*—state to display to, using the `ProCombstate` object.

The growth direction of a drawing table determines how a drawing table will expand in terms of rows and columns when repeat regions are added to the table. Use the function `ProDwgtableGrowthdirectionSet()` to set the growth direction of the table. The growth direction is specified using the enumerated data type, `ProDwgtableGrowthdirType` and has the following values:

- `PRODWGTABLEGROWTHDIR_DOWNRIGHT`
- `PRODWGTABLEGROWTHDIR_DOWNLEFT`
- `PRODWGTABLEGROWTHDIR_UPRIGHT`
- `PRODWGTABLEGROWTHDIR_UPLEFT`

#### Note

This enumerated data type `ProDwgtableGrowthdirType` is applicable for Drawing only.

---

For more information on the growth direction, see the Creo Parametric Help.

## Modifying MBD or Drawing Tables

Functions Introduced:

- **`ProTableIsFromFormat()`**
- **`ProTableRowAdd()`**
- **`ProTableColumnAdd()`**
- **`ProTableRowHeightGet()`**
- **`ProTableRowHeightSet()`**
- **`ProTableColumnWidthGet()`**
- **`ProTableColumnWidthSet()`**
- **`ProTableRowDelete()`**
- **`ProTableColumnDelete()`**

- 
- **ProTableRowheightAutoadjustSet()**
  - **ProTableRowheightAutoadjustGet()**
  - **ProTableDelete()**
  - **ProTableErase()**
  - **ProTableRotate()**
  - **ProTableSave()**
  - **ProTableCellsComment()**
  - **ProTableCellNoteGet()**
  - **ProTableCellsMerge()**
  - **ProTableCellMergeGet()**
  - **ProTableCellsRemesh()**
  - **ProDwgtableCelltextWrap()**
  - **ProDwgtableSave()**
  - **ProDwgtableColumnWidthSet()**
  - **ProDwgtableRowHeightSet()**
  - **ProDwgtableRowheightAutoadjustGet()**
  - **ProDwgtableRowheightAutoadjustSet()**

Superseded Functions:

- **ProDwgtableRowAdd()**
- **ProDwgtableColumnAdd()**
- **ProDwgtableRowDelete()**
- **ProDwgtableColumnDelete()**
- **ProDwgtableCellsMerge()**
- **ProDwgtableCellsRemesh()**
- **ProDwgtableRotate()**
- **ProDwgtableErase()**
- **ProDwgtableDelete()**

---

Use the function `ProTableIsFromFormat()` to determine if the specified table is associated with the format. If the table is associated with the format, the output argument `from_format` is a ProBoolean `PRO_B_TRUE`, else it is `PRO_B_FALSE`.

---

 **Note**

This function is applicable for Drawing only.

---

Both `ProDwgtableRowAdd()` and `ProDwgtableColumnAdd()` are deprecated. Use the functions `ProTableRowAdd()` and `ProTableColumnAdd()` instead.

Use the function `ProTableRowAdd()` to add a row to the specified table. The input arguments are as follows:

- *table*—Specify the table.
- *insert\_after\_row*— row after which the new row is to be added. Row numbers start with 1. Pass the value 0 to insert the new row at the top of the table. To append the row in the last, pass a value less than 0.(any negative value).
- *display*—flag that indicates if the table is to be displayed after creation.
- *height\_in\_chars*—height of the row in characters. Pass -1 to take value of previous row.

---

 **Note**

The function returns the error `PRO_TK_GENERAL_ERROR` if you try to insert the row in the middle of the non-template element of a repeat region.

---

Use the function `ProTableColumnAdd()` to add a column to the specified table. The input arguments are as follows:

- *table*—Specify the table.
- *insert\_after\_col*— column after which the new column is to be added. Column numbers start with 1. Pass the value 0 to insert the new columns at the top of the table. To append the column in the last, pass a value less than 0 (any negative value).
- *display*—flag that indicates if the table is to be displayed after creation.
- *width\_in\_chars*—width of the column in characters. Pass -1 to take value of previous column.

Both `ProDwgtableRowDelete()` and `ProDwgtableColumnDelete()` are deprecated. Use the functions `ProTableRowDelete()` and `ProTableColumnDelete()` instead.

---

Use the function `ProTableRowDelete()` to delete the specified row from the specified table.

Use the function `ProTableColumnDelete()` to delete the specified column from the specified table.

For both the functions `ProTableRowDelete()` and `ProTableColumnDelete()`, the input argument *display* specifies the flag that indicates if the table is to be displayed after creation. If `TRUE`, the table is displayed, if `FALSE`, the table is not displayed.

Use the function `ProTableRowHeightGet()` to get the row height of the specified table. The input arguments are as follows:

- *table*—Specify the table.
- *row*—row index.
- *size\_type*—size type is specified using the enumerated data type `ProTableSizetype`. If you specify `PROTABLESIZE_CHARACTERS`, the *row\_height* is rounded down. To avoid this, use `PROTABLESIZE_CHARS_TRUE`.

Use the function `ProTableRowHeightSet()` to set the row height of the specified table. The input arguments are as follows:

- *table*—Specify the table.
- *row*—row index.
- *row\_height*—row height.
- *size\_type*—size type is specified using the enumerated data type `ProTableSizetype`. If you specify `PROTABLESIZE_CHARACTERS`, the *row\_height* will be rounded down. To avoid this, use `PROTABLESIZE_CHARS_TRUE`.

Use the function `ProTableColumnWidthGet()` to get the column width of the specified table. The input arguments are as follows:

- *table*—Specify the table.
- *column*—column index. Column indices start at 1.
- *size\_type*—size type is specified using the enumerated data type `ProTableSizetype`. If you specify `PROTABLESIZE_CHARACTERS`, the *column\_width* will be rounded down. To avoid this, use `PROTABLESIZE_CHARS_TRUE`.

Use the function `ProTableColumnWidthSet()` to set the column width of the specified table. The input arguments are as follows:

- *table*—Specify the table.
- *column*—column index. Column indices start at 1.
- *column\_width*—column width.

- *size\_type*—size type is specified using the enumerated data type `ProTableSizetype`. If you specify `PROTABLESIZE_CHARACTERS`, the *column\_width* will be rounded down. To avoid this, use `PROTABLESIZE_CHARS_TRUE`.

Use the function `ProTableDataRowsSet()` to set up row properties. The input arguments are as follows:

- *data*—Specify using the `ProTableData` structure.
- *n\_rows*—number of rows. The maximum number of rows that can be specified is 100.
- *heights*—`ProArray` of row heights

Use the function `ProTableDataColumnsSet()` to set up the column properties. The input arguments are as follows:

- *data*—Specify using the `ProTableData` structure.
- *n\_columns*—number of columns. The maximum number of columns that can be specified is 50.
- *widths*—`ProArray` of column widths.
- *justifications*—`ProArray` of justifications using the enumerated data type `ProHorzJust`.

Use the function `ProTableRowheightAutoadjustSet()` to set the automatic height adjustment property for a specified row of the specified table. The input arguments are as follows:

- *table*—The reference to the table.
- *row*—Row number for which the property is to be set. Row numbers start with 1.
- *auto\_adjust*—Set the property using the enumerated data type `ProTableRowheightAutoadjusttype`. The valid values are:
  - `PROTBLROWHEIGHT_AUTOADJUST_TRUE`—Sets the property.
  - `PROTBLROWHEIGHT_AUTOADJUST_FALSE`—Unsets the property.

Use the function `ProTableRowheightAutoadjustGet()` to get the automatic height adjustment property for a specified row of the specified table. The input arguments are as follows:

- *table*—The reference to the table.
- *row*—Row number for which the property is to be retrieved. Row numbers start with 1.

- *size\_type*—size type is specified using the enumerated data type `ProTableSizetype`. If you specify `PROTABLESIZE_CHARACTERS`, the *row\_height* is rounded down. To avoid this, use `PROTABLESIZE_CHARS_TRUE`.
  - `PROTABLESIZE_CHARACTERS`
  - `PROTABLESIZE_MODEL_UNITS`
  - `PROTABLESIZE_CHARS_TRUE`

The function returns the following output arguments:

- *auto\_adjust*—Value for auto adjust property.
- *height*—Auto adjusted height if *auto\_adjust* is `PROTBLOWHEIGHT_AUTOADJUST_TRUE`. Ignore for `PROTBLOWHEIGHT_AUTOADJUST_FALSE`.

The function `ProDwgtableDelete()` is deprecated. Use the function `ProTableDelete()` instead.

Use the function `ProTableDelete()` to delete the specified table.

The function `ProDwgtableErase()` is deprecated. Use the function `ProTableErase()` instead.

Use the function `ProTableErase` to erase the specified table. The input argument *state* is the combination state to erase from. Pass as `NULL` for drawing table.

The function `ProDwgtableRotate()` is deprecated. Use the function `ProTableRotate()` instead.

The function `ProTableRotate()` rotates the specified table (clockwise) by 90 degree. The function does not perform a display. The input argument *display* specifies the flag that indicates if the table is to be displayed after creation. If `TRUE`, the table is displayed, if `FALSE`, the table is not displayed.

Use the function `ProTableCellIsComment()` to determine if the specified cell is a comment cell. The input arguments are as follows:

- *table*—Specify the table.
- *column*—column index. Column indices start at 1.
- *row*—row index. Row indices start at 1.

The function `ProTableCellNoteGet()` returns the note identifier for a specified cell of the table.

The function `ProDwgtableCellsMerge()` is deprecated. Use the function `ProTableCellsMerge()` instead.

The function `ProDwgtableCellsRemesh()` is deprecated. Use the function `ProTableCellsRemesh()` instead.

---

The function `ProTableCellsMerge()` takes a rectangular region of cells and merges them into a composite cell. The merged cells, rows, or columns are deleted, and the table's appearance is restored using `prodrw_remesh_table_cells()`.

---

 **Note**

This function is equivalent to the user interface options **Drawing, Table, Mod Rows/Col, Merge** in Creo Parametric. Limitations in the user interface apply to the function as well. For example, borders of merge cannot intersect the borders of another merge or repeat region.

---

The function `ProTableCellMergeGet()` gets the merge information of a specified cell. The input arguments are:

- *table*—Specify the table using `ProTable` object.
- *row*—Specify row of the cell. The row indices start at 1.
- *col*—Specify column of the cell. The column indices start at 1.

The function returns the following output arguments:

- *is\_merge*—Returns a `PRO_B_TRUE` value if the cell is merged using a `ProBoolean` object.
- *start\_row*—Row index for start merge cell. The row indices start at 1.
- *start\_col*—Column index for start merge cell. The column indices start at 1.
- *end\_row*—Row index for end merge cell. The row indices start at 1.
- *end\_col*—Column index for end merge cell. The column indices start at 1.

The function `ProTableCellsRemesh()` undoes all merges created in the specified rectangular region.

The function `ProDwgtableCelltextWrap()` wraps the text in a cell.

The function `ProDwgtableSave()` is deprecated. Use the function `ProTableSave()` instead.

Use the function `ProTableSave()` to save the table in different format. The input arguments are:

- *table*—Reference to the table.
- *path*—Full path of the location in which the table needs to be saved.
- *table\_format*—Format of the table defined using the enumerated data type `ProTableFormattype`.
- *segment\_id*—Segment of the table to save, if *table\_format* is `PROTABLEFORMAT_CSV` or `PROTABLEFORMAT_XLSX`.

---

In Creo Parametric 11.0.0.0, the enumerated data type `ProDwgtableFormatType` is deprecated. Use the enumerated data type `ProTableFormatType` instead. The valid values are:

- `PROTABLEFORMAT_TBL`—Specifies the tabular format.
- `PROTABLEFORMAT_TXT`—Specifies the text format.
- `PROTABLEFORMAT_CSV`—Specifies the CSV format.
- `PROTABLEFORMAT_XLSX`—Specifies the XLSX format.

`ProDwgtableColumnWidthSet()` and `ProDwgtableRowHeightSet()` assign the width of a specified column and the height of a specified row, respectively, depending upon the size of the drawing table. The drawing table size given by the enumerated data type `ProDwgtableSizeType` can be of the following types:

- `PRODWGTABLESIZE_CHARACTERS`—Specifies the size in characters. If the specified value for width of a column or height of a row is a fraction, `PRODWGTABLESIZE_CHARACTERS` rounds down the fractional value to the nearest whole number. In Creo Parametric 11.0.0.0, `PRODWGTABLESIZE_CHARACTERS` is deprecated.
- `PRODWGTABLESIZE_SCREEN`—Specifies the size in screen coordinates.
- `PRODWGTABLESIZE_CHARS_TRUE`—Specifies the size in characters. It enables you to specify a fractional value for the width of a column and height of a row.

To accommodate a wrapped text in a table row, you can use the Creo TOOLKIT functions to automatically adjust the height of the row to accommodate the entire text content. The functions `ProDwgtableRowheightAutoadjustGet()` and `ProDwgtableRowheightAutoadjustSet()` get and set the automatic row height adjustment property for a row of a drawing table. These functions use the enumerated type `ProDwgtableRowheightAutoadjusttype`, which has the following values:

- `PRODWGTABLEROWHEIGHT_AUTOADJUST_FALSE`—Specifies that the automatic row height adjustment property is not set.
- `PRODWGTABLEROWHEIGHT_AUTOADJUST_TRUE`—Specifies that the automatic row height adjustment property is set.

- 
- `PRODWGTBLROWHEIGHT_AUTOADJUST_TRUE_LEGACY`—Specifies a pre-Creo Parametric 1.0 release behavior. In this behavior, sometimes the row height may be automatically adjusting and sometimes may not be automatically adjusting. To set an explicit row adjustment status use the function `ProDwgtableRowheightAutoadjustSet()`.

---

 **Note**

- The value `PRODWGTBLROWHEIGHT_AUTOADJUST_TRUE_LEGACY` is not applicable to the function `ProDwgtableRowheightAutoadjustSet()`.
  - When using the function `ProDwgtableRowheightAutoadjustSet()` any changes in the height of a row will be seen only after the next regeneration, or a call to the function `ProDrawingTablesUpdate()`.
- 

## Reading MBD or DrawingTables

Functions Introduced:

- **`ProTableOriginGet()`**
- **`ProTableAnnotationPlaneGet()`**
- **`ProTableVisit()`**
- **`ProTableVisitAction()`**
- **`ProTableFilterAction()`**
- **`ProTableRowsColumnsCount()`**
- **`ProTableCelltextGet()`**
- **`ProTablesCollect()`**
- **`ProSelectionTableGet()`**
- **`ProDwgtableInfoGet()`**
- **`ProDwgtableColumnSizeGet()`**
- **`ProDwgtableRowSizeGet()`**
- **`ProDwgtableRetrieve()`**
- **`ProDwgtableByOriginRetrieve()`**
- **`ProDwgtableGrowthdirectionGet()`**
- **`ProTableCellBlankGet()`**
- **`ProTableBorderStyleGet()`**

---

- **ProTableCellFillColorGet()**

Superseded Functions:

- **ProDrawingTableVisit()**
- **ProDrawingTablesCollect()**
- **ProDwgtableColumnsCount()**
- **ProDwgtableRowsCount()**
- **ProDwgtableCellNoteGet()**
- **ProDwgtableCelltextGet()**
- **ProDwgtableIsFromFormat()**

The function `ProTableOriginGet()` acts on `ProTable` and returns the placement point which is the top left corner of the table.

Use the function `ProTableAnnotationPlaneGet()` to get the annotation plane for the specified solid table. The input argument *table* is specified using the `ProTable` object.

---

 **Note**

For drawing, the function `ProTableAnnotationPlaneGet()` returns an error.

---

`ProDrawingTableVisit()` visits all the tables in a specified drawing; it conforms to the usual standard for visit functions.

`ProDrawingTablesCollect()` is an alternative, and returns an array of `ProDwgtable` handles for a drawing.

The functions `ProDrawingTableVisit()` and `ProDrawingTablesCollect()` are deprecated. Use the functions `ProTableVisit()` and `ProTablesCollect()` instead.

A table may be divided into several segments, which are numbered sequentially from 0. The function `ProDwgtableInfoGet()` takes a `ProDwgtable` and a segment ID as input, and fills a data structure that describes the properties of the table. If the segment does not exist, it returns `PRO_TK_NOT_EXIST`. The properties of the table are as follows:

|                                      |                                                               |
|--------------------------------------|---------------------------------------------------------------|
| <code>int rotation;</code>           | The number of 90 degree turns clockwise.                      |
| <code>double seg_origin[3];</code>   | The screen coordinates of the top left corner of the segment. |
| <code>int nrows;</code>              | The number of rows.                                           |
| <code>int ncols;</code>              | The number of columns.                                        |
| <code>double outline[2][3];</code>   | The outline of the segment.                                   |
| <code>double seg_char_height;</code> | The text height used for the                                  |

---

```

double table_char_height; segment.
 The text height used for the
double char_width; drawing.
 The character width factor.

```

The function `ProTableVisit()` visits tables in the specified model. The input arguments are as follows:

- *model*—model to visit.
- *visit\_action*—visit action using the function `ProTableVisitAction()`.
- *filter\_action*—filter action using the function `ProTableFilterAction()`.
- *data*—Specify using the `ProTableData` structure.

The function `ProTableVisitAction()` is the action function called for each drawing entity during the call to the function `ProTableVisit()`.

The function `ProTableFilterAction()` is the filter function called for each table entity during the call to the function `ProTableVisit()`.

The function `ProTableRowsColumnsCount()` counts the table rows and columns.

The function `ProTableCelltextGet()` places the text of the specified table into a string array. The input arguments are as follows:

- *table*—Specify the table.
- *row*—row index. The row indices start at 1.
- *column*—column index. The column indices start at 1.
- *mode*—mode type is specified using the enumerated data type `ProTableParamMode`. Specify 1 to get the text as displayed. Specify 2 to get the text as shown in the full note editor.

The output argument `lines` is the text of the table, specified using the array of `ProWstring`. Use the function `ProWstringproarrayFree()` to free this array.

Use the function `ProTablesCollect()` to collect all tables in the specified model. The output argument `tables` is an array of tables specified using the `ProTable` object. Use the function `ProArrayFree()` to free the memory allocated by the function `ProTablesCollect()`.

For a `ProSelection` representing a cell of a table, the function `ProSelectionTableGet()` returns the table from which the cell was selected.

The functions `ProDwgtableRowsCount()` and `ProDwgtableColumnsCount()` return the number of rows and columns in a table respectively.

---

Both `ProDwgtableRowCount()` and `ProDwgtableColumnsCount()` are deprecated. Use the function `ProTableRowsColumnsCount` instead.

The functions `ProDwgtableColumnSizeGet()` and `ProDwgtableRowSizeGet()` give the column width and row height for a specified table column and row respectively.

The text item in each cell of a drawing table is stored as a detail note. If you need to modify the note in some way, for example the style, you can use the `ProDtlnote*()` functions described in the section on [Detail Items on page 1236](#). The function `ProDwgtableCellNoteGet()` returns the handle to the detail note that represents the text in a specified table cell.

The function `ProDwgtableCellNoteGet()` is deprecated. Use the function `ProTableCellNoteGet()` instead.

The function `ProDwgtableCelltextGet()` places the text of the table into a string array. `ProDwgtableCelltextGet()` is deprecated. Use the function `ProTableCelltextGet()` instead.

The function `ProDwgtableIsFromFormat()` indicates whether a table was added to the table as a result of importing a format. The function `ProDwgtableIsFromFormat()` is deprecated. Use the function `ProTableIsFromFormat()` instead.

The function `ProDwgtableRetrieve()` retrieves a drawing table from a properly formatted Creo Parametric table file, and places it in the specified drawing. It allows you to add a table to a drawing without having to specify all the table properties. This function also supports parameter tables exported in the CSV or TXT format from the **Parameters** dialog box or using `ProParameterTableExport()`. Refer to the [Core: Parameters on page 216](#) section for more information on parameters.

The input arguments are:

- `drawing`—Specifies the drawing in which the table must be retrieved.
- `file_name`—Specifies the name of the drawing table. You must not mention the extension.
- `file_path`—Specifies the path to the drawing table file. The path must be specified relative to the working directory.
- `file_version`—Species the version of the drawing table that must be retrieved. The version 0, represents the latest version of the drawing table.
- `position`—Specifies the coordinates of the point on the drawing sheet, where the table must be placed. The upper-left corner of the table is placed at this point on the drawing sheet. You must specify the value in screen coordinates.
- `solid`—Specifies the model from which data must be copied into the drawing table. If this argument is passed as `NULL`, an empty table is created.

- `simpl_rep`—Specifies a handle to the simplified representation in a solid, from which data must be copied into the drawing table. If this argument is passed as `NULL`, and the argument `solid` is not `NULL`, then data from the solid model is copied into the drawing table.

The function `ProDwgtableByOriginRetrieve()` retrieves a drawing table from a properly formatted Creo Parametric table file, and places it in the specified drawing. The function is similar to function `ProDwgtableRetrieve()`, except that it positions the origin of the table at the specified point in the drawing. Tables can be created with different origins by specifying the option **Direction**, in the **Insert Table** dialog box.

The function `ProDwgtableGrowthdirectionGet()` gets the growth direction of the table using the enumerated type `ProDwgtableGrowthdirType`. For more information on the values of `ProDwgtableGrowthdirType`, see the section [Creating MBD and Drawing Tables on page 1289](#).

Use the function `ProTableCellBlankGet()` to get the blank border information for the specified cell. The input arguments are:

- *table*—Specify the table of the blank border information using the `ProTable` object.
- *row*—Row of the cell. Row indices start at 1.
- *col*—Column of the cell. Column indices start at 1.

The output argument `blank_flags` is a bit mask that provides information about the blank border for the specified cell, such as `PROTBLCELL_BLANK_LEFT`, `RIGHT`, `TOP`, `BOTTOM`.

Use the function `ProTableBorderStyleGet()` to get the line style of the table borders. The input argument *table* is specified using the `ProTable` object.

The output arguments are:

- *line\_style*—Specifies the line style of the table borders using the `ProLinestyle` object.
- *width*—Specifies the width of the table borders.
- *clr*—Specifies the color of the table borders using the `ProColor` objects.

Use the function `ProTableCellFillColorGet()` to get the color of the specified cell. The input arguments are:

- *table*—The table specified using the `ProTable` object.
- *row*—Specifies row of the cell. Row indices start at 1.
- *col*—Specifies column of the cell. Column indices start at 1.

The output argument *color* is the color of the given table cell using the `ProColor` object.

---

## MBD Table References

Functions Introduced:

- **ProTableReferencesGet()**
- **ProTableReferenceDelete()**
- **ProTableReferencesAdd()**

These functions are applicable to MBD tables only.

Use the function `ProTableReferencesGet()` to get the table references. The output argument `p_refs` is a `ProArray` of references that can be specified using the structure `ProAnnotationReference`. Use the function `ProAnnotationreferencearrayFree()` to free the array.

Use the function `ProTableReferenceDelete()` to delete the specified table references. The input arguments are as follows:

- *table*—table for which the references need to be deleted.
- *index\_ref*—indices of references to be deleted. You can get the existing references using the function `ProTableReferencesGet()`.

Use the function `ProTableReferencesAdd()` to add the specified table references. The input arguments are as follows:

- *table*—Table for which the references need to be added.
- *index\_ref*—`ProArray` of references to be added. Only 1 reference from the type `PRO_ANNOT_REF_SRF_COLLECTION` is allowed.

## Notification Functions

Creo TOOLKIT notifications are available when a drawing table or a row from a drawing table is deleted. The notification functions are established in a session using the function `ProNotificationSet()`.

- **ProDwgtableDeletePreAction()**
- **ProDwgtableDeletePostAction()**
- **ProDwgtableRowDeletePreAction()**
- **ProDwgtableRowDeletePostAction()**

The notification function `ProDwgtableDeletePreAction()` is called before deletion of a drawing table. This function is available by calling `ProNotificationSet()` with the value of the notify type as `PRO_DWGTABLE_DELETE_PRE`.

The notification function `ProDwgtableDeletePostAction()` is called after deletion of a drawing table. This function is available by calling `ProNotificationSet()` with the value of the notify type as `PRO_DWGTABLE_DELETE_POST`.

---

The notification function `ProDwgtableRowDeletePreAction()` is called before the deletion of a row from the selected drawing table. The input arguments for this function are as follows:

- *table*—The table containing the row to be deleted.
- *i\_row*—The index of the row to be deleted.

---

 **Note**

The index of the first row is 1.

---

This function is available by calling `ProNotificationSet()` with the value of the notify type as `PRO_DWGTABLE_ROW_DELETE_PRE`. The specified row is not deleted if the application returns an error from this callback. If the user cancels the deletion, an appropriate message should be displayed, if required.

The notification function `ProDwgtableRowDeletePostAction()` is called after the deletion of a row from the selected drawing table. This function is available by calling `ProNotificationSet()` with the value of the notify type as `PRO_DWGTABLE_ROW_DELETE_POST`.

jm

### Example 15: Creation of Table Listing Datum Points

The sample code in the file `UgDwgtableExamples.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_drawing`, shows a command that creates a drawing table listing the datum points in a model shown in a drawing view.

## Drawing Table Segments

Functions Introduced:

- **`ProDwgtableSegMove()`**
- **`ProDwgtableSegCount()`**
- **`ProDwgtableSegSheetGet()`**
- **`ProDwgtableSegmentOriginSet()`**

Drawing tables can be constructed with one or more segments. Each segment can be independently placed.

---

## Note

For these functions, pass -1 to refer to the only segment of a one-segment table.

---

Move a drawing table segment to new screen coordinates with the function `ProDwgtableSegMove()`. Pass the coordinates of the target position in format `x, y, z=0` to this the function. It moves the table segment to the target position.

Determine the number of segments in a table with the function `ProDwgtableSegCount()`. Pass the name of the table to the function and it returns the number of table segments.

Use the function `ProDwgtableSegSheetGet()` to determine which sheet contains a specified drawing table segment.

Use the function `ProDwgtableSegmentOriginSet()` to assign the origin for a specified drawing table segment.

## Repeat Regions

Functions Introduced:

- **`ProDwgtableCellComponentGet()`**
- **`ProDwgtableCellRefmodelGet()`**
- **`ProDrawingTablesUpdate()`**

Superseded Functions

- **`ProDwgtableCellIsComment()`**

The functions `ProDwgtableCellIsComment()`, `ProDwgtableCellComponentGet()`, `ProDwgtableCellRefmodelGet()`, and `ProDrawingTablesUpdate()` apply to repeat regions in drawing tables.

`ProDwgtableCellIsComment()` indicates whether a cell in a repeat region contains a comment. `ProDwgtableCellIsComment()` is deprecated. Use the function `ProTableCellIsComment()` instead.

`ProDwgtableCellComponentGet()` returns the full path to the component referenced in a cell in a repeat region of a drawing table. However, this function does not return a valid path if the cell has the attribute `NO DUPLICATE` or `NO DUPLICATE/LEVEL` since there is no unique path available. In this case, use `ProDwgtableCellRefmodelGet()` to return the reference assembly and component referred to by the cell in a repeat region. This function differs

---

`fromProDwgTableCellComponentGet()` such that it returns reference objects, even if the cell attribute is set to NO DUPLICATE or NO DUPLICATE/LEVEL.

The function `ProDrawingTablesUpdate()` updates repeat regions in all tables to account for changes to the model or models. It is equivalent to the Creo Parametric command `Table,Repeat Region, or Update`. The drawing must be displayed in the current window.

---

 **Note**

You must call the function `ProMdlDisplay()` to display the drawing before using the function `ProDrawingTablesUpdate()`.

---

## Production Applications: Sheetmetal

### Geometry Analysis

This section describes the sheet metal geometry analysis and bend table functions. It also introduces and describes the feature element trees for the sheet metal features.

Creo TOOLKIT geometry analysis functions provide for analysis of sheet metal part geometry and ensure effective customization of sheet metal parts. These analyses include extracting part thickness data and obtaining edge and surface data for sheet metal components.

In addition, sheet metal bend edge and bend surface functions support analyses that:

- Extract bend information associated with bend lines (K-factor, Y-factor, bend deduction, bend allowance).
- Find bend lines when a part is in a flat state.
- Map flat state IDs to bent state IDs.

Functions Introduced:

- **`ProSmtPartThicknessGet()`**
- **`ProSmtSurfaceTypeGet()`**
- **`ProSmtedgeContourGet()`**
- **`ProSmtOppsurfGet()`**
- **`ProSmtOppedgeGet()`**
- **`ProSmtBendsrfParentGet()`**

- **ProSmtBendsrfChildGet()**
- **ProSmtBendedgeChildGet()**
- **ProSmtBendedgeParentGet()**
- **ProSmtMdlIsFlatStateInstance()**
- **ProFamInstanceIsFlatState()**
- **ProSmtBendsrfInfoGet()**

The function `ProSmtPartThicknessGet()` returns the dimension that defines the thickness of the specified sheet metal component. If the model contains the thickness parameter, then this dimension cannot be modified directly. Use the function `ProParameterValueWithUnitsSet()` to assign the value of the thickness parameter. If you specify a non sheet metal part, `ProSmtPartThicknessGet()` returns `PRO_TK_BAD_CONTEXT`.

The function `ProSmtSurfaceTypeGet()` returns the type of the specified solid surface. This enables you to determine whether a surface is created by a sheet metal feature, and to distinguish among the different types of sheet metal surfaces, such as side, white, and green.

The possible values are as follows:

- `PRO_SMT_SURF_NON_SMT`—The surface was created by a solid feature.
- `PRO_SMT_SURF_SIDE`—The surface is a side surface created by a sheet metal feature.
- `PRO_SMT_SURF_FACE`—The surface is the face (green) surface created by a sheet metal feature.
- `PRO_SMT_SURF_OFFSET`—The surface is the offset (white) surface created by a sheet metal feature.

The function `ProSmtedgeContourGet()` returns a complete contour that contains the specified edge. This function returns `PRO_TK_BAD_CONTEXT` if the edge is not on the green or white side of the specified part.

The function `ProSmtOppsurfGet()` returns a surface that is opposite (offset to) the specified surface.

The function `ProSmtOppedgeGet()` returns the edge that is opposite (offset to) the specified edge. Edge data for function `ProSmtOppedgeGet()` uses the following definitions:

- An edge is lying on a green surface if one of its surfaces has `SHEETMETAL TYPE = FACE`.
- An edge is lying on a white surface if one of its surfaces has `SHEETMETAL TYPE = OFFSET`.
- The opposite edge to an edge must be on the surface opposite the original edge's surface and must be a geometrical offset of the original edge.

- An edge is in a peripheral contour if, and only if the following are true:
  - It is in the part geometry.
  - Exactly one of its surfaces is either FACE or OFFSET.

The function `ProSmtBendsrfParentGet()` returns the parent of the specified surface. For example, if the specified surface is in bent position, this function returns the surface that is the most recent, unbent equivalent of the specified surface. See notes below.

The function `ProSmtBendsrfChildGet()` returns the active (visible) child surface of the specified, inactive (invisible) surface. A surface is active (visible) if it is in the part geometry list. See notes below.

The function `ProSmtBendedgeParentGet()` returns the parent of the specified edge. For example, if the specified edge is in bent position, this function returns the edge that is the most recent, unbent equivalent of the specified edge. See notes below.

The function `ProSmtBendedgeChildGet()` returns the active (visible) child edge of the specified, inactive (invisible) edge. An edge is active (visible) if both its surfaces are active and the edge is contained in the contours of both surfaces. See notes below.

- Edges and surfaces in quilt geometry are also visible, but they are invalid as input to sheet metal functions.
- Surface and edge parent and child functions use the following definitions:
  - An edge or surface has a parent if the edge or surface is a result of bending or unbending another edge or surface.
  - If an edge or surface is active and is a result of bending or unbending, any parent of this edge or surface that is in the chain of bends or unbends has this edge or surface as the active child.

The function `ProSmtMdlIsFlatStateInstance()` checks if the model is a flat state instance model.

The function `ProFamInstanceIsFlatState()` checks if the family instance of the model is a sheet metal flat instance or not.

The function `ProSmtBendsrfInfoGet()` gets all the information about the specified bend surface in a sheet metal part. You can specify as input, the face surface `PRO_SMT_SURF_FACE` or, the offset surface `PRO_SMT_SURF_OFFSET` which is created by the sheet metal feature. The cylindrical and planar surfaces, which are created by unbending the cylindrical surfaces, can be specified as input.

The following information is collected:

- *radius*—Specifies the bend radius.

- 
- *is\_inside\_radius*—Specifies `PRO_B_TRUE` if the bend radius is inside. It returns `PRO_B_FALSE` if the bend radius is outside.
  - *angle*—Specifies the bend angle in degrees.
  - *dev\_length*—Specifies the developed length of the surface.
  - *dev\_len\_info*—Specifies a structure, that contains information about the values of various parameters, which were used to calculate the developed length. The structure `ProSmtDvlLenCalcInfo` contains the following information:
    - *method*—Specifies the method used to calculate the developed length. The method is specified using the enumerated data type `ProDvlLenMethod`.
    - *model*—Specifies the model, whose bend allowance settings are used to calculate the developed length. Usually, the model is the part that owns the specified bend surface. A model can also be a reference part, when the specified surface has been copied from a reference part. Here the developed length is calculated according to the bend allowance settings of the reference part, or the bend allowance settings of a feature in the reference part.
    - *y\_factor\_value*—Specifies the value of K-factor or Y-factor used to calculate the developed length.

---

 **Note**

*y\_factor\_value* is specified only if the method used to calculate developed length is `PRO_DVL_LEN_DRIVEN_BY_Y_FACTOR`.

---

- *bend\_table*—Specifies the name of the bend table that controls the bend allowance calculations for the developed length.
- *formula*—Specifies the formula that was used to calculate the developed length.
- *allowance*—Specifies the value of bend allowance from the bend table.
- *dimension*—Specifies the dimension ID associated with the developed length. If the method used to calculate developed length is `PRO_DVL_LEN_DRIVEN_BY_DIMENSION`, then developed length is specified manually by the user.
- *driven\_by\_part\_settings*—Specifies if the developed length is driven by bend allowance settings of a part or by bend allowance settings of a feature. `PRO_B_TRUE` indicates that the bend allowance settings of a part are used.

---

## Bend Tables and Dimensions

Bend table functions support reading in or removing bend table data for a sheet metal part or feature in the part.

Sheet metal dimension functions find or set whether or not developed length dimensions are driven.

Functions Introduced:

- **ProSmtPartBendtableApply()**
- **ProSmtPartBendtableRemove()**
- **ProSmtFeatureBendtableApply()**
- **ProSmtFeatureBendtableRemove()**
- **ProSmtFeatureDevldimsGet()**
- **ProSmtDevldimIsDriven()**
- **ProSmtDevldimDrivenSet()**

The function `ProSmtPartBendtableApply()` applies the specified bend table to the sheet metal part. The input argument *from\_file* specifies whether the bend table is to be applied from memory or from the specified file.

The function `ProSmtPartBendtableRemove()` removes the specified bend table from the sheet metal part and the part uses the Y Factor.

The function `ProSmtFeatureBendtableApply()` applies the specified bend table to the sheet metal part feature. The input argument *from\_file* specifies whether the bend table is to be applied from memory or from the specified file.

The function `ProSmtFeatureBendtableRemove()` sets a sheet metal feature to use the part bend table instead of the feature bend table.

The function `ProSmtFeatureDevldimsGet()` returns the developed length dimensions for the specified sheet metal bend or wall feature. It also returns the surfaces whose developed length these dimensions define.

The function `ProSmtDevldimIsDriven()` specifies whether a developed length dimension is driven or not. Use the function `ProSmtDevldimDrivenSet()` to set a developed length dimension to driven.

## Bend Allowance Parameters

You can set the sheet metal bend allowance properties using the bend allowance parameters. These parameters can be defined using the `ProParameter` functions. For more information on Parameters, refer to the section [Core: Parameters on page 216](#).

You cannot edit these bend allowance parameters.

---

## Bend Allowance Type

Parameter Name—SMT\_PART\_BEND\_ALLOW\_FACTOR\_TYPE

The parameter allows you to set the bend allowance type. You can set whether the K factor or Y factor must be used.

Type—String

Values—K factor or Y factor

Default Value—Y factor

## Bend Allowance Factor Value

Parameter Name—SMT\_PART\_BEND\_ALLOWANCE\_FACTOR

The parameter allows you to set the value of the bend allowance factor.

Type—Real number

Values—Numeric value

Default Value—0.5

## Bend Allowance Table Name

Parameter Name—SMT\_PART\_BEND\_TABLE\_NAME

The parameter allows you to define the name of the bend allowance table.

Type—String

Values—Can be empty or list of all the names of the bend tables from the part.

Default Value—Empty

## Unattached Planar Wall Feature

A planar wall is a planar section of a sheet metal part. It can either be a primary wall (the first wall in the design), or a secondary wall (which is dependent on the primary wall). Planar walls can take any flat shape.

Creo TOOLKIT supports planar walls that are created using the Fill Tool or the Planar Wall tool. Planar walls created using the Fill Tool are unattached and may be the primary wall. Wall created using the Flat Wall tool are secondary walls that are attached to existing wall edges, and may or may not have a bend applied.

## Unattached Planar Wall based on the Fill Tool

A sheet metal planar wall created based on the fill tool shares most of the same elements as the standard fill feature documented in the header file

ProFlatSrf.h. The element tree should include some of the following sheet metal specific elements to generate a sheet metal feature:

- `PRO_E_IS_UNATTACHED_WALL`—Has a Boolean value that specifies whether the feature is actually a flat wall.
- `PRO_E_STD_DIRECTION`—Specifies the material creation direction of the sheet metal flat wall, which allows you to control the thickness of the first sheet metal wall.
- `PRO_E_STD_SMT_THICKNESS`—Has a double value that specifies the wall thickness. If this feature is not the first wall feature in the part, the thickness value is irrelevant and can be 0.0. The feature inherits the thickness of the first wall feature. This element is not required and cannot be modified if the sheet metal thickness parameter is already assigned in the model.
- `PRO_E_STD_SMT_SWAP_DRV_SIDE`—Specifies whether to swap the sides of the driving and the offset surfaces (the green and white surfaces of the wall).
- `PRO_E_BODY`—Compound element for body options.
  - `PRO_E_BODY_USE`—Mandatory. The valid values are :
    - ◆ `PRO_BODY_USE_NEW`—New body created and newly created geometry is added to the new body. Always marks first wall.
    - ◆ `PRO_BODY_USE_SELECTED`—Feature adds it's geometry to single selected body.
  - `PRO_E_BODY_SELECTED`—Reference to the selected bodies. Mandatory if `PRO_E_BODY_USE` is set to `PRO_BODY_USE_SELECTED`, ignored otherwise. Single reference allowed.
- `PRO_E_SMT_NEW_BODY_LINKED`—Specifies if the sheetmetal body is linked to a part. Mandatory if `PRO_E_BODY_USE` is set to `PRO_BODY_USE_NEW`.

For details on standard fill features, refer to the section [Fill Feature](#) on page 865.

## Feature Element Tree for the Attached Flat Wall Feature

The element tree for Flat Wall feature is documented in the header file `ProSmtFlatWall.h` and has a simple structure. The following figure demonstrates the feature element tree structure:

## Feature Element tree for Flat Wall Feature

## PRO\_E\_SMT\_BEND\_RELIEF

The feature element tree contains no non-standard element types. The following list details special information about some of the elements in this tree:

- PRO\_E\_FEATURE\_TYPE—Specifies the feature type and should be PRO\_FEAT\_WALL.
- PRO\_E\_SMT\_WALL\_TYPE—Specifies the wall type. For Flat Walls, this should be PRO\_SMT\_WALL\_TYPE\_FLAT.
- PRO\_E\_STD\_FEATURE\_NAME—Specifies the name of the feature.
- PRO\_E\_SMT\_FLAT\_WALL\_ATT\_EDGE—Specifies the attachment edges.

- **PRO\_E\_SMT\_FLAT\_WALL\_ANGLE**—Specifies the bend angle and consists of the following elements:
  - **PRO\_E\_SMT\_FLAT\_WALL\_ANGLE\_TYPE** specifies the angle type and is of the following types:
    - ◆ **PRO\_BND\_ANGLE\_VALUE**—uses an indicated value.
    - ◆ **PRO\_BND\_ANGLE\_BY\_PARAM**—uses the default value of the sheet metal parameter **SMT\_DFLT\_BEND\_ANGLE**.
    - ◆ **PRO\_BND\_ANGLE\_FLAT**—uses no angle for the wall.
  - **PRO\_E\_SMT\_FLAT\_WALL\_ANGLE\_VAL**—specifies the angle value.
  - **PRO\_E\_SMT\_FLAT\_WALL\_ANGLE\_FLIP**—indicates whether or not to reverse the angle direction.
- **PRO\_E\_STD\_SECTION**—Specifies the wall section. Wall sections can be standard or user-defined. Standard wall sections are stored in the location `<creo_loadpoint>\<datecode>\Common Files\text\smt`. These standard sections can be retrieved; their dimensions modified, and can be added directly into the **PRO\_E\_STD\_SECTION** element tree as the **PRO\_E\_SKETCHER** element. This does not require definition of a sketch plane or viewing direction, and it does not require an incomplete feature to be created as is described in the section [Element Trees: Sketched Features on page 1002](#). When standard sections are used to create the wall, the Creo Parametric user interface will show the correct type of section in the drop down menu (for example: **Rectangle**, **Trapezoid**, **L**, **T**).

If a user-defined section is to be used to create a flat wall, it must conform to the following restrictions:

- It must be a 2D section
- It must not be named the same name as one of the default section types from the Creo Parametric loadpoint.
- It must contain a horizontal centerline and 2 coordinate systems. The centerline represents the alignment with the attachment edge, and the coordinate systems represent the edge endpoints.
- The horizontal dimension must be specified.

When user-defined sections are used to create the wall, Creo Parametric automatically creates necessary sketching planes for the section during creation. Therefore the section may be assigned directly into the **PRO\_E\_SKETCHER** element without defining the sketch plane and without creating the feature as incomplete. After the feature has been created, the 3D section can be extracted from the feature element tree and the section can be modified to include references to other geometric entities in the sheet metal part.

- **PRO\_E\_SMT\_FILLETS**—Specifies the bend properties of the sheet metal wall:
  - **PRO\_E\_SMT\_FILLETS\_USE\_RAD**—true, a bend is applied, if false, no bend is used.
  - **PRO\_E\_SMT\_FILLETS\_SIDE**—Specifies fillet side and has the following permitted values:
    - ◆ **PRO\_BEND\_RAD\_OUTSIDE**—apply the bend radius to the outside of the bend.
    - ◆ **PRO\_BEND\_RAD\_INSIDE**—apply the bend radius to the inside of the bend.
    - ◆ **PRO\_BEND\_RAD\_PARAMETER**—apply the bend radius at the dimension location set by the **SMT\_DFLT\_RADIUS\_SIDE** parameter in Creo Parametric.
  - **PRO\_E\_SMT\_FILLETS\_VALUE**—Specifies bend radius.
- **PRO\_E\_SMT\_WALL\_HEIGHT**—Specifies the height of the attachment wall. It has the following elements:
  - **PRO\_E\_SMT\_WALL\_HEIGHT\_TYPE**—Specifies the manner in which the newly created wall feature attaches to the attachment edge. This element takes the following values:
    - ◆ **PRO\_SMT\_WALL\_HEIGHT\_AUTO**—Specifies that the wall feature attaches to the attachment edge by trimming the height of the attachment wall automatically.
    - ◆ **PRO\_SMT\_WALL\_HEIGHT\_VALUE**—Specifies that the wall feature attaches to the attachment edge by trimming the height of the attachment wall by a specified value.
    - ◆ **PRO\_SMT\_WALL\_HEIGHT\_APP\_BEND**—Specifies that the wall feature appends to the attachment edge without trimming the height of the attachment wall.
    - ◆ **PRO\_E\_SMT\_WALL\_HEIGHT\_VALUE**—specifies the value of the height of the attachment wall.
    - ◆ **PRO\_SMT\_WALL\_HEIGHT\_OFFSET\_FROM\_ORIG**—Specifies that the wall feature attaches to the selected attachment edge at the specified offset distance. The distance is measured from the position of the wall, if it was attached straight to the original edge, without bend.
    - ◆ **PRO\_SMT\_WALL\_HEIGHT\_OFFSET\_FROM\_BEND**—Specifies that the wall feature appends to the selected attachment edge at the specified offset distance. The distance is measured from the position of

---

the wall, if it was attached to the original edge with an additional bend, as with the option `PRO_SMT_WALL_HEIGHT_APP_BEND`.

- `PRO_E_SMT_BEND_RELIEF`—Specifies bend relief at the edges of the new wall feature. The relief can be specific differently on each side of the bend:

`PRO_E_SMT_BEND_RELIEF_SIDE1`—Specifies the first bend relief:

- `PRO_E_BEND_RELIEF_TYPE` specifies relief type and has the following values:
  - `PRO_BEND_RLF_NONE`—specifies attachment of the wall using no relief.
  - `PRO_BEND_RLF_RIP`— specifies ripping of the material at each attachment point.
  - `PRO_BEND_RLF_STRETCH`—specifies stretching of the material for bend relief at wall attachment point.
  - `PRO_BEND_RLF_RECTANGULAR`—specifies adding a rectangular relief at each attachment point
  - `PRO_BEND_RLF_OBROUND`—specifies adding an obround relief at each attachment point.
- `PRO_E_BEND_RELIEF_WIDTH`—specifies the relief width (for rectangular and obround relief).
- `PRO_E_BEND_RELIEF_DEPTH`—specifies relief depth (for rectangular and obround relief).
- `PRO_E_BEND_RELIEF_LENGTH_TYPE`—specifies the relief length type and is defined by the enumerated data type `ProBendRlfLengthType`. The valid values follow:
  - `PRO_BEND_RLF_LENGTH_NOT_USED`
  - `PRO_BEND_RLF_LENGTH_BLIND`—Creates the bend reliefs with a length of the specified value.
  - `PRO_BEND_RLF_LENGTH_TO_NEXT`—Creates the bend reliefs with a length to the next surface.
  - `PRO_BEND_RLF_LENGTH_THROUGH_ALL`—Creates the bend reliefs through all surfaces.
  - `PRO_BEND_RLF_LENGTH_TYPE_PARAM`—Uses the `SMT_DFLT_BEND_REL_LENGTH_TYPE` parameter value.
- `PRO_E_BEND_RELIEF_LENGTH`—specifies the relief length value.
- `PRO_E_BEND_RELIEF_ANGLE`—specifies relief angle (for stretch relief).

`PRO_E_SMT_BEND_RELIEF_SIDE2`—Includes an identical subtree for the relief applied to the second side of the wall.

- `PRO_E_SMT_WALL_THICKNESS_FLIP`—Indicates whether or not to flip the thickness direction of the new wall.
- `PRO_E_SMT_DEV_LEN_CALCULATION`—Specifies the method used to calculate the Developed Length dimensions for bends.
- `PRO_E_SMT_CORNERS_ARR`—Specifies the edge transition for a particular corner intersection. See the section [The Element Subtree for `PRO\_E\_SMT\_CORNERS\_ARR` on page 1335](#) for more information on corner treatment.
  - `PRO_E_WALL_CORNER_TREATMENT`—Specifies the corner treatment that is applied to the wall. This element is defined by the enumerated data type `ProWallCornerTreatment` and it takes the following valid values:
    - ◆ `PRO_WALL_CORNER_SEAM`—Specifies if the corner is created using a seam.
    - ◆ `PRO_WALL_CORNER_NO_SEAM`—Specifies if the corner is created without using a seam.
    - ◆ `PRO_WALL_CORNER_IGNORE`—Specifies if the corner is not created.

## The Element Subtree for `PRO_E_SMT_MTR_CUTS`

### Miter Cuts

A miter cut removes material from a flat wall feature. It is controlled by two dimensions—width and offset. Offset is the distance between the end of the miter cut and the placement chain.

- `PRO_E_SMT_MTR_CUTS_ADD`—Specifies the miter cuts to be added.
- `PRO_E_SMT_THREE_BEND_CRNR_RELIEF_TYPE`—Specifies the three bend corner relief type and is defined by the enumerated data type `ProThreeBendCornerType`.

`ProThreeBendCornerType`—Enables you to select the type of relief for the three bend corner type in a flat wall. The valid values are:

- `PRO_THREE_B_CNRTYPE_TANGENT`—Creates cut tangent in the middle bend edges to create the relief.
- `PRO_THREE_B_CNRTYPE_CLOSED`—Creates a corner tangent patch to flatten as a deformation area.
- `PRO_THREE_B_CNRTYPE_OPEN`—Creates linear cuts to the side bend vertices to create the relief.
- `PRO_THREE_B_CNRTYPE_RIP`—Creates rips to create the relief.

- `PRO_THREE_B_CNR_TYPE_NO`

---

 **Note**

- When `PRO_E_SMT_THREE_BEND_CRNR_RELIEF_TYPE` is set to `PRO_THREE_B_CNR_TYPE_CLOSED`, the valid options for `PRO_E_SMT_MITER_CUT_GROOVE_TYPE` are:
    - ◆ `PRO_MITER_CUT_NO_GAP`
    - ◆ `PRO_MITER_CUT_OBROUND`
  - When `PRO_E_SMT_THREE_BEND_CRNR_RELIEF_TYPE` is set to `PRO_THREE_B_CNR_TYPE_TANGENT`, `PRO_THREE_B_CNR_TYPE_OPEN` or `PRO_THREE_B_CNR_TYPE_RIP`, the valid options for `PRO_E_SMT_MITER_CUT_GROOVE_TYPE` are:
    - ◆ `PRO_MITER_CUT_NO_GAP`
    - ◆ `PRO_MITER_CUT_THROUGH_ALL`
- 

- `PRO_E_SMT_MITER_CUT_GROOVE_TYPE`—Specifies the groove type to be cut in the miter and is defined by the enumerated data type `ProMiterCutType`.

`ProMiterCutType`—Enables you to select the miter cut type in a flat wall. The valid values are:

- `PRO_MITER_CUT_THROUGH_ALL`—Creates the miter cut groove (all the way through) to the corner relief.  
If `PRO_E_SMT_MITER_CUT_GROOVE_TYPE` is set to `PRO_MITER_CUT_THROUGH_ALL`, only `PRO_E_SMT_MTR_CUTS_WIDTH_VAL` is used.
- `PRO_MITER_CUT_OBROUND`—Creates the miter cut groove as obround.  
If `PRO_E_SMT_MITER_CUT_GROOVE_TYPE` is set to `PRO_MITER_CUT_OBROUND`, both `PRO_E_SMT_MTR_CUTS_WIDTH_VAL` and `PRO_E_SMT_MTR_CUTS_OFFSET_VAL` are used.
- `PRO_MITER_CUT_UNDEFINED`
- `PRO_MITER_CUT_NO_GAP`—Creates the miter cut groove with zero width.  
If `PRO_E_SMT_MITER_CUT_GROOVE_TYPE` is set to `PRO_MITER_CUT_NO_GAP`, neither is used.
- `PRO_E_SMT_MTR_CUTS_WIDTH_VAL`—Specifies the width value of the miter cut.

- `PRO_E_SMT_MTR_CUTS_OFFSET_VAL`—Specifies the offset value of the miter cut.

#### The Element Subtree for Length Calculation

- `PRO_E_SMT_DEV_LEN_SOURCE`— Specifies the development length source. The valid values for this element are defined in the enumerated type `ProDvlLenSrcType`, and are as follows:
  - `PRO_DVL_SRC_NOT_DEFINED`— Specifies that source is not defined
  - `PRO_DVL_SRC_PART_YF_AND_BTAB`—uses part Y-factor and applied bend table.
  - `PRO_DVL_SRC_PART_YF_ONLY`—uses the part Y-factor.
  - `PRO_DVL_SRC_FEAT_YF_AND_BTAB`—uses the feature specific Y-factor and bend table.
  - `PRO_DVL_SRC_FEAT_BTAB_ONLY`—uses the feature specific bend table.
  - `PRO_DVL_SRC_FEAT_YF_ONLY`—uses the feature specific y-factor.
  - `PRO_DVL_SRC_USE_ORIGINAL`—calculates the development length using the same option which was used to create the original development length when the bend was created. For example, if original development length of the bend was calculated using a part bend table, the new development will also be calculated using the same table.
- `PRO_E_SMT_DEV_LEN_Y_FACTOR`—Specifies the feature Y-factor and has the following elements:
  - `PRO_E_SMT_DEV_LEN_Y_FACTOR_TYPE`—Specifies the types of Y-factor. The valid values for this element are defined in the enumerated type `ProDvlLenFactor`, and are as follows:
    - ◆ `PRO_FACTOR_NOT_DEFINED`
    - ◆ `PRO_FACTOR_Y`
    - ◆ `PRO_FACTOR_K`
  - `PRO_E_SMT_DEV_LEN_Y_FACTOR_VALUE` — Specifies the value of Y- or K- factor.
- `PRO_E_SMT_DEV_LEN_BEND_TABLE` — Specifies the development length bend table using the index of the bend table as loaded and stored in this model.

---

## Note

- Bend allowance is a method used to calculate the developed length of flat sheet metal required to make a bend of a specific radius and angle. The calculation accounts for the thickness of the sheet metal, bend radii, bend angles, and other material properties such as Y- and K-factors. Developed length fluctuates with different material types and thickness, and the bend table accounts for those variations.
  - Y- and K-factors are part constants defined by the location of the sheet metal material's neutral bend line. The neutral bend line position is based on a numeric reference for the type of sheet metal material used in your design. The numeric references range from 0 to 1, with the lower numbers representing softer material. Both the Y- and K-factors are integral elements in calculating the developed length (the length of flat sheet metal required to make a bend of a specific radius and angle) in your design.
- 

## Creating a Flat Wall Feature

Function Introduced

- **ProFeatureCreate()**

Use the function `ProFeatureCreate()` to create a Flat Wall Feature based on element tree input. For more information about `ProFeatureCreate()`, refer to the section [Overview of Feature Creation on page 771](#) in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Redefining a Flat Wall Feature

Function Introduced

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine a Flat Wall Feature based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer to the section [Feature Redefine on page 794](#) in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Accessing a Flat Wall Feature

Function Introduced

- **ProFeatureElemtreeExtract()**

---

Use the function `ProFeatureElemtreeExtract()` to create a feature element tree that describes the contents of a Flat Wall Feature and to retrieve the element tree description of a Flat Wall Feature. For more information about `ProFeatureElemtreeExtract()`, refer to the section [Feature Inquiry on page 792](#) in the [Element Trees: Principles of Feature Creation on page 771](#) section.

### **Example 1: Creation of a Rectangular Flat Wall using a preselected edge**

The sample code in `UgSmtFlatWallCreate.c` located at `creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` demonstrates how to create a rectangular flat wall using a preselected edge.

## **Flange Wall Feature**

Flange wall features may be either swept or extruded.

A swept flange wall follows the trajectory formed by the chain of tangent attachment edges. You can sketch a cross section along the attachment edge and the wall sweeps along that edge. The attachment edge need not be linear and the adjacent surface need not have to be planar.

An extruded flange wall extends from one linear edge into space. You can sketch the side section of the wall and project it to a certain length in both directions.

### **Feature Element Tree for the Flange Wall Feature**

The element tree for Flange Wall feature is documented in the header file `ProSmtFlangeWall.h`, and has a simple structure. The following figure demonstrates the feature element tree structure:

## Feature Element tree for Flange Wall Feature

```

Apart from the usual element for the tree root, a Flange Wall feature contains the following elements:

- PRO\_E\_FEATURE\_TYPE—Specifies the feature type and should be PRO\_FEAT\_WALL.

- `PRO_E_SMT_WALL_TYPE`—Specifies the wall type and must be
  - `PRO_SMT_WALL_TYPE_FLANGE`
  - `PRO_SMT_WALL_TYPE_MERGE`
- `PRO_E_STD_FEATURE_NAME`—Specifies the name of the feature.
- `PRO_E_SMT_FLANGE_TYPE`—Specifies the type of flange wall:
  - `PRO_FLANGE_WALL_TYPE_2D_SWEPT`—a swept flange wall in the default orientation.
  - `PRO_FLANGE_WALL_TYPE_3D_SWEPT`—a swept flange wall with non-default directions, orientations, and start points.
  - `PRO_FLANGE_WALL_TYPE_EXTRUDE`—a flange wall extruded from a sketching plane.
- `PRO_E_STD_CURVE_COLLECTION_APPL`—Specifies the attachment edge chain. If the type is swept, this can reference multiple non-tangent edges selected as one by one or using any of the other instruction types. If the flange wall type is to be "Extruded", this must contain a One by One chain with a linear edge.
- `PRO_E_SMT_FLANGE_TRAJ_CRV_NORM`—Specifies whether the flange wall should progress along the default edge chain direction or in the opposite direction.
- `PRO_E_STD_SECTION`—Specifies the wall section.

Wall sections can be standard or user-defined. Standard wall sections are stored in the location `<creo_loadpoint>\<datecode>\Common Files\text\smt`. These standard sections can be retrieved, their dimensions modified, and can be added directly into the `PRO_E_STD_SECTION` element tree as the `PRO_E_SKETCHER` element. This does not require definition of a sketch plane or viewing direction, and it does not require an incomplete feature to be created as is described in the section *Creating Sketched Features*. When standard sections are used to create the wall, the Creo Parametric user interface will show the correct type of section in the drop down menu (for example: **I**, **Arc**, etc.).

If a user-defined section is to be used to create a flat wall, it must conform to the following restrictions:

- It must be a 2D section.
- It must not be named the same name as one of the default section types from the Creo Parametric loadpoint.
- It must contain a horizontal centerline with a coordinate system located on it. The centerline represents the alignment with the attachment wall, and the coordinate system represents the attachment point for the section.

- The section may optionally contain bent or straight edges. It may also contain sheet metal section entities that assist in constructing the correct swept geometry.

When user-defined sections are used to create the wall, Creo Parametric automatically creates necessary sketching planes for the section during creation. Therefore the section may be assigned directly into the `PRO_E_SKETCHER` element without defining the sketch plane and without creating the feature as incomplete. After the feature has been created, if the wall type is 3D swept or Extruded, the 3D section can be extracted from the feature element tree and the section can be modified to include references to other geometric entities in the sheet metal part.

- `PRO_E_SMT_WALL_SHARPS_TO_BENDS`—If `PRO_B_TRUE` then Creo Parametric attempts to convert sharp edges in the section to bends.
- `PRO_E_SMT_FLANGE_SEC_FLIP`—Specifies whether or not to flip the direction of the section for user-defined sections.
- `PRO_E_SMT_FLANGE_DEPTH`—Specifies the depth of the flange, that is, the extent of the flange cover. This element governs the results for extruded flange walls only. For swept walls, the extents are governed by the rules in the element `PRO_E_STD_CURV_COLLECTION_APPL`, which might include trim values and boundary geometry.
- `PRO_E_SMT_FILLETS`—Specifies the bend properties of the sheet metal wall.
  - `PRO_E_SMT_FILLETS_USE_RAD`—If true, a bend is applied, if false, no bend is used.
  - `PRO_E_SMT_FILLETS_SIDE`—Specifies fillet side and has the following permitted values:
    - ◆ `PRO_BEND_RAD_OUTSIDE`—apply the bend radius to the outside of the bend.
    - ◆ `PRO_BEND_RAD_INSIDE`—apply the bend radius to the inside of the bend.
    - ◆ `PRO_BEND_RAD_PARAMETER`—apply the bend radius at the dimension location set by the `SMT_DFLT_RADIUS_SIDE` parameter in Creo Parametric.
  - `PRO_E_SMT_FILLETS_VALUE`—the bend radius.
- `PRO_E_SMT_WALL_HEIGHT`—Specifies the height of the attachment wall. It has the following elements:
  - `PRO_E_SMT_WALL_HEIGHT_TYPE`—specifies the manner in which the newly created wall feature attaches to the attachment edge. This element is

- 
- defined by the enumerated data type `ProBendPosition` and takes the following values:
- ◆ `PRO_BEND_POSITION_CONSTRAINED`—Specifies that the attached wall geometry is kept within the boundary of the attachment edge.
  - ◆ `PRO_BEND_POSITION_PROF_ON_EDGE`—Specifies that the bend geometry is added while keeping the wall profile on the original attachment edge
  - ◆ `PRO_BEND_POSITION_BEND_OUTSIDE`—Specifies that the bend geometry is added with the bend line tangent to the attachment edge.
  - ◆ `PRO_BEND_POSITION_OFFSET_BEND_APEX`—Specifies that the offset is measured from the attachment edge to the Bend Apex.
  - ◆ `PRO_BEND_POSITION_OFFSET_BEND_START`—Specifies that the offset is measured from the attachment edge to the Bend Start.
  - `PRO_E_SMT_WALL_HEIGHT_VALUE` specifies the value of the height of the attachment wall.
  - `PRO_E_SMT_BEND_RELIEF` — Specifies bend relief. Refer to the section [Feature Element Tree for the Sheetmetal Flat Wall Feature on page 1313](#) for more information on this element subtree.
  - `PRO_E_SMT_WALL_THICKNESS_FLIP` — Indicates whether or not to flip the thickness direction of the new wall.
  - `PRO_E_SMT_CORNER_RELIEF`—Indicates a compound element representing corner relief. Corner relief is added at each intersection of a pair of bends.
  - `PRO_E_SMT_MTR_CUTS`—Indicates a compound element representing miter cuts.
  - `PRO_E_SMT_AUTO_EXLD_EDGE`—Specifies whether to set automatic exclusion of edges. Creo Parametric uses the following set of rules and logic in order to execute the automatic wall segment excluding:
    - Long wall segment has lower excluding priority than short wall segment
    - Small wall segment that is neighbor to long wall has high excluding priority than other short wall segments
    - A wall segment whose overlapping area at the intersection of bend surfaces of neighborhood wall segments is maximum has the highest excluding priority
  - `PRO_E_SMT_CORNERS_ARR`—Specifies the edge transitions.
  - `PRO_E_SMT_DEV_LEN_CALCULATION`—Specifies the properties used to calculate the development length. See the section [The Element Subtree for](#)

---

[PRO\\_E\\_SMT\\_DEV\\_LEN\\_CALCULATION](#) on page 1322 for more information.

### The Element Subtree for PRO\_E\_SMT\_FLANGE\_DEPTH

PRO\_E\_SMT\_FLANGE\_DEPTH has the following elements:

- PRO\_E\_SMT\_FLANGE\_SIDE\_1\_DEPTH—Specifies first side of the flange extents and has the following elements:
  - PRO\_WALL\_LEN\_TYPE\_NONE—the flange does not extend in this direction.
  - PRO\_WALL\_LEN\_TYPE\_BLIND—the flange extends a specified length value in this direction.
  - PRO\_WALL\_LEN\_TYPE\_BLIND\_SYM—the flange extends a symmetric length value in both direction. If this is used for side 1, side 2 must use PRO\_WALL\_LEN\_TYPE\_NONE.
  - PRO\_WALL\_LEN\_TYPE\_TO\_REF—the flange extends to a selected geometric reference.
  - PRO\_WALL\_LEN\_TYPE\_TO\_END—the flange extends to the end of the attachment reference.
  - PRO\_E\_SMT\_FLANGE\_DEPTH\_OFFSET—specifies the depth offset for blind and symmetric blind extents.
  - PRO\_E\_SMT\_FLANGE\_DEPTH\_REF—specifies the depth placement reference for "to ref" extents.
- PRO\_E\_SMT\_FLANGE\_SIDE\_2\_DEPTH—Specifies side2 the second side of the flange. This subtree is identical to the first side.

### The Element Subtree for PRO\_E\_SMT\_CORNER\_RELIEF

Corner relief is required when multiple non-tangent edges are used for attachment of the flange wall. The element PRO\_E\_SMT\_CORNER\_RELIEF represents corner relief in the feature. It has the following properties:

- PRO\_E\_SMT\_CORNER\_RELIEF\_TYPE specifies the types of corner reliefs:
  - PRO\_CORNER\_RELIEF\_NO—Creo Parametric does not add relief and generates square corners.
  - PRO\_CORNER\_RELIEF\_V\_NOTCH—Creo Parametric adds a V notch shape cut at the corners.
  - PRO\_CORNER\_RELIEF\_CIRCULAR—Creo Parametric adds a circular shape relief at the corners with a radius dimension.

- `PRO_CORNER_RELIEF_OBROUND`—Creo Parametric adds an obround relief at the corners with a specified diameter and depth.
- `PRO_CORNER_RELIEF_RECTANGULAR`—Creo Parametric adds a rectangular relief at the corners with a specified width and depth.
- `PRO_E_SMT_CORNER_RELIEF_WIDTH` a compound element with the following elements:
  - `PRO_E_SMT_CORNER_RELIEF_WIDTH_TYPE`—This is one of the members of `ProSmdRelType`. See table [Relation Value Types on page 1336](#) for the list of value types permitted.
  - `PRO_E_SMT_CORNER_RELIEF_WIDTH_VAL` — This is the value for the dimension, if the width type is `PRO_DIM_ENTER`.
- `PRO_E_SMT_CORNER_RELIEF_DEPTH` a compound element with the following elements:
  - `PRO_E_SMT_CORNER_RELIEF_DEPTH_TYPE`—This is one of the members of `ProCornerRlfDepthType`. See table for the list of value types permitted.
  - `PRO_E_SMT_CORNER_RELIEF_DEPTH_VAL`—This is the value for the dimension, if the width type is `PRO_DIM_ENTER`.

### The Element Subtree for `PRO_E_SMT_MTR_CUTS`

A miter cut removes material from any profile intersecting wall segments. The miter cut is controlled by two dimensions—width and offset as shown in the figure below. Offset is the distance between the end of the miter cut to the placement chain. Creo Parametric uses half of the specified width value to cut the material of each side of the centerline of the miter cut.

#### Miter Cut

It has the following elements:

- `PRO_E_SMT_MTR_CUTS_ADD`—Specifies whether to add miter cuts.

- `PRO_E_SMT_MTR_CUTS_KEEP_DEF_AREAS`—Specifies the deformation area of the miter cut. A deformation area is a section of sheet metal that helps to accurately stretch the material when you unbend the sheet metal part.
- `PRO_E_SMT_MTR_CUTS_WIDTH`
  - `PRO_E_SMT_MTR_CUTS_WIDTH_TYPE`—This is one of the members of `ProMiterCutWidthType`. The valid types are:
    - ◆ `PRO_MITER_CUT_WIDTH_TYPE_BLIND`—Specifies the type `PRO_DIM_ENTER`
    - ◆ `PRO_MITER_CUT_WIDTH_TYPE_GAP`—Specifies the type `PRO_DIM_SMT_GAP`
    - ◆ `PRO_MITER_CUT_WIDTH_TYPE_PARAM`—Specifies the type `PRO_DIM_DFLT_MITER_CUT_WIDTH`

See table [Relation Value Types on page 1336](#) for the list of value types permitted.
  - `PRO_E_SMT_MTR_CUTS_WIDTH_VAL`—This is the value for the dimension, if the width type is `PRO_DIM_ENTER`.
- `PRO_E_SMT_MTR_CUTS_OFFSET`
  - `PRO_E_SMT_MTR_CUTS_OFFSET_TYPE`—This is one of the members of `ProMiterCutOffsetType`. The valid types are:
    - ◆ `PRO_MITER_CUT_OFFSET_TYPE_BLIND`—Specifies the type `PRO_DIM_ENTER`
    - ◆ `PRO_MITER_CUT_OFFSET_TYPE_GAP`—Specifies the type `PRO_DIM_SMT_GAP`
    - ◆ `PRO_MITER_CUT_OFFSET_TYPE_PARAM`—Specifies the type `PRO_DIM_DFLT_MITER_CUT_OFFSET`

See table [Relation Value Types on page 1336](#) for the list of value types permitted.
  - `PRO_E_SMT_MTR_CUTS_OFFSET_VAL`—This is the value for the dimension, if the width type is `PRO_DIM_ENTER`.

### The Element Subtree for `PRO_E_SMT_CORNERS_ARR`

When the flange is attached to multiple non-tangent edges, it is possible to define edge transitions for each such intersection. The members of the array element `PRO_E_SMT_CORNERS_ARR` each define the edge transition for a particular corner intersection. Each member has a subelement called `PRO_E_SMT_EDGE_RIP` which contains the following:

- `PRO_E_SMT_EDGE_RIP_TYPE` specifies edge treatment types and can be as follows:

- PRO\_EDGE\_RIP\_OPEN
  - PRO\_EDGE\_RIP\_BLIND
  - PRO\_EDGE\_RIP\_MITER\_CUT
  - PRO\_EDGE\_RIP\_OVERLAP
  - PRO\_EDGE\_RIP\_CONNECT
  - PRO\_E\_SMT\_EDGE\_RIP\_CLOSE\_CORNER specifies if the gap between the bend surfaces of a corner relief must be closed. This element is applicable only if the element PRO\_E\_SMT\_EDGE\_RIP\_TYPE is set to PRO\_EDGE\_RIP\_OPEN.
  - PRO\_E\_SMT\_EDGE\_RIP\_ADD\_GAP specifies whether to add a gap.
  - PRO\_E\_SMT\_EDGE\_RIP\_DIM\_1 specifies the first side's properties.
    - PRO\_E\_SMT\_EDGE\_RIP\_DIM\_1\_TYPE — This is one of the members of ProEdgeRipDimType. The valid types are:
      - ◆ PRO\_EDGE\_RIP\_DIM\_TYPE\_BLIND—Specifies the type PRO\_DIM\_ENTER.
      - ◆ PRO\_EDGE\_RIP\_DIM\_TYPE\_GAP—Specifies the type PRO\_DIM\_SMT\_GAP.
      - ◆ PRO\_EDGE\_RIP\_DIM\_TYPE\_PARAM—Specifies the type PRO\_DIM\_DFLT\_EDGE\_TREA\_WIDTH.
- See table [Relation Value Types on page 1336](#) for the list of value types permitted.
- PRO\_E\_SMT\_EDGE\_RIP\_DIM\_1\_VAL — This is the value for the dimension, if the width type is PRO\_DIM\_ENTER.
  - PRO\_E\_SMT\_EDGE\_RIP\_DIM\_2 specifies the second side's properties.
    - PRO\_E\_SMT\_EDGE\_RIP\_DIM\_2\_TYPE—This is one of the members of ProEdgeRipDimType. See table [Relation Value Types on page 1336](#) for the list of value types permitted.
    - PRO\_E\_SMT\_EDGE\_RIP\_DIM\_2\_VAL—This is the value for the dimension, if the width type is PRO\_DIM\_ENTER.
  - PRO\_E\_SMT\_EDGE\_RIP\_FLIP specifies whether to flip the overlapping side.

## Relation Value Types

| ProSmdRelType        | Description                                                                          |
|----------------------|--------------------------------------------------------------------------------------|
| PRO_DIM_THICK        | The part thickness. It represents the parameter SMT_THICKNESS in a sheet metal part. |
| PRO_DIM_DOUBLE_THICK | 2 x the part thickness. It represents the parameter                                  |

| ProSmdRelType                 | Description                                                                                              |
|-------------------------------|----------------------------------------------------------------------------------------------------------|
|                               | SMT_THICKNESS in a sheet metal part.                                                                     |
| PRO_DIM_ENTER                 | A user-defined value                                                                                     |
| PRO_DIM_DEF_CRN_REL_WIDTH     | The value of the sheet metal Parameter SMT_DFLT_CRNR_REL_WIDTH, only allowed for corner relief width.    |
| PRO_DIM_DEF_CRN_REL_DEPTH     | The value of the sheet metal Parameter SMT_DFLT_CRNR_REL_DEPTH, only allowed for corner relief depth.    |
| PRO_DIM_MINUS_THICK           | -1 x the part thickness                                                                                  |
| PRO_DIM_MINUS_DOUBLE_THICK    | -2 x the part thickness                                                                                  |
| PRO_DIM_DFLT_EDGE_TREA_WIDTH  | The value of the sheet metal Parameter SMT_DFLT_EDGE_TREAT_WIDTH, only allowed for edge transition width |
| PRO_DIM_DFLT_MITER_CUT_WIDTH  | The value of the sheet metal Parameter SMT_DFLT_MITER_CUT_WIDTH, only allowed for miter cut width        |
| PRO_DIM_DFLT_MITER_CUT_OFFSET | The value of the sheet metal Parameter SMT_DFLT_MITER_CUT_OFFSET, only allowed for miter cut offset      |
| PRO_DIM_THICK_1_1             | 1.1 x the part thickness                                                                                 |
| PRO_DIM_THICK_05              | 0.5 x the part thickness                                                                                 |
| PRO_DIM_SMT_GAP               | The value of the sheet metal Parameter SMT_GAP                                                           |
| PRO_DIM_MINUS_SMT_GAP         | The negative (minus) value of the sheet metal Parameter SMT_GAP                                          |
| PRO_DIM_MINUS_THICK_05        | -0.5 x the part thickness                                                                                |
| PRO_DIM_DEF_BEND_RAD          | The value of the sheet metal Parameter SMT_DFLT_BEND_RADIUS.                                             |
| PRO_DIM_UP_TO_BEND            | The relief depth type. Represents <b>Up to Bend</b> option for bend and corner reliefs.                  |
| PRO_DIM_TAN_TO_BEND           | The relief depth type. Represents <b>Up to Bend</b> option for bend and corner reliefs.                  |
| PRO_DIM_DEF_BEND_ANGLE        | The value of the sheet metal Parameter SMT_DFLT_BEND_ANGLE.                                              |
| PRO_DIM_DEF_BEND_REL_WIDTH    | The bend relief width. The value of the sheet metal Parameter SMT_DFLT_BEND_REL_WIDTH.                   |
| PRO_DIM_DEF_BEND_REL_DEPTH    | The bend relief depth. The value of the sheet metal Parameter SMT_DFLT_BEND_REL_DEPTH.                   |
| PRO_DIM_DEF_BEND_REL_ANGLE    | The bend relief angle. The value of the sheet metal Parameter SMT_DFLT_BEND_REL_ANGLE.                   |
| PRO_DIM_CRN_RLF_DEPTH_TYPE    | The corner relief depth. The value of the sheet metal Parameter SMT_DFLT_CRNR_REL_DEPTH_TYPE.            |
| PRO_DIM_BEND_RLF_DEPTH_TYPE   | The bend relief depth. The value of the sheet metal Parameter SMT_DFLT_BEND_REL_DEPTH_TYPE.              |

## Creating a Flange Wall Feature

### Function Introduced

---

- **ProFeatureCreate()**

Use the function `ProFeatureCreate()` to create a Flange Wall Feature based on element tree input. For more information about `ProFeatureCreate()`, refer to the section [Overview of Feature Creation on page 771](#) in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Redefining a Flange Wall Feature

Function Introduced

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine a Flange Wall Feature based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer to the section [Feature Redefine on page 794](#) in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Accessing a Flange Wall Feature

Function Introduced

- **ProFeatureElemtreeExtract()**

Use the function `ProFeatureElemtreeExtract()` to create a feature element tree that describes the contents of a Flange Wall Feature and to retrieve the element tree description of a Flange Wall Feature. For more information about `ProFeatureElemtreeExtract()`, refer to the section [Feature Inquiry on page 138](#) in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Example 2: Creation of Flange Wall feature using Creo TOOLKIT

The sample code in `UgSmtFlgWallCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat` demonstrates how to create a flange wall feature using Creo TOOLKIT. The feature is created using two external properties: the wall thickness determines the bend radius, and the attachment edge(s) are obtained from the currently selected edges in the Creo Parametric model. If a single edge is selected, it is converted to a tangent chain before it is used to create the feature. The section is the 2D section handle for the I-wall section provided with Creo Parametric.

## Sheet metal Wall Features

In Creo TOOLKIT, you can create extruded, revolved or swept wall features. You can specify the wall thickness, generate bends, and assign a development length calculation to the wall.

---

An extruded wall is drawn as a cross-section extruded in the specified direction. Similarly, the revolved and swept walls are drawn.

In Creo TOOLKIT, an extruded wall shares the same element tree as the basic Extrude feature documented in the header file `ProExtrude.h`. The revolved wall shares its element tree with the basic Revolve feature documented in the header file `ProRevolve.h`. The swept protrusion wall shares its element tree with the basic sweep feature documented in the header file `ProSweep.h`.

The element tree should include some of the following sheet metal-specific elements to generate a sheet metal wall feature:

- `PRO_E_STD_SMT_THICKNESS`—Has a double value that specifies the wall thickness. If this feature is not the first wall feature in the part, the thickness value is irrelevant and can be 0.0. The feature inherits the thickness of the first wall feature. This element is not required and cannot be modified if the sheet metal thickness parameter is already assigned in the model.
- `PRO_E_STD_SMT_SWAP_DRV_SIDE`—Specifies sheet metal swap sides to switch sides of driving and offset sides.
- `PRO_E_SMT_WALL_SHARPS_TO_BENDS`—Converts any sharp edges in the section to appropriate bends.
- `PRO_E_SMT_FILLETS`—Refer to the section [Feature Element Tree for the Sheetmetal Flat Wall Feature on page 771](#) for the description of the element.
- `PRO_E_SMT_DEV_LEN_CALCULATION`—Refer to the section [Feature Element Tree for the Sheetmetal Flat Wall Feature on page 771](#) for the description of the element.
- `PRO_E_SMT_MERGE_DATA`—This compound element defines the parameters required to merge the wall geometry to an existing wall.
  - `PRO_E_SMT_MERGE_AUTO`—The valid values for this element are:
    - ◆ `True`—Merges the wall geometry to an existing wall in the design.
    - ◆ `False`—Does not merge the walls.
  - `PRO_E_SMT_MERGE_KEEP_LINES`—Controls the visibility of merged edges on surface joints. The valid values for this element are:
    - ◆ `True`—Merged edges are visible on surface joints.
    - ◆ `False`—Merged edges are not visible on surface joints.
- `PRO_E_BODY_USE`—Mandatory. Specifies the body to add geometry to. The valid values are:
  - `PRO_BODY_USE_NEW`—The geometry in the feature is stored in the first wall. Same as solid.

- `PRO_BODY_USE_SELECTED`—The geometry in the feature is stored in the single selected body. Same as solid.
- `PRO_E_SMT_NEW_BODY_LINKED`—Specifies if the sheetmetal body is linked to a part. Mandatory if `PRO_E_BODY_USE` is set to `PRO_BODY_USE_NEW`.

For details on the basic Extrude and Revolve features, refer to the section [Element Trees: Extrude and Revolve on page 1009](#).

For details on the basic Sweep feature, refer to the section [Element Trees: Sweep on page .](#)

## Sheet metal Cut Features

A sheet metal cut removes material from the walls it encounters.

In Creo TOOLKIT, a sheet metal cut feature shares the same element tree as the basic extrude feature or the solidify feature or the thicken feature. The element tree should include some of the following sheet metal cut-specific elements to generate a sheet metal cut feature:

- `PRO_E_IS_SMT_CUT`—If true this feature is a sheet metal cut, otherwise it is a solid cut. It is applicable only in sheet metal parts.
- `PRO_E_SMT_CUT_NORMAL_DIR`—This element defines the surface to which the section projection will be normal. The projection normal specifies the side of the sheetmetal wall from which the sketched curve splits the wall. The values for this element are as follows:
  - `PRO_SMT_CUT_DRVSIDE_GREEN`—Specifies the normal to the driven surface. This is a direction from the green side to the white side of the sheet metal wall. This is the default value.
  - `PRO_SMT_CUT_DRVSIDE_WHITE`—Specifies the normal to the offset surface. This is a direction from the white side to the green side of the sheet metal wall.

For details on the basic Extrude feature, see the section [The Element Tree for Extruded Features on page 1010](#).

For details on the basic Solidify feature, see the section [Solidify Feature on page 879](#).

For details on the basic Thicken feature, see the section [Thicken Feature on page 876](#).

The extrude feature has additional optional element `PRO_E_SMT_PUNCH_TOOL_DATA`. This compound element defines sheet metal cut that is used to cut and relieve sheet metal walls. It is used in sheet metal manufacturing. It is applicable to sheet metal cuts, made by the Punch UDF. It defines the parameters related to the punch feature.

---

The compound element `PRO_E_SMT_PUNCH_TOOL_DATA` contains the following elements:

- `PRO_E_SMT_PUNCH_TOOL_ATTR`—Specifies the symmetry flag for the Manufacturing UDF Punch Tool. The valid values for this element are:
  - `PRO_PUNCH_TOOL_ATTR_SYM_NONE`—Specifies that the tool is not symmetric about any axis.
  - `PRO_PUNCH_TOOL_ATTR_SYM_X`—Specifies that the tool is symmetrical about the X-axis of the coordinate system
  - `PRO_PUNCH_TOOL_ATTR_SYM_Y`—Specifies that the tool is symmetrical about the Y-axis of the coordinate system.
  - `PRO_PUNCH_TOOL_ATTR_SYM_XY`—Specifies that the tool is symmetrical about both the X and Y-axis of the coordinate system.
- `PRO_E_SMT_PUNCH_TOOL_NAME`—Specifies the name of the Manufacturing UDF punch tool used.

For sheet metal cuts and punches, you can specify if the punch axis point must be created. A punch axis point is a reference point that moves with a feature during both, the unbend and bend back operations. In the element `PRO_E_SMT_PUNCH_AXIS_PNT`, specify `PRO_B_TRUE` to create the punch axis point in the sheet metal feature.

## Extend\_Wall\_Feature

### Feature Element Tree for the Extend Wall Feature

The Extend Wall feature allows you to extend an attachment wall with a straight edge.

The element tree for the Extend Wall feature is documented in the header file `ProSmtExtendWall.h`. The following figure shows the feature element tree structure.

## Feature Element Tree for Extend Wall Feature

```
PRO_E_FEATURE_TREE
|
|-- PRO_E_FEATURE_TYPE
|
|-- PRO_E_SMT_WALL_TYPE
|
|-- PRO_E_STD_FEATURE_NAME
|
|-- PRO_E_SMT_EXTEND_WALL_EDGE
|
|-- PRO_E_SMT_EXTEND_WALL_DIST
| |
| |-- PRO_E_SMT_EXTEND_DIST_TYPE
| |
| |-- PRO_E_SMT_EXTEND_DIST_VALUE
| |
| |-- PRO_E_SMT_EXTEND_DIST_REF
| |
|-- PRO_E_SMT_EXTEND_WALL_EXTENSIONS_CMP
```

## PRO\_E\_SMT\_EXTEND\_WALL\_EXTENSIONS\_CMP

```
PRO_E_SMT_EXTEND_WALL_EXTENSIONS_CMP
|
|-- PRO_E_SMT_EXTEND_SIDE1_EXTENSION_CMP
| |
| |-- PRO_E_SMT_EXTEND_EXTENSION_TYPE_OPT
| |
| |-- PRO_E_SMT_EXTEND_ADJUST_SRF
|
|-- PRO_E_SMT_EXTEND_SIDE2_EXTENSION_CMP
| |
| |-- PRO_E_SMT_EXTEND_EXTENSION_TYPE_OPT
| |
| |-- PRO_E_SMT_EXTEND_ADJUST_SRF
```

The elements in this tree are described as follows:

- PRO\_E\_FEATURE\_TYPE—Specifies the feature type and should be PRO\_FEAT\_WALL.
- PRO\_E\_SMT\_WALL\_TYPE—Specifies the sheet metal wall type and its value is PRO\_SMT\_WALL\_TYPE\_EXTEND.
- PRO\_E\_STD\_FEATURE\_NAME—Specifies the feature name.

- `PRO_E_SMT_EXTEND_WALL_EDGE`—Specifies the edge of the attachment wall you select for extension.
- `PRO_E_SMT_EXTEND_WALL_DIST`—Specifies the distance properties for the attachment wall to be extended. This compound element consists of the following elements:
  - `PRO_E_SMT_EXTEND_DIST_TYPE`—Specifies the distance type used for extension. It takes the following values
    - ◆ `PRO_EXTEND_DIST_BY_VALUE`—Specifies that the attachment wall is extended by a specified value and remains parallel to the selected edge.
    - ◆ `PRO_EXTEND_DIST_TO_THROUGH_UNTIL`—Specifies that the attachment wall is extended normally to the selected edge until it intersects the referenced plane.
    - ◆ `PRO_EXTEND_DIST_TO_SELECTED`—Specifies that the attachment wall is extended normally to the selected edge until it intersects the referenced plane and remains parallel to the selected edge.
  - `PRO_E_SMT_EXTEND_DIST_VALUE`—Specifies the distance value. This element is applicable only if the element `PRO_E_SMT_EXTEND_DIST_TYPE` has the value `PRO_EXTEND_DIST_BY_VALUE`.
  - `PRO_E_SMT_EXTEND_DIST_REF`—Specifies the plane or surface selected as the reference. This element is applicable only if the element `PRO_E_SMT_EXTEND_DIST_TYPE` has the value `PRO_EXTEND_DIST_TO_THROUGH_UNTIL` or `PRO_EXTEND_DIST_TO_SELECTED`.
- `PRO_E_SMT_EXTEND_WALL_EXTENSIONS_CMP`—Specifies the extension properties of the two sides of the attachment wall.

#### The Element Subtree for `PRO_E_SMT_EXTEND_WALL_EXTENSIONS_CMP`

`PRO_E_SMT_EXTEND_WALL_EXTENSIONS_CMP` is a compound element and consists of the following elements:

- `PRO_E_SMT_EXTEND_SIDE1_EXTENSION_CMP`—Specifies the extension properties of the side 1. This compound element consists of the following elements:
  - `PRO_E_SMT_EXTEND_EXTENSION_TYPE_OPT`—Specifies the extension type. It is given by the enumerated type `ProExtendExtensionType` and takes the following values:

- ◆ `PRO_EXTEND_EXT_NORMAL_TO_EDGE`—Specifies that the side 1 of the attachment wall is extended normal to the selected edge.
- ◆ `PRO_EXTEND_EXT_ALONG_BOUND_EDGE`—Specifies that the side 1 of the attachment wall is extended along the boundary of the selected edge.
- `PRO_E_SMT_EXTEND_ADJUST_SRF`—Specifies whether the surface adjacent to side 1 of the extended edge is also extended. The values for this element are specified by the enumerated type `ProExtendAdjSrf` and are as follows:
  - ◆ `PRO_EXTEND_ADJ_SRF_FALSE`
  - ◆ `PRO_EXTEND_ADJ_SRF_TRUE`
- `PRO_E_SMT_EXTEND_SIDE2_EXTENSION_CMP`—Specifies the extension properties of the side 2. This compound element consists of the same elements as the element `PRO_E_SMT_EXTEND_SIDE1_EXTENSION_CMP`.

## Creating a Extend Wall Feature

Function Introduced

- **ProFeatureCreate()**

Use the function `ProFeatureCreate()` to create a Extend Wall feature based on the element tree definition. For more information about `ProFeatureCreate()`, refer to the [Overview of Feature Creation on page 771](#) section in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Redefining a Extend Wall Feature

Function Introduced

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine a Extend Wall feature based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer the [Feature Redefine on page 794](#) section in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Accessing a Extend Wall Feature

Function Introduced

- **ProFeatureElemtreeExtract()**

---

Use the function `ProFeatureElemtreeExtract()` to retrieve the element tree description of the Extend Wall feature. For more information about `ProFeatureElemtreeExtract()`, refer the [Feature Inquiry on page 792](#) section in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Split\_Area\_Feature

### Feature Element Tree for the Split Area Feature

The element tree for the Split Area feature is documented in the header file `ProSmtSplitArea.h`. The following figure shows the feature element tree structure.

#### Feature Element Tree for Split Area Feature

```
PRO_E_FEATURE_TREE
|
|--PRO_E_FEATURE_TYPE
|
|--PRO_E_STD_FEATURE_NAME
|
|--PRO_E_SMT_CUT_NORMAL_DIR
|
|--PRO_E_STD_SECTION
|
|--PRO_E_SMT_PROJ_DIR
|
|--PRO_E_STD_MATRLSIDE
```

The elements in this tree are as follows:

- `PRO_E_FEATURE_TYPE`—Specifies the feature type and should be `PRO_FEAT_DEFORM_AREA`.
- `PRO_E_STD_FEATURE_NAME`—Specifies the name of the feature.
- `PRO_E_SMT_CUT_NORMAL_DIR`—Specifies the normal of projection. The projection normal specifies the side of the sheemetal wall from which the sketched curve splits the wall. The values for this element are as follows:
  - `PRO_SMT_CUT_DRVSIDE_GREEN`—Specifies the normal to the driven surface. This is a direction from the green side to the white side of the sheet metal wall. This is the default value.
  - `PRO_SMT_CUT_DRVSIDE_WHITE`—Specifies the normal to the offset surface. This is a direction from the white side to the green side of the sheet metal wall.

- 
- **PRO\_E\_STD\_SECTION**—Specifies the sketch selected for the split. You can create a new section or select an internal sketch from the model.
  - **PRO\_E\_SMT\_PROJ\_DIR**—Specifies the projection direction. It is specified by the enumerated type `ProSmtProjDir`. The valid values are:
    - **PRO\_SMT\_PROJ\_DIR\_ONE**—Specifies the projection to one side. This is the default value.
    - **PRO\_SMT\_PROJ\_DIR\_TWO**—Specifies the projection to the opposite side.
    - **PRO\_SMT\_PROJ\_DIR\_BOTH**—Specifies the projection to both the sides.
  - **PRO\_E\_STD\_MATRLSIDE**—Specifies the direction in which the area of the sheet metal wall is split. It is specified by the enumerated type `ProSplitAreaMatSide`. The valid values are:
    - **PRO\_SPLITAREA\_MATSIDE\_ONE**—Specifies the split in one direction.
    - **PRO\_SPLITAREA\_MATSIDE\_TWO**—Specifies the split in the opposite direction. This is the default value.

## Creating a Split Area Feature

Function Introduced

- **ProFeatureCreate()**

Use the function `ProFeatureCreate()` to create a Split Area feature based on the element tree definition. For more information about `ProFeatureCreate()`, refer the [Overview of Feature Creation on page 771](#) section in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Redefining a Split Area Feature

Function Introduced

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine a Split Area feature based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer the [Feature Redefine on page 794](#) section in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Accessing a Split Area Feature

Function Introduced

- **ProFeatureElemtreeExtract()**

---

Use the function `ProFeatureElemtreeExtract()` to retrieve the element tree description of the Split Area feature. For more information about `ProFeatureElemtreeExtract()`, refer the [Feature Inquiry on page 792](#) section in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Punch and Die Form Features

A Form is a sheet metal wall molded by a template (reference part). Merging the geometry of a reference part creates the Form feature.

Punch Form feature molds the sheet metal wall using only the reference part geometry whereas Die Form feature molds the sheet metal using the reference part to form the geometry (convex or concave) surrounded by a bounding plane.

## Feature Element Tree for the Punch and Die Form Features

The element tree for the Punch and Die Form features is documented in the header file `ProSmtForm.h` and can be used to create both punch and die form features. The following figure shows the feature element tree structure:

### Feature Element Tree for Punch Form Feature

```
PRO_E_FEATURE_TREE
|
|-PRO_E_FEATURE_TYPE
|-PRO_E_STD_FEATURE_NAME
|-PRO_E_GMRG_SMT_TYPE
|-PRO_E_GMRG_FEAT_TYPE
|-PRO_E_DSF_REF_MDL
| |--PRO_E_DSF_SEL_REF_MDL
|-PRO_E_COMP_PLACE_INTERFACE

|-PRO_E_SMT_TRIM_FORM_SIDES
```

## PRO\_SMT\_SURF\_FACE

The surface is the face (green) surface created by a sheet metal feature.

## PRO\_SMT\_SURF\_OFFSET

The surface is the offset (white) surface created by a sheet metal feature.

The elements in this tree are as follows:

- PRO\_E\_FEATURE\_TYPE—Specifies the feature type and should be PRO\_FEAT\_GEN\_MERGE.
- PRO\_E\_STD\_FEATURE\_NAME—Specifies the name of the feature.

- `PRO_E_GMRG_SMT_TYPE`—Specifies the type of sheet metal feature. The values for this element are specified by the enumerated type `ProGenMergeSmtType` and the valid values are:
  - `PRO_GEN_MERGE_SMT_TYPE_FORM`—Specifies the Punch Form in all the versions.

---

 **Note**

Use the element `PRO_GEN_MERGE_SMT_TYPE_FORM_PUNCH` instead of `PRO_GEN_MERGE_SMT_TYPE_FORM` from Creo Parametric3.0 onwards.

---

- `PRO_GEN_MERGE_SMT_TYPE_FORM_PUNCH`—Specifies the Punch Form feature for parts created in Creo Parametric3.0 onward.
- `PRO_GEN_MERGE_SMT_TYPE_NOT_SMT`—Specifies a merge, inheritance or any other type of General Merge feature.
- `PRO_GEN_MERGE_SMT_TYPE_FORM_DIE`—Specifies the Die Form feature.
- `PRO_E_GMRG_FEAT_TYPE`—Specifies the type of General Merge feature.

---

 **Note**

For General Merge feature of type `PRO_GEN_MERGE_TYPE_MERGE`, the element `PRO_E_DSF_DEPENDENCY` can be set to `PRO_DSF_UPDATE_AUTOMATICALLY` only.

---

For more information on the types of General Merge features, refer the [General Merge \(Merge, Cutout and Inheritance Feature\) on page 1191](#) section in the [Assembly: Data Sharing Features on page 1179](#) section.

- `PRO_E_DSF_REF_MDL`—Specifies the punch or die model used to create the Punch or Die Form feature. It consists of the following element:
  - `PRO_E_DSF_SEL_REF_MDL`—Specifies the selected punch or die model.
- `PRO_E_COMP_PLACE_INTERFACE`—Specifies the assembly component interfaces used to define the placement of the punch or die model in the sheet metal geometry. For more information on the elements contained by the placement interfaces element, refer the [Placement via Interface on page 1155](#) section in the [Assembly: Assembling Components on page 1141](#) section.

- 
- `PRO_E_COMPONENT_CONSTRAINTS`—Specifies the assembly component constraints used to define the placement of the punch or die model in the sheet metal geometry. For more information on the component constraints elements, refer the [Placement Constraints on page 1153](#) section in the Assembly: Assembling Components [Assembly: Assembling Components on page 1141](#) section.

---

 **Note**

The placement by coordinate system option in the Creo Parametric user interface for the Punch or Die Form feature is not available via Creo Parametric TOOLKIT. To place the model in the sheet metal geometry using a coordinate system, define a coordinate system feature in the sheet metal model and use it for placement.

---

- `PRO_E_GMRG_VARIED_ITEMS`—Specifies a pointer element that defines the Inheritance feature varied items and their values. This element is available only when the Punch or Die Form feature is of the type `PRO_GEN_MERGE_TYPE_INHERITANCE`. For more information on this element, refer the [Inheritance Feature and Flexible Component Variant Items on page 1195](#) section in the [Assembly: Data Sharing Features on page 1179](#) section.
- `PRO_E_DSF_DEPENDENCY`—Specifies the dependency type. The values for this element are specified by the enumerated type `ProDsFDependency`.

---

 **Note**

From Creo Parametric 3.0 onward, the enumerated type `ProDsFDependency` has been deprecated. Use the enumerated type `ProDSFDependency` instead.

---

The valid values for the dependency status are:

- `PRO_DSF_UPDATE_AUTOMATICALLY`—Specifies that the geometry of the Punch or Die Form feature depends upon the geometry of the model used during feature creation. The Punch or Die Form feature reflects all the changes made in the parent model.

---

 **Note**

From Creo Parametric 3.0 onward, the value `PRO_DSf_DEPENDENT` has been deprecated. Use the enumerated value `PRO_DSf_UPDATE_AUTOMATICALLY` instead.

---

- `PRO_DSf_UPDATE_MANUALLY`—Specifies that the geometry of the Punch or Die Form feature is independent of the geometry of the model used during feature creation. If you update the model, the feature does not change.

---

 **Note**

From Creo Parametric 3.0 onward, the value `PRO_DSf_INDEPENDENT` has been deprecated. Use the enumerated value `PRO_DSf_UPDATE_MANUALLY` instead.

---

- `PRO_DSf_NO_DEPENDENCY`—Specifies that there is no dependency between the geometry of the Punch or Die Form feature and the geometry of the Punch or Die model used during feature creation.

---

 **Note**

All the dependency statuses specified in the enumerated type `ProDsFDependency` are defined in the header file `ProDataShareFeat.h`. For more information on the values, refer to the section [Feature Element Tree on page 1191](#) in *Assembly: Data Sharing Features*.

---

- `PRO_E_FORM_PUNCH_SIDE`—Specifies the Punch direction. The direction specifies a side of a wall from which the model penetrates the sheet metal geometry. The values for this element are specified by the enumerated type `ProSmtSurfType`. The surface types are as follows:
  - `PRO_SMT_SURF_FACE`—The punch model moves in a direction from the green side to the white side of the sheet metal model. Refer to the figure [PRO\\_SMT\\_SURF\\_FACE on page 1348](#)
  - `PRO_SMT_SURF_OFFSET`—The punch model moves in a direction from the white side to the green side of the sheet metal model. Refer to the figure [PRO\\_SMT\\_SURF\\_OFFSET on page 1348](#).

- `PRO_E_STD_SURF_COLLECTION_APPL`—Specifies a collection of surfaces to be excluded from the Punch or Die model during feature creation.
- `PRO_E_FORM_DIE_POCKET_GEOM_CMP`—Compound element. Specify this element only if the enumerated type `ProGenMergeSmtType` is set to `PRO_GEN_MERGE_SMT_TYPE_FORM_DIE` type.

---

### Note

This element cannot be used for creating Punch Form features and is specific to Die Form features only.

---

- `PRO_E_STD_SURF_COLLECTION_APPL`—Specifies the collection of selected surfaces to be used for Pocket Geometry during the feature creation.
- `PRO_E_FORM_TOOL_CSYS`—Specifies the reference coordinate system used during the manufacturing process. The coordinate system in the Punch model is used by default.
- `PRO_E_FORM_TOOL_NAME`—Specifies the name of the manufacturing tool used to create the Punch or Die model. The name specified by the `SMT_FORM_TOOL_NAME` parameter in the model is used by default.
- `PRO_E_GMRG_FORM_AUTO_ROUNDS`—Specifies the `ProBoolean` option to round the non-placement sharp edges (that do not lie on the placement surface). This optional element uses a constant outside radius of value equal to the thickness of the original sheet metal part.
- `PRO_E_SMT_FILLET_INTERSECT`—Specifies the option to round the placement sharp edges (that lie on the placement surface and intersect the sheet metal geometry). This optional element consists of the following elements:
  - `PRO_E_SMT_FILLET_RADIUS_USEFLAG`—Specifies whether a fillet radius is used.
  - `PRO_E_SMT_FILLET_RADIUS_SIDE`—Specifies the radius direction, that is, outside or inside. The values for this element, specified by the enumerated type `ProSmdRadType`, are as follows:
    - ◆ `PRO_BEND_RAD_OUTSIDE`—The radius is applied to the outside of the sheet metal geometry.
    - ◆ `PRO_BEND_RAD_INSIDE`—The radius is applied to the inside of the sheet metal geometry.
  - `PRO_E_SMT_FILLET_RADIUS_VALUE` — Specifies the radius value.

- 
- `PRO_E_SMT_TRIM_FORM_SIDES`—Trim edges of sheared form. Specifies if Creo Parametric applies trimming of sheet metal side surfaces during form feature generation. The valid values for this element follow:
    - `PRO_B_TRUE`
    - `PRO_B_FALSE`

## Creating a Punch or Die Form Feature

### Function Introduced

- **ProFeatureCreate()**

Use the function `ProFeatureCreate()` to create a Punch or Die Form feature based on the element tree definition. For more information about `ProFeatureCreate()`, refer the [Overview of Feature Creation on page 771](#) section in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Redefining a Punch or Die Form Feature

### Function Introduced

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine a Punch or Die Form feature based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer the [Feature Redefine on page 794](#) section in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Accessing a Punch or Die Form Feature

### Function Introduced

- **ProFeatureElemtreeExtract()**

Use the function `ProFeatureElemtreeExtract()` to retrieve the element tree description of the Punch or Die Form feature. For more information about `ProFeatureElemtreeExtract()`, refer the [Feature Inquiry on page 792](#) section in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Quilt\_Form\_Feature

### Feature Element Tree for the Quilt Form Feature

The Quilt Form feature molds the sheet metal wall using a referenced closed or open datum quilt.

The element tree for the Quilt Form feature is documented in the header file `ProSmtPunchQuilt.h`. The following figure shows the feature element tree structure:

### Feature Element Tree for Quilt Form Feature

The elements in this tree are as follows:

- `PRO_E_FEATURE_TYPE`—Specifies the feature type and should be `PRO_FEAT_PUNCH_QUILT`.
- `PRO_E_STD_FEATURE_NAME`—Specifies the name of the feature.
- `PRO_E_FORM_PUNCH_QUILT`—Specifies the referenced datum quilt. The geometry of the referenced quilt is merged with the sheet metal part.

- 
- **PRO\_E\_FORM\_PUNCH\_SIDE**—Specifies the punch direction. The punch direction specifies a side of a wall from which the punch model penetrates the sheet metal geometry. The values for this element are specified by the enumerated type `ProSmtSurfType`. The surface types are as follows:
    - **PRO\_SMT\_SURF\_FACE**—The punch model moves in a direction from the green side to the white side of the sheet metal model. Refer to the figure [PRO\\_SMT\\_SURF\\_FACE on page 1348](#).
    - **PRO\_SMT\_SURF\_OFFSET**—The punch model moves in a direction from the white side to the green side of the sheet metal model. Refer to the figure [PRO\\_SMT\\_SURF\\_OFFSET on page 1348](#).
  - **PRO\_E\_FORM\_PUNCH\_MATERIAL\_SIDE** — Specifies whether the resultant sheet metal geometry lies inside or outside the referenced quilt after the feature is created. The geometry is placed inside or outside the referenced quilt using the thickness value of the original sheet metal part. The values for this element, specified by the enumerated type `ProSmdPunchMatSide`, are as follows:
    - **PRO\_SMT\_PUNCH\_MAT\_INSIDE**
    - **PRO\_SMT\_PUNCH\_MAT\_OUTSIDE**
  - **PRO\_E\_STD\_SURF\_COLLECTION\_APPL** — Specifies a collection of surfaces to be excluded from the referenced quilt when the feature is created.
  - **PRO\_E\_SMT\_FILLET\_INTERSECT**—Specifies the set of fillets that are added to the contours created by the intersection of the referenced quilt with the sheet metal part. This element consists of the following elements:
    - **PRO\_E\_SMT\_FILLET\_RADIUS\_USEFLAG**—Specifies whether a fillet radius is used.
    - **PRO\_E\_SMT\_FILLET\_RADIUS\_SIDE**—Specifies the radius direction (outside or inside). The values for this element, specified by the enumerated type `ProSmdRadType`, are as follows:
      - ◆ **PRO\_BEND\_RAD\_OUTSIDE**—The radius is applied to the outside of the sheet metal geometry.
      - ◆ **PRO\_BEND\_RAD\_INSIDE**—The radius is applied to the inside of the sheet metal geometry.
    - **PRO\_E\_SMT\_FILLET\_RADIUS\_VALUE**—Specifies the radius value.
  - **PRO\_E\_SMT\_FILLET\_QUILT**—Specifies the set of fillets that are added to sharps (edges between non-tangent geometries) on the referenced quilt. This element consists of the same set of elements as **PRO\_E\_SMT\_FILLET\_INTERSECT**.

- 
- **PRO\_E\_FORM\_PUNCH\_HIDE\_QUILT**—Specifies whether the referenced quilt will be hidden in the feature. The values for this element, specified by the enumerated type `ProSmdPunchHideQuilt`, are as follows:
    - `PRO_SMT_PUNCH_HIDE_ORIGINAL`
    - `PRO_SMT_PUNCH_KEEP_ORIGINAL`
  - **PRO\_E\_SMT\_TRIM\_FORM\_SIDES**—Trim edges of sheared form. Specifies if Creo Parametric applies trimming of sheet metal side surfaces during form feature generation. The valid values for this element follow:
    - `PRO_B_TRUE`
    - `PRO_B_FALSE`

## Creating a Quilt Form Feature

Function Introduced

- **ProFeatureCreate()**

Use the function `ProFeatureCreate()` to create a Quilt Form feature based on the element tree definition. For more information about `ProFeatureCreate()`, refer the [Overview of Feature Creation on page 771](#) section in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Redefining a Quilt Form Feature

Function Introduced

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine a Quilt Form feature based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer the [Feature Redefine on page 794](#) section in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Accessing a Quilt Form Feature

Function Introduced

- **ProFeatureElemtreeExtract()**

Use the function `ProFeatureElemtreeExtract()` to retrieve the element tree description of the Quilt Form feature. For more information about `ProFeatureElemtreeExtract()`, refer the [Feature Inquiry on page 792](#) section in the [Element Trees: Principles of Feature Creation on page 771](#) section.

---

## Flatten\_Form\_Feature

### Feature Element Tree for Flatten Form Feature

The Flatten Form feature allows you to flatten existing Form features in your model.

The element tree for a Flatten Form feature is documented in the header file `ProSmtFlattenForm.h` and has a simple structure. The following figure demonstrates the structure of the feature element tree.

#### Flatten Form Element Tree

```
PRO_E_FEATURE_TREE
|
|--PRO_E_FEATURE_TYPE
|
|--PRO_E_STD_FEATURE_NAME
|
|--PRO_E_SMT_FLATTEN_REF_TYPE
|
|--PRO_E_STEP_SEL_FORM
|
|--PRO_E_SMT_FLATTEN_PROJ_CUTS
```

The elements in this tree are described as follows:

- `PRO_E_FEATURE_TYPE`—Specifies the feature type and should be `PRO_FEAT_FLATTEN`.
- `PRO_E_STD_FEATURE_NAME`—Specifies the name of the feature.
- `PRO_E_SMT_FLATTEN_REF_TYPE`—Specifies the selection type for the Form features to be flattened. It is specified by the enumerated type `ProFlattenRefType`. The valid selection types are:
  - `PRO_FLATTEN_FORM_REFSEL`—Specifies the type where you select an array of Form features from the model. This is the default value.
  - `PRO_FLATTEN_FORM_ALLSEL`—Specifies the type where Creo Parametric finds and selects all the Form features from the model.
- `PRO_E_STEP_SEL_FORM`—Specifies the array of Form features you select.
- `PRO_E_SMT_FLATTEN_PROJ_CUTS`—Specifies if cuts must be projected to the flattened form.

### Creating a Flatten Form Feature

Function Introduced

---

- **ProFeatureCreate()**

Use the function `ProFeatureCreate()` to create a Flatten Form feature based on the element tree definition. For more information about `ProFeatureCreate()`, refer the [Overview of Feature Creation on page 771](#) section in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Redefining a Flatten Form Feature

Function Introduced

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine a Flatten Form feature based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer the [Feature Redefine on page 794](#) section in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Accessing a Flatten Form Feature

Function Introduced

- **ProFeatureElemtreeExtract()**

Use the function `ProFeatureElemtreeExtract()` to retrieve the element tree description of the Flatten Form feature. For more information about `ProFeatureElemtreeExtract()`, refer the [Feature Inquiry on page 792](#) section in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Convert\_Features

### Shell Feature

You can use the convert features to convert a solid part into a sheet metal part. For a block-like part, use the Shell feature to remove one or more walls that hollows the inside of the model, leaving a shell of the specified wall thickness.

The element tree for the Shell feature is documented in the header file `ProSmtShell.h`, and is shown in the following figure:

## Element Tree for Shell Feature

The elements in this tree are described as follows:

| Element ID                  | Data Type                | Description                                                                                                                               |
|-----------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE          | PRO_VALUE_TYPE_INT       | Specifies the type of feature. The value of this feature must be PRO_FEAT_DATUM_SURF.                                                     |
| PRO_E_STD_FEATURE_NAME      | PRO_VALUE_TYPE_WSTRING   | Specifies the name of the feature. The default value is Shell_1.                                                                          |
| PRO_E_DTM_SRF_TYPE          | PRO_VALUE_TYPE_INT       | Specifies the Datum Surface Type using the enumerated type ProSmtDtmSrfType. The value of this feature must be PRO_DTM_SRF_AS_WALL_SHELL. |
| PRO_E_SMT_CONV_BODY         | PRO_VALUE_TYPE_SELECTION | Specifies the body to be selected to convert to a sheet metal part.                                                                       |
| PRO_E_SHELL_SRF             | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the collection of surfaces to be removed to shell the solid.                                                  |
| PRO_E_STD_SMT_THICKNESS     | PRO_ELEM_TYPE_DOUBLE     | Specifies the thickness of the wall. It must be positive a number.                                                                        |
| PRO_E_STD_MATRLSIDE         | PRO_VALUE_TYPE_INT       | Specifies the direction of material thickness.                                                                                            |
| PRO_E_STD_SMT_SWAP_DRV_SIDE | PRO_VALUE_TYPE_INT       | Specifies sheet metal swap sides to switch sides of shelled and driving surfaces.                                                         |

## Driving Surface Feature

The Driving Surface feature converts a solid geometry to sheet metal part. For thin protrusions with constant thickness, use the Driving Surface feature to select a surface as the driving surface and to set the wall thickness.

The element tree for the Driving Surface feature is documented in the header file `ProSmtDrvSurf.h` and is shown in the following figure:

### Element Tree for Driving Surface Feature

The elements in this tree are described as follows:

| Element ID                  | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE          | PRO_VALUE_TYPE_INT       | Specifies the type of feature. The value of this feature must be PRO_FEAT_DATUM_SURF.                                                                                                                                                                                                                                                                                                                                                                                                           |
| PRO_E_STD_FEATURE_NAME      | PRO_VALUE_TYPE_WSTRING   | Specifies the name of the feature. The default value is Driving_Surface_1.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_DTM_SRF_TYPE          | PRO_VALUE_TYPE_INT       | Specifies the Datum Surface Type using the enumerated type ProSmtDtmSrfType. The value of this feature must be PRO_DTM_SRF_AS_WALL. For an empty body, the value of this feature must be PRO_DTM_SRF_EMPTY_BODY_CONV.                                                                                                                                                                                                                                                                           |
| PRO_E_SMT_CONV_BODY         | PRO_VALUE_TYPE_SELECTION | Specifies the body to be selected to be converted to a sheet metal part.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_SMT_DRV_SURF          | PRO_VALUE_TYPE_SELECTION | Specifies the collection of a solid surface to be used as the driving surface.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| PRO_E_STD_SMT_THICKNESS     | PRO_ELEM_TYPE_DOUBLE     | Specifies the thickness of the wall.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_STD_MATRLSIDE         | PRO_VALUE_TYPE_INT       | Specifies the direction of material thickness.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| PRO_E_STD_SMT_SWAP_DRV_SIDE | PRO_VALUE_TYPE_INT       | Specifies sheet metal swap sides to switch sides of driving and selected surfaces.                                                                                                                                                                                                                                                                                                                                                                                                              |
| PRO_E_SMT_DRV_ADD_SURF      | Compound                 | Specifies the additional surface to be used as a driving surface for the sheet metal body part.                                                                                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_SMT_DRV_EXCL_SURF     | Compound                 | Specifies the surfaces to be excluded so that they are not treated as face surfaces in the sheet metal body.                                                                                                                                                                                                                                                                                                                                                                                    |
| PRO_E_SMT_ADJACENT_RND_OPTS | PRO_VALUE_TYPE_INT       | Specifies the adjacent round options and is defined by the enumerated data type ProSmtAdjRndOpts. The valid values follow: <ul style="list-style-type: none"> <li>PRO_SMT_ADJ_RND_RECREATE—Removes rounds and chamfers and recreates them after the part is converted to a sheet metal part.</li> <li>PRO_SMT_ADJ_RND_REMOVE—Removes the rounded geometry. The resulting geometry is similar to the geometry before the round operation.</li> <li>PRO_SMT_ADJ_RND_IGNORE—Ignores the</li> </ul> |

| Element ID                     | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                |                    | rounded geometry. The resulting geometry is without the rounded geometry.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_SMT_KEEP_NOT_CLASS_SURFS | PRO_VALUE_TYPE_INT | <p>Specifies the keep not classified surfaces and is defined by the enumerated data type <code>ProSmtKeepNotClassSurfsType</code>. The valid values follow:</p> <ul style="list-style-type: none"> <li>PRO_SMT_IGNORE_NOT_CLASS_SURFS—Ignores surfaces that are not classified as the driving surface, additional surfaces, and excluded surfaces as separate quilts.</li> <li>PRO_SMT_KEEP_NOT_CLASS_SURFS—Keeps surfaces that are not classified as the driving surface, additional surfaces, and excluded surfaces as separate quilts.</li> </ul> |
| PRO_E_SMT_AUTOCALC_THICKNESS   | PRO_VALUE_TYPE_INT | When enabled, calculates the thickness of the solid geometry after each regeneration and uses this thickness as a Sheetmetal parameter. Consequently, the thickness of the resulting Sheetmetal geometry is automatically updated based on the thickness of the solid geometry. The value is set to <code>PRO_B_FALSE</code> .                                                                                                                                                                                                                       |
| PRO_E_SMT_NEW_BODY_LINKED      | PRO_VALUE_TYPE_INT | Specifies a feature already used in the Sheetmetal First Wall, indicating whether the new Sheetmetal body created by the feature has its Sheetmetal parameters linked to the part (the same as the part) or if it is independent. This feature is also used not only for creating new Sheetmetal bodies but also in the Body Convert feature when existing solid bodies are converted to Sheetmetal. The value is set to <code>PRO_B_TRUE</code> .                                                                                                   |

---

## Rip Features

Rip features allow you to tear a continuous piece of sheet metal material so that when you unbend a design, it tears along the ripped section. There are four types of rips available:

- **Sketched Rip**—Tears the sheet metal part along a sketched path. You can exclude surfaces to protect them from rip.
- **Surface Rip**—Cuts out a surface patch from the sheet metal part and in the process removes volume from the part.
- **Edge Rip**—Tears the sheet metal part along an edge. You can define edge treatment for the ripped edges.
- **Rip Connect**—Tears the sheet metal part between two datum points or vertices or a combination of both.

The four rip types are specified by the enumerated type `ProSmtRipType` and take the following values:

- `PRO_SMT_RIP_REGULAR`—Specifies a Sketched Rip.
- `PRO_SMT_RIP_SURFACE`—Specifies a Surface Rip.
- `PRO_SMT_RIP_EDGE`—Specifies an Edge Rip.
- `PRO_SMT_RIP_CONNECT`—Specifies a Connect Rip.

### Sketched Rip Feature

The Sketched Rip feature allows you to tear the sheet metal part along a sketched path.

#### Feature Element Tree for Sketched Rip Feature

The element tree for a Sketched Rip feature is documented in the header file `ProSmtRegularRip.h` and has a simple structure. The following figure demonstrates the structure of the feature element tree.

## Sketched Rip Element Tree

```
PRO_E_FEATURE_TREE
|
|--PRO_E_FEATURE_TYPE
|
|--PRO_E_STD_FEATURE_NAME
|
|--PRO_E_SMT_RIP_TYPE
|
|--PRO_E_STD_SECTION
|
|--PRO_E_SMT_CUT_NORMAL_DIR
|
|--PRO_E_SMT_PROJ_DIR
|
|--PRO_E_STD_MATRLSIDE
|
|--PRO_E_STD_SURF_COLLECTION_APPL
```

The elements in this tree are described as follows:

- PRO\_E\_FEATURE\_TYPE—Specifies the feature type and should be PRO\_FEAT\_RIP.
- PRO\_E\_STD\_FEATURE\_NAME—Specifies the name of the feature.
- PRO\_E\_SMT\_RIP\_TYPE—Specifies the rip type and should have the value PRO\_SMT\_RIP\_REGULAR.
- PRO\_E\_STD\_SECTION—Specifies the sketch selected for the rip. You can create a new section or select an internal sketch from the model.
- PRO\_E\_SMT\_CUT\_NORMAL\_DIR—Specifies the normal of projection. The projection normal specifies the side of the sheemetal part from where the sketched curve rips the part. The values for this element are as follows:
  - PRO\_SMT\_CUT\_DRVSIDE\_GREEN—Specifies the normal to the driven surface. This is a direction from the green side to the white side of the sheet metal part. This is the default value.
  - PRO\_SMT\_CUT\_DRVSIDE\_WHITE—Specifies the normal to the offset surface. This is a direction from the white side to the green side of the sheet metal part.
- PRO\_E\_SMT\_PROJ\_DIR—Specifies the projection direction. It is specified by the enumerated type ProSmtProjDir. The valid values are:
  - PRO\_SMT\_PROJ\_DIR\_ONE—Specifies the projection to one side. This is the default value.

- PRO\_SMT\_PROJ\_DIR\_TWO—Specifies the projection to the opposite side.
- PRO\_SMT\_PROJ\_DIR\_BOTH—Specifies the projection to both the sides.
- PRO\_E\_STD\_MATRLSIDE—Specifies the direction in which the area of the sheet metal part is ripped. It is specified by the enumerated type ProSketchRipMatSide. The valid values are:
  - PRO\_SKETCHRIP\_MATSIDE\_ONE—Specifies the rip in one direction.
  - PRO\_SKETCHRIP\_MATSIDE\_TWO—Specifies the rip in the opposite direction. This is the default value.
- PRO\_E\_STD\_SURF\_COLLECTION\_APPL—Specifies a collection of surfaces that are excluded from the rip operation. This element is optional.
- PRO\_E\_BODY—Specifies the body options. Valid only when PRO\_E\_SMT\_FLATTEN\_REF\_TYPE is PRO\_FLATTEN\_FORM\_ALLSEL
  - PRO\_E\_BODY\_USE—must be PRO\_BODY\_USE\_SELECTED
  - PRO\_E\_BODY\_SELECT—must contain a single selected body

## Surface Rip Feature

The Surface Rip feature allows you to cut out a surface patch from the sheet metal part and in the process removes volume from the part.

### Feature Element Tree for Surface Rip Feature

The element tree for a Surface Rip feature is documented in the header file ProSmtSurfaceRip.h and has a simple structure. The following figure demonstrates the structure of the feature element tree.

### Surface Rip Element Tree

```

PRO_E_FEATURE_TREE
|
|--PRO_E_FEATURE_TYPE
|
|--PRO_E_STD_FEATURE_NAME
|
|--PRO_E_SMT_RIP_TYPE
|
|--PRO_E_STD_SURF_COLLECTION_APPL

```

The elements in this tree are described as follows:

- `PRO_E_FEATURE_TYPE`—Specifies the feature type and should be `PRO_FEAT_RIP`.
- `PRO_E_STD_FEATURE_NAME`—Specifies the name of the feature.
- `PRO_E_SMT_RIP_TYPE`—Specifies the rip type and should have the value `PRO_SMT_RIP_SURFACE`.
- `PRO_E_STD_SURF_COLLECTION_APPL`—Specifies the collection of surfaces you select to be ripped.

## Edge Rip Feature

The Edge Rip feature allows you to tear the sheet metal part along an edge.

### Feature Element Tree for Edge Rip Feature

The element tree for a Edge Rip feature is documented in the header file `ProSmtEdgeRip.h` and has a simple structure. The following figure demonstrates the structure of the feature element tree.

### Edge Rip Element Tree

```

PRO_E_FEATURE_TREE
|
|--PRO_E_FEATURE_TYPE
|
|--PRO_E_STD_FEATURE_NAME
|
|--PRO_E_SMT_RIP_TYPE
|
|--PRO_E_SMT_EDGE_RIP_ARRAY
|
| PRO_E_SMT_EDGE_RIP_SET
| |
| |--PRO_E_SMT_EDGE_RIP_REFERENCES
| |
| | |--PRO_E_SMT_EDGE_REFERENCES
| | |
| | |--PRO_E_STD_CURVE_COLLECTION_APPL
| |
| |-- PRO_E_SMT_EDGE_RIP

```

## PRO\_E\_SMT\_EDGE\_RIP

```
|-- PRO_E_SMT_EDGE_RIP
 |--PRO_E_SMT_EDGE_RIP_TYPE

The elements in this tree are described as follows:

- PRO\_E\_FEATURE\_TYPE—Specifies the feature type and should be PRO\_FEAT\_RIP.
- PRO\_E\_STD\_FEATURE\_NAME—Specifies the name of the feature.
- PRO\_E\_SMT\_RIP\_TYPE—Specifies the rip type and should have the value PRO\_SMT\_RIP\_EDGE.
- PRO\_E\_SMT\_EDGE\_RIP\_ARRAY—Specifies an array of the element PRO\_E\_SMT\_EDGE\_RIP\_SET. PRO\_E\_SMT\_EDGE\_RIP\_SET is a compound element that consists of the following elements:
  - PRO\_E\_SMT\_EDGE\_RIP\_REFERENCES—Specifies an array of the element PRO\_E\_SMT\_EDGE\_REFERENCES. PRO\_E\_SMT\_EDGE\_REFERENCES is a compound element that consists of the following element:
    - ◆ PRO\_E\_STD\_CURVE\_COLLECTION\_APPL—Specifies the chain of edges selected for the rip.
  - PRO\_E\_SMT\_EDGE\_RIP—Specifies the types and options for the treatment of the ripped edges.

---

## The Element Subtree for PRO\_E\_SMT\_EDGE\_RIP

PRO\_E\_SMT\_EDGE\_RIP is a compound element that consists of the following elements:

- PRO\_E\_SMT\_EDGE\_RIP\_TYPE—Specifies the edge treatment types. It is specified by the enumerated type ProEdgeRipType. The valid types are:
  - PRO\_EDGE\_RIP\_OPEN—Rips the sheet metal walls at their point of intersection.
  - PRO\_EDGE\_RIP\_BLIND—Rips the sheet metal part with a gap specified by two dimensions.
  - PRO\_EDGE\_RIP\_MITER\_CUT—Rips the sheet metal part with a gap specified by a single dimension.
  - PRO\_EDGE\_RIP\_OVERLAP—Rips the sheet metal part such that one side overlaps the other.
  - PRO\_EDGE\_RIP\_PARAM—Rips the sheet metal part by the value specified by the defined SMT\_GAP parameter.
- PRO\_E\_SMT\_EDGE\_RIP\_FLIP—Specifies whether to flip the overlapping side. This element is available only if the PRO\_E\_SMT\_EDGE\_RIP\_TYPE has the value PRO\_EDGE\_RIP\_OVERLAP.
- PRO\_E\_SMT\_EDGE\_RIP\_ADD\_GAP—Specifies whether to add a gap clearance. This element is applicable only if the element PRO\_E\_SMT\_EDGE\_RIP\_TYPE has the value PRO\_EDGE\_RIP\_OVERLAP or PRO\_EDGE\_RIP\_PARAM.
- PRO\_E\_SMT\_EDGE\_RIP\_CLOSE\_CORNER—Specifies if the gap between the bend surfaces of an edge rip must be closed. This element is applicable only if the element PRO\_E\_SMT\_EDGE\_RIP\_TYPE is set to PRO\_EDGE\_RIP\_OPEN.
- PRO\_E\_SMT\_EDGE\_RIP\_DIM\_1—Specifies the properties of side 1. This element consists of the following elements:
  - PRO\_E\_SMT\_DIMENSION\_TYPE—Specifies the dimension type. It is specified by the enumerated type ProEdgeRipDimType. The valid types are:
    - ◆ PRO\_EDGE\_RIP\_DIM\_TYPE\_BLIND—Specifies the type PRO\_DIM\_ENTER.
    - ◆ PRO\_EDGE\_RIP\_DIM\_TYPE\_GAP—Specifies the type PRO\_DIM\_SMT\_GAP.
    - ◆ PRO\_EDGE\_RIP\_DIM\_TYPE\_PARAM—Specifies the type PRO\_DIM\_DFLT\_EDGE\_TREA\_WIDTH.

See table [Relation Value Types on page 1336](#) for the descriptions of the above list of value types.

- PRO\_E\_SMT\_DIMENSION\_VALUE—Specifies the dimension value for the type selected.
- PRO\_E\_SMT\_EDGE\_RIP\_DIM\_2—Specifies the properties of side 2. This compound element consists of the same elements as the element PRO\_E\_SMT\_EDGE\_RIP\_DIM\_1.

## Rip Connect Feature

The Rip Connect feature allows you to tear the sheet metal part between two datum points or vertices or a combination of both. A rip connect endpoint must be either a datum point, or a vertex and must lie at the end of an edge rip or on the part border.

The element tree for the Rip Connect feature is documented in the header file ProSmtConnectRip.h and is as shown in the following figure:

### Element Tree for Rip Connect Feature

The elements in this tree are described as follows:

| Element ID                  | Data Type                | Description                                                                                                                                                         |
|-----------------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE          | PRO_VALUE_TYPE_INT       | Specifies the type of feature. The value of this feature must be PRO_FEAT_RIP.                                                                                      |
| PRO_E_STD_FEATURE_NAME      | PRO_VALUE_TYPE_WSTRING   | Specifies the name of the feature. The default value is Rip_Connect_1.                                                                                              |
| PRO_E_SMT_RIP_TYPE          | PRO_VALUE_TYPE_INT       | Specifies the rip type. The valid value for this element is PRO_SMT_RIP_CONNECT.                                                                                    |
| PRO_E_SMT_RIP_CONNECT_COMP  | Compound                 | Specifies a compound element.                                                                                                                                       |
| PRO_E_SMT_RIP_CONNECT_SETS  | Array                    | Specifies an array of rip connect sets.                                                                                                                             |
| PRO_E_SMT_RIP_CONNECT_SET   | Compound                 | Specifies a compound element of reference points and gap parameters.                                                                                                |
| PRO_E_SMT_RIP_CONN_REFS     | Array                    | Specifies an array element containing the starting and end point of the rip connect feature. You can specify up to two elements in this array.                      |
| PRO_E_SMT_RIP_CONN_REF      | Compound                 | Specifies a compound element of vertex or datum points.                                                                                                             |
| PRO_E_SMT_RIP_CONN_END      | PRO_VALUE_TYPE_SELECTION | Specifies a vertex or datum point to define the start or end of the rip. This vertex or datum point must be placed on the edge or the border of a sheet metal part. |
| PRO_E_SMT_RIP_CONN_GAP_COMP | Compound                 | Specifies a compound element of gap parameters.                                                                                                                     |
| PRO_E_SMT_RIP_CONN_ADD_GAP  | PRO_VALUE_TYPE_BOOLEAN   | Specifies if a gap clearance should be added to the selected set of the rip connect. The valid values are TRUE or FALSE.                                            |
| PRO_E_SMT_RIP_CONN_GAP_VAL  | PRO_VALUE_TYPE_DOUBLE    | Specifies the gap value.                                                                                                                                            |

## Creating a Rip Feature

### Function Introduced

- **ProFeatureCreate()**

Use the function `ProFeatureCreate()` to create a specific Rip feature based on the element tree definition. For more information about `ProFeatureCreate()`, refer the [Overview of Feature Creation on page 771](#) section in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Redefining a Rip Feature

### Function Introduced

---

- **ProFeatureRedefine()**

Use the function `ProFeatureRedefine()` to redefine a Rip feature based on the changes made in the element tree. For more information about `ProFeatureRedefine()`, refer the [Feature Redefine on page 794](#) section in the [Element Trees: Principles of Feature Creation on page 771](#) section.

#### Accessing a Rip Feature

##### Function Introduced

- **ProFeatureElemtreeExtract()**

Use the function `ProFeatureElemtreeExtract()` to retrieve the element tree description of the Rip feature. For more information about `ProFeatureElemtreeExtract()`, refer the [Feature Inquiry on page 792](#) section in the [Element Trees: Principles of Feature Creation on page 771](#) section.

## Corner Relief Feature

Corner relief can be added at each intersection of a pair of bends. When you add relief, sheet metal sections are removed from the model.

The element tree for the Corner Relief feature is documented in the header file `ProSmtCornerRelief.h` and is shown in the following figure:

## Element Tree for Corner Relief Feature

The elements in this tree are described as follows:

| Element ID                    | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_STD_FEATURE_NAME        | PRO_VALUE_TYPE_WSTRING | Specifies the name of the feature. The default value is Corner_Relief_1.                                                                                                                                                                                                                                                                                                              |
| PRO_E_CORNER_RELIEFS          | Compound               | This compound element defines the corner relief sets.                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_CORNER_RELIEFS_CR_STATE | PRO_VALUE_TYPE_INT     | Specifies the corner relief state using the enumerated data type ProCrnRelCrState and has the values: <ul style="list-style-type: none"> <li>PRO_CRN_REL_CR_IN_FORMED—Creates corner relief geometry only when the corner bends are in formed state.</li> <li>PRO_CRN_REL_CR_IN_UNBEND_ONLY—Creates corner relief geometry only when the corner bends are in unbend state.</li> </ul> |
| PRO_E_CORNER_RELIEFS_ARR      | Array                  | An array element of corner relief sets.                                                                                                                                                                                                                                                                                                                                               |

| Element ID                    | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_CORNER_RELIEF_SET       | Compound                 | This compound element contains a corner relief set.                                                                                                                                                                                                                                                                                                                                                           |
| PRO_E_CORNER_RELIEF_REF_ARR   | Array                    | An array element that contains the corners selected in this set.                                                                                                                                                                                                                                                                                                                                              |
| PRO_E_CORNER_RELIEF_REF_SET   | Compound                 | A set of elements that defines a selected corner.                                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_CORNER_RELIEF_REF_TYPE  | PRO_VALUE_TYPE_INT       | Specifies the type of corner relief using the enumerated data type <code>ProCrnRelRefType</code> . The valid values for this element are: <ul style="list-style-type: none"> <li>• <code>PRO_CRN_REL_3_SURFACES</code>—Corner relief must be applied to the specified corners in the model.</li> <li>• <code>PRO_CRN_REL_ALL</code>—Corner relief must be applied to all the corners in the model.</li> </ul> |
| PRO_E_CORNER_RELIEF_REF_FLAT  | PRO_VALUE_TYPE_SELECTION | Specifies selection of a flat surface that is used to locate the corner.                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_CORNER_RELIEF_REF_BND_1 | PRO_VALUE_TYPE_SELECTION | Specifies selection of a first cylindrical surface that is used to locate the corner.                                                                                                                                                                                                                                                                                                                         |
| PRO_E_CORNER_RELIEF_REF_BND_2 | PRO_VALUE_TYPE_SELECTION | Specifies selection of a second cylindrical surface that is used to locate the corner.                                                                                                                                                                                                                                                                                                                        |
| PRO_E_CORNER_RELIEF_DEFINE    | Compound                 | A corner relief compound element.<br><br>Refer to the section <a href="#">Corner Relief Options on page 1374</a> for more details on this element and subsequent child elements.                                                                                                                                                                                                                              |

## Corner Relief Options

The compound element `PRO_E_CORNER_RELIEF_DEFINE` defines the options and values for a corner relief feature.

### Element Tree for Corner Relief Feature Options

```
|-- PRO_E_CORNER_RELIEF_DEFINE (compound)
|
|-- PRO_E_SMT_CORNER_RELIEF (compound)
|
|-- PRO_E_SMT_CORNER_RELIEF_TYPE (option)
|
|-- PRO_E_SMT_CORNER_RELIEF_WIDTH (compound)
|
| |-- PRO_E_SMT_CORNER_RELIEF_WIDTH_TYPE (option)
| |
| |-- PRO_E_SMT_CORNER_RELIEF_WIDTH_VAL (double)
| |
|
|-- PRO_E_SMT_CORNER_RELIEF_DEPTH (compound)
|
| |-- PRO_E_SMT_CORNER_RELIEF_DEPTH_TYPE (option)
| |
| |-- PRO_E_SMT_CORNER_RELIEF_DEPTH_VAL (double)
| |
|
|-- PRO_E_SMT_CORNER_RELIEF_ROTATE (compound)
|
| |-- PRO_E_SMT_CORNER_RELIEF_ROTATE_ADD (option)
| |
| |-- PRO_E_SMT_CORNER_RELIEF_ROTATE_VAL (double)
| |
|
|-- PRO_E_SMT_CORNER_RELIEF_OFFSET (compound)
|
| |-- PRO_E_SMT_CORNER_RELIEF_OFFSET_ADD (option)
| |
| |-- PRO_E_SMT_CORNER_RELIEF_OFFSET_VAL (double)
| |
|
|-- PRO_E_CORNER_RELIEFS_DIM_SCHEME (option)
```

The elements of `PRO_E_CORNER_RELIEF_DEFINE` are described as follows:

| Element ID                                | Data Type                       | Description                                                                                                                    |
|-------------------------------------------|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>PRO_E_CORNER_RELIEF_DEFINE</code>   | Compound                        | A corner relief compound element.                                                                                              |
| <code>PRO_E_SMT_CORNER_RELIEF</code>      | Compound                        | This compound element defines the corner relief properties.                                                                    |
| <code>PRO_E_SMT_CORNER_RELIEF_TYPE</code> | <code>PRO_VALUE_TYPE_INT</code> | Specifies the type of corner relief using the enumerated data type <code>ProCornerRelType</code> and has the following values: |

| Element ID                         | Data Type             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                    |                       | <ul style="list-style-type: none"> <li>• PRO_CORNER_RELIEF_V_NOTCH—Adds a V notch shape cut at the corners.</li> <li>• PRO_CORNER_RELIEF_CIRCULAR—Adds a circular shape relief at the corners with a radius dimension.</li> <li>• PRO_CORNER_RELIEF_RECTANGULAR—Adds a rectangular relief at the corners with a specified width and depth.</li> <li>• PRO_CORNER_RELIEF_OBROUND—Adds an obround relief at the corners with a specified diameter and depth.</li> <li>• PRO_CORNER_RELIEF_NO—Does not add relief and generates square corners.</li> <li>• PRO_CORNER_RELIEF_PARAM—Adds the corner relief as set by the SMT_DFLT_CRNR_REL_TYPE parameter in Creo Parametric.</li> </ul> |
| PRO_E_SMT_CORNER_RELIEF_WIDTH      | Compound              | This compound element defines the width type and width value for corner relief.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_SMT_CORNER_RELIEF_WIDTH_TYPE | PRO_VALUE_TYPE_INT    | Specifies the type of width for the corner relief using the enumerated data type ProSmdRelType and uses one of the values listed in <a href="#">Relation Value Types on page 1336</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PRO_E_SMT_CORNER_RELIEF_WIDTH_VAL  | PRO_VALUE_TYPE_DOUBLE | Specifies the value of width for the corner relief.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| PRO_E_SMT_CORNER_RELIEF_DEPTH      | Compound              | This compound element defines the depth type and depth value for corner relief.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_SMT_CORNER_RELIEF_DEPTH_TYPE | PRO_VALUE_TYPE_INT    | Specifies the type of depth for the corner relief using the enumerated data type ProCornerRlfDepthType and uses one of the values listed in <a href="#">Relation Value Types on page 1336</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Element ID                         | Data Type             | Description                                                                                                                                                                                                                   |
|------------------------------------|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                    |                       | <a href="#">1336</a>                                                                                                                                                                                                          |
| PRO_E_SMT_CORNER_RELIEF_DEPTH_VAL  | PRO_VALUE_TYPE_DOUBLE | Specifies the value of depth value for the corner relief.                                                                                                                                                                     |
| PRO_E_SMT_CORNER_RELIEF_ROTATE     | Compound              | This compound element defines the rotation parameters for corner relief and is applicable only if PRO_E_SMT_CORNER_RELIEF_TYPE value is PRO_CORNER_RELIEF_OBROUND or PRO_CORNER_RELIEF_RECTANGULAR.                           |
| PRO_E_SMT_CORNER_RELIEF_ROTATE_ADD | PRO_VALUE_TYPE_INT    | Specifies if rotation should be added to the relief placement. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE</li> <li>PRO_B_FALSE</li> </ul>                                       |
| PRO_E_SMT_CORNER_RELIEF_ROTATE_VAL | PRO_VALUE_TYPE_DOUBLE | Specifies the value of rotation.                                                                                                                                                                                              |
| PRO_E_SMT_CORNER_RELIEF_OFFSET     | Compound              | This compound element defines the offset parameters for corner relief and is applicable only if PRO_E_SMT_CORNER_RELIEF_TYPE value is PRO_CORNER_RELIEF_CIRCULAR, PRO_CORNER_RELIEF_OBROUND or PRO_CORNER_RELIEF_RECTANGULAR. |
| PRO_E_SMT_CORNER_RELIEF_OFFSET_ADD | PRO_VALUE_TYPE_INT    | Specifies if offset should be added to the relief placement. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE</li> <li>PRO_B_FALSE</li> </ul>                                         |

| Element ID                         | Data Type             | Description                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_SMT_CORNER_RELIEF_OFFSET_VAL | PRO_VALUE_TYPE_DOUBLE | Specifies the offset value.                                                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_CORNER_RELIEFS_DIM_SCHEME    | PRO_VALUE_TYPE_INT    | <p>Specifies the dimension scheme using the enumerated data type <code>ProCrnRelDimRefType</code> and has the values:</p> <ul style="list-style-type: none"> <li>PRO_CRN_REL_DIM_REF_BEND_AXES_XSECTION—Places the relief at the point where the bend edges intersect.</li> <li>PRO_CRN_REL_DIM_REF_CORNER_VERTEX—Places the relief at the point where the bend lines intersect.</li> </ul> |

## Editing Corner Relief Feature

The **Edit Corner Relief** feature removes or edits multiple corner relief design objects in your model. When you edit corner reliefs, you can change the width and depth of different types of reliefs and you can set bounding surfaces to remove. You can edit corner reliefs to no relief or to any one of the types of corner reliefs.

The element tree for the **Edit Corner Relief** feature is documented in the header file `ProSmtEditCornerRelief.h` and is shown in the following figure:

```

| PRO_E_EDIT_CORNER_SEAM_SEL_MODE | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the mode for selecting corner seams. The valid values are: <ul style="list-style-type: none"> <li>PRO_SMT_RECOGNITION_MANUAL_SEL—Specifies manual selection of corner seams to edit.</li> <li>PRO_SMT_RECOGNITION_AUTO_SEL—Specifies automatic selection of corner seams to edit.</li> </ul>                                                                                                                           |
| PRO_E_EDIT_CORNER_SEAM_GEOMS    | Multi Collector        | This element is mandatory when the selection mode is set to PRO_SMT_RECOGNITION_MANUAL_SEL.<br><br>Specifies the selection of geometry for corner seams.                                                                                                                                                                                                                                                                                            |
| PRO_E_REMOVE_CORNER_SEAM        | PRO_VALUE_TYPE_BOOLEAN | Specifies that the corner seam must be removed.                                                                                                                                                                                                                                                                                                                                                                                                     |
| PRO_E_EDIT_CORNER_SEAM_SHAPE    | Compound               | This element is mandatory when the element PRO_E_REMOVE_CORNER_SEAM is set to false.<br><br>This compound element defines the options and sets the values for corner seam edges.                                                                                                                                                                                                                                                                    |
| PRO_E_EDIT_BEND_RCR_CRNR        | PRO_VALUE_BOOLEAN      | Specifies if the corner reliefs must be automatically changed to V notch corner type.                                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_CRNR_SEAM_CR_RND_CHMF     | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies if the rounds and chamfers must be recreated after the corner seams are edited. The input to the element are the values defined by the enumerated data type ProEditBendCrRndChmfOpt. The valid values are: <ul style="list-style-type: none"> <li>PRO_ED_CR_CRNR_SEAM_RND_CHMF— The rounds and chamfers are recreated.</li> <li>PRO_ED_NO_CR_CRNR_SEAM_RND_CHMF— The rounds and chamfers are not recreated.</li> </ul> |
| PRO_E_SMT_EDGE_RIP_TYPE         | PRO_VALUE_TYPE_INT     | Specifies the type of corner seam using the enumerated data type ProEdgeRipType. The valid values are: <ul style="list-style-type: none"> <li>PRO_EDGE_RIP_OPEN— Edits the corner seam at the intersection point of edges.</li> </ul>                                                                                                                                                                                                               |

| Element ID                      | Data Type              | Description                                                                                                                                                                                                                                                                                                                     |
|---------------------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 |                        | <ul style="list-style-type: none"> <li>PRO_EDGE_RIP_BLIND—Edits the corner seam with a gap specified by two dimensions.</li> <li>PRO_EDGE_RIP_MITER_CUT—Edits the corner seam with a gap specified by a single dimension.</li> <li>PRO_EDGE_RIP_OVERLAP—Edits the corner seam such that one edge overlaps the other.</li> </ul> |
| PRO_E_SMT_EDGE_RIP_ADD_GAP      | PRO_VALUE_TYPE_BOOLEAN | Specifies whether to add a gap clearance. This element is applicable only if the element PRO_E_SMT_EDGE_RIP_TYPE is set to PRO_EDGE_RIP_MITER_CUT or PRO_EDGE_RIP_OVERLAP.                                                                                                                                                      |
| PRO_E_SMT_EDGE_RIP_CLOSE_CORNER | PRO_VALUE_TYPE_BOOLEAN | Specifies if the gap between the bend surfaces of a corner relief must be closed. This element is applicable only if the element PRO_E_SMT_EDGE_RIP_TYPE is set to PRO_EDGE_RIP_OPEN.                                                                                                                                           |
| PRO_E_SMT_EDGE_RIP_DIM_1        | Compound               | <p>This element is mandatory when the element PRO_E_SMT_EDGE_RIP_TYPE is set to PRO_EDGE_RIP_BLIND.</p> <p>Specifies a compound element that defines the properties of side 1.</p>                                                                                                                                              |
| PRO_E_SMT_DIMENSION_TYPE        | PRO_VALUE_TYPE_INT     | Specifies the dimension type. For PRO_EDGE_RIP_DIM_TYPE_BLIND dimension type, the relation value is set to PRO_DIM_ENTER.                                                                                                                                                                                                       |
| PRO_E_SMT_DIMENSION_VALUE       | PRO_VALUE_TYPE_DOUBLE  | Specifies the dimension value for side 1.                                                                                                                                                                                                                                                                                       |
| PRO_E_SMT_EDGE_RIP_DIM_2        | Compound               | <p>This element is mandatory when the element PRO_E_SMT_EDGE_RIP_TYPE is set to PRO_EDGE_RIP_BLIND.</p> <p>Specifies a compound element that defines the properties of side 2.</p>                                                                                                                                              |
| PRO_E_SMT_DIMENSION_TYPE        | PRO_VALUE_TYPE_INT     | Specifies the dimension type. For PRO_EDGE_RIP_DIM_TYPE_BLIND dimension type, the relation value is set to PRO_DIM_ENTER.                                                                                                                                                                                                       |
| PRO_E_SMT_DIMENSION_VALUE       | PRO_VALUE_TYPE_DOUBLE  | Specifies the dimension value for                                                                                                                                                                                                                                                                                               |

| Element ID                       | Data Type                | Description                                                                                                                                                                                                                                                                                             |
|----------------------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VALUE                            |                          | side 2.                                                                                                                                                                                                                                                                                                 |
| PRO_E_SMT_EDGE_RIP_GAP           | Compound                 | <p>This element is mandatory when the element PRO_E_SMT_EDGE_RIP_TYPE is set to PRO_EDGE_RIP_MITER_CUT or PRO_E_SMT_EDGE_RIP_ADD_GAP is set to true.</p> <p>Specifies the properties for the gap.</p>                                                                                                   |
| PRO_E_SMT_DIMENSION_TYPE         | PRO_VALUE_TYPE_INT       | Specifies the gap type. For PRO_EDGE_RIP_MITER_CUT and PRO_EDGE_RIP_OVERLAP dimension types the relation value is set to PRO_DIM_ENTER.                                                                                                                                                                 |
| PRO_E_SMT_DIMENSION_VALUE        | PRO_VALUE_TYPE_DOUBLE    | Specifies the value for the gap.                                                                                                                                                                                                                                                                        |
| PRO_E_SMT_EDGE_RIP_FLIP          | PRO_VALUE_TYPE_BOOLEAN   | Specifies if the side of corner seam that overlaps must be flipped.                                                                                                                                                                                                                                     |
| PRO_E_EDIT_CORNER_SEAM_TABLE     | Array                    | Specifies an array element that defines the options to remove the corner seam.                                                                                                                                                                                                                          |
| PRO_E_CORNER_SEAM_RMV_SETTINGS   | Compound                 | Specifies a compound element that defines the options to remove the corner seam.                                                                                                                                                                                                                        |
| PRO_E_EDIT_CORNER_SEAM_RMV_REFS  | Compound                 | Specifies a compound element that defines the corner reference geometry to which the seam is attached. The surface should be planar or two cylinders.                                                                                                                                                   |
| PRO_E_CORNER_SEAM_RMV_FLAT       | PRO_VALUE_TYPE_SELECTION | Specifies a flat surface.                                                                                                                                                                                                                                                                               |
| PRO_E_CORNER_SEAM_RMV_BEND_1     | PRO_VALUE_TYPE_SELECTION | Specifies the first bend surface.                                                                                                                                                                                                                                                                       |
| PRO_E_CORNER_SEAM_RMV_BEND_2     | PRO_VALUE_TYPE_SELECTION | Specifies the second bend surface.                                                                                                                                                                                                                                                                      |
| PRO_E_CORNER_SEAM_BOUNDARIES     | Multi Collector          | Specifies collection of bounding surfaces.                                                                                                                                                                                                                                                              |
| PRO_E_CORNER_SEAM_RMV_SIDE_1     | Compound                 | Specifies a compound element that defines the properties of side 1.                                                                                                                                                                                                                                     |
| PRO_E_CORNER_SEAM_RMV_DEFAULT    | PRO_VALUE_TYPE_BOOLEAN   | Specifies the default option to remove the corner seam for side 1.                                                                                                                                                                                                                                      |
| PRO_E_EDIT_CORNER_SEM_RMV_METHOD | PRO_VALUE_TYPE_INT       | <p>Specifies the method to remove the corner seam for side 1. The valid values are specified using the enumerated data type ProEditCornerSeamRemove Type:</p> <ul style="list-style-type: none"> <li>PRO_CORNER_SEAM_REMOVE_TANGENT—Extends or trims the bounding surface making it a planar</li> </ul> |

| Element ID                       | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                  |                        | <p>surface tangent to original surface.</p> <ul style="list-style-type: none"> <li>• PRO_CORNER_SEAM_REMOVE_SAME—Extends or trims the bounding surface by continuing past its original boundaries and keeping the same type of surface.</li> <li>• PRO_CORNER_SEAM_REMOVE_PARALLEL—Extends or trims the bounding surface parallel to the bend axis.</li> <li>• PRO_CORNER_SEAM_REMOVE_COMMON_VERTEX—Extends or trims the bounding surface normal to the corner.</li> <li>• PRO_CORNER_SEAM_REMOVE_NORMAL—Finds the common vertex for intersection of both bounding surfaces.</li> </ul> |
| PRO_E_CORNER_SEAM_RMV_SIDE_2     | Compound               | Specifies a compound element that defines the properties of side 2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| PRO_E_CORNER_SEAM_RMV_DEFAULT    | PRO_VALUE_TYPE_BOOLEAN | Specifies the default option to remove the corner seam for side 2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_EDIT_CORNER_SEM_RMV_METHOD | PRO_VALUE_TYPE_INT     | Specifies the method to remove the corner seam for side 2 using the enumerated data type ProEditCornerSeamRemove Type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Bend Feature

The Bend feature allows you to bend the sheet metal in different ways using the bend line or an edge or a curve and by defining specific radius and angle.

The element tree for the Bend feature is documented in the header file ProSmtBend.h and is as shown in the following figure:

## Feature Element Tree for Bend Feature

The elements in this tree are described as follows:

| Element ID                | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE        | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_BEND.                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_STD_FEATURE_NAME    | PRO_VALUE_TYPE_WSTRING | Specifies the name of the feature. The default value is Bend_1.                                                                                                                                                                                                                                                                                                                                                                                     |
| PRO_E_SMT_BEND_FORM       | PRO_VALUE_TYPE_INT     | Specifies the type of bend using the enumerated data type ProBendForm. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_SMT_BEND_FORM_ANGLE—Specifies an angled type of bend.</li> <li>PRO_SMT_BEND_FORM_ROLL—Specifies a rolled type of bend.</li> </ul>                                                                                                                                                          |
| PRO_E_SMT_BEND_LINE       | Compound               | This compound element defines the bend line properties. For more information, see the section <a href="#">Bend Line Elements on page 1388</a> .                                                                                                                                                                                                                                                                                                     |
| PRO_E_SMT_BEND_FIXED_SIDE | PRO_VALUE_TYPE_INT     | Specifies the fixed side of the bend using the enumerated data type ProBendSide. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_SMT_BEND_SIDE_ONE—Specifies first side as the fixed side.</li> <li>PRO_SMT_BEND_SIDE_TWO—Specifies the second side as the fixed side.</li> </ul>                                                                                                                                 |
| PRO_E_SMT_BEND_LOCATION   | PRO_VALUE_TYPE_INT     | Specifies the location of the bend in relation to the bend line, using the enumerated data type ProBendSide. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_SMT_BEND_SIDE_ONE—Specifies a bend up to the bend line.</li> <li>PRO_SMT_BEND_SIDE_TWO—Specifies a bend up to the other side of the bend line.</li> <li>PRO_SMT_BEND_BOTH_SIDES—Specifies a bend centered on both sides of the bend line.</li> </ul> |
| PRO_E_SMT_BEND_DIRECTION  | PRO_VALUE_TYPE_INT     | Specifies the direction of the bend using the enumerated data type ProBendSide. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_SMT_BEND_SIDE_ONE—Specifies the bend direction normal to the</li> </ul>                                                                                                                                                                                                           |

| Element ID                 | Data Type             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            |                       | <p>selected surface.</p> <ul style="list-style-type: none"> <li>PRO_SMT_BEND_SIDE_TWO—Flips the bend direction.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| PRO_E_SMT_BEND_ANGLE       | Compound              | <p>This compound element and its sub-elements are available when the element PRO_E_SMT_BEND_FORM has its value as PRO_SMT_BEND_FORM_ANGLE.</p> <p>The compound element defines the bend angle.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| PRO_E_SMT_BEND_ANGLE_TYPE  | PRO_VALUE_TYPE_INT    | <p>Specifies the bend angle type using the enumerated data type ProBendAngleType. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_SMT_BEND_ANGLE_INTERNAL—Specifies the resulting internal bend angle.</li> <li>PRO_SMT_BEND_ANGLE_EXTERNAL—Specifies the bend angle deflection from straight.</li> </ul>                                                                                                                                                                                                                                                                                     |
| PRO_E_SMT_BEND_ANGLE_VALUE | PRO_VALUE_TYPE_DOUBLE | Specifies the value of the bend angle.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PRO_E_SMT_BEND_TRANS_FLIP  | PRO_VALUE_TYPE_INT    | <p>Flips the direction where the bend cylinder will be created along the bend transition line using the enumerated data type ProBendSide. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_SMT_BEND_SIDE_ONE—Creates the cylinder along the first line of the transition.</li> <li>PRO_SMT_BEND_SIDE_TWO—Creates the cylinder along the second line of the transition.</li> </ul> <p> <b>Note</b></p> <p>The transition flip element is available only if there is one transition set in the feature.</p> |
| PRO_E_SMT_BEND_TRANS_AREAS | Array                 | An array element of bend transition lines that defines the bend transition area.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| PRO_E_SMT_BEND_TRANS_SET   | Compound              | This compound element defines the bend transition lines.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_STD_SECTION          | Compound              | This compound element specifies a sketched section for the bend line. For more information on how                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Element ID                    | Data Type             | Description                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               |                       | to create features that contain sketched sections, refer to the section <a href="#">Creating Features Containing Sections on page 1004</a> .                                                                                                                                                                                                                                                                             |
| PRO_E_SMT_FILLETS             | Compound              | This compound element defines the bend properties of the sheet metal wall and the value of bend radius.                                                                                                                                                                                                                                                                                                                  |
| PRO_E_SMT_FILLETS_SIDE        | PRO_VALUE_TYPE_INT    | Specifies the fillet side. The valid values are: <ul style="list-style-type: none"> <li>PRO_BEND_RAD_OUTSIDE—Applies the bend radius to the outer surface of the bend.</li> <li>PRO_BEND_RAD_INSIDE—Applies the bend radius to the inner surface of the bend.</li> <li>PRO_BEND_RAD_PARAMETER—Applies the bend radius at the dimension location set by the SMT_DFLT_RADIUS_SIDE parameter in Creo Parametric.</li> </ul> |
| PRO_E_SMT_FILLETS_VALUE       | PRO_VALUE_TYPE_DOUBLE | Specifies the value of the bend radius.                                                                                                                                                                                                                                                                                                                                                                                  |
| PRO_E_SMT_BEND_RELIEF         | Compound              | This compound element defines the bend relief at the edges. For more information see the section <a href="#">Bend Relief Elements on page 1392</a> .                                                                                                                                                                                                                                                                     |
| PRO_E_SMT_DEV_LEN_CALCULATION | Compound              | This compound element defines the method used to calculate the Developed Length dimensions for the bends. For more information see the section <a href="#">The Element Subtree for Length Calculation on page 1322</a> .                                                                                                                                                                                                 |

## Bend Line Elements

This compound element PRO\_E\_SMT\_BEND\_LINE defines the bend line, its properties and references for sheet metal bends.

```

```

The elements of PRO\_E\_SMT\_BEND\_LINE are described as follows:

| Element ID                 | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_SMT_BEND_LINE_TYPE   | PRO_VALUE_TYPE_INT       | <p>Specifies the type of bend using the enumerated data type <code>ProBendLineType</code>. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>• <code>PRO_SMT_BEND_LINE_NOT_DEFINED</code>—Specifies an undefined bend line.</li> <li>• <code>PRO_SMT_BEND_LINE_SKETCH</code> Specifies a user defined bend line.</li> <li>• <code>PRO_SMT_BEND_LINE_CURVE</code>—Specifies a linear chain to be used as the bend line.</li> <li>• <code>PRO_SMT_BEND_LINE_INTERNAL_LINE</code>—Specifies the bend line that will be created based on the compound element <code>PRO_E_SMT_BEND_LINE_INTERNAL</code>.</li> </ul> |
| PRO_E_SMT_BEND_REF_SURFACE | PRO_VALUE_TYPE_SELECTION | <p>This element is available when the value of element <code>PRO_E_SMT_BEND_LINE_TYPE</code> is <code>PRO_SMT_BEND_LINE_INTERNAL_LINE</code> or <code>PRO_SMT_BEND_LINE_SKETCH</code>.</p> <p>Specifies the surface to be bent. This is the surface on which the bend line is set.</p>                                                                                                                                                                                                                                                                                                                                                          |
| PRO_E_STD_SECTION          | Compound                 | <p>This compound element and its sub-elements are available only if the element <code>PRO_E_SMT_BEND_LINE_TYPE</code> has its value as <code>PRO_SMT_BEND_LINE_SKETCH</code>.</p> <p>The compound element specifies a sketched section for the bend line. For more information on how to create features that contain sketched sections, refer to the section <i>Creating Features Containing Sections</i> on page 1147.</p>                                                                                                                                                                                                                    |
| PRO_E_SMT_BEND_CURVE       | Compound                 | <p>This element and its sub-elements are available when the element <code>PRO_E_SMT_BEND_LINE_TYPE</code> has its value as <code>PRO_SMT_BEND_LINE_CURVE</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Element ID                        | Data Type                | Description                                                                                                                                                                                                                              |
|-----------------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   |                          | This compound element defines the curve references and bend curve offset value.                                                                                                                                                          |
| PRO_E_STD_CURVE_COLLECTION_APPL   | PRO_VALUE_TYPE_POINTER   | Specifies a surface edge or a curve that defines the bend line.                                                                                                                                                                          |
| PRO_E_SMT_BEND_CURVE_USE_OFFSET   | PRO_VALUE_TYPE_INT       | Specifies whether to offset the bend curve from the selected reference. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE</li> <li>PRO_B_FALSE</li> </ul>                                         |
| PRO_E_SMT_BEND_CURVE_OFFSET_VALUE | PRO_VALUE_TYPE_DOUBLE    | Specifies the offset value for the bend curve.                                                                                                                                                                                           |
| PRO_E_SMT_BEND_LINE_INTERNAL      | Compound                 | This element and its sub-elements are available when the element PRO_E_SMT_BEND_LINE_TYPE has its value as PRO_SMT_BEND_LINE_INTERNAL_LINE.<br><br>The compound element defines the bend line reference ends, offsets and offset values. |
| PRO_E_SMT_BEND_LINE_REF_END1      | PRO_VALUE_TYPE_SELECTION | Specifies a vertex or an edge as the placement reference for the first end of the bend line.                                                                                                                                             |
| PRO_E_SMT_BEND_LINE_REF_END2      | PRO_VALUE_TYPE_SELECTION | Specifies a vertex or an edge as the placement reference for the second end of the bend line.                                                                                                                                            |
| PRO_E_SMT_BEND_LINE_REF_OFFSET1   | PRO_VALUE_TYPE_SELECTION | This element is available when you choose an edge reference in the element PRO_E_SMT_BEND_LINE_REF_END1.<br><br>Specifies an edge as the offset reference for the first end of the bend line.                                            |
| PRO_E_SMT_BEND_LINE_REF_OFFSET2   | PRO_VALUE_TYPE_SELECTION | This element is available when you choose an edge reference in the element PRO_E_SMT_BEND_LINE_REF_END2.<br><br>Specifies an edge as the offset reference for the second end of the bend line.                                           |

| Element ID                            | Data Type             | Description                                                                                                                                                                             |
|---------------------------------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_SMT_BEND_LINE_REF_OFFSET1_VALUE | PRO_VALUE_TYPE_DOUBLE | <p>This element is available when you choose an edge reference in the element PRO_E_SMT_BEND_LINE_REF_END1.</p> <p>Specifies the offset value from the first end of the bend line.</p>  |
| PRO_E_SMT_BEND_LINE_REF_OFFSET2_VALUE | PRO_VALUE_TYPE_DOUBLE | <p>This element is available when you choose an edge reference in the element PRO_E_SMT_BEND_LINE_REF_END2.</p> <p>Specifies the offset value from the second end of the bend line.</p> |

## Bend Relief Elements

The compound element PRO\_E\_SMT\_BEND\_RELIEF defines the bend relief elements. The relief can be specified differently on each side of the bend.

```

--PRO_E_SMT_BEND_RELIEF
|
| --PRO_E_SMT_BEND_RELIEF_SIDE1
| |
| | --PRO_E_BEND_RELIEF_TYPE
| |
| | --PRO_E_BEND_RELIEF_WIDTH
| |
| | --PRO_E_BEND_RELIEF_DEPTH_TYPE
| |
| | --PRO_E_BEND_RELIEF_DEPTH
| |
| | --PRO_E_BEND_RELIEF_LENGTH_TYPE
| |
| | --PRO_E_BEND_RELIEF_LENGTH
| |
| | --PRO_E_BEND_RELIEF_ANGLE
| |
| --PRO_E_SMT_BEND_RELIEF_SIDE2
| |
| | --PRO_E_BEND_RELIEF_TYPE
| |
| | --PRO_E_BEND_RELIEF_WIDTH
| |
| | --PRO_E_BEND_RELIEF_DEPTH_TYPE
| |
| | --PRO_E_BEND_RELIEF_DEPTH
| |
| | --PRO_E_BEND_RELIEF_LENGTH_TYPE
| |
| | --PRO_E_BEND_RELIEF_LENGTH
| |
| | --PRO_E_BEND_RELIEF_ANGLE
|

```

The two main elements of PRO\_E\_SMT\_BEND\_RELIEF are:

- PRO\_E\_SMT\_BEND\_RELIEF\_SIDE1—This compound element specifies the bend relief applied to the first side of the end of the bend.
- PRO\_E\_SMT\_BEND\_RELIEF\_SIDE2—This compound element specifies the bend relief applied to the second side of the end of the bend.

The following elements are common to the both the compound elements:

| Element ID                   | Data Type             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_BEND_RELIEF_TYPE       | PRO_VALUE_TYPE_INT    | <p>Specifies the relief type using the enumerated data type <code>ProBendRlfType</code>. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>• <code>PRO_BEND_RLF_NONE</code>— Specifies no relief.</li> <li>• <code>PRO_BEND_RLF_RIP</code>— Specifies ripping of the material.</li> <li>• <code>PRO_BEND_RLF_STRETCH</code>— Specifies stretching of the material for bend relief.</li> <li>• <code>PRO_BEND_RLF_RECTANGULAR</code>— Specifies adding a rectangular relief.</li> <li>• <code>PRO_BEND_RLF_OBROUND</code>— Specifies adding an obround relief.</li> <li>• <code>PRO_BEND_RLF_PARAM</code>— Specifies relief type set by the part parameter <code>SMT_DFLT_BEND_REL_TYPE</code>.</li> </ul> |
| PRO_E_BEND_RELIEF_WIDTH      | PRO_VALUE_TYPE_DOUBLE | <p>Specifies the relief width and is applicable only if the value of <code>PRO_E_BEND_RELIEF_TYPE</code> is <code>PRO_BEND_RLF_RECTANGULAR</code>, <code>PRO_BEND_RLF_STRETCH</code> or <code>PRO_BEND_RLF_OBROUND</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_BEND_RELIEF_DEPTH_TYPE | PRO_VALUE_TYPE_INT    | <p>Specifies the type of depth relief. The valid values for this element are defined in the enumerated type <code>ProBendRlfDepthType</code> and are as follows:</p> <ul style="list-style-type: none"> <li>• <code>PRO_BEND_RLF_DEPTH_NOT_USED</code>— Specifies that the depth for the relief is not used.</li> <li>• <code>PRO_BEND_RLF_DEPTH_BLIND</code>— Creates a relief through the geometry as per the specified value.</li> <li>• <code>PRO_BEND_RLF_DEPTH_UP_TO_BEND</code>— Creates a relief up to the bend.</li> <li>• <code>PRO_BEND_RLF_DEPTH_TAN_TO_BEND</code>— Creates a relief tangential to the bend. <code>PRO_BEND_RLF_DEPTH_TAN_TO_BEND</code> is applicable</li> </ul>                                            |

| Element ID | Data Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            |           | <p>only when relief type is set to PRO_BEND_RLF_OBROUND.</p> <ul style="list-style-type: none"> <li>PRO_BEND_RLF_DEPTH_TYPE_PARAM— Specifies the depth type of the relief at the dimension location and is set by part parameter SMT_DFLT_BEND_REL_DEPTH_TYPE.</li> </ul> <p>This element decides the visibility of the bend relief depth element PRO_E_BEND_RELIEF_DEPTH. If PRO_E_BEND_RELIEF_DEPTH_TYPE is set to PRO_BEND_RLF_DEPTH_BLIND or PRO_BEND_RLF_DEPTH_TYPE_PARAM and the part parameter SMT_DFLT_BEND_REL_DEPTH_TYPE is set to <b>Blind</b>, then the existing element PRO_E_BEND_RELIEF_DEPTH is used.</p> <p>PTC recommends that you define the element PRO_E_BEND_RELIEF_DEPTH_TYPE explicitly for all Creo TOOLKIT applications. If the element PRO_E_BEND_RELIEF_DEPTH_TYPE is not defined, the default value is used. The default value from Creo Parametric 1.0 onwards, depends on the part parameter SMT_DFLT_BEND_REL_DEPTH_TYPE and the configuration option SMT_DRIVE_TOOLS_BY_PARAMETERS.</p> <p>If the value of the configuration option SMT_DRIVE_TOOLS_BY_PARAMETERS is set to No, then the default value is the last bend relief type, as selected in Creo Parametric during the creation of the new feature. For the Pro/TOOLKIT applications</p> |

| Element ID                    | Data Type             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               |                       | prior to Creo Parametric 1.0, if the default value is not Blind, then the element PRO_E_BEND_RELIEF_DEPTH_TYPE is not used. For such cases, set the PRO_E_BEND_RELIEF_DEPTH_TYPE to PRO_BEND_RLF_DEPTH_BLIND.                                                                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_BEND_RELIEF_DEPTH       | PRO_VALUE_TYPE_DOUBLE | Specifies the relief depth and is applicable only if the value of PRO_E_BEND_RELIEF_TYPE is PRO_BEND_RLF_RECTANGULAR or PRO_BEND_RLF_OBROUND.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_BEND_RELIEF_LENGTH_TYPE | PRO_VALUE_TYPE_INT    | Specifies the type of the relief length and is defined by the enumerated data type ProBendRlfLengthType. The valid values follow: <ul style="list-style-type: none"> <li>PRO_BEND_RLF_LENGTH_NOT_USED</li> <li>PRO_BEND_RLF_LENGTH_BLIND—Creates the bend reliefs with a length of the specified value.</li> <li>PRO_BEND_RLF_LENGTH_TO_NEXT—Creates the bend reliefs with a length to the next surface.</li> <li>PRO_BEND_RLF_LENGTH_THROUGH_ALL—Creates the bend reliefs through all surfaces.</li> <li>PRO_BEND_RLF_LENGTH_TYPE_PARAM—Uses the SMT_DFLT_BEND_REL_LENGTH_TYPE parameter value.</li> </ul> |
| PRO_E_BEND_RELIEF_LENGTH      | PRO_VALUE_TYPE_DOUBLE | Specifies the value of the relief length.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| PRO_E_BEND_RELIEF_ANGLE       | PRO_VALUE_TYPE_DOUBLE | Specifies the relief angle and is applicable only if the value of PRO_E_BEND_RELIEF_TYPE is PRO_BEND_RLF_STRETCH.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Editing Bend Reliefs

The Edit Bend Relief feature enables you to edit bend reliefs in existing bends.

The element tree for the Edit Bend Relief feature is documented in the header file `ProSmtEditBendRelief.h` and is shown in the following figure:

### Feature Element Tree for Edit Bend Relief Feature

The elements in this tree are described as follows:

| Element ID                      | Data Type              | Description                                                                                                                                                    |
|---------------------------------|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE              | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the type of feature. The value of this feature must be PRO_FEAT_EDIT_BEND_RELIEF.                                                 |
| PRO_E_STD_FEATURE_NAME          | PRO_VALUE_TYPE_WSTRING | Mandatory element. Specifies the name of the feature. The default value is EDIT_BEND_RELIEF_1.                                                                 |
| PRO_E_EDIT_BEND_RELIEF          | Compound               | Mandatory element. This compound element defines the options and sets the values for editing a bend relief.                                                    |
| PRO_E_EDIT_BEND_RELIEF_SEL_MODE | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the mode for selecting bend reliefs. The valid values are: <ul style="list-style-type: none"> <li>PRO_SMT_RECOGNITION_</li> </ul> |

| Element ID                   | Data Type             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              |                       | <p>MANUAL_SEL—Specifies manual selection of bend reliefs to edit.</p> <ul style="list-style-type: none"> <li>PRO_SMT_RECOGNITION_AUTO_SEL—Specifies automatic selection of bend reliefs to edit.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_EDIT_BEND_RELIEF_GEOMS | Multi Collector       | <p>This element is mandatory when the selection mode is set to PRO_SMT_RECOGNITION_MANUAL_SEL. Specifies the selection of geometry for bend reliefs.</p> <p>You can select valid bend relief design objects, geometry of recognizable bend reliefs, or surfaces of bends for which bend reliefs can be edited. You can also select planes with adjacent bends. If an intent surface is selected, all the surfaces which are not relevant will be ignored. Thickness edges can be selected when side surfaces cannot be selected. Bend relief vertices can be selected when neither side surfaces nor thickness edges can be selected.</p> |
| PRO_E_EDIT_BEND_RELIEF_SHAPE | Compound              | Mandatory element. This compound element specifies the options that define the shape of a bend relief.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| PRO_E_BEND_RELIEF_TYPE       | PRO_VALUE_TYPE_INT    | <p>Mandatory element. Specifies the type of bend relief. The valid values are:</p> <ul style="list-style-type: none"> <li>PRO_BEND_RLF_RIP—The selected bend reliefs are edited to rip reliefs with no dimensions.</li> <li>PRO_BEND_RLF_RECTANGULAR—The selected bend reliefs are edited to rectangular reliefs with width and depth dimensions.</li> <li>PRO_BEND_RLF_OBROUND—The bend relief is edited to an obround relief with width and depth dimensions.</li> </ul>                                                                                                                                                                |
| PRO_E_BEND_RELIEF_WIDTH      | PRO_VALUE_TYPE_DOUBLE | This element is mandatory when the element PRO_E_BEND_                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Element ID                    | Data Type             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               |                       | <p>RELIEF_TYPE is set to PRO_BEND_RLF_RECTANGULAR or PRO_BEND_RLF_OBROUND.</p> <p>Specifies the value for width in a bend relief.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PRO_E_BEND_RELIEF_DEPTH_TYPE  | PRO_VALUE_TYPE_INT    | <p>This element is mandatory when the element PRO_E_BEND_RELIEF_TYPE is set to PRO_BEND_RLF_RECTANGULAR or PRO_BEND_RLF_OBROUND.</p> <p>Specifies the type of depth for bend relief. The valid values are:</p> <ul style="list-style-type: none"> <li>PRO_BEND_RLF_DEPTH_BLIND—Creates a relief through the geometry as per the specified value.</li> <li>PRO_BEND_RLF_DEPTH_UP_TO_BEND—Creates a relief up to the bend.</li> <li>PRO_BEND_RLF_DEPTH_TAN_TO_BEND—This depth type is applicable only for bend relief type PRO_BEND_RLF_OBROUND. Creates a relief tangential to the bend.</li> </ul> |
| PRO_E_BEND_RELIEF_DEPTH       | PRO_VALUE_TYPE_DOUBLE | <p>This element is mandatory when the element PRO_E_BEND_RELIEF_DEPTH_TYPE is set to PRO_BEND_RLF_DEPTH_BLIND.</p> <p>Specifies the value for depth in a bend relief. The depth is measured from the edge of the bend.</p>                                                                                                                                                                                                                                                                                                                                                                         |
| PRO_E_BEND_RELIEF_LENGTH_TYPE | PRO_VALUE_TYPE_INT    | <p>This element is mandatory and it specifies the type of the relief length. It is defined by the enumerated data type ProBendRlfLengthType and the valid values follow:</p> <ul style="list-style-type: none"> <li>PRO_BEND_RLF_LENGTH_NOT_USED</li> <li>PRO_BEND_RLF_LENGTH_BLIND—Creates the bend reliefs with a length of the specified value.</li> <li>PRO_BEND_RLF_LENGTH_TO_NEXT—Creates the bend</li> </ul>                                                                                                                                                                                |

| Element ID                                | Data Type                          | Description                                                                                                                                                                                                                                                                                                                   |

## Edge Bend Feature

The Edge Bend feature allows you to round sharp edges of a sheet metal.

The element tree for the Edge Bend feature is documented in the header file `ProSmtEdgeBend.h` and is shown in the following figure:

## Feature Element Tree for Edge Bend Feature

The elements in this tree are described as follows:

| Element ID                      | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE              | PRO_VALUE_TYPE_INT     | Specifies the type of feature. The value of this feature must be PRO_FEAT_EDGE_BEND.                                                                                                                                                                                                                                                                                                                                                                                                              |
| PRO_E_STD_FEATURE_NAME          | PRO_VALUE_TYPE_WSTRING | Specifies the name of the feature. The default value is Edge_Bend_1.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PRO_E_SMT_EDGE_BEND_ARRAY       | Array                  | An array element of single or multiple Edge Bend sets.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_SMT_EDGE_BEND_SET         | Compound               | This compound element contains a single edge bend set.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_SMT_EDGE_BEND_REFERENCES  | Array                  | An array element of surface edges, that form an edge bend set.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| PRO_E_SMT_EDGE_REFERENCES       | Compound               | This compound element defines the collection of surface edge or a curve.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| PRO_E_STD_CURVE_COLLECTION_APPL | PRO_VALUE_TYPE_POINTER | Specifies the sharp edges to be rounded.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| PRO_E_SMT_FILLET_SELECT         | Compound               | This compound element defines the bend properties and the value of the bend radius.                                                                                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_SMT_FILLET_RADIUS_SIDE    | PRO_VALUE_TYPE_INT     | Specifies the fillet side using the enumerated data type ProSmdRadType. The valid values for this element are as follows: <ul style="list-style-type: none"> <li>PRO_BEND_RAD_OUTSIDE—Applies the bend radius to the outer surface of the bend.</li> <li>PRO_BEND_RAD_INSIDE—Applies the bend radius to the inner surface of the bend.</li> <li>PRO_BEND_RAD_PARAMETER—Applies the bend radius at the dimension location set by the SMT_DFLT_RADIUS_SIDE parameter in Creo Parametric.</li> </ul> |
| PRO_E_SMT_FILLET_RADIUS_VALUE   | PRO_VALUE_TYPE_DOUBLE  | Specifies the value of the bend radius.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Element ID                    | Data Type | Description                                                                                                                                                                                                          |
|-------------------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_SMT_BEND_RELIEF         | Compound  | This compound element defines the bend relief at the edges. Refer to the section <a href="#">Bend Relief Elements on page 1392</a> for more information.                                                             |
| PRO_E_SMT_DEV_LEN_CALCULATION | Compound  | This compound element defines the method used to calculate the Developed Length dimensions for bends. For more information see the section <a href="#">The Element Subtree for Length Calculation on page 1322</a> . |

## Unbend Feature

The unbend feature allows you to unbend one or more cylinder based curvature surfaces such as bends or curved walls in a sheet metal part.

The element tree for the Unbend feature is documented in the header file `ProRegularUnbend.h` and is shown in the following figure:

## Feature Element Tree for Unbend Feature

| Element ID                        | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   |                          | element takes the valid value<br>PRO_SMT_REGULAR_UNBEND.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_SMT_UNBEND_SUB_TYPE         | PRO_VALUE_TYPE_INT       | Specifies the type of unbend execution using the enumerated data type ProUnbendSubType which has the following values: <ul style="list-style-type: none"> <li>PRO_UNBEND_ALL—Specifies that all the curved surfaces and edges must be automatically selected for unbend.</li> <li>PRO_UNBEND_SELECTED—Specifies that the curved surfaces and edges must be manually selected for unbend.</li> </ul>                                                                                                                  |
| PRO_E_SMT_PRIMARY_FIXED_GEOM      | Compound                 | This compound element defines a surface or an edge that remains fixed during the unbending.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| PRO_E_SMT_FIXED_REF               | PRO_VALUE_TYPE_SELECTION | Specifies a surface or edge that remains fixed during unbending.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| PRO_E_SMT_FIXED_REF_SIDE          | PRO_VALUE_TYPE_INT       | This element is applicable only if a sharp edge is selected as the fixed reference in the element PRO_E_SMT_FIXED_REF.<br><br>Flips the edge and one of the surfaces the edge lies in between, to remain fixed during unbending, using the enumerated data type ProSmtFixedRefSide. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_SMT_FIXED_SIDE_ONE—First side from the edge will be fixed.</li> <li>PRO_SMT_FIXED_SIDE_TWO—Second side from the edge will be fixed.</li> </ul> |
| PRO_E_SMT_UNBEND_REF_ARR          | Array                    | An array element defining the list of edges to unbend.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_SMT_UNBEND_REF              | Compound                 | This compound element defines collection of geometry to be unbent.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| PRO_E_SMT_UNBEND_SINGLE_REF       | PRO_VALUE_TYPE_SELECTION | Specifies edge or surface or intent surface or intent chain to unbend.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_SMT_DEFORM_SURFACES         | Compound                 | This compound element defines the deformation surfaces.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PRO_E_STD_SURF_COLLECTION_APPL    | PRO_VALUE_TYPE_POINTER   | Collects the surfaces to be used as deformation areas.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_SMT_ADD_CORNER_RELIEFS_OPTS | Compound                 | This compound element defines the relief parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Element ID                        | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_SMT_ADD_CORNER_RELIEFS      | PRO_VALUE_TYPE_BOOLEAN | Specifies if the relief geometry must be created. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE</li> <li>PRO_B_FALSE</li> </ul>                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_SMT_ADD_CORNER_RELIEFS_TYPE | PRO_VALUE_TYPE_INT     | Specifies the corner relief settings using the enumerated data type <code>ProSmtAddCornRelType</code> . The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_SMT_ADD_CORN_REL_UNDEF—Specifies that the corner relief parameter is undefined.</li> <li>PRO_SMT_ADD_CORN_REL_BY_FLAT_PAT—Creates the corner relief geometry on the model.</li> <li>PRO_SMT_ADD_CORN_REL_BY_PARAMS—Does not create the corner relief geometry on the model.</li> </ul>                                 |
| PRO_E_SMT_FLATTEN_FORM_WALLS      | PRO_VALUE_TYPE_BOOLEAN | Specifies if the walls adjusted to form geometry must be unbent. When forms are also flattened, geometry is first unbent. The valid values are: <ul style="list-style-type: none"> <li>PRO_B_TRUE</li> <li>PRO_B_FALSE</li> </ul> <div>  <b>Note</b> <p>You can specify the value for this element only if the enumerated data type <code>ProUnbendSubType</code> is set to the value <code>PRO_UNBEND_ALL</code>.</p> </div> |
| PRO_E_SMT_FLATTEN_ALL_FORMS       | PRO_VALUE_TYPE_BOOLEAN | Specifies if all the forms in the model must be flattened. The valid values are: <ul style="list-style-type: none"> <li>PRO_B_TRUE</li> </ul>                                                                                                                                                                                                                                                                                                                                                                    |

| Element ID                  | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                             |                        | <ul style="list-style-type: none"> <li>PRO_B_FALSE</li> </ul> <p> <b>Note</b></p> <p>You can specify the value for this element only if the enumerated data type <code>ProSmtUnbendType</code> is set to the value <code>PRO_SMT_FLAT_PATTERN</code>.</p>                                                                                                                                             |
| PRO_E_SMT_FLATTEN_PROJ_CUTS | PRO_VALUE_TYPE_BOOLEAN | Specifies if cuts must be projected to the flattened form.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_SMT_MERGE_SAME_SIDES  | PRO_VALUE_TYPE_BOOLEAN | <p>Specifies if the side surfaces located in the same location must be kept. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_B_TRUE</li> <li>PRO_B_FALSE</li> </ul> <p> <b>Note</b></p> <p>You can specify the value for this element only if the enumerated data type <code>ProSmtUnbendType</code> is set to the value <code>PRO_SMT_FLAT_PATTERN</code>.</p> |

## Flat Pattern Feature

The Flat Pattern feature creates a flattened version of a sheet metal part.

This feature uses the same element tree as the Unbend feature documented in the header file `ProRegularUnbend.h`. It shares most of the elements with the Unbend feature tree. The following elements are specific to Flat Pattern feature:

- PRO\_E\_FEATURE\_TYPE—Specifies the type of feature. The value of this feature must be `PRO_FEAT_FLAT_PAT`.
- PRO\_E\_SMT\_UNBEND\_TYPE—Creates a flattened sheet metal part using the enumerated data type `ProSmtUnbendType`. This element takes the valid value `PRO_SMT_FLAT_PATTERN`.
- PRO\_E\_SMT\_FLATTEN\_ALL\_FORMS—Specifies if all the forms in the model must be flattened. The valid values are:
  - PRO\_B\_TRUE
  - PRO\_B\_FALSE

- `PRO_E_SMT_MERGE_SAME_SIDES`—Specifies if the side surfaces located in the same location must be kept. The valid values for this element are:
  - `PRO_B_TRUE`
  - `PRO_B_FALSE`

## Bend Back Feature

The bend back feature allows you to return the unbent walls to their formed bent positions in a sheet metal part.

The element tree for the bend back feature is documented in the header file `ProSmtBendBack.h` and is shown in the following figure:

### Element Tree for Bend Back Feature

| Element ID                        | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE                | PRO_VALUE_TYPE_INT       | Specifies the type of feature. The value of this feature must be PRO_FEAT_BEND_BACK.                                                                                                                                                                                                                                                                                                                                                                                    |
| PRO_E_STD_FEATURE_NAME            | PRO_VALUE_TYPE_WSTRING   | Specifies the name of the feature. The default value is Bend_Back_1.                                                                                                                                                                                                                                                                                                                                                                                                    |
| PRO_E_SMT_BEND_BACK_SUB_TYPE      | PRO_VALUE_TYPE_INT       | Specifies if all or selected geometry must be bent. The enumerated data type ProBendBackSubType contains the valid values for this element and are as follows: <ul style="list-style-type: none"> <li>PRO_BEND_BACK_ALL— Specifies that all unbent geometry must be bent back.</li> <li>PRO_BEND_BACK_SELECTED— Specifies that only the specified geometry must be bent back.</li> </ul>                                                                                |
| PRO_E_SMT_PRIMARY_FIXED_GEOM      | Compound                 | This compound element defines the fixed geometry during the bend back operation.                                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_SMT_FIXED_REF               | PRO_VALUE_TYPE_SELECTION | Specifies a surface or edge that remains fixed during the bend back operation.                                                                                                                                                                                                                                                                                                                                                                                          |
| PRO_E_SMT_FIXED_REF_SIDE          | PRO_VALUE_TYPE_INT       | Specifies the flip option for the side of the edge that will remain fixed during the bend back operation. The valid values for this element are defined in the enumerated data type ProSmtFixedRefSide and are as follows: <ul style="list-style-type: none"> <li>PRO_SMT_FIXED_SIDE_ONE—First edge side of the selected fixed geometry will be fixed.</li> <li>PRO_SMT_FIXED_SIDE_TWO—Second edge side normal to the selected fixed geometry will be fixed.</li> </ul> |
| PRO_E_SMT_BBACK_REF_ARR           | Array                    | An array element of edges or surfaces to be bent back.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| PRO_E_SMT_BBACK_REF               | Compound                 | This compound element defines collection of edges or surfaces to be bent back.                                                                                                                                                                                                                                                                                                                                                                                          |
| PRO_E_SMT_BBACK_SINGLE_REF        | PRO_VALUE_TYPE_SELECTION | Specifies collection of edges, surfaces, intent surfaces and chains to be bent back.                                                                                                                                                                                                                                                                                                                                                                                    |
| PRO_E_SMT_BBACK_FLAT_CONTOURS_ARR | Array                    | An array element that specifies which contours that partially intersect a bend line shall remain                                                                                                                                                                                                                                                                                                                                                                        |

| Element ID                  | Data Type                | Description                                                                                                                    |
|-----------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------|
|                             |                          | flat during the bend back operation.                                                                                           |
| PRO_E_SMT_GEOM_CONTOUR      | Compound                 | This compound element specifies the collection of contour geometry to remain flat during the bend back operation.              |
| PRO_E_SMT_GEOM_CONTOUR_GEOM | PRO_VALUE_TYPE_SELECTION | Specifies the driven or offset sheet metal surface or surfaces from the element PRO_E_SMT_BBACK_SINGLE_REF that form contours. |
| PRO_E_SMT_GEOM_CONTOUR_EDGE | PRO_VALUE_TYPE_SELECTION | Specifies edges from the element PRO_E_SMT_GEOM_CONTOUR_GEOM that form contours.                                               |

## Sketch Form Feature

The sketch form feature helps you to create a punch or a piercing using a sketch. You can also select an existing sketch or define an internal one. This sketch based form tool enables you to specify the punch and the piercing depth.

The element tree for the sketch form feature is documented in the header file `ProSmtSketchForm.h` and is shown in the following figure:

## Element Tree for Sketch Form Feature

The following table describes the elements in the element tree for the Sketch Form feature.

| Element ID                       | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE               | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_SMT_SKETCH_FORM.                                                                                                                                                                                                                                                                                             |
| PRO_E_STD_FEATURE_NAME           | PRO_VALUE_TYPE_WSTRING | Specifies the name for the sheet metal sequence. The default value is Sketched_Form_1.                                                                                                                                                                                                                                                                                                                          |
| PRO_E_STD_SECTION                | Compound               | Mandatory element.                                                                                                                                                                                                                                                                                                                                                                                              |
| PRO_E_SKETCH_FORM_TYPE           | PRO_VALUE_TYPE_INT     | Specifies the type of the sketched form feature. The valid values for this element are defined in the enumerated type ProSketchFormType: <ul style="list-style-type: none"> <li>PRO_SMT_SKETCH_FORM_TYPE_PUNCH— Specify the value 1 if you want to select punch as your form type.</li> <li>PRO_SMT_SKETCH_FORM_TYPE_PIERCING— Specify the value 2 if you want to select piercing as your form type.</li> </ul> |
| PRO_E_SKETCH_FORM_DEPTH_PUNCH    | PRO_VALUE_TYPE_DOUBLE  | Defines the depth of the penetration of the punching operation. <p> <b>Note</b></p> <p>Specify a value for this element only if the element PRO_E_SKETCH_FORM_TYPE is set to PRO_SMT_SKETCH_FORM_TYPE_PUNCH.</p>                                                                                                             |
| PRO_E_SKETCH_FORM_DEPTH_PIERCING | PRO_VALUE_TYPE_DOUBLE  | Defines the depth of the penetration of the piercing operation. <p> <b>Note</b></p> <p>Specify a value for this element only if the element PRO_E_SKETCH_FORM_TYPE is set to PRO_SMT_SKETCH_FORM_TYPE_PIERCING.</p>                                                                                                          |
| PRO_E_SKETCH_FORM_DIR            | PRO_VALUE_TYPE_INT     | This element changes the direction of the form. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE— Specifies</li> </ul>                                                                                                                                                                                                                                                  |

| Element ID               | Data Type             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| PRO_E_SMT_FILLET_QUILT    | PRO_VALUE_TYPE_INT | This compound element specifies the option to round the non placement sharp edges that do not lie on the placement references and are created by the deformation of the sheet metal geometry based on the quilt. For more information on the elements related to PRO_E_SMT_FILLET_QUILT, refer to the section <a href="#">Sub Elements of PRO_E_SMT_FILLET_INTERSECT</a> and <a href="#">PRO_E_SMT_FILLET_QUILT</a> on page 1415. |
| PRO_E_SMT_TRIM_FORM_SIDES | PRO_VALUE_TYPE_INT | Trim edges of sheared form. Specifies if Creo Parametric applies trimming of sheet metal side surfaces during form feature generation. The valid values for this element follow: <ul style="list-style-type: none"> <li>• PRO_B_TRUE</li> <li>• PRO_B_FALSE</li> </ul>                                                                                                                                                            |

## Sub Elements of PRO\_E\_SMT\_FILLET\_INTERSECT and PRO\_E\_SMT\_FILLET\_QUILT

The following table lists all the elements that are common to the compound elements PRO\_E\_SMT\_FILLET\_INTERSECT and PRO\_E\_SMT\_FILLET\_QUILT.

| Element ID                      | Data Type             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_SMT_FILLET_RADIUS_USEFLAG | PRO_VALUE_TYPE_INT    | Specifies whether a fillet radius is used. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE— Specifies that a fillet is used.</li> <li>PRO_B_FALSE— Specifies that the fillet is not used.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_SMT_FILLET_RADIUS_SIDE    | PRO_VALUE_TYPE_INT    | Specifies the radius direction. The values for this element are specified in the enumerated type ProSmdRadType, are as follows: <ul style="list-style-type: none"> <li>PRO_BEND_RAD_OUTSIDE— Specifies that the radius is applied to the outside of the sheet metal geometry.</li> <li>PRO_BEND_RAD_INSIDE— Specifies that the radius is applied to the inside of the sheet metal geometry.</li> </ul> <p> <b>Note</b></p> <p>Use this element only if the element PRO_E_SKETCH_FORM_TYPE is set to PRO_SMT_SKETCH_FORM_TYPE_PUNCH.</p> |
| PRO_E_SMT_FILLET_RADIUS_VALUE   | PRO_VALUE_TYPE_DOUBLE | Specifies the radius value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Join Feature

The Join feature helps you to connect two intersecting walls in a sheet metal part. You can trim the non intersecting portions of the walls as well as add a bend and bend relief at the intersection. You can also control the location of the intersection in which the feature would be created.

The element tree for the Join feature is documented in the header file ProSmtJoinWalls.h and is shown in the following figure:

## Element Tree for Join Feature

```

The following table describes the elements in the element tree for the Join feature.

| Element ID                     | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE             | PRO_VALUE_TYPE_INT     | Specifies the type of the sheet metal feature. The valid value for this element is PRO_FEAT_JOIN_WALLS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PRO_E_STD_FEATURE_NAME         | PRO_VALUE_TYPE_WSTRING | Specifies the name for the sheet metal feature. The default value is JOIN_1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| PRO_E_SMT_WALL_JOIN_TRIM       | PRO_VALUE_TYPE_INT     | <p>Specifies an option for trimming the non intersecting geometry. The valid values for this element are defined in the enumerated type ProSmtJoinWallsTrimType and are as follows:</p> <ul style="list-style-type: none"> <li>PRO_INTWLS_TRIM_OPEN_CUTS— Specifies the original intersecting walls without being trimmed.</li> <li>PRO_INTWLS_TRIM_BNDR_EXTS— Specifies that the non intersection portions up to the intersection between the surfaces will be removed.</li> <li>PRO_INTWLS_TRIM_BEND_LINE— Specifies that the non intersecting surfaces will be trimmed up to the bend.</li> </ul> |
| PRO_E_SMT_WALL_JOIN_EXTEND     | PRO_VALUE_TYPE_INT     | <p>The valid values for this element are defined in the enumerated type ProSmtJoinWallsExtType and are as follows:</p> <ul style="list-style-type: none"> <li>PRO_INTWLS_EXT_LINE_TO_INT — Extends the intersection line to the intersection area.</li> <li>PRO_INTWLS_EXT_LINE_TO_ALL— Extends the intersection line to the intersection plane.</li> </ul> <p> <b>Note</b></p> <p>The intersecting walls must be planar.</p>                                                                                     |
| PRO_E_SMT_WALL_JOIN_REFS       | Array                  | An array element of only two surfaces, that form a join feature set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_SMT_WALL_JOIN_REFS_CMPND | Compound               | This compound element defines the collection of geometry to be joined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Element ID                    | Data Type             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_SMT_WALL_JOIN_REFS_SRF  | PRO_ELEM_TYPE_SELECT  | Select the surfaces which are to be connected by the join feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| PRO_E_SMT_WALL_JOIN_FLIP      | PRO_VALUE_TYPE_INT    | This element flips the wall join direction. The selection point of each wall determines which side of the walls will be kept.                                                                                                                                                                                                                                                                                                                                                                                                          |
| PRO_E_SMT_FILLETS             | Compound              | This compound element defines the bend types of the sheet metal wall and the value of bend radius.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| PRO_E_SMT_FILLETS_SIDE        | PRO_VALUE_TYPE_INT    | Specifies the fillet side. The valid values for this element are defined in the enumerated type <code>ProSmdRadType</code> and are as follows: <ul style="list-style-type: none"> <li>PRO_BEND_RAD_OUTSIDE— Applies the bend radius to the outer surface of the bend.</li> <li>PRO_BEND_RAD_INSIDE— Applies the bend radius to the inner surface of the bend.</li> <li>PRO_BEND_RAD_PARAMETER— Applies the bend radius at the dimension location set by the <code>SMT_DFLT_RADIUS_SIDE</code> parameter in Creo Parametric.</li> </ul> |
| PRO_E_SMT_FILLETS_VALUE       | PRO_VALUE_TYPE_DOUBLE | Specifies the value of the bend radius.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| PRO_E_SMT_BEND_RELIEF         | Compound              | This compound element defines the bend relief at the edges. For more information see the section <a href="#">Bend Relief Elements on page 1392</a> .                                                                                                                                                                                                                                                                                                                                                                                   |
| PRO_E_SMT_DEV_LEN_CALCULATION | Compound              | This compound element defines the method used to calculate the Developed Length dimensions for bends. For more information see the section <a href="#">The Element Subtree for Length Calculation on page 1322</a> .                                                                                                                                                                                                                                                                                                                   |

| Element ID                           | Data Type            | Description                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_SMT_WALL_JOIN_EXTEND_EDGES     | PRO_ELEM_TYPE_SELECT | Select the extended edges to be connected by the join feature.                                                                                                                                                                                                                                                                                                              |
| PRO_E_SMT_WALL_JOIN_EXTEND_EDGES_OPT | PRO_VALUE_TYPE_INT   | Specifies the method to extend the edges and is specified using the enumerated data type <code>ProSmtJoinWallsEdgeExtType</code> . The valid values are: <ul style="list-style-type: none"> <li>• <code>PRO_INTWLS_EXT_EDGE_ALONG=0</code>, -extend along boundary edges.</li> <li>• <code>PRO_INTWLS_EXT_EDGE_NORMAL=1</code>, extend normal to selected edges.</li> </ul> |

## Twist Wall Feature

The twist wall feature enables you to create a spiral or coil-shaped section of sheet metal. The twist wall can be attached to a straight edge on an existing planar wall. The twist wall typically serves as a transition between two areas of sheet metal because it can change the plane of a sheet metal part. The twist can be rectangular or trapezoidal.

The element tree for the twist wall feature is documented in the header file `ProSmtTwist.h` and is shown in the following figure:

The following table describes the elements in the element tree for the twist wall feature.

| Element ID                                                         | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------------------------------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE                                                 | PRO_VALUE_TYPE_INT       | Specifies the type of the sheet metal feature. The valid value for this element is PRO_FEAT_TWIST.                                                                                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_STD_FEATURE_NAME                                             | PRO_VALUE_TYPE_WSTRING   | Specifies the name for the sheet metal feature. The default value is Twist_1.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| PRO_E_SMT_TWIST_ATT_EDGE                                           | PRO_VALUE_TYPE_SELECTION | Specifies an edge to which the twist wall will be attached.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_SMT_TWIST_TYPE                                               | PRO_VALUE_TYPE_INT       | Specifies the width options for the walls.<br><br>The valid values for this element are defined by the enumerated data type ProSmtTwistType and are as follows: <ul style="list-style-type: none"> <li>PRO_SMT_TWIST_TRIM_EDGES—Calculates the wall width from the ends of the attachment edges. The walls are offset by the specified value from the attachment ends.</li> <li>PRO_SMT_TWIST_TYPE_PNT—Calculates and centers the wall width from the twist axis by the specified dimension.</li> </ul> |
| PRO_E_SMT_TWIST_TRIM_EDGES                                         | Compound                 | Specifies a compound element which defines options for twist wall ends.<br><br>This element is available when the value of the element PRO_E_SMT_TWIST_TYPE is set to PRO_SMT_TWIST_TRIM_EDGES.                                                                                                                                                                                                                                                                                                         |
| PRO_E_SMT_TWIST_SIDE_1_OFFSET<br><br>PRO_E_SMT_TWIST_SIDE_2_OFFSET | Compound                 | Specifies the trim option and offset value for the first and second direction of wall ends.<br><br>The elements PRO_E_SMT_TWIST_OFFSET_TYPE and PRO_E_SMT_TWIST_OFFSET_VAL are common to the compound elements in both directions.                                                                                                                                                                                                                                                                      |

| PRO_E_SMT_TWIST_AXIS_POINT      | Compound                 | <p>Specifies a compound element which defines options for twist axis.</p> <p>This element is available when the value of the element PRO_E_SMT_TWIST_TYPE is set to PRO_SMT_TWIST_TYPE_PNT.</p>                                                                                                                                                                                                            |
| PRO_E_SMT_TWIST_POINT_TYPE      | PRO_VALUE_TYPE_INT       | <p>Specifies the location of the twist axis using the enumerated data type ProSmtTwistPointType.</p> <p>The valid values are:</p> <ul style="list-style-type: none"> <li>PRO_SMT_TWIST_MID_PNT—Specifies that the twist axis is located at the center of the wall width.</li> <li>PRO_SMT_TWIST_DTM_PNT—Specifies that the twist axis is located on the specified datum point.</li> </ul>                  |
| PRO_E_SMT_TWIST_START_WIDTH_VAL | PRO_VALUE_TYPE_DOUBLE    | Specifies the width of the start wall.                                                                                                                                                                                                                                                                                                                                                                     |
| PRO_E_SMT_TWIST_ATT_POINT_REF   | PRO_VALUE_TYPE_SELECTION | <p>This element is available when the value of the element PRO_E_SMT_TWIST_POINT_TYPE is set to PRO_SMT_TWIST_DTM_PNT.</p>                                                                                                                                                                                                                                                                                 |

| Element ID                      | Data Type             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 |                       | Specifies a datum point on the attachment edge. The centerline of the twist wall passes through this datum point. The centerline of the twist axis is perpendicular to the start edge and coplanar with the existing wall.                                                                                                                                                                                                                     |
| PRO_E_SMT_TWIST_ANGLE_VAL       | PRO_VALUE_TYPE_DOUBLE | Specifies the rotation angle of the twist wall.                                                                                                                                                                                                                                                                                                                                                                                                |
| PRO_E_SMT_TWIST_WALL_LENGTH_VAL | PRO_VALUE_TYPE_DOUBLE | Specifies the length of the twist wall, measured from the attachment edge to the end of the twist axis.                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_SMT_TWIST_END_WIDTH       | Compound              | Specifies a compound which defines options to change the width of the end wall.                                                                                                                                                                                                                                                                                                                                                                |
| PRO_E_SMT_TWIST_END_WIDTH_TYPE  | PRO_VALUE_TYPE_INT    | Specifies the width option for the end wall using the enumerated data type <code>ProSmtTwistEndWidthType</code> . The valid values are: <ul style="list-style-type: none"> <li><code>PRO_TWIST_END_WIDTH_SAME_AS_START</code>—Specifies that the width of the end wall must be same as the start wall.</li> <li><code>PRO_TWIST_END_WIDTH_BLIND</code>—Specifies that the width of the end wall must be set to the specified value.</li> </ul> |
| PRO_E_SMT_TWIST_END_WIDTH_VAL   | PRO_VALUE_TYPE_DOUBLE | Specifies the width of the end wall.                                                                                                                                                                                                                                                                                                                                                                                                           |
| PRO_E_SMT_TWIST_DEV_LEN_VAL     | PRO_VALUE_TYPE_DOUBLE | Specifies the length of wall in unbent state.                                                                                                                                                                                                                                                                                                                                                                                                  |

## Merge Wall Feature

The merge wall feature enables you to collect unattached walls to merge them together into one piece using the base reference collector. The edges between certain pieces of walls can be excluded from the merge operation to keep the corresponding areas disconnected.

The element tree for the merge wall feature is documented in the header file `ProSmtMergeWalls.h` and is shown in the following figure:

### Element Tree for Merge Wall Feature

```

```

The following table describes the elements in the element tree for the merge wall feature.

| Element ID          | Data Type          | Description                                                                                                                                                                  |
|---------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE  | PRO_VALUE_TYPE_INT | Specifies the type of the sheet metal feature. The valid value for this element is PRO_FEAT_WALL.                                                                            |
| PRO_E_SMT_WALL_TYPE | PRO_VALUE_TYPE_INT | Specifies the wall type for the sheet metal feature. The default value is specified by the enumerated typeProSmtWallWallType and the valid value is PRO_SMT_WALL_TYPE_MERGE. |

| Element ID                      | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_STD_FEATURE_NAME          | PRO_VALUE_TYPE_WSTRING   | Specifies the feature name of the sheet metal feature.                                                                                                                                                                                                                                                                                                               |
| PRO_E_SMT_WALL_MERGE_BASE_REF   | Compound                 | Specifies a collection of surfaces for merging with the base wall.                                                                                                                                                                                                                                                                                                   |
| PRO_E_STD_SURF_COLLECTION_APPL  | Surface Collection       | Specifies the selection of merge geometry that can be selected to be designated as sheet metal design objects.                                                                                                                                                                                                                                                       |
| PRO_E_SMT_WALL_MERGE_GEOM_REF   | Compound                 | Specifies the surfaces of one or more unattached flat walls to merge with the base wall.                                                                                                                                                                                                                                                                             |
| PRO_E_STEP_MERGE_EDGE           | PRO_VALUE_TYPE_SELECTION | Specifies the excluded edges that are included by the merge of the surfaces.                                                                                                                                                                                                                                                                                         |
| PRO_E_SMT_MERGE_KEEP_LINES      | PRO_VALUE_TYPE_BOOLEAN   | Controls the visibility of merged edges on surface joints. The valid values for this element are: <ul style="list-style-type: none"> <li>Pro_B_True—Merged edges are visible on surface joints.</li> <li>Pro_B_False—Merged edges are not visible on surface joints.</li> </ul>                                                                                      |
| PRO_E_SMT_MERGE_KEEP_BEND_EDGES | PRO_VALUE_TYPE_BOOLEAN   | Controls the ability to keep edges between the bend surfaces while merging surfaces in the merged walls. The valid values are as follows: <ul style="list-style-type: none"> <li>Pro_B_True—Keep edges of bend surfaces between existing bend surfaces in the merged walls</li> <li>Pro_B_False—Does not keep edges of bend surfaces in the merged walls.</li> </ul> |

## Recognizing Sheetmetal Design Objects

From Creo Parametric 4.0 F000 onward, the Sheetmetal Design items are created as design objects. Bends, bend reliefs, corner reliefs, corner seams, and forms are sheet metal design objects. The Recognition commands enable you to tag surfaces as sheet metal design objects or not sheet metal design objects. The following sheet metal objects can be recognized as, or recognized as not, a sheet metal design object:

- Bends
- Bend reliefs
- Corner reliefs
- Corner seams

- 
- Forms

---

 **Note**

In the `ProSmtRecognition.h` element tree, you can tag objects of the same type at a time as sheet metal design object or not sheet metal design object. This means only one compound element for objects of the same type can be defined at a time for a feature.

---

The element tree to recognize as sheet metal design objects or not sheet metal design objects is documented in the header file `ProSmtRecognition.h` and is shown in the following figure:

The following table describes the elements in the element tree:

| Element ID                     | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE             | PRO_VALUE_TYPE_INT       | Specifies the type of the sheet metal feature. The valid value for this element is PRO_FEAT_SMT_RECOGNITION.                                                                                                                                                                                                                                                                                          |
| PRO_E_STD_FEATURE_NAME         | PRO_VALUE_TYPE_WSTRING   | Specifies the name for the sheet metal feature.                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_SMT_BND_RLF_RCG          | Compound                 | Specifies a compound element which defines bend reliefs as sheet metal design objects.                                                                                                                                                                                                                                                                                                                |
| PRO_E_SMT_RECOGNITION_SEL_TYPE | PRO_VALUE_TYPE_INT       | Specifies the mode for selecting bend reliefs. See the section <a href="#">Values for PRO_E_SMT_RECOGNITION_SEL_TYPE on page 1432</a> for more information on valid values.                                                                                                                                                                                                                           |
| PRO_E_SMT_PIO_SCOPE            | PRO_VALUE_TYPE_SELECTION | Specifies the geometry that can be selected to be designated as sheet metal design objects. You can select driven or offset sheet metal surface, intent surface that contains at least one side of bend relief, a design object which is not bend relief, thickness edge if the bend relief does not contain any surface, bend relief vertex if the bend relief does not contain any surface or edge. |
| PRO_E_SMT_CRN_RLF_RCG          | Compound                 | Specifies a compound element which defines corner reliefs as sheet metal design objects.                                                                                                                                                                                                                                                                                                              |
| PRO_E_SMT_RECOGNITION_SEL_TYPE | PRO_VALUE_TYPE_INT       | Specifies the mode for selecting corner relief. See the section <a href="#">Values for PRO_E_SMT_RECOGNITION_SEL_TYPE on page 1432</a> , for more information on valid values.                                                                                                                                                                                                                        |
| PRO_E_SMT_PIO_SCOPE            | PRO_VALUE_TYPE_SELECTION | Specifies the corner relief geometry that can be selected to be designated as sheet metal design objects.                                                                                                                                                                                                                                                                                             |
| PRO_E_SMT_BEND_RCG             | Compound                 | Specifies a compound element which defines bends as sheet metal design objects.                                                                                                                                                                                                                                                                                                                       |
| PRO_E_SMT_RECOGNITION_SEL_TYPE | PRO_VALUE_TYPE_INT       | Specifies the mode for selecting bends. See the section <a href="#">Values for PRO_E_SMT_RECOGNITION_SEL_TYPE on page 1432</a> , for more information on valid values.                                                                                                                                                                                                                                |
| PRO_E_SMT_PIO_SCOPE            | PRO_VALUE_TYPE_SELECTION | Specifies the bend geometry that can be selected to be designated as sheet metal design objects. You can select cylindrical bend surface, intent surface that contains a                                                                                                                                                                                                                              |

| Element ID                     | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                |                          | cylindrical bend or a design object which is not a bend.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| PRO_E_SMT_CRN_SEAM_RCG         | Compound                 | Specifies a compound element which defines corner seams as sheet metal design objects.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_SMT_RECOGNITION_SEL_TYPE | PRO_VALUE_TYPE_INT       | Specifies the mode for selecting corner seams. See the section <a href="#">Values for PRO_E_SMT_RECOGNITION_SEL_TYPE on page 1432</a> , for more information on valid values.                                                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_SMT_PIO_SCOPE            | PRO_VALUE_TYPE_SELECTION | <p>Specifies the corner seam geometry that can be selected to be designated as sheet metal design objects.</p> <p>You can select one or more references from the following:</p> <ul style="list-style-type: none"> <li>• Side surface that can be associated with a corner seam.</li> <li>• Not Corner Seam design objects.</li> <li>• Planar face or offset surface, which will be considered as the reference for all neighbor corner seams.</li> <li>• Bend surface, which will be considered as the reference for all neighbor corner seams.</li> </ul> |
| PRO_E_SMT_FORM_RCG             | Compound                 | Specifies a compound element which defines forms as sheet metal design objects.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_SMT_RECOGNITION_SEL_TYPE | PRO_VALUE_TYPE_INT       | Specifies the mode for selecting forms. See the section <a href="#">Values for PRO_E_SMT_RECOGNITION_SEL_TYPE on page 1432</a> , for more information on valid values.                                                                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_SMT_RCG_FORM_AS_ONE      | PRO_VALUE_TYPE_BOOLEAN   | Specifies if the selected form geometry must be considered as one form design object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_STD_SURF_COLLECTION_APPL | PRO_VALUE_TYPE_SELECTION | Specifies the selection of form geometry that can be selected to be designated as sheet metal design objects.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_SMT_FORM_BOUND_REFS      | PRO_VALUE_TYPE_SELECTION | Specifies the forms on a reference surface. You can select driven or offset sheet metal surfaces or intent surfaces that contain driven or offset sheet metal surfaces.                                                                                                                                                                                                                                                                                                                                                                                     |

| Element ID               | Data Type | Description                                                                                                                                                                                   |
|--------------------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_SMT_BND_RLF_UNRCG  | Compound  | <p>Specifies a compound element which defines bend reliefs as not sheet metal design objects.</p> <p>The child elements and their values are same as the PRO_E_SMT_BND_RLF_RCG element.</p>   |
| PRO_E_SMT_CRN_RLF_UNRCG  | Compound  | <p>Specifies a compound element which defines corner reliefs as not sheet metal design objects.</p> <p>The child elements and their values are same as the PRO_E_SMT_CRN_RLF_RCG element.</p> |
| PRO_E_SMT_BEND_UNRCG     | Compound  | <p>Specifies a compound element which defines bends as not sheet metal design objects.</p> <p>The child elements and their values are same as the PRO_E_SMT_BEND_RCG element.</p>             |
| PRO_E_SMT_CRN_SEAM_UNRCG | Compound  | <p>Specifies a compound element which defines corner seams as not sheet metal design objects.</p> <p>The child elements and their values are same as the PRO_E_SMT_CRN_SEAM_RCG element.</p>  |

| Element ID           | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_SMT_PIO_SCOPE  | PRO_VALUE_TYPE_SELECTION | <p>Specifies the corner seam geometry that can be selected to be designated as not sheet metal design objects.</p> <p>You can select one or more references from the following:</p> <ul style="list-style-type: none"> <li>• Side surface that can be associated with a corner seam.</li> <li>• Corner Seam design objects.</li> <li>• Planar face or offset surface, which will be considered as the reference for all neighbor corner seams.</li> <li>• Bend surface, which will be considered as the reference for all neighbor corner seams.</li> </ul> |
| PRO_E_SMT_FORM_UNRCG | Compound                 | <p>Specifies a compound element which defines forms as not sheet metal design objects.</p> <p>The child elements and their values are same as the PRO_E_SMT_FORM_RCG element.</p>                                                                                                                                                                                                                                                                                                                                                                           |

## Values for PRO\_E\_SMT\_RECOGNITION\_SEL\_TYPE

This element specifies the mode for selecting bends, bend reliefs, corner reliefs, corner seams, and forms as sheet metal design objects. The valid values are:

- PRO\_SMT\_RECOGNITION\_MANUAL\_SEL—Specifies manual selection of the sheet metal design object.
- PRO\_SMT\_RECOGNITION\_AUTO\_SEL—Specifies automatic selection of the sheet metal design object.

## Multibodies in Sheetmetal Design

In Creo Parametric 11.0.0.0 and later, a sheetmetal body part can have any number of sheet metal bodies and any number of solid bodies. A part with at least one sheet metal body is a sheet metal part. You cannot remove the last, single, sheet metal body from a sheet metal part or convert a single sheet metal body to a solid body. You can, however, convert the sheet metal part to a solid part. For more information about Multibodies in Sheetmetal Design, refer to the Creo Online Help.

Methods Introduced:

- **ProSmtPartThicknessValueGet()**

- **ProSmtBodyThicknessValueGet()**
- **ProSmtBodyIsLinkedToPart()**
- **ProSmtBodyLinkToPart()**

Use the function `ProSmtPartThicknessValueGet()` to get the absolute thickness value of the specified sheetmetal part.

Use the function `ProSmtBodyThicknessValueGet()` to get the absolute thickness value of the specified sheetmetal body.

Use the function `ProSmtBodyIsLinkedToPart()` to check if the specified sheetmetal body is linked to a part. The output argument `is_linked` is a `ProBoolean`. The function returns `PRO_B_TRUE`, if the sheetmetal body is linked to a part, else it returns `PRO_B_FALSE`.

Use the function `ProSmtBodyLinkToPart()` to link or unlink a sheetmetal body to a sheetmetal part. The input argument *link* is a `ProBoolean`. Pass it as `PRO_B_TRUE`, if you want to link a sheetmetal body to a sheetmetal part. Pass `PRO_B_FALSE` to unlink.

## Production Applications: Manufacturing

### Production Applications: Manufacturing

This section describes the Creo TOOLKIT functions for manufacturing operations. Familiarity with Creo NC functions simplifies the use of these manufacturing functions.

### Manufacturing Models

Functions Introduced:

- **ProMfgAssemGet()**
- **ProMfgTypeGet()**

You can use the function `ProSolidFeatVisit()` to visit all the components in a manufacturing model. However, this function requires a `ProSolid` (or one of its instances, `ProPart` or `ProAssembly`) handle to the model as input. The function `ProMfgAssemGet()` outputs a `ProAssembly` handle to the top-level assembly in the manufacturing model, given its `ProMfg` handle. This assembly handle can then be passed to `ProSolidFeatVisit()`.

Manufacturing models, like other models in Creo Parametric, are uniquely identified by name and type. However, there are several different varieties of manufacturing models. For example, assembly machining, sheetmetal manufacturing, and mold manufacturing are all types of manufacturing models. The `ProMfg` object is a general purpose, opaque handle used to represent any of

---

the different manufacturing model varieties. To distinguish between the different types of manufacturing model, there are manufacturing subtypes. The complete list of subtypes is as follows:

- `PRO_MFGTYPE_MACH_ASSEM`
- `PRO_MFGTYPE_SHEET_METAL`
- `PRO_MFGTYPE_MOLD`
- `PRO_MFGTYPE_CAST`
- `PRO_MFGTYPE_CMM`

The function `ProMfgTypeGet()` outputs the subtype, given the `ProMfg` handle to the manufacturing object.

## Creating a Manufacturing Model

Function Introduced

- **`ProMfgMdlCreate()`**

The function `ProMfgMdlCreate()` outputs an initialized `ProMfg` object handle, given the model name, manufacturing subtype, and name of the reference model. For sheetmetal manufacturing, this should be the sheetmetal workpiece. For all other subtypes, the reference model argument is ignored.

## Analyzing a Manufacturing Model

Creo NC has two modes of operation—part and assembly manufacturing. In both cases, the top-level model is an assembly that contains the description of the tools. The following diagram shows the hierarchy of part and assembly manufacturing models.

## Part and Assembly Manufacturing Model Hierarchy

In part manufacturing, the storage solid is a part that represents the workpiece or stock, and the design piece is another component at the same level. In assembly manufacturing, the storage solid is the actual assembly representing the design model. The workpiece can be at any level inside this assembly. In both types of manufacturing, the manufacturing operations are described as features of the storage solid.

The important tasks for Creo TOOLKIT are to traverse the manufacturing assembly components, identify the storage solid that contains the manufacturing operations as its features, and list the manufacturing tools.

This section contains the following subsections:

- [Traversing Manufacturing Components on page 1436](#)
- [Identifying the Storage Solid on page 1436](#)

- [Visiting Manufacturing Tools on page 1437](#)

## Traversing Manufacturing Components

Function Introduced:

- **ProAsmcompTypeGet()**

You can visit the components in a manufacturing assembly using the same functions that enable you to visit the components of a regular assembly. For a full description of these functions, see the [Assembly: Basic Assembly Access on page 1115](#) section.

The components within a manufacturing assembly perform a variety of different roles. The function `ProAsmcompTypeGet()` provides the role of any model under a manufacturing assembly. The possible roles are as follows:

- `PRO_ASM_COMP_TYPE_NONE`—A regular component (no special manufacturing role)
- `PRO_ASM_COMP_TYPE_WORKPIECE`—A workpiece
- `PRO_ASM_COMP_TYPE_REF_MODEL`—A reference model
- `PRO_ASM_COMP_TYPE_FIXTURE`—A fixture
- `PRO_ASM_COMP_TYPE_MOLD_BASE`—A mold base
- `PRO_ASM_COMP_TYPE_MOLD_COMP`—A mold component
- `PRO_ASM_COMP_TYPE_MOLD_ASSEM`—A mold assembly
- `PRO_ASM_COMP_TYPE_GEN_ASSEM`—A general assembly
- `PRO_ASM_COMP_TYPE_CAST_ASSEM`—A cast assembly
- `PRO_ASM_COMP_TYPE_DIE_BLOCK`—A die block
- `PRO_ASM_COMP_TYPE_DIE_COMP`—A die component
- `PRO_ASM_COMP_TYPE_SAND_CORE`—A sand core
- `PRO_ASM_COMP_TYPE_CAST_RESULT`—A cast result

## Identifying the Storage Solid

Functions Introduced:

- **ProMfgSolidGet()**
- **ProMfgFeatureOwnerGet()**

Another important task in using Creo TOOLKIT for accessing Creo NC models is to find the storage solid inside the manufacturing model. This model is important because the manufacturing operations—workcells, NC sequences, and so on—are represented as features within it.

---

Manufacturing features are treated like all other features in Creo TOOLKIT. This enables you to search for NC sequences as you would for solid features. For example, to visit all the workcells of a manufacturing solid, you can use the `ProSolidFeatVisit()` function and filter out any model items not of type `PRO_E_WCELL`.

The function `ProMfgSolidGet()` returns the handle to the storage solid, and `ProMfgFeatureOwnerGet()` returns the component path to the solid from the top-level assembly.

### Example 1: Identifying Workcell Features of a NC Model

The sample code in `UgMfgWcellIdentify.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_mfg` shows how to identify workcell features.

## Visiting Manufacturing Tools

Functions Introduced:

- **ProMfgToolVisit()**
- **ProToolTypeGet()**
- **ProToolModelMdlnameGet()**
- **ProToolParamGet()**
- **ProToolAttributesGet()**
- **ProToolVerify()**

Tools are not stored as features of the manufacturing solid, nor as components in the assembly; they are special objects within the top-level manufacturing model, so they need their own visit function. This function is `ProMfgToolVisit()`, which has the same form as other visit functions in Creo TOOLKIT, except it does not offer the option of a user-defined filter function. You call the action function with an input argument of type `ProTool` to identify the tool.

The other functions analyze the tool being visited.

The function `ProToolTypeGet()` returns the tool type. Examples of the types are as follows:

- `PRO_TOOL_DRILL`
- `PRO_TOOL_TURN`
- `PRO_TOOL_SAW`
- `PRO_TOOL_MILL`

The `ProToolModelMdlnameGet()` function outputs the model name and type of a tool, given its `ProTool` handle.

---

The function `ProToolParamGet()` retrieves the value of a specified tool parameter. This yields a value in terms of the type `ProParamvalue` (see the [Core: Parameters on page 216](#) section for more information).

The function `ProToolAttributesGet()` provides the current setting of several Boolean attributes of the tool in the form of an integer bitmap. Currently, the attributes define whether a solid tool is to be by reference or by copy. See the section [Creating NC Sequences on page 1448](#) for more information on creating tools.

The function `ProToolVerify()` returns a Boolean showing whether a specified tool handle corresponds to an existing tool.

## Creating Manufacturing Objects

This section explains how to create all types of manufacturing feature. This section assumes you have an understanding of element trees for feature creation and Creo NC. For an introduction to element trees, see [Element Trees: Principles of Feature Creation on page 771](#).

### Note

You must have a Creo NC license to create manufacturing features using Creo TOOLKIT.

---

An important principle of creating manufacturing features is that all the elements required to be defined interactively must also be defined when you create that feature using Creo TOOLKIT.

As with creating solid features, manufacturing features use element trees to define the feature before you call `ProFeatureCreate()` to create the feature. However, the method of creating tools is slightly different, as described in the following sections.

## Creating Tools

Functions Introduced:

- **ProToolinputAlloc()**
- **ProToolinputTypeSet()**
- **ProToolElemParamAdd()**
- **ProToolElemModelSet()**
- **ProToolinputElemAdd()**
- **ProToolInit()**

- **ProToolCreate()**
- **ProToolinputFree()**
- **ProToolFileRead()**
- **ProToolFileWrite()**

In Creo Parametric, and therefore in Creo TOOLKIT, tools are not features, and must be created in a slightly different manner for solid and manufacturing features.

Tool creation involves initializing an input structure using a call to `ProToolinputAlloc()`.

You set the tool type (for example, center drill or ream) directly in the input structure using the function `ProToolinputTypeSet()`.

You can then add tool elements to this input structure using a three-step process. First, initialize each element using the function `ProElementAlloc()`. Next, add data to this element using an element-specific function. Finally, add the element to the tool input structure using `ProToolinputElemAdd()`.

As in Creo Parametric, tools can be defined by parameter or by model. To add a parameter to a tool, first allocate the space for a parameter element using a call such as this:

```
status = ProElementAlloc (PRO_E_PARAM, &element);
```

Next, add the parameter to the element using the function `ProToolElemParamAdd()`, then add the element itself to the input structure using the function `ProToolinputElemAdd()`.

The following table lists the parameters required to be defined for each turning tool.

| Parameter      | Turn | Turn Groove |
|----------------|------|-------------|
| NOSE_RADIUS    | •    | •           |
| TOOL_WIDTH     | •    | •           |
| SIDE_WIDTH     | •    |             |
| LENGTH         | •    | •           |
| SIDE_ANGLE     | •    | •           |
| END_ANGLE      | •    | •           |
| GAUGE_X_LENGTH | •    | •           |
| GAUGE_Z_LENGTH | •    | •           |
| TOOL_MATERIAL  | •    | •           |
| HOLDER_TYPE    | •    |             |

The following table lists the parameters required to be defined for milling tools.

| Parameter     | Mill | Side Mill | Thread Mill | Groove |
|---------------|------|-----------|-------------|--------|
| CUTTER_DIAM   | •    | •         | •           | •      |
| CORNER_RADIUS | •    | •         |             | •      |
| CUTTER_WIDTH  |      | •         |             |        |

| Parameter      | Mill | Side Mill | Thread Mill | Groove |
|----------------|------|-----------|-------------|--------|
| SHANK_DIAM     |      | •         |             |        |
| LENGTH         | •    | •         | •           | •      |
| INSERT_LENGTH  |      |           | •           |        |
| END_OFFSET     |      |           | •           |        |
| SIDE_ANGLE     | •    | •         |             |        |
| GAUGE_X_LENGTH | •    | •         |             |        |
| GAUGE_Z_LENGTH | •    | •         |             | •      |
| NUM_OF_TEETH   | •    | •         | •           |        |
| TOOL_MATERIAL  | •    | •         |             |        |

The following table lists the parameters required to be defined for auxiliary and contouring tools.

| Parameter   | Auxiliary | Contouring |
|-------------|-----------|------------|
| CUTTER_DIAM | •         | •          |
| LENGTH      | •         | •          |

The following table lists the parameters required to be defined for holmaking tools.

| Parameter      | Drill | Csink | Tap | Ream | Center Drill | Bore | Back-Spot |
|----------------|-------|-------|-----|------|--------------|------|-----------|
| CUTTER_DIAM    | •     | •     | •   | •    | •            | •    | •         |
| POINT_DIAMETER |       | •     | •   |      |              |      |           |
| DRILL_DIAMETER |       |       |     |      | •            |      |           |
| BODY_DIAMETER  |       |       |     |      |              |      | •         |
| LENGTH         | •     | •     | •   | •    | •            | •    | •         |
| CHAMFER_LENGTH |       |       | •   |      |              |      |           |
| DRILL_LENGTH   |       |       |     |      | •            |      |           |
| INSERT_LENGTH  |       |       |     |      |              |      | •         |
| TIP_OFFSET     |       | •     |     |      |              |      |           |
| GAUGE_OFFSET   |       | •     |     |      |              |      |           |
| CUTTING_OFFSET |       |       |     |      |              |      | •         |
| SIDE_ANGLE     |       |       |     | •    |              |      |           |
| POINT_ANGLE    | •     | •     |     |      | •            |      |           |
| CSINK_ANGLE    |       |       |     |      | •            |      | •         |
| GAUGE_X_LENGTH | •     | •     | •   | •    | •            | •    | •         |
| GAUGE_Z_LENGTH | •     | •     | •   | •    | •            | •    | •         |
| TOOL_MATERIAL  | •     | •     | •   | •    | •            | •    | •         |

Refer to the Creo Parametric NC Manufacturing Help for more information.

Creating a tool using a tool model is similar to the previous process. First, allocate space for an element of type `PRO_E_TOOL_MODEL`. Set the model in the element using the function `ProToolElemModelSet()`, then add it to the input structure using `ProToolInputElemAdd()`. As in Creo NC, you must specify the required number of dimensions within the tool model.

Creating the tool requires two steps. First, initialize a tool handle using `ProToolInit()`. This creates a tool identifier that uniquely defines the tool and is used to reference that tool within the manufacturing model. You pass this identifier, together with the completed input structure, to the function `ProToolCreate()`, which actually creates the tool.

Once the tool has been created, release the memory used by the tool input structure and its associated elements using the function `ProToolInputFree()`.

The following table shows the elements required for tool creation. In this table, the Value column specifies whether the element is required (R) or optional (O).

| Element                                      | Description                        | Value |
|----------------------------------------------|------------------------------------|-------|
| Name                                         | The name used to identify the tool | R     |
| Type                                         | Mill, drill, and so on             | R     |
| Parameters (for parameter-driven tools only) | Tool parameters                    | R     |
| Model (for solid tools only)                 | Model that represents the tool     | R     |

The function `ProToolFileRead()` creates a new tool or redefines an existing tool. The input arguments for this function are as follows:

- `tool_handle`—Specify the handle to the tool to be created or redefined.
- `input_file`—Specify the full path and name of the input file that contains all the parameter information about the tool to be created or redefined.

The function `ProToolFileWrite()` writes all information about the tool into a file. Pass the following as input arguments to this function:

- `tool_handle`—Specify the handle to the tool whose information is to be saved.
- `output_file`—Specify the full path and name of the output file where the tool information is to be saved.

### Example 2: Creating a Tool from a Solid Model

The sample code in `UgMfgSldToolCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_mfg` shows how to create a tool from solid model.

### Example 3: Creating a Parameter-Driven Tool

The sample code in `UgMfgParamToolCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_mfg` shows how to create a drilling tool from parameters.

### Example 4: Creating a Milling Workcell

The sample code in `UgMfgWcellCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_mfg` shows the process to create a milling workcell. Copy the `mill_d20.xml` file from `<creo_toolkit_loadpoint>/protk_appls/models/mfg` to your working directory to create a workcell using the sample code.

## Manufacturing Parameters

In general, there are a number of parameters that are mandatory for a given tool type or NC sequence, and others that are optional. For example, a milling tool requires that its length and diameter be specified, while other parameters such as the number of teeth, or tool material are optional.

The addition of manufacturing parameters to both workcells and operations is optional.

The following figure shows a parameter element subtree.

### Parameter Element Subtree

The process of creating a parameter element subtree is the same for workcells, operations, and NC sequences. First, allocate the space for the `PRO_E_MFG_PARAMS` array element. The simplest method of creating the tree is to delay adding the `PRO_E_MFG_PARAMS` element to its parent until you have fully defined the tree. As you define each `PRO_E_MFG_PARAM` element, add it to the

---

PRO\_E\_MFG\_PARAMS array using `ProElemtreeElementAdd()`. Use `NULL` for the element path as each `PRO_E_MFG_PARAM` element is added to the parameter element tree.

The `PRO_E_MFG_PARAM` element itself is a compound element and requires two children to be defined. One is the `PRO_E_MFG_PARAM_NAME` element, a string (not a wide string) that represents the parameter name to define. The other is a `PRO_E_MFG_PARAMVAL` element, which represents the value of the parameter. Depending on the context, this might be an integer, double, or wide string. For example, `CUT_FEED` is represented by a double, whereas `NUMBER_OF_ARC_PNTS` is an integer. Refer to the Creo Parametric NC Manufacturing Help for more information on manufacturing parameters.

#### Example 4: Creating a Parameter Tree

The sample code in `UgMfgParamTreeCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_mfg` shows how to create a parameter element tree.

### Using External Functions to Define Parameters in the Manufacturing Step Table

Creo TOOLKIT provides the capability to define customized functions that are available from within the Relations user interface and can be used to define relations for a given item. This capability is described in the section [Adding a Customized Function to the Relations Dialog in Creo Parametric on page 214](#) in the section [Core: Relations on page 211](#). External relation functions can also be used within relations stored in steps in the Manufacturing Step Table.

External functions can be used to define new parameters for the members of the step table. For example, if a parameter 'sample\_parameter' is defined as follows:

```
sample_parameter = protk_user_defined_function (list of arguments)
```

The definition suggests that the value of the parameter `sample_parameter` is set as a result of the calculation done using the function `protk_user_defined_function`.

The following steps are required to define new parameters using external relation functions:

1. Within the Creo TOOLKIT application, register an appropriate external function using `ProRelationFunctionRegister()`.
2. In the user interface for the step table, define the relation calling the externally registered functions.

Creo TOOLKIT relation functions called from an entry in the Step Table will have one of two owners for the relation set (`ProRelSet`) depending on the following cases:

---

Case 1: If the step has been applied

The owner will be the manufacturing feature created by this step table entry.

Case 2: If the step has not been applied

The owner will be an object whose type is `PRO_NC_STEP_OBJECT`.

Using external functions, it is possible to interact with an external database or application, in order to set the value of some parameters in the Process Table. Because relations may be reevaluated many times during a regeneration cycle, PTC recommends that the external functions contain some control that prevents reconnection to the external database on each invocation.

---

 **Note**

If no Creo TOOLKIT application has registered the needed external function, any relation using the function cannot be evaluated and is shown as an error. However, when defining Global Relations, even if an undefined function is encountered, the relation will pass the validation, but, the relation will not be applied to the steps because the function is not found.

---

## Creating Manufacturing Features

The creation of manufacturing features mirrors the creation of solid features in Creo TOOLKIT. All features at the very least must define a feature type. Certain manufacturing features also have a requirement that some “non-redefinable” elements must be defined.

With the exception of fixtures, all features are created in the manufacturing solid. However, fixtures are owned by the manufacturing assembly.

Like solid feature creation, manufacturing feature creation consists of several distinct steps:

1. Create the feature element tree.
2. Add nodes or subtrees to the feature tree.
3. Create a selection that represents the model in which to construct the feature.
4. Create the feature.

The following sections document only the first two steps for manufacturing features, because the actual process of feature creation is common to all.

## Creating Fixtures

A fixture setup feature is one of the simplest manufacturing features and contains a maximum of four elements.

---

You should name a fixture setup feature. Optionally, you can define the following:

- The time required to perform the setup
- The identifiers of the fixturing components
- Associated comments

### To Create an Element Tree for a Fixture Setup Feature

1. Allocate space for the tree using the following call:  

```
ProElementAlloc (PRO_E_FEATURE_TREE);
```
2. Define the feature type element (PRO\_E\_FEATURE\_TYPE) to be an integer of value PRO\_FEAT\_FIXSETUP.
3. Define the name (PRO\_E\_FEAT\_NAME) to be a wide string.
4. Optionally, add the setup time (PRO\_E\_SETUP\_TIME) as a double.
5. Optionally, add the component identifiers of the fixturing models (PRO\_E\_FIXT\_COMPONENTS).

---

#### Note

Because this is a multivalue element, you can add multiple (integer) values to the PRO\_E\_FIXT\_COMPONENT element.

---

When the tree is complete, you can pass it (and a selection handle that represents the manufacturing assembly) to the function `ProFeatureCreate()`.

## Creating Workcells

The element tree for workcells is described in the include file `ProWcell.h`. For this feature, the feature type element is `PRO_FEAT_WORKCELL`.

The following table shows the required and optional elements for workcell features. In this table, the “Value” column specifies whether the element is required (R) or optional (O).

| Element              | Description                                    | Value |
|----------------------|------------------------------------------------|-------|
| Cell type            | Mill, mill/turn, and so on.                    | R     |
| Number of axes       | The number of axes.                            | R     |
| Table direction      | Horizontal or vertical (for turn or mill/turn) | R     |
| Machine number heads | 1 or 2 (for turn or mill/turn)                 | R     |
| Name                 | The workcell name.                             | O     |
| Tooling              | Add tools to the workcell.                     | O     |

| Element    | Description                           | Value |
|------------|---------------------------------------|-------|
| Tool table | Manipulate the tools in a tool table. | O     |
| Parameters | The workcell parameters.              | O     |

The feature element has two complex elements—`PRO_E_MFG_PARAMS`, described in the section [Manufacturing Parameters on page 1442](#), and `PRO_E_TOOL_TABLE`. The following figure shows how the tool table element is constructed.

### Tool Table Element

The first thing to note is that a workcell can have multiple tool tables, if it has more than one machine head. In this case, you can create a tool table for each head.

A manufacturing table is made up of an array of `PRO_E_MFG_TABLE_ROW` elements, which is itself an array of `PRO_E_MFG_TABLE_CELL` elements. Each `PRO_E_MFG_TABLE_CELL` is a compound element that contains two more elements—the cell type and its value.

The following examples show how to create a tool table with five drill bits, ranging in size from M8 to M16. The tool table for most workcells (excluding CMM) is of the following format:

| POSITION | TOOL_ID   | REGISTER | COMMENTS   |
|----------|-----------|----------|------------|
| 1        | drill_M8  |          | 8MM Drill  |
| 2        | drill_M10 |          | 10MM Drill |

For example, to create the first row of the table, you would define the following `PRO_E_MFG_TABLE_CELLS`:

- To define the first cell so the position of the tool is index 1, set the value of the `PRO_E_MFG_TABLE_CELL_TYPE` to `PRO_TOOL_TABLE_INDEX`, and set the value of `PRO_E_MFG_TABLE_CELL_VALUE` to the integer value 1.
- Similarly, define the tool identifier to be a `drill_M8`. Set the cell type element to `PRO_TOOL_TABLE_TOOL_ID`, and set the value to a wide string of value `drill_M8`. Because the register column is empty, it can be ignored. To set the comments element, set the type to `PRO_TOOL_TABLE_COMMENTS`, and set the value to a wide string of value “8MM Drill.”

### Example 5: Creating a 2-Axis Lathe Workcell

The sample code in `UgMfgWcellCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_mfg` shows how to set up a simple 2-axis, horizontal lathe, using the previously created tool table. Note that both the `PRO_E_LATHE_DIR` and `PRO_E_MACH_NUM_HEADS` are required for this workcell type. All the other elements are optional.

## Creating Operations

The element tree for manufacturing operations is described in the header file `ProMfgoper.h`. For this feature, the feature type element is `PRO_FEAT_WORKCELL`.

The following table shows the elements of a manufacturing operation. In this table, the “Value” column specifies whether the element is required (R) or optional (O).

| Element                   | Description                                                              | Value |
|---------------------------|--------------------------------------------------------------------------|-------|
| Workcell                  | The identifier of the workcell feature in which to perform the operation | R     |
| Machine coordinate system | The identifier of the machining coordinate system                        | R     |
| Name                      | The operation name                                                       | O     |
| Comments                  | The operation comments                                                   | O     |
| From point                | The datum point from which to start the operation                        | O     |
| Home point                | The datum point on which to end the operation                            | O     |
| Parameters                | The operation parameters                                                 | O     |

The creation of the feature tree is simple, apart from the home and point elements. The following figure shows the element tree for the home points.

## Home Point Element Tree

In this example, there is a from and home point defined for each machining head. If there is only one head, the value of the `PRO_E_MACH_HEAD` element should be 1. Note that the `PRO_E_POINT_SEL` selection should be initialized not to the datum point feature, but to the datum point geometry. To find this geometry, call the function `ProFeatureGeomitemVisit()`.

### Example 6: Creating an Operation

The sample code in `UgMfgOperCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_mfg` shows how to create an operation.

## Creating NC Sequences

Header file `ProNcseq.h` describes the element tree for manufacturing NC sequences.

There are supported NC sequence types:

- `PRO_NCSEQ_PROF_SUR_MILL`—Profile milling, feature type `PRO_FEAT_MILL`
- `PRO_NCSEQ_VOL_MILL`—Volume milling, feature type `PRO_FEAT_MILL`
- `PRO_NCSEQ_CONV_SURF_MILL`—Conventional surface, feature type `PRO_FEAT_MILL`
- `PRO_NCSEQ_FACE_MILL`—Face milling, feature type `PRO_FEAT_MILL`
- `PRO_NCSEQ_PREV_TOOL_MILL`—Local milling using previous tool, feature type `PRO_FEAT_MILL`
- `PRO_NCSEQ_HOLEMAKING`—Holemaking, type `PRO_FEAT_DRILL`
- `PRO_NCSEQ_MW_ROTARY_FINISH_MILLING`—High speed milling `PRO_FEAT_MILL`
- `PRO_NCSEQ_MW_UNDERCUT_MACHINING`—High speed milling `PRO_FEAT_MILL`

Like workcells, an NC sequence feature has a number of non-redefinable elements. For all NC sequences, the `PRO_E_NCSEQ_TYPE` and `PRO_E_NUM_AXES` elements are non-redefinable. For holmaking sequences, the `PRO_E_HOLEMAKING_TYPE`, `PRO_E_PECK_TYPE`, and `PRO_E_HOLE_CYCLE_TYPE` elements are non-redefinable. These elements are specific to holmaking sequences and need not be defined for milling sequences. The following table shows the elements of an NC sequence. In this table, the Value column specifies whether the element is required (R) or optional (O).

| Element                 | Description                               | Value |
|-------------------------|-------------------------------------------|-------|
| Feature type            | The feature type                          | R     |
| Type                    | The sequence type                         | R     |
| Operation               | Operation to which to add the NC sequence | R     |
| Retraction plane        | The retraction plane                      | R     |
| Tool                    | The tool                                  | R     |
| Csys                    | The manufacturing coordinate system       | R     |
| Parameters              | The manufacturing parameters              | R     |
| Name                    | The name of the NC sequence               | O     |
| Number of axes          | The number of axes                        | O     |
| Machine head            | The machine head                          | O     |
| Fixture                 | The fixture                               | O     |
| Entities to be machined |                                           |       |
| Surface                 | The surface                               | R     |
| Holes or volume         | The holes or volume                       | R     |
| Start path              | The start path                            | R     |
| End path                | The end path                              | R     |

The retraction plane that must be defined as part of the NC sequence requires the identifier of the underlying geometry of the datum plane. To obtain this identifier, visit the datum plane geometry items using `ProFeatureGeomitemVisit()`.

There are also a number of required parameters for each NC sequence that must be defined. For conventional milling, the following parameters are required:

- `CUT_FEED`
- `TOLERANCE`
- `STEP_OVER`
- `SPINDLE_SPEED`
- `CLEAR_DIST`

For face milling, the following parameters are required:

- `CUT_FEED`
- `STEP_DEPTH`
- `TOLERANCE`

- 
- STEP\_OVER
  - SPINDLE\_SPEED
  - CLEAR\_DIST

For holmaking, the following parameters are required:

- CUT\_FEED
- TOLERANCE
- SPINDLE\_SPEED
- CLEAR\_DIST

Both milling and holmaking features elements require that the entities (and some associated properties) to be machined are set by API functions, rather than by element tree. Like the standard elements, these functions require a call to `ProElementAlloc()` to reserve space for the elements. Once the elements are complete, you can add them to the tree like the other standard elements.

#### Note

Currently, using `ProFeatureElemtreeExtract()` with NC sequences yields an element tree without holes or surface elements. In other words, there is no way to retrieve hole set or surface information.

---

### Milling-Specific Functions

Functions Introduced:

- **ProNcseqElemSurfaceAdd()**
- **ProNcseqElemMillsurfSet()**
- **ProNcseqElemSurfaceflipSet()**

After you allocate the surface element with `ProElementAlloc()`, you can add the surface to be milled to the element using the function `ProNcseqElemSurfaceAdd()`.

If the model contains a milling surface, you can set the whole surface in the NC sequence using `ProNcseqElemMillsurfSet()`. To control its orientation, call `ProNcseqElemSurfaceflipSet()`.

### Example 7: Adding Surfaces

The sample code in `UgMfgSrfAdd.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_mfg` shows how to use the function `ProNcseqElemSurfaceAdd()`.

---

## Holemaking-Specific Functions

To add hole sets to an element tree, first, obtain the hole set number by calling the function `ProNcseqElemHolesetAdd()`. This hole set is used to reference a set of holes with the same properties, including depth, direction, countersink diameter, and so on. Note that feature element `PRO_E_HOLESETS` has limited support for drill point sets, but allows the user to identify and to delete existing drill point sets in a feature, or to overwrite drill point sets with drill axes sets.

For example, you might want one set of holes to be countersunk to a diameter of 10mm, and another set to 14mm. Because these countersinking operations are done with the same tool, they should be in the same NC sequence. Because the countersink diameter is different for each, you should create two hole sets.

### Note

The following functions (and the element tree `PRO_E_HOLES`) exist in Pro/TOOLKIT Revisions 20 and later only to provide backwards compatibility. Use the more complete and powerful element tree `PRO_E_HOLESETS` for holemaking functions.

- `ProNcseqElemHolesetAdd()`
  - `ProNcseqElemHolesetDepthTypeSet()`
  - `ProNcseqElemHolesetDepthBySet()`
  - `ProNcseqElemHolesetDepthSet()`
  - `ProNcseqElemHolesetStartSet()`
  - `ProNcseqElemHolesetEndSet()`
  - `ProNcseqElemHolesetDirectionSet()`
  - `ProNcseqElemHolesetAxisAdd()`
  - `ProNcseqElemHolesetDrillpartAdd()`
  - `ProNcseqElemHolesetCsinkdiamSet()`
- 

## Creating Material Removal Volumes

In Creo Parametric, material removal features can be created by defining geometry to represent the volume removed, or they can be calculated automatically from the NC sequence. The current release of Creo TOOLKIT supports automatic material removal feature creation only.

The feature tree is very simple, as shown in the following figure.

## Feature Tree

Set the `PRO_E_FEATURE_TYPE` value to `PRO_FEAT_MAT_REMOVAL`, and set the `PRO_E_REF_SEQ` to the identifier of the NC sequence feature from which to create the material removal volume.

### Example 8: Creating a Conventional Milling Sequence

The sample code in `UgMfgMillSeqCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_mfg` shows how to create a milling feature using an element tree.

## Analyzing Manufacturing Features

Functions Introduced:

- **ProMfgoperToolpathDisplay()**
- **ProNcseqToolpathDisplay()**
- **ProNcseqNumGet()**
- **ProNcseqCutTimeGet()**
- **ProNcseqRemovedVolGet()**

You can use the functions `ProMfgoperToolpathDisplay()` and `ProNcseqToolpathDisplay()` to invoke the corresponding toolpath for the specified object. The function `ProNcseqNumGet()` returns the number of the specified NC sequence.

The final two functions access the machining time and the volume of material removed during the machining sequence.

## Production Applications: Customized Tool Database

Creo TOOLKIT supports integration of the Creo NC tool search command with external tool databases. These functions and callbacks allow users to create queries for third-party tool manager applications. These applications query external databases (you can specify more than one) and return logical tool data to Creo Parametric.

---

## Overview

Creo TOOLKIT supplies functions that allow integration of the Tool Selection user interface with a third-party tool manager application. This integration consists of includes three areas of functionality:

- The ability to preregister one or more databases with the Creo Parametric user interface, and to assign custom search parameters to each database. Custom search parameters are items which would not be included natively inside of Creo Parametric, but which could be used to initiate or narrow the tool search.
- Callback functions, that are invoked when the user opts to search inside the tool database. Within the callback functions, the application can extract the native and non-negative search parameters and use these parameters to execute the search.
- The ability to return a list of detailed results to Creo Parametric to be displayed in the results dialog box.

## Setting up the Database and Custom Search Parameters

The functions described in this section enable you to setup the external database and custom search parameters supported by the database.

Functions Introduced:

- **ProMfgdbDataAlloc()**
- **ProMfgdbDataDbnameAdd()**
- **ProMfgdbNameCreate()**
- **ProMfgdbSearchoptCreate()**
- **ProMfgdbDataSearchoptAdd()**
- **ProMfgdbSearchoptApplicDataAdd()**
- **ProMfgdbSearchoptAllowedValueAdd()**

The function `ProMfgdbDataAlloc()` allocates a `ProMfgdbData` handle containing database and search information.

The function `ProMfgdbDataDbnameAdd()` adds the name of an external tool database to the handle allocated by `ProMfgdbDataAlloc()`. To specify more than one database, make multiple calls to `ProMfgdbDataDbnameAdd()`.

The function `ProMfgdbNameCreate()` allocates memory for a handle containing the name of a group into which search options are organized.

The function `ProMfgdbSearchoptCreate()` allocates and initializes a structure for a custom search option. It requires that the option be assigned to a group, typically this would be allocated from `ProMfgdbNameCreate()`.

The function `ProMfgdbDataSearchoptAdd()` adds a custom search option to the `ProMfgdbData` handle.

The function `ProMfgdbSearchoptApplicDataAdd()` specifies the category and object type for which a custom search option is valid. Call this function at least once for each option. Assign an option to multiple categories or object types with multiple calls to this function.

The function `ProMfgdbSearchoptAllowedValueAdd()` adds valid values available for a search option. Assign multiple values with multiple calls to this function.

## Registering the External Database

The function described in this section allows you to register the Creo TOOLKIT application to search the external tool database.

Function Introduced:

- **ProMfgdbRegister()**

The function `ProMfgdbRegister()` registers an external database with Creo Parametric. You should supply the `ProMfgdbData` handle you created for your external database(s).

The function also requires that you supply three callbacks:

- A `ProMfgdbLoginAction`, which is called by Creo Parametric when the user attempts to initiate access to the external database.
- A `ProMfgdbLogoffAction`, which is called when the user is ready to close the connection to the external database.
- A `ProMfgdbSearchAction`, which provides the custom implementation for the search, and provides the results back to Creo Parametric.

Finally, the function requires that you supply the object category. Although there are several categories listed for this function, currently the function supports only the following category:

- `PROMFGDBCAT_CUTTING_TOOL`
  - When one or more external databases have been registered with Creo Parametric, a search icon is displayed in the **Tool Setup** dialog box in Creo Parametric as shown in the following figure. Click the search icon to invoke the **Cutting Tool Search** dialog box.

## Querying the External Database

When users invoke the Search icon to construct a query, they will be presented with the Cutting Tool Search dialog, as shown in the following figure. Within the dialog, users can specify the query parameters, values and group the query constraints with logical operators. When the user completes the query and executes the Find command, Creo Parametric will call the Creo TOOLKIT application with the data from this dialog.

**Cutting Tool Search**

File

Tool Type:

Parameter Owner:

| Group of Parameters | Value   |
|---------------------|---------|

```

The functions described in this section enable you to convert the Creo Parametric queries into a format that can be used with the external database.

Creo Parametric tool database queries are arranged in a tree format, as shown in the following figure. Leaf nodes contain expressions, for example, units and type.

Functions Introduced:

- **ProMfgdbQuerynodeIsLeaf()**
- **ProMfgdbQuerynodeLeftChildGet()**
- **ProMfgdbQuerynodeRightChildGet()**
- **ProMfgdbQuerynodeLogicOperGet()**
- **ProMfgdbQuerynodeExprGet()**
- **ProMfgdbQueryTargetGet()**
- **ProMfgdbExprNameGet()**
- **ProMfgdbExprCategoryGet()**
- **ProMfgdbExprValueGet()**

- **ProMfgdbExprValueTypeGet()**
- **ProMfgdbExprCompopGet()**

`ProMfgdbQuerynodeIsLeaf()`

The functions `ProMfgdbQuerynodeLeftChildGet()` and `ProMfgdbQuerynodeRightChildGet()` return either the left or right branch of a query node, respectively.

`ProMfgdbQuerynodeLogicOperGet()` `ProMfgdbQuerynodeIsLeaf()`

`ProMfgdbQuerynodeExprGet()`

`ProMfgdbQueryTargetGet()`

After the query functions return expressions from a leaf node, your Creo TOOLKIT application can gather information contained in the expressions. The following functions return attributes and operators contained in the returned expressions of a leaf node.

The function `ProMfgdbExprNameGet()` returns the name of the attribute contained in the specified expression. The function `ProMfgdbExprCategoryGet()` returns the category of the attribute contained in the specified expression. The functions `ProMfgdbExprValueGet()` and `ProMfgdbExprValueTypeGet()` return the value and value type contained in the specified expression, respectively. The function `ProMfgdbExprCompopGet()` returns the comparison operator (=, <, >, and so on) contained in the specified expression.

## Returning the Search Results

The functions in this section enable you to populate the results of the query to the external database and pass them back to Creo Parametric so that Creo Parametric will display them appropriately in the results window.

Functions Introduced:

- **ProMfgdbMatchAlloc()**
- **ProMfgdbMatchParamAdd()**

Use the function `ProMfgdbMatchAlloc()` to allocate memory for the structure used to store a match to the query.

The function `ProMfgdbMatchParamAdd()` adds a parameter to the match structure. Make multiple calls to this function to add multiple parameters to the match.

An example of the results passed back from a database query is shown in the following figure:

| Search result #2 - number of rows: 4 |               |              |               |              |
|--------------------------------------|---------------|--------------|---------------|--------------|
| TOOL_TYPE                            | TOOL_ID       | LENGTH_UNITS | TOOL_MATERIAL | NUM_OF_TEETH |
| MILLING                              | T0001         | INCH         | T-15 COBALT   | 6.000000     |
| MILLING                              | KMC950        | Millimeter   | T-18 COBALT   | 4.000000     |
| DRILLING                             | DRILL_W_ERROR | INCH         | COBALT        |              |
| DRILLING                             | JOBBER_2      | INCH         | COBALT        |              |

## Production Applications: Creo NC Sequences, Operations and Work Centers

### Overview

This section describes the Creo TOOLKIT support for Creo NC sequences.

This section describes the Creo TOOLKIT functions that enable you to access the following types of manufacturing features of Creo NC Sequences, Operations and Work Centers.

| Creo NC Step                    | Header File                 |
|---------------------------------|-----------------------------|
| Roughing                        | ProMfgFeatRoughing.h        |
| Reroughing                      | ProMfgFeatReroughing.h      |
| Finishing                       | ProMfgFeatFinishing.h       |
| Corner Finishing                | ProMfgFeatCornerFinishing.h |
| 2-Axis Curve Trajectory Milling | ProMfgFeat2xCurvTraj.h      |
| 3-Axis Trajectory Milling       | ProMfgFeatTrajectory.h      |
| Profile Milling                 | ProMfgFeatProfMilling.h     |
| Manual Cycle                    | ProMfgFeatManualCycle.h     |
| Thread Milling                  | ProMfgFeatThreadMilling.h   |
| Area Turning                    | ProMfgFeatTurning.h         |
| Groove Turning                  | ProMfgFeatTurning.h         |
| Profile Turning                 | ProMfgFeatTurning.h         |
| Face Milling                    | ProMfgFeatFacing.h          |
| Creo NC Operation Definition    | ProMfgFeatOperation.h       |
| Workcell Definition             | ProMfgFeatWcellWedm.h       |
|                                 | ProMfgFeatWcellMill.h       |
|                                 | ProMfgFeatWcellMillTurn.h   |
|                                 | ProMfgFeatWcellLathe.h      |

| Creo NC Step             | Header File                     |
|--------------------------|---------------------------------|
|                          | ProMfgFeatWcellCmm.h            |
| Fixture Definition       | ProMfgFeatFixture.h             |
| Thread Turning           | ProMfgFeatTurnThread.h          |
| Holemaking               | ProMfgFeatHolemaking.h          |
| Shut-off Surface Feature | ProMoldShutSrf.h                |
| Round and Chamfer        | ProMfgFeatRoundChamferMilling.h |
| Engraving                | ProMfgFeatEngraving.h           |
| Cutline Milling          | ProMfgFeatCutlineMilling.h      |
| Drill Group Feature      | ProMfgFeatDrillGroup.h          |

## Element Trees: Roughing Step

This section describes how to construct and access the element tree for a milling roughing feature. It also describes how to create, redefine, and access the properties of these features.

### The Roughing Feature Element Tree:

This section describes how to construct and access the element tree for a milling roughing feature. It also describes how to create, redefine, and access the properties of these features.

The element tree for the milling roughing sequence is documented in the header file `ProMfgFeatRoughing.h`, and is as shown in the following figure:

## Element Tree for Roughing feature

The following table describes the elements in the element tree for the Roughing feature.

| Element ID                  | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE          | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_MILL.                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_STD_FEATURE_NAME      | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name for the Creo NC sequence. The default value is Roughing_1.                                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_NCSEQ_TYPE            | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of Creo NC sequence. The valid value for this element is PRO_NCSEQ_ROUGHVOL_MILL.                                                                                                                                                                                                                                                                                                                              |
| PRO_E_MFG_OPER_REF          | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the operation feature selection.                                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_NCSEQ_CSYS            | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the datum coordinate system that will be used as the coordinate system for the Creo NC sequence.                                                                                                                                                                                                                                                                                                                        |
| PRO_E_RETR_SURF             | Compound                 | Mandatory compound element. Specifies retract definition. For more information, refer to the section <a href="#">Retract Elements on page 1657</a> .                                                                                                                                                                                                                                                                                                 |
| PRO_E_MFG_SUB_SPINDLE_OPT   | PRO_VALUE_TYPE_INT       | Optional Element. Specifies the type of spindle assigned to the sequence. This element can be used when two parts are machined during the same operation in different spindles, that is in the main spindle and in the sub spindle. The valid values for this element are defined by the enumerated type ProSubSpindleOpt. For more information on the values of ProSubSpindleOpt, refer to the section <a href="#">Spindle Types on page 1674</a> . |
| PRO_E_MFG_TOOL_REF_COMPOUND | Compound                 | Mandatory compound element. Specifies tool reference definition. For more information, refer to the section <a href="#">Tool Reference on page 1660</a> .                                                                                                                                                                                                                                                                                            |
| PRO_E_MFG_TOOL_ADAPTER_NAME | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the tool adapter model name.                                                                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_MFG_PARAM_SITE_NAME   | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name of the site file with default values for manufacturing parameters.                                                                                                                                                                                                                                                                                                                                              |

| Element ID                 | Data Type                | Description                                                                                                                                                                                                                                                                                    |
|----------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            |                          |  <b>Note</b><br>The site file name will be ignored if the site does not exist in the manufacturing model.                                                                                                     |
| PRO_E_MFG_PARAM_ARR        | Array                    | Mandatory element. Defines an array of manufacturing parameters. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> .                                                                                                                            |
| PRO_E_MFG_CMP_MILL_WIND    | Compound                 | Mandatory compound element. Specifies the mill window compound definition. For more information, refer to the section <a href="#">Surface Collection with Mill Window on page 1664</a> .                                                                                                       |
| PRO_E_TOOL_MTN_ARR         | Array                    | Mandatory element. Specifies an array of tool motions.                                                                                                                                                                                                                                         |
| PRO_E_TOOL_MTN             | Compound                 | Mandatory compound element. Specifies the tool motion compound specifications. The applicable tool motion type for this element is : PRO_TM_TYPE_AUTOMATIC_CUT.<br><br>For more information, refer to the section <a href="#">Tool Motion — Auto Cut on page 1750</a> .                        |
| PRO_E_MFG_START_PNT        | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to start the machining at the specified position.                                                                                                                                                                             |
| PRO_E_MFG_END_PNT          | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to end the machining at the specified position.                                                                                                                                                                               |
| PRO_E_MFG_PREREQUISITE_ARR | Array                    | Optional element. This array specifies the Ids of the prerequisite sequences. For more information, refer to the section <a href="#">Sequence Prerequisites on page 1666</a> .                                                                                                                 |
| PRO_E_MFG_PROCESS_REF      | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the reference selections such as part, feature, curve, surface, datum plane, axis, point, and datum coordinate. It allows you to create additional geometric references to be used only in special process application. This element supports multiple selections. |

| Element ID               | Data Type              | Description                                                                                                                                                                                                                                                                                                                                  |
|--------------------------|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_FEAT_VIEW_NAME | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the name of the view. This element allows you to associate a specific view with the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                      |
| PRO_E_MFG_SIMP_REP_NAME  | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the simplified representation name. This element allows you to associate the specific simplified representation with the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application. |
| PRO_E_MFG_TIME_ESTIMATE  | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the time estimated for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                                                                             |
| PRO_E_MFG_COST_ESTIMATE  | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the cost estimate for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                                                                              |
| PRO_E_MFG_TIME_ACTUAL    | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the actual time for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                                                                                |
| PRO_E_MFG_COMMENTS       | PRO_VALUE_TYPE_WSTRING | Specifies the sequence comments.                                                                                                                                                                                                                                                                                                             |

## Element Trees: Reroughing Step

This section describes how to construct and access the element tree for a milling reroughing feature. It also describes how to create, redefine, and access the properties of these features.

---

## The Reroughing Feature Element Tree:

This section describes how to construct and access the element tree for a milling reroughing feature. It also describes how to create, redefine, and access the properties of these features.

The element tree for the milling reroughing sequence is documented in the header file `ProMfgFeatReroughing.h`, and is as shown in the following figure:

## Element Tree for Reroughing feature

The following table describes the elements in the element tree for the Reroughing feature.

| Element ID                  | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE          | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of the feature . The valid value for this element is PRO_FEAT_MILL.                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_STD_FEATURE_NAME      | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name for the Creo NC sequence feature name. The default value is Re-roughing_1.                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_NCSEQ_TYPE            | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of Creo NC sequence type. The valid value for this element is PRO_NCSEQ_REROUGH_MILL.                                                                                                                                                                                                                                                                                                                          |
| PRO_E_MFG_OPER_REF          | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the operation feature selection.                                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_NCSEQ_CSYS            | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the datum coordinate system that will be used as the coordinate system for the Creo NC sequence.                                                                                                                                                                                                                                                                                                                        |
| PRO_E_RETR_SURF             | Compound                 | Mandatory compound element. Specifies retract definition. For more information, refer to the section <a href="#">Retract Elements on page 1657</a> .                                                                                                                                                                                                                                                                                                 |
| PRO_E_MFG_SUB_SPINDLE_OPT   | PRO_VALUE_TYPE_INT       | Optional Element. Specifies the type of spindle assigned to the sequence. This element can be used when two parts are machined during the same operation in different spindles, that is in the main spindle and in the sub spindle. The valid values for this element are defined by the enumerated type ProSubSpindleOpt. For more information on the values of ProSubSpindleOpt, refer to the section <a href="#">Spindle Types on page 1674</a> . |
| PRO_E_MFG_TOOL_REF_COMPOUND | Compound                 | Mandatory compound element. Specifies tool reference definition. For more information, refer to the section <a href="#">Tool Reference on page 1660</a> .                                                                                                                                                                                                                                                                                            |
| PRO_E_MFG_TOOL_ADAPTER_NAME | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the tool adapter model name.                                                                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_MFG_PARAM_SITE_NAME   | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name of the site file with default values for manufacturing parameters.                                                                                                                                                                                                                                                                                                                                              |

| Element ID                 | Data Type                | Description                                                                                                                                                                                                                                                                   |
|----------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            |                          |  <b>Note</b><br>The site file name will be ignored if the site does not exist in the manufacturing model.                                                                                  |
| PRO_E_MFG_PARAM_ARR        | Array                    | Mandatory element. Defines an array of manufacturing parameters. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> .                                                                                                           |
| PRO_E_MFG_CMP_MILL_WIND    | Compound                 | Mandatory compound element. Specifies the mill window compound definition. For more information, refer to the section <a href="#">Surface Collection with Mill Window on page 1664</a> .                                                                                      |
| PRO_E_MFG_PREV_SEQ         | PRO_VALUE_TYPE_SELECTION | Mandatory Element. Specifies the selection sequence feature that requires removal of left over material. The valid values for this element are: <ul style="list-style-type: none"> <li>• Volume Milling</li> <li>• Profile Milling</li> <li>• Re-roughing sequence</li> </ul> |
| PRO_E_TOOL_MTN_ARR         | Array                    | Mandatory element. Specifies an array of tool motions.                                                                                                                                                                                                                        |
| PRO_E_TOOL_MTN             | Compound                 | Mandatory compound element. Specifies the tool motion compound specifications. The applicable tool motion type for this element is PRO_TM_TYPE_AUTOMATIC_CUT. For more information, refer to the section <a href="#">Tool Motion — Auto Cut on page 1750</a> .                |
| PRO_E_MFG_START_PNT        | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to start the machining at the specified position.                                                                                                                                                            |
| PRO_E_MFG_END_PNT          | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to end the machining at the specified position.                                                                                                                                                              |
| PRO_E_MFG_PREREQUISITE_ARR | Array                    | Optional element. This array specifies the Ids of the prerequisite sequences. For more information, refer to the section <a href="#">Sequence Prerequisites on page 1666</a> .                                                                                                |
| PRO_E_MFG_PROCESS_REF      | PRO_VALUE_TYPE_          | Optional element. Specifies the                                                                                                                                                                                                                                               |

| Element ID               | Data Type              | Description                                                                                                                                                                                                                                                                                                                              |
|--------------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | SELECTION              | reference selections such as part, feature, curve, surface, datum plane, axis, point, and datum coordinate. It allows you to create additional geometric references to be used only in special process application. This element supports multiple selections.                                                                           |
| PRO_E_MFG_FEAT_VIEW_NAME | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the name of the view. This element allows you to associate a specific view with the machining step.<br><br> <b>Note</b><br>This element is used only in special process application.                                        |
| PRO_E_MFG_SIMP_REP_NAME  | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the simplified representation name. This element allows you to associate the specific simplified representation with the machining step.<br><br> <b>Note</b><br>This element is used only in special process application. |
| PRO_E_MFG_TIME_ESTIMATE  | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the time estimated for the machining step.<br><br> <b>Note</b><br>This element is used only in special process application.                                                                                               |
| PRO_E_MFG_COST_ESTIMATE  | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the cost estimate for the machining step.<br><br> <b>Note</b><br>This element is used only in special process application.                                                                                                |
| PRO_E_MFG_TIME_ACTUAL    | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the actual time for the machining step..<br><br> <b>Note</b><br>This element is used only in special process application.                                                                                                 |
| PRO_E_MFG_COMMENTS       | PRO_VALUE_TYPE_WSTRING | Specifies the sequence comments.                                                                                                                                                                                                                                                                                                         |

---

## Element Trees: Finishing Step

This section describes how to construct and access the element tree for milling Finishing feature. It also describes how to create, redefine, and access the properties of these features.

### The Finishing Feature Element Tree:

This section describes how to construct and access the element tree for milling Finishing feature. It also describes how to create, redefine, and access the properties of these features.

The element tree for the milling Finishing sequence is documented in the header file `ProMfgFeatFinishing.h`, and is as shown in the following figure:

## Element Tree for Finishing feature

The following table describes the elements in the element tree for the Finishing feature.

| Element ID                  | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE          | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_MILL.                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_STD_FEATURE_NAME      | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name for the Creo NC sequence. The default value is Finishing_1.                                                                                                                                                                                                                                                                                                                                                     |
| PRO_E_NCSEQ_TYPE            | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of Creo NC sequence. The valid value for this element is PRO_NCSEQ_CVNC_FINISH_MILL.                                                                                                                                                                                                                                                                                                                           |
| PRO_E_MFG_OPER_REF          | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the operation feature selection.                                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_NCSEQ_CSYS            | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the datum coordinate system that will be used as the coordinate system for the Creo NC sequence.                                                                                                                                                                                                                                                                                                                        |
| PRO_E_RETR_SURF             | Compound                 | Mandatory compound element. Specifies retract definition. For more information, refer to the section <a href="#">Retract Elements on page 1657</a> .                                                                                                                                                                                                                                                                                                 |
| PRO_E_MFG_SUB_SPINDLE_OPT   | PRO_VALUE_TYPE_INT       | Optional Element. Specifies the type of spindle assigned to the sequence. This element can be used when two parts are machined during the same operation in different spindles, that is in the main spindle and in the sub spindle. The valid values for this element are defined by the enumerated type ProSubSpindleOpt. For more information on the values of ProSubSpindleOpt, refer to the section <a href="#">Spindle Types on page 1674</a> . |
| PRO_E_MFG_TOOL_REF_COMPOUND | Compound                 | Mandatory compound element. Specifies tool reference definition. For more information, refer to the section <a href="#">Tool Reference on page 1660</a> .                                                                                                                                                                                                                                                                                            |
| PRO_E_MFG_TOOL_ADAPTER_NAME | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the tool adapter model name.                                                                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_MFG_PARAM_SITE_NAME   | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name of the site file with default values for manufacturing parameters.                                                                                                                                                                                                                                                                                                                                              |

| Element ID                 | Data Type                | Description                                                                                                                                                                                                                                                                                    |
|----------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            |                          |  <b>Note</b><br>The site file name will be ignored if the site does not exist in the manufacturing model.                                                                                                     |
| PRO_E_MFG_PARAM_ARR        | Array                    | Mandatory element. Defines an array of manufacturing parameters. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> .                                                                                                                            |
| PRO_E_MFG_CMP_MILL_WIND    | Compound                 | Mandatory compound element. Specifies the mill window compound definition. For more information, refer to the section <a href="#">Surface Collection with Mill Window on page 1664</a> .                                                                                                       |
| PRO_E_TOOL_MTN_ARR         | Array                    | Mandatory element. Specifies an array of tool motions.                                                                                                                                                                                                                                         |
| PRO_E_TOOL_MTN             | Compound                 | Mandatory compound element. Specifies the tool motion compound specifications. The applicable tool motion type for this element is : PRO_TM_TYPE_AUTOMATIC_CUT.<br><br>For more information, refer to the section <a href="#">Tool Motion — Auto Cut on page 1750</a> .                        |
| PRO_E_MFG_START_PNT        | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to start the machining at the specified position.                                                                                                                                                                             |
| PRO_E_MFG_END_PNT          | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to end the machining at the specified position.                                                                                                                                                                               |
| PRO_E_MFG_PREREQUISITE_ARR | Array                    | Optional element. This array specifies the Ids of the prerequisite sequences. For more information, refer to the section <a href="#">Sequence Prerequisites on page 1666</a> .                                                                                                                 |
| PRO_E_MFG_PROCESS_REF      | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the reference selections such as part, feature, curve, surface, datum plane, axis, point, and datum coordinate. It allows you to create additional geometric references to be used only in special process application. This element supports multiple selections. |

| Element ID               | Data Type              | Description                                                                                                                                                                                                                                                                                                                                  |
|--------------------------|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_FEAT_VIEW_NAME | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the name of the view. This element allows you to associate a specific view with the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                      |
| PRO_E_MFG_SIMP_REP_NAME  | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the simplified representation name. This element allows you to associate the specific simplified representation with the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application. |
| PRO_E_MFG_TIME_ESTIMATE  | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the time estimated for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                                                                             |
| PRO_E_MFG_COST_ESTIMATE  | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the cost estimate for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                                                                              |
| PRO_E_MFG_TIME_ACTUAL    | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the actual time for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                                                                                |
| PRO_E_MFG_COMMENTS       | PRO_VALUE_TYPE_WSTRING | Specifies the sequence comments.                                                                                                                                                                                                                                                                                                             |

## Element Trees: Corner Finishing Step

This section describes how to construct and access the element tree for a corner finishing step. It also describes how to create, redefine, and access the properties of these features.

## Element Trees: 3-Axis Trajectory Milling Step

This section describes how to construct and access the element tree for the 3 Axis Trajectory Milling feature. It also describes how to create, redefine, and access the properties of these features. For 2-axis curve trajectory milling step, refer to the section [Manufacturing 2-Axis Curve Trajectory Milling Step on page 1474](#).

## Manufacturing 2-Axis Curve Trajectory Milling Step

The element tree for the 2-axis curve trajectory sequence is documented in the header file `ProMfgFeat2xCurvTraj.h`, and is as shown in the following figure:

```
PRO E FEATURE TREE
-- PRO E FEATURE TYPE
-- PRO E STD FEATURE NAME

The following table describes the elements in the element tree for the 2-axis curve trajectory sequence feature.

| Element ID                  | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE          | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of the feature . The valid value for this element is PRO_FEAT_MILL.                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_STD_FEATURE_NAME      | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the sequence feature name. The default value is Curve_Trajectory_1.                                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_NCSEQ_TYPE            | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of Creo NC sequence type. The valid value for this element is PRO_NCSEQ_FF_TRAJ_MILL.                                                                                                                                                                                                                                                                                                                          |
| PRO_E_MFG_OPER_REF          | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the operation feature selection.                                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_NCSEQ_CSYS            | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the coordinate system datum feature to be used as a sequence coordinate system.                                                                                                                                                                                                                                                                                                                                         |
| PRO_E_RETR_SURF             | Compound                 | Mandatory element. Specifies the retract compound definition. The element tree for the Retract Elements is defined in the section <a href="#">Retract Elements on page 1657</a> . For more information, refer to the section Retract Elements for more information on the element tree.                                                                                                                                                              |
| PRO_E_MFG_SUB_SPINDLE_OPT   | PRO_VALUE_TYPE_INT       | Optional Element. Specifies the type of spindle assigned to the sequence. This element can be used when two parts are machined during the same operation in different spindles, that is in the main spindle and in the sub spindle. The valid values for this element are defined by the enumerated type ProSubSpindleOpt. For more information on the values of ProSubSpindleOpt, refer to the section <a href="#">Spindle Types on page 1674</a> . |
| PRO_E_MFG_TOOL_REF_COMPOUND | Compound                 | Mandatory element. Specifies the tool reference compound definition. The element tree for the Tool Reference is defined in the header file ProMfgElemToolRef.h. For more information, refer to the section <a href="#">Tool Reference on page 1660</a> for more information on the element tree.                                                                                                                                                     |
| PRO_E_MFG_TOOL_ADAPTER_     | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Element ID                      | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME                            |                          | tool adapter model name.                                                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_MFG_PARAM_SITE_NAME       | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name of site with default values for manufacturing parameters.<br><br> <b>Note</b><br><br>The name is going to be ignored if site does not exist in the manufacturing model.                                                                                                 |
| PRO_E_MFG_PARAM_ARR             | Array                    | Mandatory element. Specifies an array of manufacturing parameters. See the Creo NC online help for more information on manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file ProMfgElemParam.h. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree. |
| PRO_E_MFG_LOOP_SURF_REF         | PRO_VALUE_TYPE_SELECTION | Optional element. Select the surfaces for which the loops of edges must be collected. The collected loops of edges are machined.                                                                                                                                                                                                                                                              |
| PRO_E_MFG_TRAJ_CRV              | Compound                 | Mandatory element. Specifies the machining curves compound definition.                                                                                                                                                                                                                                                                                                                        |
| PRO_E_STD_CURVE_COLLECTION_APPL | Curve Collection         | Mandatory element. Specifies the curve collection.                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_FF_TRAJ_FLIP_OPT          | PRO_VALUE_TYPE_INT       | Optional element. Flips the machining direction of the tool. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE—Specifies that the default direction on the curve will be used.</li> <li>PRO_B_FALSE—Specifies that the opposite direction on the curve will be used.</li> </ul>                                                                        |
| PRO_E_MFG_OFFSET                | Compound                 | Optional element. Specifies the offset compound definition.                                                                                                                                                                                                                                                                                                                                   |
| PRO_E_MFG_OFFSET_CUT            | PRO_VALUE_TYPE_INT       | Optional element. Specifies the offset cut. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE—Tool offset will be applied.</li> <li>PRO_B_FALSE—Tool offset will not be applied.</li> </ul>                                                                                                                                                            |
| PRO_E_MFG_MAT_TO_RMV            | PRO_VALUE_TYPE_INT       | Optional element. Specifies the                                                                                                                                                                                                                                                                                                                                                               |

| Element ID                 | Data Type                | Description                                                                                                                                                                                                                                                                                                                             |
|----------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            |                          | material side. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_MFG_DIR_SAME—Specifies the default side will be used.</li> <li>PRO_MFG_DIR_OPPOSITE—Specifies that the default side will be flipped.</li> </ul>                                                                                        |
| PRO_E_MFG_DRV_SRF_DIR      | PRO_VALUE_TYPE_INT       | Optional element. Specifies the flip drive Surface direction. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_FALSE—Specifies that the default direction on the drive surface will be used.</li> <li>PRO_B_TRUE—Specifies that the opposite direction on the drive surface will be used.</li> </ul> |
| PRO_E_MFG_START_HEIGHT     | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the selection of the plane where machining will begin.                                                                                                                                                                                                                                                      |
| PRO_E_MFG_HEIGHT           | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies single selection of the plane for the tool tip to follow.                                                                                                                                                                                                                                                   |
| PRO_E_TOOL_MTN_ARR         | Array                    | Optional element. Specifies an array of tool motions.                                                                                                                                                                                                                                                                                   |
| PRO_E_TOOL_MTN             | Compound                 | Optional element. Specifies the tool motion compound specification.                                                                                                                                                                                                                                                                     |
| PRO_E_MFG_START_PNT        | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. Allows to start machining at the specified position.                                                                                                                                                                                                                             |
| PRO_E_MFG_END_PNT          | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. Allows to end machining at the specified position.                                                                                                                                                                                                                               |
| PRO_E_MFG_PREREQUISITE_ARR | Array                    | Optional element. Specifies the array of ids of prerequisite sequences. The element tree for the Sequence Prerequisites is defined in the header file <code>ProMfgElemPrerequisite.h</code> . For more information, refer to the section <a href="#">Sequence Prerequisites</a> on page 1666 for more information on the element tree.  |
| PRO_E_MFG_PROCESS_REF      | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the reference selections such as part, feature, curve, surface, datum plane, axis, point, and datum coordinate. It allows you to create                                                                                                                                                                     |

| Element ID               | Data Type              | Description                                                                                                                                                                                                                                                                                                                  |
|--------------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                        | additional geometry references to be used only in special process application. This element supports multiple selections.                                                                                                                                                                                                    |
| PRO_E_MFG_FEAT_VIEW_NAME | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the view name. It allows you to associate specific view with a machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                             |
| PRO_E_MFG_SIMP_REP_NAME  | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the simplified representation name. It allows you to associate a specific simplified representation with a machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application. |
| PRO_E_MFG_TIME_ESTIMATE  | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the time estimate. It allows you to specify time estimate for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                        |
| PRO_E_MFG_COST_ESTIMATE  | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the cost estimate. It allows you to specify cost estimate for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                        |
| PRO_E_MFG_TIME_ACTUAL    | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the actual time. It allows you to specify actual time for the machining step<br><br> <b>Note</b><br><br>This element is used only in special process application.                                             |
| PRO_E_MFG_COMMENTS       | PRO_VALUE_TYPE_WSTRING | Specifies the sequence comments.                                                                                                                                                                                                                                                                                             |

---

## The Corner Finishing Element Tree:

This section describes how to construct and access the element tree for a corner finishing step. It also describes how to create, redefine, and access the properties of these features.

The element tree for the corner finishing sequence is documented in the header file `ProMfgFeatCornerFinishing.h`, and is as shown in the following figure:

## Element Tree for Corner Finishing Step

| Element ID                  | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE          | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_MILL.                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_STD_FEATURE_NAME      | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name for the Creo NC sequence. The default value is Corner_Finishing_1.                                                                                                                                                                                                                                                                                                                                              |
| PRO_E_NCSEQ_TYPE            | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of Creo NC sequence. The valid value for this element is PRO_NCSEQ_CVNC_CORN_MILL.                                                                                                                                                                                                                                                                                                                             |
| PRO_E_MFG_OPER_REF          | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the operation feature selection.                                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_NCSEQ_CSYS            | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the datum coordinate system that will be used as the coordinate system for the Creo NC sequence.                                                                                                                                                                                                                                                                                                                        |
| PRO_E_RETR_SURF             | Compound                 | Mandatory compound element. Specifies retract definition. For more information, refer to the section <a href="#">Retract Elements on page 1657</a> .                                                                                                                                                                                                                                                                                                 |
| PRO_E_MFG_SUB_SPINDLE_OPT   | PRO_VALUE_TYPE_INT       | Optional Element. Specifies the type of spindle assigned to the sequence. This element can be used when two parts are machined during the same operation in different spindles, that is in the main spindle and in the sub spindle. The valid values for this element are defined by the enumerated type ProSubSpindleOpt. For more information on the values of ProSubSpindleOpt, refer to the section <a href="#">Spindle Types on page 1674</a> . |
| PRO_E_MFG_TOOL_REF_COMPOUND | Compound                 | Mandatory compound element. Specifies tool reference definition. For more information, refer to the section <a href="#">Tool Reference on page 1660</a> .                                                                                                                                                                                                                                                                                            |
| PRO_E_MFG_TOOL_ADAPTER_NAME | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the tool adapter model name.                                                                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_MFG_PARAM_SITE_NAME   | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name of the site file with default values for manufacturing parameters.                                                                                                                                                                                                                                                                                                                                              |

| Element ID                 | Data Type                | Description                                                                                                                                                                                                                                                      |
|----------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            |                          |  <b>Note</b><br>The site file name will be ignored if the site does not exist in the manufacturing model.                                                                       |
| PRO_E_MFG_PARAM_ARR        | Array                    | Mandatory element. Defines an array of manufacturing parameters. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> .                                                                                              |
| PRO_E_MFG_CMP_MILL_WIND    | Compound                 | Mandatory compound element. Specifies the mill window compound definition. For more information, refer to the section <a href="#">Surface Collection with Mill Window on page 1664</a> .                                                                         |
| PRO_E_MFG_PREV_TOOL_ID     | PRO_VALUE_TYPE_WSTRING   | Optional element. Name of cutting tool (tool id) which will be used for calculating the remainder material.                                                                                                                                                      |
| PRO_E_TOOL_MTN_ARR         | Array                    | Mandatory element. Specifies an array of tool motions.                                                                                                                                                                                                           |
| PRO_E_TOOL_MTN             | Compound                 | Mandatory compound element. Specifies the tool motion compound specifications. The applicable tool motion type for this element is : PRO_TM_TYPE_AUTOMATIC_CUT. For more information, refer to the section <a href="#">Tool Motion — Auto Cut on page 1750</a> . |
| PRO_E_MFG_START_PNT        | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to start the machining at the specified position.                                                                                                                                               |
| PRO_E_MFG_END_PNT          | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to end the machining at the specified position.                                                                                                                                                 |
| PRO_E_MFG_PREREQUISITE_ARR | Array                    | Optional element. This array specifies the Ids of the prerequisite sequences. For more information, refer to the section <a href="#">Sequence Prerequisites on page 1666</a> .                                                                                   |
| PRO_E_MFG_PROCESS_REF      | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the reference selections such as part, feature, curve, surface, datum plane, axis, point, and datum coordinate. It allows you to create additional geometric references to                                                           |

| Element ID               | Data Type              | Description                                                                                                                                                                                                                                                                                                                                  |
|--------------------------|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                        | be used only in special process application. This element supports multiple selections.                                                                                                                                                                                                                                                      |
| PRO_E_MFG_FEAT_VIEW_NAME | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the name of the view. This element allows you to associate a specific view with the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                      |
| PRO_E_MFG_SIMP_REP_NAME  | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the simplified representation name. This element allows you to associate the specific simplified representation with the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application. |
| PRO_E_MFG_TIME_ESTIMATE  | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the time estimated for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                                                                             |
| PRO_E_MFG_COST_ESTIMATE  | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the cost estimate for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                                                                              |
| PRO_E_MFG_TIME_ACTUAL    | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the actual time for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                                                                                |
| PRO_E_MFG_COMMENTS       | PRO_VALUE_TYPE_WSTRING | Specifies the sequence comments.                                                                                                                                                                                                                                                                                                             |

## Element Trees: Manual Cycle Step

This section describes how to construct and access the element tree for manual milling cycle feature. It also describes how to create, redefine, and access the properties of these features.

### The Manual Cycle Step Feature Element Tree:

This section describes how to construct and access the element tree for manual milling cycle feature. It also describes how to create, redefine, and access the properties of these features.

The element tree for the manual cycle step feature is documented in the header file `ProMfgFeatManualCycle.h`, and is as shown in the following figure:

## Element Tree for Manual Cycle Step feature

The following table lists the contents of PRO\_E\_TOOL\_MTN element.

| Element ID                | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE        | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of the feature . The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_FEAT_MILL— For milling manual cycle.</li> <li>PRO_FEAT_TURN— For turning manual cycle.</li> </ul>                                                                                                                                                                                                    |
| PRO_E_STD_FEATURE_NAME    | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name for the Creo NC sequence. The default value is Manual_Cycle_1.                                                                                                                                                                                                                                                                                                                                           |
| PRO_E_NCSEQ_TYPE          | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of Creo NC sequence. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_SEQ_MANUAL_CYCLE_MILL— For milling manual cycle.</li> <li>PRO_SEQ_MANUAL_CYCLE_TURN— For turning manual cycle.</li> </ul>                                                                                                                                                                        |
| PRO_E_MFG_OPER_REF        | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the operation feature selection.                                                                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_Creo NC SEQ_CSYS    | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the datum coordinate system that will be used as the coordinate system for the Creo NC sequence.                                                                                                                                                                                                                                                                                                                 |
| PRO_E_RETR_SURF           | Compound                 | This compound element specifies retract definition. For more information, refer to the section <a href="#">Retract Elements. on page 1657</a> <div>  <b>Note</b> <p>This element is mandatory for milling manual Creo NC sequences and is ignored for turning manual sequences.</p> </div>                                                                 |
| PRO_E_MFG_SUB_SPINDLE_OPT | PRO_VALUE_TYPE_INT       | Optional Element. Specifies the type of spindle assigned to the sequence. This element can be used when two parts are machined during the same operation in different spindles, that is in the main spindle and in the sub spindle. The valid values for this element are defined by the enumerated type ProSubSpindleOpt. For more information on the values of ProSubSpindleOpt, refer to the section <a href="#">Spindle Types on page</a> |

| Element ID                  | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                             |                        | <a href="#">1674.</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| PRO_E_MFG_TOOL_REF_COMPOUND | Compound               | Mandatory compound element. Specifies tool reference definition. For more information, refer to the section <a href="#">Tool Reference on page 1660.</a>                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_MFG_TOOL_ADAPTER_NAME | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the tool adapter model name.<br><br> <b>Note</b><br><br>This element is optional for milling manual sequences and is ignored for turning manual sequences.                                                                                                                                                                                                                                                                                                                      |
| PRO_E_MFG_PARAM_SITE_NAME   | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the name of the site file with default values for manufacturing parameters.<br><br> <b>Note</b><br><br>The site file name will be ignored if the site does not exist in the manufacturing model.                                                                                                                                                                                                                                                                                |
| PRO_E_MFG_PARAM_ARR         | Array                  | Mandatory element. Defines an array of manufacturing parameters. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661.</a>                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_TOOL_MTN_ARR          | Array                  | Mandatory element. Specifies an array of tool motions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| PRO_E_TOOL_MTN              | Compound               | Mandatory compound element. Specifies the tool motion compound specifications. The applicable tool motion types for this element are: <ul style="list-style-type: none"> <li>• PRO_TM_TYPE_FOLLOW_CURVE. For more information, refer to the section <a href="#">Tool Motion — Follow Curve on page 1678.</a></li> <li>• PRO_TM_TYPE_GOTO_POINT. For more information, refer to the section <a href="#">Tool Motion — Go To Point on page 1680.</a></li> <li>• PRO_TM_TYPE_GO_DELTA. For more information, refer to the section <a href="#">Tool Motion — Go Delta on page 1684.</a></li> </ul> |

| Element ID          | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| PRO_E_MFG_START_PNT | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to start the machining at the specified position.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| PRO_E_MFG_END_PNT   | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Element ID                 | Data Type                | Description                                                                                                                                                                                                                                                                                                                                    |
|----------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            |                          | end the machining at the specified position.                                                                                                                                                                                                                                                                                                   |
| PRO_E_MFG_PREREQUISITE_ARR | Array                    | Optional element. This array specifies the Ids of the prerequisite sequences. For more information, refer to the section <a href="#">Sequence Prerequisites on page 1666</a> .                                                                                                                                                                 |
| PRO_E_MFG_PROCESS_REF      | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the reference selections such as part, feature, curve, surface, datum plane, axis, point, and datum coordinate. It allows you to create additional geometric references to be used only in special process application. This element supports multiple selections.                                                 |
| PRO_E_MFG_FEAT_VIEW_NAME   | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name of the view. This element allows you to associate a specific view with the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                        |
| PRO_E_MFG_SIMP_REP_NAME    | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the simplified representation name. This element allows you to associate the specific simplified representation with the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application. |
| PRO_E_MFG_TIME_ESTIMATE    | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the time estimated for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                                                                               |
| PRO_E_MFG_COST_ESTIMATE    | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the cost estimate for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                                                                                |

| Element ID            | Data Type              | Description                                                                                                                                                                                                                           |
|-----------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_TIME_ACTUAL | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the actual time for the machining step.<br><br> <b>Note</b><br>This element is used only in special process application. |
| PRO_E_MFG_COMMENTS    | PRO_VALUE_TYPE_WSTRING | Specifies the sequence comments.                                                                                                                                                                                                      |

## Element Trees: Thread Milling

This section describes how to construct and access the element tree for a thread roughing feature. It also describes how to create, redefine, and access the properties of these features.

### The Thread Milling Feature Element Tree:

This section describes how to construct and access the element tree for a thread roughing feature. It also describes how to create, redefine, and access the properties of these features.

The element tree for the thread milling Creo NC sequence is documented in the header file `ProMfgFeatThreadMilling.h`, and is as shown in the following figure:

## Element tree for PRO\_E\_TOOL\_MTN element

| Element ID                      | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE              | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_MILL.                                                                                                                                                                                                                                                                                                      |
| PRO_E_STD_FEATURE_NAME          | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name for the Creo NC sequence. The default value is Thread_Milling_1.                                                                                                                                                                                                                                                                                                         |
| PRO_E_NCSEQ_TYPE                | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of Creo NC sequence. The valid value for this element is PRO_NCSEQ_THREAD_MILL.                                                                                                                                                                                                                                                                                         |
| PRO_E_MFG_OPER_REF              | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the operation feature selection.                                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_NCSEQ_CSYS                | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the datum coordinate system that will be used as the coordinate system for the Creo NC sequence.                                                                                                                                                                                                                                                                                 |
| PRO_E_RETR_SURF                 | Compound                 | <p>Mandatory compound element. Specifies retract definition. For more information, refer to the section <a href="#">Retract Elements on page 1657</a>.</p> <p> <b>Note</b></p> <p>This element is mandatory when PRO_E_DRILL_MODE is set to PRO_DRILL_HOLE_ON_MILL and is ignored when set to PRO_DRILL_HOLE_ON_LATHE.</p> |
| PRO_E_MFG_MILL_THREAD_TYPE_OPT  | PRO_VALUE_TYPE_INT       | <p>Mandatory element. Specifies the thread type. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>External</li> <li>Internal</li> </ul> <p>The value for this element is defined by the ProMillThreadType parameter.</p>                                                                                                                                                     |
| PRO_E_MFG_MILL_THREAD_TAPER_OPT | PRO_VALUE_TYPE_INT       | <p>Mandatory element. Specifies the taper type. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>None</li> <li>NTP</li> <li>Custom</li> </ul> <p>The value for this element is defined by the ProMillThreadTaperType</p>                                                                                                                                                     |

| Element ID                  | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                             |                        | parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_MFG_SUB_SPINDLE_OPT   | PRO_VALUE_TYPE_INT     | Optional Element. Specifies the type of spindle assigned to the sequence. This element can be used when two parts are machined during the same operation in different spindles, that is in the main spindle and in the sub spindle. The valid values for this element are defined by the enumerated type <code>ProSubSpindleOpt</code> . For more information on the values of <code>ProSubSpindleOpt</code> , refer to the section <a href="#">Spindle Types on page 1674</a> . |
| PRO_E_MFG_TOOL_REF_COMPOUND | Compound               | Mandatory compound element. Specifies tool reference definition. For more information, refer to the section <a href="#">Tool Reference on page 1660</a> .                                                                                                                                                                                                                                                                                                                        |
| PRO_E_MFG_TOOL_ADAPTER_NAME | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the tool adapter model name.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| PRO_E_MFG_PARAM_SITE_NAME   | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the name of the site file with default values for manufacturing parameters.<br><br> <b>Note</b><br><br>The site file name will be ignored if the site does not exist in the manufacturing model.                                                                                                                                                                |
| PRO_E_MFG_PARAM_ARR         | Array                  | Mandatory element. Defines an array of manufacturing parameters. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> .                                                                                                                                                                                                                                                                                                              |
| PRO_E_MFG_THRM_HOLESET_ARR  | Array                  | Specifies an array of thread holesets. It gives specification of threads to machine. For more information, refer to the section <a href="#">Manufacturing Thread Milling Holeset on page 1496</a> .                                                                                                                                                                                                                                                                              |
| PRO_E_TOOL_MTN_ARR          | Array                  | Mandatory element. Specifies an array of tool motions.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| PRO_E_TOOL_MTN              | Compound               | Mandatory compound element. Specifies the tool motion compound specifications. The applicable tool motion types for this element are: <ul style="list-style-type: none"> <li>• <code>PRO_TM_TYPE_THREAD_</code></li> </ul>                                                                                                                                                                                                                                                       |

| Element ID | Data Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| PRO_E_MFG_START_PNT        | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to start the machining at the specified position.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_MFG_END_PNT          | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to end the machining at the specified position.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| PRO_E_MFG_PREREQUISITE_ARR | Array                    | Optional element. This array specifies the Ids of the prerequisite sequences. For more information, refer to the section <a href="#">Sequence Prerequisites</a> on page 1666.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_MFG_PROCESS_REF      | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the reference selections such as part, feature, curve, surface, datum plane, axis, point, and datum coordinate. It allows you to create additional geometric references to be used only in special process application. This element supports                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Element ID               | Data Type              | Description                                                                                                                                                                                                                                                                                                                                |
|--------------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                        | multiple selections.                                                                                                                                                                                                                                                                                                                       |
| PRO_E_MFG_FEAT_VIEW_NAME | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the name of the view. This element allows you to associate a specific view with the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                      |
| PRO_E_MFG_SIMP_REP_NAME  | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the simplified representation name. This element allows you to associate the specific simplified representation with the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application. |
| PRO_E_MFG_TIME_ESTIMATE  | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the time estimated for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                                                                             |
| PRO_E_MFG_COST_ESTIMATE  | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the cost estimate for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                                                                              |
| PRO_E_MFG_TIME_ACTUAL    | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the actual time for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                                                                                |
| PRO_E_MFG_COMMENTS       | PRO_VALUE_TYPE_WSTRING | Specifies the sequence comments.                                                                                                                                                                                                                                                                                                           |

## Manufacturing Thread Milling Holeset

The element PRO\_E\_MFG\_THRM\_HOLESET\_ARR is documented in the header file ProMfgElemThreadHoleset.h, and is shown in the following figure.

## Element tree for Manufacturing Thread Milling Holeset

The following table lists the contents of PRO\_E\_MFG\_THRM\_HOLESET\_ARR element.

| Element ID                       | Data Type                | Description                                                                                                                                                                                                                                                        |
|----------------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_THRM_HOLESET_ARR       | Array                    | This element specifies an array of thread holesets. It gives specifications about machining references.                                                                                                                                                            |
| PRO_E_MFG_THRM_HOLESET_COMPOUND  | Compound                 | Mandatory element. This compound element specifies the thread holeset definition.<br><br> <b>Note</b><br>Specify this element only when the holeset array has at least one member |
| PRO_E_HOLESET_TYPE               | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the holeset type. The valid value for this element is PRO_HOLESET_DRILL_AXES.                                                                                                                                                         |
| PRO_E_HOLESET_START              | Compound                 | Mandatory element. Specifies the holmaking start compound specification.                                                                                                                                                                                           |
| PRO_E_HOLESET_START_TYPE         | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the start surface option using the enumerated value ProDrillStartType.                                                                                                                                                                |
| PRO_E_HOLESET_START_SURFACE      | PRO_VALUE_TYPE_SELECTION | Specifies the starting surface or quilt selection.<br><br> <b>Note</b><br>This element is mandatory if the element PRO_E_HOLESET_START_TYPE is set to PRO_DRILL_FROM_SURFACE.   |
| PRO_E_MFG_THRM_HSET_END_COMPOUND | Compound                 | Mandatory element. Specifies the thread depth compound specification.                                                                                                                                                                                              |
| PRO_E_HOLESET_END_TYPE           | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the end type option. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_DRILL_UPTO_SURFACE</li> <li>PRO_DRILL_AUTO_END</li> <li>PRO_DRILL_OFFSET_FROM_START</li> </ul>                                 |
| PRO_E_HOLESET_END_SURFACE        | PRO_VALUE_TYPE_SELECTION | Specifies the end surface or quilt                                                                                                                                                                                                                                 |

| Element ID                 | Data Type             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|-----------------------------------|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_HOLESET_SEL_<br>UNSEL_AXES  | PRO_VALUE_TYPE_<br>SELECTION | Optional element. Specifies the selection of axes of holes to be excluded for machining. This element supports multiple selections. |
| PRO_E_MFG_HSET_START_<br>HOLE_REF | PRO_VALUE_TYPE_<br>SELECTION | Optional element. Specifies the axis selection for the hole to be machined first.                                                   |

## Element Trees: Turning Step

This section describes how to construct and access the element tree for a turning step. It also describes how to create, redefine, and access the properties of these features. Refer to the Creo NC Help for more information on the Turn type Creo NC sequences.

### The Turning Element Tree:

The element tree for the turning step is documented in the header file `ProMfgFeatTurning.h`, and is as shown in the following figure:

## Element Tree for Turning feature

The following table describes the elements in the element tree for the area turning feature.

| Element ID             | Data Type              | Description                                                                                              |
|------------------------|------------------------|----------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE     | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_TURN. |
| PRO_E_STD_FEATURE_NAME | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the name for the Creo NC sequence. The default values for this element       |

| Element ID                  | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                             |                          | <p>are:</p> <ul style="list-style-type: none"> <li>Area_Turning_2—For area turning Creo NC sequences.</li> <li>Profile_Turning_1—For profile turning Creo NC sequences.</li> <li>Groove_Turning_1—For groove turning Creo NC sequences.</li> </ul>                                                                                                                                                                                                                                           |
| PRO_E_SEQ_TYPE              | PRO_VALUE_TYPE_INT       | <p>Mandatory element. Specifies the type of Creo NC sequence. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_SEQ_AREA_TURN—For an area turning sequence.</li> <li>PRO_SEQ_GROOVE_TURN—For a groove turning sequence.</li> <li>PRO_SEQ_PROF_TURN—For a profile turning sequence.</li> </ul>                                                                                                                                                            |
| PRO_E_MFG_OPER_REF          | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the operation feature selection.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| PRO_E_SEQ_CSYS              | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the datum coordinate system that will be used as the coordinate system for the Creo NC sequence.                                                                                                                                                                                                                                                                                                                                                                |
| PRO_E_MFG_SUB_SPINDLE_OPT   | PRO_VALUE_TYPE_INT       | <p>Optional Element. Specifies the type of spindle assigned to the Creo NC sequence. This element can be used when two parts are machined during the same operation in different spindles, that is in the main spindle and in the sub spindle. The valid values for this element are defined by the enumerated type <code>ProSubSpindleOpt</code>. For more information on the values of <code>ProSubSpindleOpt</code>, refer to the section <a href="#">Spindle Types on page 1674</a>.</p> |
| PRO_E_MFG_TOOL_REF_COMPOUND | Compound                 | Mandatory compound element. Specifies retract definition. For more information, refer to the section <a href="#">Retract Elements on page 1657</a> .                                                                                                                                                                                                                                                                                                                                         |
| PRO_E_MFG_PARAM_SITE_NAME   | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name of the site file with default values for manufacturing parameters.                                                                                                                                                                                                                                                                                                                                                                                      |

| Element ID          | Data Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Element ID                 | Data Type                | Description                                                                                                                                                                                                                                                                                                                                    |
|----------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_START_PNT        | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to start the machining at the specified position.                                                                                                                                                                                                                             |
| PRO_E_MFG_END_PNT          | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to end the machining at the specified position.                                                                                                                                                                                                                               |
| PRO_E_MFG_PREREQUISITE_ARR | Array                    | Optional element. This array specifies the Ids of the prerequisite Creo NC sequences. For more information, refer to the section <a href="#">Sequence Prerequisites</a> on page 1666.                                                                                                                                                          |
| PRO_E_MFG_PROCESS_REF      | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the reference selections such as part, feature, curve, surface, datum plane, axis, point, and datum coordinate. It allows you to create additional geometric references to be used only in special process application. This element supports multiple selections.                                                 |
| PRO_E_MFG_FEAT_VIEW_NAME   | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name of the view. This element allows you to associate a specific view with the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                      |
| PRO_E_MFG_SIMP_REP_NAME    | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the simplified representation name. This element allows you to associate the specific simplified representation with the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application. |
| PRO_E_MFG_TIME_ESTIMATE    | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the time estimated for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                                                                               |
| PRO_E_MFG_COST_ESTIMATE    | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the cost estimate for the machining                                                                                                                                                                                                                                                                                |

| Element ID            | Data Type              | Description                                                                                                                                                                                                                           |
|-----------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       |                        | step.<br><br> <b>Note</b><br>This element is used only in special process application.                                                               |
| PRO_E_MFG_TIME_ACTUAL | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the actual time for the machining step.<br><br> <b>Note</b><br>This element is used only in special process application. |
| PRO_E_MFG_COMMENTS    | PRO_VALUE_TYPE_WSTRING | Specifies the sequence comments.                                                                                                                                                                                                      |

## Element Trees: Thread Turning Step

This section describes how to construct and access the element tree for a thread turning step. It also describes how to create, redefine, and access the properties of these features.

### The Thread Turning Element Tree:

This section describes how to construct and access the element tree for a thread turning step. It also describes how to create, redefine, and access the properties of these features.

The element tree for the thread turning Creo NCsequence is documented in the header file `ProMfgFeatTurnThread.h`, and is as shown in the following figure:

## Element Tree for Thread Turning feature

| Element ID                      | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE              | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_TURN.                                                                                                                                                                                                                                                       |
| PRO_E_STD_FEATURE_NAME          | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name for the Creo NC sequence. The default value for this element is Thread_Turning_1.                                                                                                                                                                                                                                         |
| PRO_E_SEQ_TYPE                  | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of Creo NC sequence. The valid value for this element is PRO_SEQ_THREAD_TURN                                                                                                                                                                                                                                             |
| PRO_E_MFG_OPER_REF              | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the operation feature selection.                                                                                                                                                                                                                                                                                                  |
| PRO_E_TURN_THREAD_LOCATION_TYPE | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the location of the thread. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_E_TURN_OPTION_OUT—For external threads</li> <li>PRO_E_TURN_OPTION_IN—For internal threads</li> </ul>                                                                                                                |
| PRO_E_TURN_THREAD_OUTPUT_TYPE   | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of output You can specify one of the following valid values for this element: <ul style="list-style-type: none"> <li>PRO_E_TURN_THREAD_ISO</li> <li>PRO_E_TURN_THREAD_AI_MACRO</li> </ul>                                                                                                                                |
| PRO_E_TURN_THREAD_FORM_TYPE     | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of the thread. . The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_E_TURN_THREAD_UNIFIED—For Unified threads</li> <li>PRO_E_TURN_THREAD_GENERAL—For General threads</li> <li>PRO_E_TURN_THREAD_BUTTRESS—For Buttress threads</li> <li>PRO_E_TURN_THREAD_ACME—For Acme threads</li> </ul> |
| PRO_E_SEQ_CSYS                  | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the datum coordinate system that will be used as the coordinate system for the Creo NC sequence.                                                                                                                                                                                                                                  |
| PRO_E_MFG_SUB_SPINDLE_OPT       | PRO_VALUE_TYPE_INT       | Optional Element. Specifies the type of spindle assigned to the sequence. This element can be used when two parts are machined during the same operation in                                                                                                                                                                                                    |

| Element ID                  | Data Type                | Description                                                                                                                                                                                                                                                                                                     |
|-----------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                             |                          | different spindles, that is in the main spindle and in the sub spindle. The valid values for this element are defined by the enumerated type ProSubSpindleOpt. For more information on the values of ProSubSpindleOpt, refer to the section <a href="#">Spindle Types on page 1674</a>                          |
| PRO_E_MFG_TOOL_REF_COMPOUND | Compound                 | Mandatory compound element. Specifies retract definition. For more information, refer to the section <a href="#">Retract Elements on page 1657</a> .                                                                                                                                                            |
| PRO_E_MFG_PARAM_SITE_NAME   | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name of the site file with default values for manufacturing parameters.<br><br> <b>Note</b><br><br>The site file name will be ignored if the site does not exist in the manufacturing model. |
| PRO_E_MFG_PARAM_ARR         | Array                    | Mandatory element. Defines an array of manufacturing parameters. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> .                                                                                                                                             |
| PRO_E_TURN_PROFILE          | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies turn profile selection.                                                                                                                                                                                                                                                            |
| PRO_E_TOOL_MTN_ARR          | Array                    | Mandatory element. Specifies an array of tool motions.                                                                                                                                                                                                                                                          |
| PRO_E_TOOL_MTN              | Compound                 | Mandatory compound element. Specifies the tool motion compound specifications. For more information, refer to the section <a href="#">Tool Motion — Auto Cut on page 1750</a> .                                                                                                                                 |
| PRO_E_MFG_START_PNT         | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to start the machining at the specified position.                                                                                                                                                                                              |
| PRO_E_MFG_END_PNT           | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to end the machining at the specified position.                                                                                                                                                                                                |
| PRO_E_MFG_PREREQUISITE_ARR  | Array                    | Optional element. This array specifies the Ids of the prerequisite sequences. For more information,                                                                                                                                                                                                             |

| Element ID               | Data Type                | Description                                                                                                                                                                                                                                                                                                                              |
|--------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                          | refer to the section <a href="#">Sequence Prerequisites</a> on page 1666.                                                                                                                                                                                                                                                                |
| PRO_E_MFG_PROCESS_REF    | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the reference selections such as part, feature, curve, surface, datum plane, axis, point, and datum coordinate. It allows you to create additional geometric references to be used only in special process application. This element supports multiple selections.                                           |
| PRO_E_MFG_FEAT_VIEW_NAME | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name of the view. This element allows you to associate a specific view with the machining step.<br><br> <b>Note</b><br>This element is used only in special process application.                                        |
| PRO_E_MFG_SIMP_REP_NAME  | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the simplified representation name. This element allows you to associate the specific simplified representation with the machining step.<br><br> <b>Note</b><br>This element is used only in special process application. |
| PRO_E_MFG_TIME_ESTIMATE  | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the time estimated for the machining step.<br><br> <b>Note</b><br>This element is used only in special process application.                                                                                               |
| PRO_E_MFG_COST_ESTIMATE  | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the cost estimate for the machining step.<br><br> <b>Note</b><br>This element is used only in special process application.                                                                                                |

| Element ID            | Data Type              | Description                                                                                                                                                                                                                             |
|-----------------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| PRO_E_MFG_COMMENTS    | PRO_VALUE_TYPE_WSTRING | Specifies the sequence comments                                                                                                                                                                                                         |

## Element Trees: Creo NC Operation Definition

This section describes how to construct and access the element tree for a Creo NC operation definition feature. It also describes how to create, redefine, and access the properties of these features.

### The Creo NC Operation Definition Element Tree:

This section describes how to construct and access the element tree for a Creo NC operation definition feature. It also describes how to create, redefine, and access the properties of these features.

The element tree for the Creo NC operation sequence is documented in the header file `ProMfgFeatOperation.h`, and is as shown in the following figure:

## Element Tree for Creo NC operation definition feature

| Element ID             | Data Type              | Description                                                                                                   |
|------------------------|------------------------|---------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE     | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_OPERATION. |
| PRO_E_STD_FEATURE_NAME | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the name for the Creo NC sequence. The default value for this element is OP040.   |

| Element ID            | Data Type                | Description                                                                                                                                                                                                                                                                                                                          |
|-----------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_OPER_CSYS       | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the datum coordinate system that will be used as the operation coordinate system for the Creo NC sequence.                                                                                                                                                                                              |
| PRO_E_OPER_SUBSP_CSYS | PRO_VALUE_TYPE_SELECTION | Optional element. Select a coordinate system geometry item which can be used as a sub-spindle coordinate system.                                                                                                                                                                                                                     |
| PRO_E_MFG_WCELL_REF   | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the workcell feature selection.                                                                                                                                                                                                                                                                         |
| PRO_E_RETR_SURF       | Compound                 | Mandatory compound element. Specifies retract definition. For more information, refer to the section <a href="#">Retract Elements on page 1657</a> .                                                                                                                                                                                 |
| PRO_E_MFG_FROM1_PNT   | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. Allows to start machining by the head 1 tool at the specified position.                                                                                                                                                                                                       |
| PRO_E_MFG_HOME1_PNT   | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. Allows to end machining by the head 1 tool at the specified position.                                                                                                                                                                                                         |
| PRO_E_MFG_FROM2_PNT   | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. Allows to start machining by the head 2 tool at the specified position.<br><br> <b>Note</b><br><br>This element is ignored for workcells with single head.                               |
| PRO_E_MFG_HOME2_PNT   | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. Allows to end machining by head the 2 tool at the specified position.<br><br> <b>Note</b><br><br>This element is ignored for workcells with single head.                                 |
| PRO_E_MFG_FROM3_PNT   | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point geometry item selection. Allows to start machining by the head 3 tool at the specified position.<br><br> <b>Note</b><br><br>This element is ignored for workcells with number of heads less than 3. |

| Element ID          | Data Type                | Description                                                                                                                                                                                                                                                                                                                             |
|---------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_HOME3_PNT | PRO_VALUE_TYPE_SELECTION | <p>Optional element. Specifies the datum point geometry item selection. Allows to end machining by the head 3 tool at the specified position.</p> <p> <b>Note</b></p> <p>This element is ignored for workcells with number of heads less than 3.</p>   |
| PRO_E_MFG_FROM4_PNT | PRO_VALUE_TYPE_SELECTION | <p>Optional element. Specifies the datum point geometry item selection. Allows to start machining by the head 4 tool at the specified position.</p> <p> <b>Note</b></p> <p>This element is ignored for workcells with number of heads less than 4.</p> |
| PRO_E_MFG_HOME4_PNT | PRO_VALUE_TYPE_SELECTION | <p>Optional element. Specifies the datum point geometry item selection. Allows to end machining by the head 4 tool at the specified position.</p> <p> <b>Note</b></p> <p>This element is ignored for workcells with number of heads less than 4.</p> |
| PRO_E_MFG_PARAM_ARR | Array                    | <p>Mandatory element. Specifies an array of applicable manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file <code>ProMfgElemParam.h</code>.</p>                                                                                                                                     |

| Element ID                    | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               |                          | <p>For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree.</p> <p> <b>Note</b></p> <p>For new features, if the parameter array is not specified the default values will be assigned to the corresponding manufacturing parameters of the created feature.</p> |
| PRO_E_MFG_OPER_STOCK_MATERIAL | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the stock material name.                                                                                                                                                                                                                                                                                                                                                                                |
| PRO_E_MFG_FIXTURE_REF         | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the selection of a fixture setup feature.                                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_FIXTURE_COMPONENT_REF   | Array                    | Optional element. Specifies an array of operation fixture setup components that can be inserted into the top assembly. This array can be specified either in combination with or without a fixture setup reference specified by PRO_E_MFG_FIXTURE_REF. This element supports multiple selections.                                                                                                                                   |
| PRO_E_MFG_TIME_ESTIMATE       | PRO_VALUE_TYPE_DOUBLE    | <p>Optional element. Specifies the time estimated for the machining step.</p> <p> <b>Note</b></p> <p>This element is used only in special process application.</p>                                                                                                                                                                             |
| PRO_E_MFG_COST_ESTIMATE       | PRO_VALUE_TYPE_DOUBLE    | <p>Optional element. Specifies the cost estimate for the machining step.</p> <p> <b>Note</b></p> <p>This element is used only in special process application.</p>                                                                                                                                                                              |

| Element ID            | Data Type              | Description                                                                                                                                                                                                                               |
|-----------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| PRO_E_MFG_COMMENTS    | PRO_VALUE_TYPE_WSTRING | Specifies the sequence comments.                                                                                                                                                                                                          |

## Element Trees: Workcell Definition

This section describes how to construct and access the element tree for a workcell definition. It also describes how to create, redefine, and access the properties of these features.

### The Manufacturing WEDM Workcell Element Tree

This section describes how to construct and access the element tree for a workcell definition. It also describes how to create, redefine, and access the properties of these features.

The element tree for the WEDM workcell type is documented in the header file `ProMfgFeatWcellWedm.h`, and is as shown in the following figure:

## Element Tree for WEDM workcell feature

```

PRO_E_FEATURE_TREE
|
|-- PRO_E_FEATURE_TYPE
|
|-- PRO_E_STD_FEATURE_NAME
|
|-- PRO_E_WCELL_TYPE
|
|-- PRO_E_MFG_WCELL_NUM_AXES
|
|-- PRO_E_MFG_ENABLE_CMM_OPT
|
|-- PRO_E_MFG_PARAM_ARR
|
|-- PRO_E_MFG_WCELL_HEAD_1
| |
| |-- PRO_E_MFG_WCELL_TOOL_SETUP_ARR

|
|-- PRO_E_MFG_COMMENTS

```

The following table describes the elements in the element tree for the WEDM workcell feature.

| Element ID               | Data Type              | Description                                                                                                                              |
|--------------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE       | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_WORKCELL.                             |
| PRO_E_STD_FEATURE_NAME   | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the name for the Creo NC sequence. The default value for this element is WEDM01.                             |
| PRO_E_WCELL_TYPE         | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the type of the workcell used for the Creo NC sequence. The valid value for this element is PRO_WCELL_WEDM. |
| PRO_E_MFG_WCELL_NUM_AXES | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the number of controlled axes                                                                               |

| Element ID                     | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                |                        | (number of programmable motion directions). The valid values for this element are: <ul style="list-style-type: none"> <li>• PRO_WCELL_2_AXIS</li> <li>• PRO_WCELL_4_AXIS</li> </ul>                                                                                                                                                                                                                                                                                                                                     |
| PRO_E_MFG_ENABLE_CMM_OPT       | PRO_VALUE_TYPE_INT     | Allows enabling/disabling of the tool head for the creation of CMM sequences. The valid values for this element are: <ul style="list-style-type: none"> <li>• PRO_B_TRUE: Enables tool head with CMM probes and allows the creation of CMM sequences</li> <li>• PRO_B_FALSE: Disables CMM tool head and creation of CMM sequences.</li> </ul> <p> <b>Note</b></p> <p>This element is optional , when CMM tool head is not defined.</p> |
| PRO_E_MFG_PARAM_ARR            | Array                  | Mandatory element. Defines an array of manufacturing parameters. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> .                                                                                                                                                                                                                                                                                                                                                     |
| PRO_E_MFG_WCELL_HEAD_1         | Compound               | Optional element. Specifies the tool head compound definition.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| PRO_E_MFG_WCELL_TOOL_SETUP_ARR | Array                  | Optional element. Specifies the tool setup array. For more information, refer to the section <a href="#">Element Trees: Tool Setup on page 1667</a> .                                                                                                                                                                                                                                                                                                                                                                   |
| PRO_E_MFG_WCELL_CMM_HEAD       | Compound               | Optional element. Specifies the CMM probes head compound definition. <p> <b>Note</b></p> <p>This element is ignored if PRO_E_MFG_ENABLE_CMM_OPT is set to PRO_B_FALSE.</p>                                                                                                                                                                                                                                                           |
| PRO_E_MFG_CMM_TOOL_SETUP_ARR   | Array                  | Optional element. Specifies the CMM probes setup array. For more information, refer to the section <a href="#">Element Trees: CMM Probe Setup on page 1670</a> .                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_MFG_COMMENTS             | PRO_VALUE_TYPE_WSTRING | Specifies the workcell comments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Element Trees: Manufacturing Mill Workcell

This section describes how to construct and access the element tree for manufacturing mill workcell feature. It also describes how to create, redefine, and access the properties of these features.

### The Mill Workcell Feature Element Tree:

This section describes how to construct and access the element tree for manufacturing mill workcell feature. It also describes how to create, redefine, and access the properties of these features.

The element tree for the manufacturing mill workcell feature is documented in the header file `ProMfgFeatWcellMill.h`, and is as shown in the following figure:

## Element Tree for Mill Workcell feature

| Element ID             | Data Type              | Description                                                                                                  |
|------------------------|------------------------|--------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE     | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_WORKCELL. |
| PRO_E_STD_FEATURE_NAME | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the name for the Creo NC sequence. The default value for this element is MILL01. |

| Element ID                     | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_WCELL_TYPE               | PRO_VALUE_TYPE_INT | Mandatory element. Specifies the type of the workcell used for the Creo NC sequence. The valid value for this element is PRO_WCELL_MILL.                                                                                                                                                                                                                                                                                                                                                                                                         |
| PRO_E_MFG_WCELL_NUM_AXES       | PRO_VALUE_TYPE_INT | Mandatory element. Specifies the number of controlled axes (number of programmable motion directions). The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_WCELL_3_AXIS</li> <li>PRO_WCELL_4_AXIS</li> <li>PRO_WCELL_5_AXIS</li> </ul>                                                                                                                                                                                                                                                                             |
| PRO_E_MFG_ENABLE_CMM_OPT       | PRO_VALUE_TYPE_INT | Specifies enabling/disabling of the tool head for the creation of CMM sequences. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE: Enables tool head with CMM probes and allows the creation of CMM sequences</li> <li>PRO_B_FALSE: Disables CMM tool head and creation of the CMM sequences.</li> </ul> <div>  <b>Note</b><br/> This element is optional, when CMM tool head is not defined or is disabled. </div> |
| PRO_E_MFG_PARAM_ARR            | Array              | Mandatory element. Defines an array of manufacturing parameters. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> .                                                                                                                                                                                                                                                                                                                                                                              |
| PRO_E_MFG_WCELL_HEAD_1         | Compound           | Optional element. Specifies the tool head compound definition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| PRO_E_MFG_WCELL_TOOL_SETUP_ARR | Array              | Optional element. Specifies the tool setup array. For more information, refer to the section <a href="#">Element Trees: Tool Setup on page 1667</a> .                                                                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_MFG_WCELL_CMM_HEAD       | Compound           | Optional compound element. Specifies the CMM probes head                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Element ID                      | Data Type              | Description                                                                                                                                                                                                                          |
|---------------------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| PRO_E_MFG_CMM_TOOL_SETUP_ARR    | Array                  | Optional element. Specifies the CMM probes setup array. For more information, refer to the section <a href="#">Element Trees: CMM Probe Setup on page 1670</a> .                                                                     |
| PRO_E_MFG_WCELL_CUST_CYCLE_ARR  | Array                  | Optional element. Specifies the array of custom cycle names (to be used by holmaking sequences). For holmaking sequences, For more information, refer to the section <a href="#">Manufacturing Holmaking Step on page 1561</a> .     |
| PRO_E_MFG_WCELL_CUST_CYCLE_COMP | Compound               | Optional compound element. Specifies the compound definition of a custom cycle name.                                                                                                                                                 |
| PRO_E_MFG_WCELL_CUST_CYCLE_NAME | PRO_VALUE_TYPE_WSTRING | Specifies the custom cycle name.<br><br> <b>Note</b><br>This element is a mandatory child of PRO_E_MFG_WCELL_CUST_CYCLE_COMP element.             |
| PRO_E_MFG_WCELL_ASSEM_COMPOUND  | Compound               | Optional compound element. Specifies the Simulation assembly compound definition.                                                                                                                                                    |
| PRO_E_MFG_WCELL_ASSEMBLY_NAME   | Assembly Name          | Specifies the simulation assembly model name.<br><br> <b>Note</b><br>This element is a mandatory child of PRO_E_MFG_WCELL_ASSEM_COMPOUND element. |

| Element ID                     | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_WCELL_LOCAL_CSYS_REF | PRO_VALUE_TYPE_SELECTION | <p>Specifies the coordinate system datum feature. It will be aligned with the simulation assembly coordinate system during machining simulation.</p> <p> <b>Note</b></p> <ul style="list-style-type: none"> <li>This element is a mandatory child element of PRO_E_MFG_WCELL_ASSEMBLY_COMPOUND element.</li> </ul> |
| PRO_E_MFG_COMMENTS             | PRO_VALUE_TYPE_WSTRING   | Specifies the workcell comments.                                                                                                                                                                                                                                                                                                                                                                      |

### Example 1: Creating or Redefining a Tool from a File

The sample code in `UgMfgToolFileReadWrite.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_mfg` shows how to create a tool or redefine it from a file and save the information about the tool to a file.

### Example 1: Creating or Redefining a Tool from a File

The sample code in `UgMfgToolFileReadWrite.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_mfg` shows how to create a tool or redefine it from a file and save the information about the tool to a file.

## Element Trees: Manufacturing Mill/Turn Workcell

This section describes how to construct and access the element tree for a mill turn workcell. It also describes how to create, redefine, and access the properties of these features.

### The Mill/Turn Workcell Element Tree:

This section describes how to construct and access the element tree for a mill turn workcell. It also describes how to create, redefine, and access the properties of these features.

The element tree for the mill/turn workcell is documented in the header file `ProMfgFeatWcellMillTurn.h`, and is as shown in the following figure:

## Element Tree for Mill/Turn Workcell

| Element ID             | Data Type              | Description                                                                                                                                    |
|------------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE     | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_WORKCELL.                                   |
| PRO_E_STD_FEATURE_NAME | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the name for the Creo NC sequence. The default value for this element is MILL01.                                   |
| PRO_E_WCELL_TYPE       | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the type of the workcell used for the Creo NC sequence. The valid value for this element is PRO_WCELL_MILL_N_TRN. |

| Element ID                      | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_WCELL_NUM_HEADS       | PRO_VALUE_TYPE_INT | Optional element. Specifies the number of tool heads (turrets). The valid values are: <ul style="list-style-type: none"> <li>PRO_MFG_ONE_HEAD_WCELL—This is the default value.</li> <li>PRO_MFG_TWO_HEAD_WCELL</li> </ul>                                                                                                                                      |
| PRO_E_MFG_WCELL_NUM_SPINDLES    | PRO_VALUE_TYPE_INT | Optional element. Specifies the number of spindles to be used for the feature creation. The valid values for this element are defined in the enumerated type <code>ProMfgWcellNumSpindles</code> and are as follows: <ul style="list-style-type: none"> <li>PRO_MFG_ONE_SPINDLE_WCELL—This is the default value.</li> <li>PRO_MFG_TWO_SPINDLE_WCELL</li> </ul> |
| PRO_E_MFG_LATHE_DIR_OPT         | PRO_VALUE_TYPE_INT | Optional element. Specifies the lathe orientation . The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_WCELL_LATHE_HORIZONTAL—This is the default value.</li> <li>PRO_WCELL_LATHE_VERTICAL</li> </ul>                                                                                                                           |
| PRO_E_MFG_WCELL_ENABLE_TURN_OPT | PRO_VALUE_TYPE_INT | Optional element. Specifies the enabling/disabling of the turning machine. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE—Enables the turning machining on the workcell. This is the default value.</li> <li>PRO_B_FALSE—Disables the turning machining on the workcell.</li> </ul>                                  |
| PRO_E_MFG_ENABLE_CMM_OPT        | PRO_VALUE_TYPE_INT | Optional element. Initializes a CMM operation. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE: Enables the tool head with CMM probes and allows the creation of CMM sequences.</li> <li>PRO_B_FALSE: Disables the CMM tool head and allows the creation of CMM sequences.</li> </ul>                                 |
| PRO_E_MFG_WCELL_NUM_AXES        | PRO_VALUE_TYPE_INT | Mandatory element. Specifies the number of controlled axes enabled                                                                                                                                                                                                                                                                                             |

| Element ID                     | Data Type | Description                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                |           | for milling sequences. The valid values for this element are: <ul style="list-style-type: none"> <li>• PRO_WCELL_3_AXIS</li> <li>• PRO_WCELL_4_AXIS</li> <li>• PRO_WCELL_5_AXIS</li> </ul>                                                                                                                                                                           |
| PRO_E_MFG_PARAM_ARR            | Array     | Mandatory element. Defines an array of manufacturing parameters. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> .                                                                                                                                                                                                  |
| PRO_E_MFG_WCELL_HEAD_1         | Compound  | Optional compound element. Specifies the compound definition for tool head 1.                                                                                                                                                                                                                                                                                        |
| PRO_E_MFG_WCELL_HEAD_2         | Compound  | Optional element. Specifies the compound definition for tool head 2. <p> <b>Note</b></p> <p>This element is ignored if you have set the element PRO_E_MFG_WCELL_NUM_HEADS to PRO_MFG_ONE_HEAD_WCELL value.</p>                                                                      |
| PRO_E_MFG_WCELL_TOOL_SETUP_ARR | Array     | Optional element. Specifies the Tool setup array. For more information, refer to the section <a href="#">Element Trees: Tool Setup on page 1667</a> .                                                                                                                                                                                                                |
| PRO_E_MFG_WCELL_HEAD_3         | Compound  | Optional element. Specifies the tools specification for head 3. <p> <b>Note</b></p> <p>This element is ignored for workcells with number of heads less than 3 that is, when the element PRO_E_MFG_WCELL_NUM_HEADS is set to PRO_MFG_ONE_HEAD_WCELL or PRO_MFG_TWO_HEAD_WCELL.</p> |
| PRO_E_MFG_WCELL_TOOL_SETUP_ARR | Array     | Optional element. Specifies the Tool setup array. For more information, refer to the section <a href="#">Element Trees: Tool Setup on page 1667</a> .                                                                                                                                                                                                                |
| PRO_E_MFG_WCELL_HEAD_4         | Compound  | Optional element. Specifies the                                                                                                                                                                                                                                                                                                                                      |

| Element ID                      | Data Type | Description                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 |           | <p>tools specification for head 4.</p> <p> <b>Note</b></p> <p>This element is ignored for workcells with number of heads less than 4 that is, when the element PRO_E_MFG_WCELL_NUM_HEADS is set to PRO_MFG_ONE_HEAD_WCELL, PRO_MFG_TWO_HEAD_WCELL or PRO_MFG_THREE_HEAD_WCELL.</p> |
| PRO_E_MFG_WCELL_TOOL_SETUP_ARR  | Array     | Optional element. Specifies the Tool setup array. For more information, refer to the section <a href="#">Element Trees: Tool Setup on page 1667</a> .                                                                                                                                                                                                                 |
| PRO_E_MFG_WCELL_CMM_HEAD        | Compound  | <p>Optional compound element. Specifies the CMM probes head compound definition.</p> <p> <b>Note</b></p> <p>This element is ignored if PRO_E_MFG_ENABLE_CMM_OPT is set to PRO_B_FALSE.</p>                                                                                       |
| PRO_E_MFG_CMM_TOOL_SETUP_ARR    | Array     | Optional element. Specifies the CMM probes setup array. For more information, refer to the section <a href="#">Element Trees: CMM Probe Setup on page 1670</a> .                                                                                                                                                                                                      |
| PRO_E_MFG_WCELL_CUST_CYCLE_ARR  | Array     | Optional element. Specifies the array of custom cycle names (to be used by holmaking sequences). For holmaking sequences, For more information, refer to the section <a href="#">Manufacturing Holmaking Step on page 1561</a> .                                                                                                                                      |
| PRO_E_MFG_WCELL_CUST_CYCLE_COMP | Compound  | Optional compound element. Specifies the compound definition of a custom cycle name.                                                                                                                                                                                                                                                                                  |

| Element ID                      | Data Type                | Description                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_WCELL_CUST_CYCLE_NAME | PRO_VALUE_TYPE_WSTRING   | Specifies the custom cycle name.<br><br> <b>Note</b><br><br>This element is a mandatory child of PRO_E_MFG_WCELL_CUST_CYCLE_COMP element.                                                                                                                       |
| PRO_E_MFG_WCELL_ASSEM_COMPOUND  | Compound                 | Optional compound element. Specifies the simulation assembly compound definition.                                                                                                                                                                                                                                                                |
| PRO_E_MFG_WCELL_ASSEMBLY_NAME   | Assembly Name            | Specifies the simulation assembly model name.<br><br> <b>Note</b><br><br>This element is a mandatory child of PRO_E_MFG_WCELL_ASSEM_COMPOUND element.                                                                                                           |
| PRO_E_MFG_WCELL_LOCAL_CSYS_REF  | PRO_VALUE_TYPE_SELECTION | Specifies the coordinate system datum feature. It will be aligned with the simulation assembly coordinate system during machining simulation.<br><br> <b>Note</b><br><br>This element is a mandatory child element of PRO_E_MFG_WCELL_ASSEM_COMPOUND element. |
| PRO_E_MFG_COMMENTS              | PRO_VALUE_TYPE_WSTRING   | Specifies the workcell comments.                                                                                                                                                                                                                                                                                                                 |

## PRO\_E\_MFG\_MILLTURN\_HEADS Element

The compound element PRO\_E\_MFG\_MILLTURN\_HEADS contains elements that can be used to define the parameters for the turret head. The elements of PRO\_E\_MFG\_MILLTURN\_HEADS are as follows:

- PRO\_E\_MFG\_MILLTURN\_HEAD\_1—Contains the options for the first turret.
- PRO\_E\_MFG\_MILLTURN\_HEAD\_2—Contains the options for the second turret.
- PRO\_E\_MFG\_MILLTURN\_HEAD\_3—Contains the options for the third turret.
- PRO\_E\_MFG\_MILLTURN\_HEAD\_4—Contains the options for the fourth turret.

- PRO\_E\_MILLTURN\_TOOL\_ROT\_DIR\_OPT

The elements PRO\_E\_MFG\_MILLTURN\_HEAD\_1, PRO\_E\_MFG\_MILLTURN\_HEAD\_2, PRO\_E\_MFG\_MILLTURN\_HEAD\_3 and PRO\_E\_MFG\_MILLTURN\_HEAD\_4 contain the following elements:

| Element ID                   | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_WCELL_HEAD_MILL_OPT    | PRO_VALUE_TYPE_INT | Optional element. Specifies the turret milling option. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE—Enables the milling operations for the turret head.</li> <li>PRO_B_FALSE—Disables the milling operations for the turret head.</li> </ul>                                                                                                                                                                                                                                            |
| PRO_E_WCELL_HEAD_TURN_OPT    | PRO_VALUE_TYPE_INT | Specifies the enabling/disabling of the turning option for the turret. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE—Enables the turning operations for the turret. This is the default value.</li> <li>PRO_B_FALSE—Disables the turning operations for the turret.</li> </ul> <p> <b>Note</b></p> <p>This element is ignored if the element PRO_E_MFG_WCELL_ENABLE_TURN_OPT is set to PRO_B_FALSE.</p> |
| PRO_E_WCELL_HEAD_FLASH_OPT   | PRO_VALUE_TYPE_INT | Optional element. Specifies the turret flash tool option. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE—Enables the flash tool for the turret.</li> <li>PRO_B_FALSE—Disables the flash tool for the turret.</li> </ul>                                                                                                                                                                                                                                                                   |
| PRO_E_WCELL_HEAD_ROT_POS_OPT | PRO_VALUE_TYPE_INT | Optional element. Specifies the turret rotation positioning option. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE—Enables the rotation positioning for the turret.</li> <li>PRO_B_FALSE—Disables the rotation positioning for the turret.</li> </ul>                                                                                                                                                                                                                                     |

---

## Element Trees: Manufacturing Lathe Workcell

This section describes how to construct and access the element tree for a lathe workcell. It also describes how to create, redefine, and access the properties of these features.

### The Lathe Workcell Element Tree:

This section describes how to construct and access the element tree for a lathe workcell. It also describes how to create, redefine, and access the properties of these features.

The element tree for the lathe workcell is documented in the header file `ProMfgFeatWcellLathe.h`, and is as shown in the following figure:

## Element Tree for Lathe Workcell

| Element ID                   | Data Type          | Description                                                                                                                                                                                                                                                                                                                                       |
|------------------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              |                    | type of the workcell used for the Creo NC sequence. The valid value for this element is PRO_WCELL_LATHE.                                                                                                                                                                                                                                          |
| PRO_E_MFG_WCELL_NUM_HEADS    | PRO_VALUE_TYPE_INT | Optional element. Specifies the number of tool heads (turrets). The valid values are: <ul style="list-style-type: none"> <li>PRO_MFG_ONE_HEAD_WCELL—This is the default value.</li> <li>PRO_MFG_TWO_HEAD_WCELL</li> </ul>                                                                                                                         |
| PRO_E_MFG_WCELL_NUM_SPINDLES | PRO_VALUE_TYPE_INT | Optional element. Specifies the number of spindles to be used for the feature creation. The valid values for this element are defined in the enumerated type ProMfgWcellNumSpindles and are as follows: <ul style="list-style-type: none"> <li>PRO_MFG_ONE_SPINDLE_WCELL—This is the default value.</li> <li>PRO_MFG_TWO_SPINDLE_WCELL</li> </ul> |
| PRO_E_MFG_LATHE_DIR_OPT      | PRO_VALUE_TYPE_INT | Optional element. Specifies the lathe orientation . The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_WCELL_LATHE_HORIZONTAL—This is the default value.</li> <li>PRO_WCELL_LATHE_VERTICAL</li> </ul>                                                                                                              |
| PRO_E_MFG_ENABLE_CMM_OPT     | PRO_VALUE_TYPE_INT | Optional element. Initializes a CMM operation. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE: Enables the tool head with CMM probes and allows the creation of CMM sequences.</li> <li>PRO_B_FALSE: Disables the CMM tool head and allows the creation of CMM sequences.</li> </ul>                    |
| PRO_E_MFG_PARAM_ARR          | Array              | Mandatory element. Defines an array of manufacturing parameters. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> .                                                                                                                                                                               |
| PRO_E_MFG_WCELL_HEAD_1       | Compound           | Optional compound element. Specifies the compound definition for tool head 1.                                                                                                                                                                                                                                                                     |
| PRO_E_MFG_WCELL_HEAD_2       | Compound           | Optional element. Specifies the                                                                                                                                                                                                                                                                                                                   |

| Element ID                      | Data Type              | Description                                                                                                                                                                                                                                                      |
|---------------------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 |                        | compound definition for tool head 2.<br><br> <b>Note</b><br>This element is ignored if you have set the element PRO_E_MFG_WCELL_NUM_HEADS to PRO_MFG_ONE_HEAD_WCELL value.      |
| PRO_E_MFG_WCELL_TOOL_SETUP_ARR  | Array                  | Optional element. Specifies the Tool setup array. For more information, refer to the section <a href="#">Element Trees: Tool Setup on page 1667</a> .                                                                                                            |
| PRO_E_MFG_WCELL_CMM_HEAD        | Compound               | Optional compound element. Specifies the CMM probes head compound definition.<br><br> <b>Note</b><br>This element is ignored if PRO_E_MFG_ENABLE_CMM_OPT is set to PRO_B_FALSE. |
| PRO_E_MFG_CMM_TOOL_SETUP_ARR    | Array                  | Optional element. Specifies the CMM probes setup array. For more information, refer to the section <a href="#">Element Trees: CMM Probe Setup on page 1670</a> .                                                                                                 |
| PRO_E_MFG_WCELL_CUST_CYCLE_ARR  | Array                  | Optional element. Specifies the array of custom cycle names (to be used by holmaking sequences). For holmaking sequences, For more information, refer to the section <a href="#">Manufacturing Holmaking Step on page 1561</a> .                                 |
| PRO_E_MFG_WCELL_CUST_CYCLE_COMP | Compound               | Optional compound element. Specifies the compound definition of a custom cycle name.                                                                                                                                                                             |
| PRO_E_MFG_WCELL_CUST_CYCLE_NAME | PRO_VALUE_TYPE_WSTRING | Specifies the custom cycle name.<br><br> <b>Note</b><br>This element is a mandatory child of PRO_E_MFG_WCELL_CUST_CYCLE_COMP element.                                         |
| PRO_E_MFG_WCELL_ASSEM_COMPOUND  | Compound               | Optional compound element. Specifies the Simulation assembly                                                                                                                                                                                                     |

| Element ID                     | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                     |

| Element ID               | Data Type              | Description                                                                                                                                                         |
|--------------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE       | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_WORKCELL.                                                        |
| PRO_E_STD_FEATURE_NAME   | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the name for the Creo NC sequence. The default value for this element is Add default value.                                             |
| PRO_E_WCELL_TYPE         | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the type of the workcell used for the Creo NC sequence. The valid value for this element is PRO_WCELL_CMM.                             |
| PRO_E_MFG_PARAM_ARR      | Array                  | Mandatory element. Defines an array of manufacturing parameters. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> . |
| PRO_E_MFG_WCELL_CMM_HEAD | Compound               | Optional compound element. Specifies the CMM probes head compound definition.                                                                                       |

| Element ID                                | Data Type                | Description                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_CMM_TOOL_SETUP_ARR              | Array                    | Optional element. Specifies the CMM probes setup array. For more information, refer to the section <a href="#">The CMM probe Setup Element Tree: on page 1670</a> .                                                                                                                                                                                   |
| PRO_E_MFG_WCELL_ASSEMBLY_COMPOUND         | Compound                 | Optional compound element. Specifies the simulation assembly compound definition.                                                                                                                                                                                                                                                                     |
| PRO_E_MFG_WCELL_ASSEMBLY_NAME             | Assembly Name            | Specifies the simulation assembly model name.<br><br> <b>Note</b><br><br>This element is a mandatory child of PRO_E_MFG_WCELL_ASSEMBLY_COMPOUND element.                                                                                                           |
| PRO_E_MFG_WCELL_LOCAL_CSYS_REF            | PRO_VALUE_TYPE_SELECTION | Specifies the coordinate system datum feature. It will be aligned with the simulation assembly coordinate system during machining simulation.<br><br> <b>Note</b><br><br>This element is a mandatory child element of PRO_E_MFG_WCELL_ASSEMBLY_COMPOUND element. |
| PRO_E_MFG_COMMENTS                        | PRO_VALUE_TYPE_WSTRING   | Specifies the workcell comments.                                                                                                                                                                                                                                                                                                                      |
| PRO_E_MFG_WCELL_ENABLE_GENERIC_CUTCOM_OPT | PRO_VALUE_TYPE_INT       | This parameter specifies a generic cutter compensation. When it is unselected, you can access the "Turn Cutter Compensation" layout, enabling you to refer to the unique cutcom for turning sequences. Toolpath computation uses the cutcom values based on the type of milling or turning                                                            |

## Element Trees: Profile Milling Step

This section describes how to construct and access the element tree for a profile milling step. It also describes how to create, redefine, and access the properties of these features.

## The Profile Milling Element Tree:

The element tree for the profile milling Creo NC sequence is documented in the header file `ProMfgFeatProfMilling.h`, and is as shown in the following figure:

### Element Tree for Profile Milling Sequence

| Element ID                 | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE         | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_MILL.                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_STD_FEATURE_NAME     | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name for the Creo NC sequence. The default value is Profile_Milling_1.                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_SEQ_TYPE             | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of Creo NC sequence. The valid value for this element is PRO_SEQ_PROF_SURF_MILL.                                                                                                                                                                                                                                                                                                                               |
| PRO_E_MFG_OPER_REF         | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the operation feature selection.                                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_MFG_SEQ_NUM_AXES_OPT | PRO_VALUE_TYPE_INT       | Specifies the number of controlled axes. The valid values are: <ul style="list-style-type: none"> <li>• 3—Applicable if work center allows 3-axis machining. This is the default value.</li> <li>• 4—Applicable if work center allows 4-axis or 5-axis machining. It is used for machining with the tool axis parallel to the plane specified in PRO_E_MFG_4_AXIS_PLANE.</li> <li>• 5—Applicable if work center allows 5-axis machining.</li> </ul>  |
| PRO_E_SEQ_CSYS             | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the datum coordinate system that will be used as the coordinate system for the Creo NC sequence.                                                                                                                                                                                                                                                                                                                        |
| PRO_E_RETR_SURF            | Compound                 | Mandatory compound element. Specifies retract definition. For more information, refer to the section <a href="#">Retract Elements on page 1657</a> .                                                                                                                                                                                                                                                                                                 |
| PRO_E_MFG_SUB_SPINDLE_OPT  | PRO_VALUE_TYPE_INT       | Optional Element. Specifies the type of spindle assigned to the sequence. This element can be used when two parts are machined during the same operation in different spindles, that is in the main spindle and in the sub spindle. The valid values for this element are defined by the enumerated type ProSubSpindleOpt. For more information on the values of ProSubSpindleOpt, refer to the section <a href="#">Spindle Types on page 1674</a> . |

| Element ID                     | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_TOOL_REF_COMPOUND    | Compound                 | Mandatory compound element. Specifies tool reference definition. For more information, refer to the section <a href="#">Tool Reference on page 1660</a> .                                                                                                                                                                                                                   |
| PRO_E_MFG_TOOL_ADAPTER_NAME    | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the tool adapter model name.                                                                                                                                                                                                                                                                                                                    |
| PRO_E_MFG_PARAM_SITE_NAME      | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name of the site file with default values for manufacturing parameters.<br><br> <b>Note</b><br><br>The site file name will be ignored if the site does not exist in the manufacturing model.                                                               |
| PRO_E_MFG_PARAM_ARR            | Array                    | Mandatory element. Defines an array of manufacturing parameters. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> .                                                                                                                                                                                                         |
| PRO_E_MACH_SURFS               | Compound                 | Mandatory element. Specifies the machining surfaces compound definition.                                                                                                                                                                                                                                                                                                    |
| PRO_E_MFG_SURF_SIDE_COMPOUND   | Compound                 | Optional compound element. Specifies the surfaces side compound definition. For more information, refer to the section <a href="#">Manufacturing Surface Side on page 1549</a> .                                                                                                                                                                                            |
| PRO_E_MFG_4_AXIS_PLANE         | PRO_VALUE_TYPE_SELECTION | Specifies the selection of datum plane or planar surface.<br><br> <b>Note</b> <ul style="list-style-type: none"><li>• This element is mandatory for 4-axis machining (PRO_E_MFG_SEQ_NUM_AXES_OPT set to 4).</li><li>• This element is ignored for 3-axis and 5-axis machining.</li></ul> |
| PRO_E_SCALLOP_SURF_COLL        | Compound                 | Optional compound element. Specifies the scallop surfaces compound definition.                                                                                                                                                                                                                                                                                              |
| PRO_E_STD_SURF_COLLECTION_APPL | Surface Collection       | Optional element. Specifies the scallop surfaces collection.                                                                                                                                                                                                                                                                                                                |
| PRO_E_CHECK_SURF_COLL          | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the check surfaces compound definition. For more information, refer to the section <a href="#">Checking</a>                                                                                                                                                                                                                                     |

| Element ID                  | Data Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                             |           | <a href="#">Surfaces on page 1671.</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_MFG_CMP_APPROACH_EXIT | Compound  | Optional element. Specifies the approach and exit compound definition. For more information, refer to the section <a href="#">Approach and Exit on page 1673.</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_TOOL_MTN_ARR          | Array     | Mandatory element. Specifies an array of tool motions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_TOOL_MTN              | Compound  | <p>Optional element. Specifies the tool motion compound specification and the applicable tool motion types for this element are:</p> <ul style="list-style-type: none"> <li>• <a href="#">Tool Motion — Profile Mill Cut on page 1748</a></li> <li>• <a href="#">Tool Motion — Follow Cut on page 1754</a></li> <li>• <a href="#">Tool Motion — Follow Curve on page 1678</a></li> <li>• <a href="#">Tool Motion — Go To Point on page 1680</a></li> <li>• <a href="#">Tool Motion — Go Delta on page 1684</a></li> <li>• <a href="#">Tool Motion — Go Home on page 1688</a></li> <li>• <a href="#">Tool Motion — Plunge on page 1756</a></li> <li>• <a href="#">Tool Motion — Go Retract on page 1693</a></li> <li>• <a href="#">Tool Motion — Tangent Approach on page 1710</a></li> <li>• <a href="#">Tool Motion — Tangent Exit on page 1712</a></li> <li>• <a href="#">Tool Motion — Normal Approach on page 1694</a></li> <li>• <a href="#">Tool Motion — Normal Exit on page 1697</a></li> <li>• <a href="#">Tool Motion — Lead In on page 1690</a></li> <li>• <a href="#">Tool Motion — Lead Out on page 1699</a></li> <li>• <a href="#">Tool Motion — Helical Approach on page 1701</a></li> <li>• <a href="#">Tool Motion — Helical Exit on page 1704</a></li> <li>• <a href="#">Tool Motion — Follow Curve on page 1678—For 4 and 5 axis machining.</a></li> </ul> |

| Element ID                 | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            |                          | <ul style="list-style-type: none"> <li>Approach Along Tool Axis on page 1674</li> <li>Exit Along Tool Axis on page 1676—For 4 and 5 axis machining.</li> </ul> <p> <b>Note</b></p> <p>The Follow Cut motion must be placed just after the element PRO_TM_TYPE_PROFILE_MILL_CUT, motion or another Follow Cut motion.</p> |
| PRO_E_MFG_START_PNT        | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to start the machining at the specified position.                                                                                                                                                                                                                                                                                        |
| PRO_E_MFG_END_PNT          | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to end the machining at the specified position.                                                                                                                                                                                                                                                                                          |
| PRO_E_MFG_PREREQUISITE_ARR | Array                    | Optional element. This array specifies the Ids of the prerequisite sequences. For more information, refer to the section <a href="#">Sequence Prerequisites on page 1666</a> .                                                                                                                                                                                                                            |
| PRO_E_MFG_PROCESS_REF      | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the reference selections such as part, feature, curve, surface, datum plane, axis, point, and datum coordinate. It allows you to create additional geometric references to be used only in special process application. This element supports multiple selections.                                                                                                            |
| PRO_E_MFG_FEAT_VIEW_NAME   | PRO_VALUE_TYPE_WSTRING   | <p>Optional element. Specifies the name of the view. This element allows you to associate a specific view with the machining step.</p> <p> <b>Note</b></p> <p>This element is used only in special process application.</p>                                                                                            |
| PRO_E_MFG_SIMP_REP_NAME    | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the simplified representation name. This element allows you to associate the specific simplified representation with the machining                                                                                                                                                                                                                                            |

| Element ID              | Data Type              | Description                                                                                                                                                                                                                            |
|-------------------------|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         |                        | step.<br> <b>Note</b><br>This element is used only in special process application.                                                                  |
| PRO_E_MFG_TIME_ESTIMATE | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the time estimated for the machining step.<br> <b>Note</b><br>This element is used only in special process application. |
| PRO_E_MFG_COST_ESTIMATE | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the cost estimate for the machining step.<br> <b>Note</b><br>This element is used only in special process application.  |
| PRO_E_MFG_TIME_ACTUAL   | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the actual time for the machining step.<br> <b>Note</b><br>This element is used only in special process application.  |
| PRO_E_MFG_COMMENTS      | PRO_VALUE_TYPE_WSTRING | Specifies the sequence comments.                                                                                                                                                                                                       |

## Manufacturing Surface Side

The element `PRO_E_MFG_SURF_SIDE_COMPOUND` is documented in the header file `ProMfgElemSurfSide.h`, and is as shown in the following figure:

```
-- PRO_E_MFG_SURF_SIDE_COMPOUND
|
| -- PRO_E_MFG_SURF_SIDE_TOLERANCE
|
| -- PRO_E_MFG_SURF_SIDE_FLIP_QUILTS
```

The following table describes the elements in the element tree for the surface side feature.

|                                 |                          |                                                                                                                                                                                                                                                            |
|---------------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_SURF_SIDE_COMPOUND    | Compound                 | Specifies the surface Side compound.                                                                                                                                                                                                                       |
| PRO_E_MFG_SURF_SIDE_TOLERAE     | PRO_VALUE_TYPE_DOUBLE    | Mandatory element. Specifies the tolerance used for composing groups of adjacent quilts. <div>  <b>Note</b><br/> The value for this element should be nonnegative. </div> |
| PRO_E_MFG_SURF_SIDE_FLIP_QUILTS | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the selection of quilts to be flipped. This element supports multiple selections.                                                                                                                                              |

## Element Trees: Face Milling Step

This section describes how to construct and access the element tree for a Face Milling feature. It also describes how to create, redefine, and access the properties of these features.

### The Face Milling Element Tree:

This section describes how to construct and access the element tree for a Face Milling feature. It also describes how to create, redefine, and access the properties of these features.

The element tree for the face milling feature is documented in the header file `ProMfgFeatFacing.h`, and is as shown in the following figure:

### Element Tree for Face Milling feature

The following table lists the contents of `PRO_E_FEATURE_TREE` element.

| Element ID                  | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE          | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_MILL.                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_STD_FEATURE_NAME      | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name for the Creo NC sequence. The default value is Face_Milling_1.                                                                                                                                                                                                                                                                                                                                                  |
| PRO_E_SEQ_TYPE              | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of Creo NC sequence. The valid value for this element is PRO_SEQ_FACE_MILL.                                                                                                                                                                                                                                                                                                                                    |
| PRO_E_MFG_OPER_REF          | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the operation feature selection.                                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_SEQ_CSYS              | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the datum coordinate system that will be used as the coordinate system for the Creo NC sequence.                                                                                                                                                                                                                                                                                                                        |
| PRO_E_RETR_SURF             | Compound                 | Mandatory compound element. Specifies retract definition. For more information, refer to the section <a href="#">Retract Elements on page 1657</a> .                                                                                                                                                                                                                                                                                                 |
| PRO_E_MFG_SUB_SPINDLE_OPT   | PRO_VALUE_TYPE_INT       | Optional Element. Specifies the type of spindle assigned to the sequence. This element can be used when two parts are machined during the same operation in different spindles, that is in the main spindle and in the sub spindle. The valid values for this element are defined by the enumerated type ProSubSpindleOpt. For more information on the values of ProSubSpindleOpt, refer to the section <a href="#">Spindle Types on page 1674</a> . |
| PRO_E_MFG_TOOL_REF_COMPOUND | Compound                 | Mandatory compound element. Specifies tool reference definition. For more information, refer to the section <a href="#">Tool Reference on page 1660</a> .                                                                                                                                                                                                                                                                                            |
| PRO_E_MFG_TOOL_ADAPTER_NAME | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the tool adapter model name.                                                                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_MFG_PARAM_SITE_NAME   | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name of the site file with default values for manufacturing parameters.                                                                                                                                                                                                                                                                                                                                              |

| Element ID                  | Data Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                             |           |  <b>Note</b><br>The site file name will be ignored if the site does not exist in the manufacturing model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_MFG_PARAM_ARR         | Array     | Mandatory element. Defines an array of manufacturing parameters. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| PRO_E_MACH_SURFS            | Compound  | Mandatory compound element. Specifies the machining surfaces compound definition. For more information, refer to the section <a href="#">Element Trees: Machining Surfaces on page 1556</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| PRO_E_MFG_CMP_APPROACH_EXIT | Compound  | Optional compound element. Specifies the approach and exit compound definition. For more information, refer to the section <a href="#">Approach and Exit on page 1673</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| PRO_E_TOOL_MTN_ARR          | Array     | Mandatory element. Specifies an array of tool motions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_TOOL_MTN              | Compound  | Mandatory compound element. Specifies the tool motion compound specifications. The applicable tool motion types for this element are : <ul style="list-style-type: none"> <li>• PRO_TM_TYPE_FACE_MILLING. For more information, refer to the section <a href="#">Tool Motion — Face Milling on page 1761</a>.</li> <li>• PRO_TM_TYPE_FOLLOW_CUT. For more information, refer to the section <a href="#">Tool Motion — Follow Cut on page 1754</a>.</li> <li>• PRO_TM_TYPE_FOLLOW_CURVE. For more information, refer to the section <a href="#">Tool Motion — Follow Curve on page 1678</a>.</li> <li>• PRO_TM_TYPE_GOTO_POINT. For more information, refer to the section <a href="#">Tool Motion — Go To Point on page 1680</a>.</li> <li>• PRO_TM_TYPE_GO_DELTA. For more information, refer to</li> </ul> |

| Element ID | Data Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| PRO_E_MFG_START_PNT        | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to start the machining at the specified position.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| PRO_E_MFG_END_PNT          | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to end the machining at the specified position.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| PRO_E_MFG_ENTRY_PNT_REF    | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the entry point selection. Effects start location of the first cut.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_MFG_PREREQUISITE_ARR | Array                    | Optional element. This array specifies the Ids of the prerequisite sequences. For more information, refer to the section <a href="#">Sequence Prerequisites</a> on page 1666.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_MFG_PROCESS_REF      | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the reference selections such as part, feature, curve, surface, datum plane, axis, point, and datum coordinate. It allows you to create additional geometric references to be used only in special process application. This element supports multiple selections.                                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_MFG_FEAT_VIEW_NAME   | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name of the view. This element allows you to associate a specific view with the machining step.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Element ID              | Data Type              | Description                                                                                                                                                                                                                                                                                                                        |
|-------------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         |                        |  <b>Note</b><br>This element is used only in special process application.                                                                                                                                                                         |
| PRO_E_MFG_SIMP_REP_NAME | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the simplified representation name. This element allows you to associate the specific simplified representation with the machining step.<br> <b>Note</b><br>This element is used only in special process application. |
| PRO_E_MFG_TIME_ESTIMATE | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the time estimated for the machining step.<br> <b>Note</b><br>This element is used only in special process application.                                                                                               |
| PRO_E_MFG_COST_ESTIMATE | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the cost estimate for the machining step.<br> <b>Note</b><br>This element is used only in special process application.                                                                                              |
| PRO_E_MFG_TIME_ACTUAL   | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the actual time for the machining step.<br> <b>Note</b><br>This element is used only in special process application.                                                                                                |
| PRO_E_MFG_COMMENTS      | PRO_VALUE_TYPE_WSTRING | Specifies the sequence comments.                                                                                                                                                                                                                                                                                                   |

## Element Trees: Machining Surfaces

The Machining Surface Element Tree:

The element tree for the machining surfaces feature is documented in the header file `ProMfgElemMachSurf.h`, and is as shown in the following figure:

## Element Tree for Machining Surface Feature

```

## Element Trees: Fixture Definition

This section describes how to construct and access the element tree for Manufacturing Fixture Setup. It also describes how to create, redefine, and access the properties of these features.

### The Manufacturing Fixture Setup Element Tree:

The element tree for the manufacturing fixture setup is documented in the header file `ProMfgFeatFixture.h`, and is as shown in the following figure:

## Element Tree for Manufacturing Fixture Setup feature

The following table lists the contents of PRO\_E\_FEATURE\_TREE element.

| Element ID                  | Data Type                | Description                                                                                                                                                                                                                                                                                                           |
|-----------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE          | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_FIXSETUP.                                                                                                                                                                                                          |
| PRO_E_STD_FEATURE_NAME      | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name for the Creo NC sequence. The default value is FSETP1.                                                                                                                                                                                                                           |
| PRO_E_MFG_OPER_REF          | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the operation feature selection.                                                                                                                                                                                                                                                         |
| PRO_E_FIXTURE_COMPONENT_REF | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the selection of the reference components. This element supports multiple selections.<br><br> <b>Note</b><br><br>Specify this element only if the component is inserted in the manufacturing assembly. |

| Element ID               | Data Type              | Description                                                                                                                                                                                                                                                                                                                                  |
|--------------------------|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_FEAT_VIEW_NAME | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the name of the view. This element allows you to associate a specific view with the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                      |
| PRO_E_MFG_SIMP_REP_NAME  | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the simplified representation name. This element allows you to associate the specific simplified representation with the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application. |
| PRO_E_MFG_TIME_ESTIMATE  | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the time estimated for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                                                                             |
| PRO_E_MFG_COST_ESTIMATE  | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the cost estimate for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                                                                              |
| PRO_E_MFG_TIME_ACTUAL    | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the actual time for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                                                                                |
| PRO_E_MFG_COMMENTS       | PRO_VALUE_TYPE_WSTRING | Specifies the sequence comments.                                                                                                                                                                                                                                                                                                             |

## Manufacturing Holemaking Step

The element tree for PRO\_E\_FEATURE\_TREE is documented in the header file ProMfgFeatHolemaking.h, and is shown in the following figure.

The following table lists the contents of PRO\_E\_FEATURE\_TREE element.

| Element ID             | Data Type              | Description                                                                                               |
|------------------------|------------------------|-----------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE     | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_DRILL. |
| PRO_E_STD_FEATURE_NAME | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the sequence feature name.                                                    |

| Element ID                      | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_SEQ_TYPE                  | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the sequence type. The valid value for this element is PRO_SEQ_HOLEMAKING.                                                                                                                                                                                                                                                                                                                       |
| PRO_E_HOLEMAKING_TYPE           | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of holemaking sequence using the enumerated value ProHolemakingType.                                                                                                                                                                                                                                                                                                                    |
| PRO_E_DRILL_MODE                | PRO_VALUE_TYPE_INT       | Specifies the holemaking mode - machining with rotating part or rotating tool using the enumerated value ProDrillModeOption.<br><br> <b>Note</b><br><br>This element is mandatory for drilling on mill-turn work center.                                                                                                                   |
| PRO_E_MFG_OPER_REF              | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the operation feature selection.                                                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_MFG_HOLEMAKING_CYCLE_TYPE | PRO_VALUE_TYPE_INT       | Specifies the holemaking cycle type using the enumerated value ProHmCycleType.<br><br> <b>Note</b><br><br>This element is mandatory for drilling, tapping, counterboring, countersinking. For countersinking, this element should be set to the value PRO_HM_CYCLE_TYPE_STANDARD. This element is ignored for other types of holemaking. |
| PRO_E_MFG_SEQ_NUM_AXES_OPT      | PRO_VALUE_TYPE_INT       | Specifies the number of axes. The valid value for this element are: <ul style="list-style-type: none"> <li>• 3</li> <li>• 5</li> </ul>  <b>Note</b><br><br>This element can be set to 5 only if work center allows 5-axis machining.                                                                                                     |
| PRO_E_NCSEQ_CSYS                | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the coordinate system datum feature to be used as a sequence coordinate system.                                                                                                                                                                                                                                                                                                                  |

| Element ID                  | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_RETR_SURF             | Compound               | <p>Specifies the retract compound definition. For more information, refer to the section <a href="#">Retract Elements on page 1657</a> for more information on the element tree.</p> <p> <b>Note</b></p> <ul style="list-style-type: none"> <li>This element is mandatory when the element PRO_E_DRILL_MODE is set to PRO_DRILL_HOLE_ON_MILL.</li> <li>This element is ignored when the element PRO_E_DRILL_MODE is set to PRO_DRILL_HOLE_ON_LATHE.</li> </ul> |
| PRO_E_MFG_SUB_SPINDLE_OPT   | PRO_VALUE_TYPE_INT     | <p>Optional Element. Specifies the type of spindle assigned to the sequence. This element can be used when two parts are machined during the same operation in different spindles, that is in the main spindle and in the sub spindle. The valid values for this element are defined by the enumerated type ProSubSpindleOpt. For more information on the values of ProSubSpindleOpt, refer to the section <a href="#">Spindle Types on page 1674</a>.</p>                                                                                      |
| PRO_E_MFG_TOOL_REF_COMPOUND | Compound               | <p>Specifies the tool reference compound definition. For more information, refer to the section <a href="#">Tool Reference on page 1660</a> for more information on the element tree.</p>                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_MFG_TOOL_ADAPTER_NAME | PRO_VALUE_TYPE_WSTRING | <p>Optional element. Specifies the tool adapter model name.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_MFG_PARAM_SITE_NAME   | PRO_VALUE_TYPE_WSTRING | <p>Optional element. Specifies the name of site with default values</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Element ID                  | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                             |                          | <p>for manufacturing parameters.</p> <p> <b>Note</b></p> <p>The name will be ignored if site does not exist in the manufacturing model.</p>                                                                                                                                                                                                                                                                   |
| PRO_E_MFG_PARAM_ARR         | Array                    | <p>Mandatory element. Specifies an array of manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file <code>ProMfgElemParam.h</code>. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree.</p>                                                                                                                                                              |
| PRO_E_MFG_CUSTOM_CYCLE_NAME | PRO_VALUE_TYPE_WSTRING   | <p>Specifies the name of custom cycle which will be used to define machining strategy.</p> <p> <b>Note</b></p> <ul style="list-style-type: none"> <li>• A custom cycle with specified name must exists in manufacturing model.</li> <li>• This element is mandatory for custom cycle holmaking (when the element <code>PRO_E_HOLEMAKING_TYPE</code> is not set to <code>PRO_HOLE_MK_CUSTOM</code>)</li> </ul> |
| PRO_E_HOLESETS              | Array                    | <p>Specifies an array of holesets which gives specification of holes to machine. For more information, refer to the section <a href="#">Manufacturing Holmaking Holeset on page 1567</a> for more information on the element tree.</p>                                                                                                                                                                                                                                                           |
| PRO_E_CHECK_SURF_COLL       | PRO_VALUE_TYPE_SELECTION | <p>Specifies the check surfaces compound definition. The element tree for the Checking Surfaces is defined in the header file <code>ProMfgElemCheckSurf.h</code>. For more information, refer to the section <a href="#">Checking Surfaces on page 1671</a> for more information on the element tree.</p>                                                                                                                                                                                        |

| Element ID                 | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN_ARR         | Array                    | Optional element. Specifies an array of tool motions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_TOOL_MTN             | Compound                 | Optional element. Specifies the tool motion compound specification. The applicable tool motion types for this element are: <ul style="list-style-type: none"> <li>• <a href="#">Tool Motion — Auto Cut on page 1750</a></li> <li>• <a href="#">Tool Motion — Go To Point on page 1680</a></li> <li>• <a href="#">Tool Motion — Go Delta on page 1684</a></li> <li>• <a href="#">Tool Motion — Go Home on page 1688</a></li> <li>• <a href="#">Tool Motion — Go Retract on page 1693</a></li> <li>• <a href="#">Tool Motion — Connect on page 1746</a></li> <li>• <a href="#">Tool Motion — CL Command on page 1751</a></li> </ul> |
| PRO_E_MFG_START_PNT        | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. Allows to start machining at the specified position.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_MFG_END_PNT          | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. Allows to end machining at the specified position.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| PRO_E_MFG_PREREQUISITE_ARR | Array                    | Optional element. Specifies the array of ids of prerequisite sequences. The element tree for the Sequence Prerequisites is defined in the header file <code>ProMfgElemPrerequisite.h</code> . For more information, refer to the section <a href="#">Sequence Prerequisites on page 1666</a> for more information on the element tree.                                                                                                                                                                                                                                                                                            |
| PRO_E_MFG_PROCESS_REF      | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the reference selections such as part, feature, curve, surface, datum plane, axis, point, and datum coordinate. It allows you to create additional geometry references to be used only in special process application. This element supports multiple selections.                                                                                                                                                                                                                                                                                                                                     |
| PRO_E_MFG_FEAT_VIEW_NAME   | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the view name. It allows you to associate specific view with a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Element ID              | Data Type              | Description                                                                                                                                                                                                                                                                                                                           |
|-------------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         |                        | <p>machining step.</p> <p> <b>Note</b></p> <p>This element is used only in special process application.</p>                                                                                                                                        |
| PRO_E_MFG_SIMP_REP_NAME | PRO_VALUE_TYPE_WSTRING | <p>Optional element. Specifies the simplified representation name. It allows you to associate a specific simplified representation with a machining step.</p> <p> <b>Note</b></p> <p>This element is used only in special process application.</p> |
| PRO_E_MFG_TIME_ESTIMATE | PRO_VALUE_TYPE_DOUBLE  | <p>Optional element. Specifies the time estimate. It allows you to specify time estimate for the machining step.</p> <p> <b>Note</b></p> <p>This element is used only in special process application.</p>                                          |
| PRO_E_MFG_COST_ESTIMATE | PRO_VALUE_TYPE_DOUBLE  | <p>Optional element. Specifies the cost estimate. It allows you to specify cost estimate for the machining step.</p> <p> <b>Note</b></p> <p>This element is used only in special process application.</p>                                        |
| PRO_E_MFG_TIME_ACTUAL   | PRO_VALUE_TYPE_DOUBLE  | <p>Optional element. Specifies the actual time. It allows you to specify actual time for the machining step</p> <p> <b>Note</b></p> <p>This element is used only in special process application.</p>                                             |
| PRO_E_MFG_COMMENTS      | PRO_VALUE_TYPE_WSTRING | Specifies the sequence comments.                                                                                                                                                                                                                                                                                                      |

## Manufacturing Holemaking Holeset

The element PRO\_E\_HOLESETS specifies an array of holesets and gives specifications about machining references. This element is documented in the header file `ProMfgElemHoleset.h`, and is shown in the following figure.

## Element tree for Manufacturing Holemaking Holeset

The following table lists the contents of PRO\_E\_HOLESETS element.

| Element ID                        | Data Type          | Description                                                                                                                                                                                                                                                              |
|-----------------------------------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_HOLESET                     | Compound           | Mandatory element. Specifies the holeset definition.<br><br> <b>Note</b><br><br>The holeset array must have at least one member.                                                      |
| PRO_E_HOLESET_TYPE                | PRO_VALUE_TYPE_INT | Mandatory element. Specifies the holeset type - axes, points or geometry. The values for this element are defined by ProHolesetType.                                                                                                                                     |
| PRO_E_HOLESET_START               | Compound           | Mandatory element. Specifies the holmaking start compound specification.<br><br> <b>Note</b><br><br>This element is ignored for web drilling. Mandatory for other types of holmaking. |
| PRO_E_HOLESET_END                 | Compound           | Specifies the holmaking depth compound specification.<br><br> <b>Note</b><br><br>This element is ignored for web drilling. Mandatory for other types of holmaking.                  |
| PRO_E_HOLESET_DEPTH               | Compound           | Specifies the web drilling depth compound specification.<br><br> <b>Note</b><br><br>Mandatory for web drilling. Ignored for other types of holmaking.                               |
| PRO_E_HOLESET_CUSTOM_CYCLE_PLATES | Compound           | Specifies the compound definition of the custom cycle.<br><br> <b>Note</b><br><br>This element is mandatory for custom cycle holmaking. Ignored for other types of holmaking.       |
| PRO_E_DRILL_PART_DATA             | Compound           | Specifies the compound information about components used in depth computation.                                                                                                                                                                                           |

| Element ID                     | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                |                          | <p>Mandatory element if start or end of machining has to be computed and at least one of the following hold true:</p> <ul style="list-style-type: none"> <li>• PRO_E_HOLESET_START_TYPE is set to PRO_DRILL_AUTO_START.</li> <li>• PRO_E_HOLESET_END_TYPE is set to PRO_DRILL_AUTO or PRO_DRILL_THRU_ALL.</li> <li>• PRO_E_HOLESET_DEPTH_TYPE is set to PRO_DRILL_AUTO or PRO_DRILL_THRU_ALL.</li> </ul> |
| PRO_E_AUTO_SEL_DRILL_PARTS     | PRO_VALUE_TYPE_INT       | <p>Mandatory element. The option defines the way components are collected. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>• TRUE—All components of type "reference part" or "workpiece" are considered for depth calculation.</li> <li>• FALSE—Only selected components are considered in depth calculation.</li> </ul>                                               |
| PRO_E_DRILL_PARTS              | PRO_VALUE_TYPE_SELECTION | <p>Specifies the components selections. This element supports multiple selections.</p> <p> <b>Note</b></p> <p>Mandatory element if PRO_E_AUTO_SEL_DRILL_PARTS is set to FALSE.</p>                                                                                                                                    |
| PRO_E_AUTODRILL_INFO           | Compound                 | <p>A compound element specifying auto drilling information.</p> <p> <b>Note</b></p> <p>This element is mandatory for auto drilling hole sets.</p>                                                                                                                                                                     |
| PRO_E_AUTODRILL_DEPTH_BY_TABLE | PRO_VALUE_TYPE_INT       | <p>This element is used for auto drilling hole sets. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>• TRUE—It reads the depth information from the auto drilling table.</li> <li>• FALSE—It takes the depth information from the hole set</li> </ul>                                                                                                                  |

| Element ID                 | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            |                          | <p>definition.</p> <p> <b>Note</b></p> <p>This element is mandatory for auto drilling hole sets.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_HOLESET_ORIENT_TYPE  | PRO_VALUE_TYPE_INT       | <p>Specifies the machining direction option for 5-axis holmaking from the selected reference. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>• Away</li> <li>• Toward</li> </ul> <p>The values for this element are defined by ProDrillOrientType.</p> <p> <b>Note</b></p> <p>This element is optional for axes holeset for 5-axis holmaking. Ignored in all other cases.</p>                                                                                                                                                |
| PRO_E_HOLESET_ORIENT_REF   | PRO_VALUE_TYPE_SELECTION | <p>Specifies the single reference selection (surface, point, axis) to define the direction of machining for 5-axis holmaking. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>• Away—Applicable when the element PRO_E_HOLESET_ORIENT_TYPE is set to PRO_DRILL_ORIENT_TO_REF.</li> <li>• Toward—Applicable when the element PRO_E_HOLESET_ORIENT_TYPE is set to PRO_DRILL_ORIENT_FROM_REF</li> </ul> <p> <b>Note</b></p> <p>This element is optional for axes holeset for 5-axis holmaking. Ignored in all other cases.</p> |
| PRO_E_HOLESET_TIP_CTRL_PNT | PRO_VALUE_TYPE_INT       | <p>Optional element. Specifies the cutting tool control tip number. It defines a point on the cutting tool to be controlled during machining</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Element ID                    | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                               |                          | <p>of the hole set.</p> <p> <b>Note</b></p> <p>The first point of the tool is used if the element does not exist.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| PRO_E_HOLESET_SELECTION_RULES | Compound                 | <p>Mandatory element. Specifies the compound information about location of holes to drill.</p> <p> <b>Note</b></p> <p>Define this element when at least one of the following child elements are defined:</p> <ul style="list-style-type: none"> <li>• PRO_E_HOLESET_SEL_PNTS_ON_SURFACES</li> <li>• PRO_E_HOLESET_SEL_INDIV_PNTS</li> <li>• PRO_E_HOLESET_SEL_PNTS_BY_FEATURE</li> <li>• PRO_E_HOLESET_SEL_AUTO_CHAMFER</li> <li>• PRO_E_HOLESET_SEL_INDIV_AXES</li> <li>• PRO_E_HOLESET_SEL_AXIS_PATTS</li> <li>• PRO_E_MFG_HSET_DRILL_GROUP_REF</li> <li>• PRO_E_HOLESET_SEL_BY_SURFACES</li> <li>• PRO_E_MFG_HSET_DIAM_TYPE_OPT</li> <li>• PRO_E_MFG_HSET_DIAM_ARR</li> <li>• PRO_E_MFG_HSET_PARAM_ARR</li> </ul> |
| PRO_E_MFG_HSET_START_HOLE_REF | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the axis selection (for axes holeset) or                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Element ID                     | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                |                          | point selection (for points holeset) for the hole to be drilled first.                                                                                                                                                                                                                                                                                                                        |
| PRO_E_HOLESET_UNFLIPPED_AXES   | PRO_VALUE_TYPE_SELECTION | <p>Specifies the axis selections for holes that should be drilled as per orientation of the axis entities. This element supports multiple selections.</p> <p> <b>Note</b></p> <p>This element is optional for axes holeset for 5-axis holmaking. Ignored in all other cases.</p>                           |
| PRO_E_HOLESET_FLIPPED_AXES     | PRO_VALUE_TYPE_SELECTION | <p>Specifies the axis selections for holes that should be drilled in the direction opposite to the orientation of the axis entities. This element supports multiple selections.</p> <p> <b>Note</b></p> <p>This element is optional for axes holeset for 5-axis holmaking. Ignored in all other cases.</p> |
| PRO_E_HOLESET_GANG_TOOL_INFO   | Compound                 | Optional element. A compound element specifying the gang tool properties.                                                                                                                                                                                                                                                                                                                     |
| PRO_E_HSET_GANG_TOOL_PARENT_ID | PRO_VALUE_TYPE_INT       | This element is mandatory for gang tool specification. Specifies the parent step id.                                                                                                                                                                                                                                                                                                          |
| PRO_E_HSET_IS_GANG_TOOL_LEADER | PRO_VALUE_TYPE_INT       | <p>This element is mandatory for gang tool specification. Specifies if holeset is a leader of the gang tool. It takes the following values:</p> <ul style="list-style-type: none"> <li>• <b>True</b>—Specifies that the holeset is a leader of the gang tool.</li> <li>• <b>False</b>—Specifies that the holeset is not a leader of the gang tool.</li> </ul>                                 |

### Element tree for PRO\_E\_HOLESET\_START

The element tree for PRO\_E\_HOLESET\_START is as shown in the figure below:

```

|-- PRO_E_HOLESET_START
|
| |--PRO_E_HOLESET_START_TYPE
| |
| |--PRO_E_HOLESET_START_SURFACE
| |
| |--PRO_E_HOLESET_START_Z_OFFSET
|

```

The following table lists the sub elements of the element PRO\_E\_HOLESET\_START defined in the header file ProMfgElemHoleset.h.

| Element ID               | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_HOLESET_START      | Compound           | <p>Mandatory element. Specifies the holmaking start compound specification.</p> <p> <b>Note</b></p> <p>This element is ignored for web drilling. Mandatory for other types of holmaking.</p>                                                                                                                             |
| PRO_E_HOLESET_START_TYPE | PRO_VALUE_TYPE_INT | <p>Mandatory element. Specifies the start surface option using the enumerated value ProDrillStartType.</p> <p> <b>Note</b></p> <p>This element is ignored for web drilling and countersinking (when PRO_E_HOLEMAKING_TYPE is set to PRO_HOLE_MK_CSINK or PRO_HOLE_MK_WEB). Mandatory for other types of holmaking.</p> |

| Element ID                   | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_HOLESET_START_SURFACE  | PRO_VALUE_TYPE_SELECTION | <p>Specifies the starting surface or quilt selection.</p> <p> <b>Note</b></p> <ul style="list-style-type: none"> <li>For countersink, this element is optional if auto_chamfer rule is set and there is no explicit axes selection.</li> <li>For web drilling this element is ignored.</li> <li>For other holmaking types this element is mandatory if PRO_E_HOLESET_START_TYPE is set to PRO_DRILL_FROM_SURFACE.</li> </ul> |
| PRO_E_HOLESET_START_Z_OFFSET | PRO_VALUE_TYPE_DOUBLE    | <p>Specifies that the drilling will start at this offset from sequence coordinate system origin.</p> <p> <b>Note</b></p> <p>This element is mandatory if the element PRO_E_HOLESET_START_TYPE is set to PRO_DRILL_START_OFFSET_FROM_CSYS. Ignored in all other cases.</p>                                                                                                                                                  |

#### Element tree for PRO\_E\_HOLESET\_END

The element tree for PRO\_E\_HOLESET\_END is as shown in the figure below:

```

|-- PRO_E_HOLESET_END
|
| |--PRO_E_HOLESET_END_TYPE
|
| |--PRO_E_HOLESET_END_MEASURE_BY
|
| |--PRO_E_HOLESET_END_SURFACE
|
| |--PRO_E_HOLESET_DEPTH_VALUE
|
| |--PRO_E_HOLESET_END_Z_OFFSET
|
| |--PRO_E_HOLESET_CSINK_DIAM
|
| |--PRO_E_HOLESET_USE_BRKOUT_DIST
|

```

The following table lists the sub elements of the element PRO\_E\_HOLESET\_END defined in the header file ProMfgElemHoleset.h.

| Element ID                   | Data Type          | Description                                                                                                                                                                                                                                                                             |
|------------------------------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_HOLESET_END            | Compound           | Specifies the holmaking depth compound specification.<br><br> <b>Note</b><br>This element is ignored for web drilling. Mandatory for other types of holmaking.                                       |
| PRO_E_HOLESET_END_TYPE       | PRO_VALUE_TYPE_INT | Specifies the end type option. The values for this element are defined by ProDrillEndType.<br><br> <b>Note</b><br>This element is ignored for counersinking. Mandatory for other types of holmaking. |
| PRO_E_HOLESET_END_MEASURE_BY | PRO_VALUE_TYPE_INT | Specifies the depth calculation option. The valid values for this element are <ul style="list-style-type: none"> <li>• Tip</li> <li>• Shoulder</li> </ul>                                                                                                                               |

### Element Tree for PRO\_E\_HOLESET\_CUSTOM\_CYCLE\_PLATES

The element tree for PRO\_E\_HOLESET\_CUSTOM\_CYCLE\_PLATES is as shown in the figure below:

```

|-- PRO_E_HOLESET_CUSTOM_CYCLE_PLATES
|
| |--PRO_E_HOLESET_CUSTOM_CYCLE_REFERENCES
| |
| | |--PRO_E_HOLESET_CUSTOM_CYCLE_REF
| | |
| | | |--PRO_E_MFG_CUST_CYCLE_PLATE_NAME
| | | |--PRO_E_HOLESET_CUSTOM_CYCLE_REF_OPT
| | | |--PRO_E_HOLESET_CUSTOM_CYCLE_REF_SEL
| | | |--PRO_E_HOLESET_CUSTOM_CYCLE_REF_Z_OFFSET
| | | |--PRO_E_HOLESET_CUSTOM_CYCLE_REF_DEPTH
| |
| |--PRO_E_HOLESET_CUSTOM_CYCLE_VARIABLES
| |
| | |--PRO_E_HOLESET_CUSTOM_CYCLE_VAR
| | |
| | | |--PRO_E_MFG_CUST_CYCLE_VAR_NAME
| | | |--PRO_E_HOLESET_CUSTOM_CYCLE_VAR_VALUE

```

The following table lists the sub elements of the element PRO\_E\_HOLESET\_CUSTOM\_CYCLE\_PLATES defined in the header file ProMfgElemHoleset.h.

| Element ID                            | Data Type | Description                                                                                                                                                                                                                                                                 |
|---------------------------------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_HOLESET_CUSTOM_CYCLE_PLATES     | Compound  | Specifies the compound definition of the custom cycle.<br><br><div>  <b>Note</b><br/> This element is mandatory for custom cycle holmaking. Ignored for other types of holmaking. </div> |
| PRO_E_HOLESET_CUSTOM_CYCLE_REFERENCES | Array     | Specifies an array of custom cycle                                                                                                                                                                                                                                          |

| Element ID                              | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                         |                          | <p>references.</p> <p> <b>Note</b></p> <ul style="list-style-type: none"> <li>The number of members in array should match with number of references in custom cycle definition (stored in manufacturing model).</li> <li>Mandatory if references are used in the custom cycle definition (see PRO_E_MFG_CUSTOM_CYCLE_NAME).</li> </ul> |
| PRO_E_HOLESET_CUSTOM_CYCLE_REF          | Compound                 | Mandatory element for custom cycle with references. Specifies the compound definition of a custom cycle reference.                                                                                                                                                                                                                                                                                                        |
| PRO_E_MFG_CUST_CYCLE_PLATE_NAME         | Compound                 | Mandatory element for reference definition. Specifies the name of custom cycle reference.                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_HOLESET_CUSTOM_CYCLE_REF_OPT      | PRO_VALUE_TYPE_INT       | Mandatory element for reference definition. Specifies the type of reference specification. The values for this element are defined by ProCustomRefOption.                                                                                                                                                                                                                                                                 |
| PRO_E_HOLESET_CUSTOM_CYCLE_REF_SEL      | PRO_VALUE_TYPE_SELECTION | <p>Specifies the custom cycle reference surface or quilt selection.</p> <p> <b>Note</b></p> <p>Mandatory if PRO_E_HOLESET_CUSTOM_CYCLE_REF_OPT is set to PRO_CUSTOM_DRILL_SELECT_REFERENCE. Ignored in all other cases.</p>                                                                                                          |
| PRO_E_HOLESET_CUSTOM_CYCLE_REF_Z_OFFSET | PRO_VALUE_TYPE_DOUBLE    | Specifies the custom cycle reference specification by offset value from sequence coordinate                                                                                                                                                                                                                                                                                                                               |

| Element ID                           | Data Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                      |           | <p>system origin.</p> <p> <b>Note</b></p> <p>Mandatory if PRO_E_HOLESET_CUSTOM_CYCLE_REF_OPT is set to PRO_CUSTOM_DRILL_OFFSET_FROM_CSYS. Ignored in all other cases.</p>                                                                                                                                                                                               |
| PRO_E_HOLESET_CUSTOM_CYCLE_REF_DEPTH |           | <p>Specifies the custom cycle reference specification by offset value from start surface.</p> <p> <b>Note</b></p> <p>Mandatory if PRO_E_HOLESET_CUSTOM_CYCLE_REF_OPT is set to PRO_CUSTOM_DRILL_OFFSET_FROM_START. Ignored in all other cases.</p>                                                                                                                      |
| PRO_E_HOLESET_CUSTOM_CYCLE_VARIABLES | Array     | <p>Specifies an array of custom cycle variables.</p> <p> <b>Note</b></p> <ul style="list-style-type: none"> <li>• The number of members in array should match with number of variables in the custom cycle definition (stored in manufacturing model).</li> <li>• Mandatory if variables are used in named custom cycle (see PRO_E_MFG_CUSTOM_CYCLE_NAME).</li> </ul> |
| PRO_E_HOLESET_CUSTOM_CYCLE_VAR       | Compound  | <p>Mandatory element for custom cycle with variables. Specifies the compound definition of a custom cycle variable.</p>                                                                                                                                                                                                                                                                                                                                  |

| Element ID                           | Data Type              | Description                                                                             |
|--------------------------------------|------------------------|-----------------------------------------------------------------------------------------|
| PRO_E_MFG_CUST_CYCLE_VAR_NAME        | PRO_VALUE_TYPE_WSTRING | Mandatory element for variable definition. Specifies the name of custom cycle variable. |
| PRO_E_HOLESET_CUSTOM_CYCLE_VAR_VALUE | PRO_VALUE_TYPE_DOUBLE  | Mandatory element for variable definition. Specifies the Custom cycle variable value.   |

#### Element tree for PRO\_E\_HOLESET\_SELECTION\_RULES

The element tree for PRO\_E\_HOLESET\_SELECTION\_RULES is as shown in the figure below:

## Shut off Surface Feature Element Tree

The shut off tool creates a surface that caps an opening in a molded part. In the Mold and Cast Design mode, the shut off tool creates an assembly surface that references the quilts, surfaces and edges of a part. In the Part design mode, the shut off tool creates part surfaces that reference solid surfaces and quilt surfaces with single-sided or double-sided edges.

The element tree for the shut off surface feature is documented in the header file `ProMoldShutSrf.h`, and is as shown in the following figure:

### Element Tree for Mold Shut Off feature:

```
PRO_E_FEATURE_TREE
|
|-- PRO_E_FEATURE_TYPE
|
|-- PRO_E_STD_FEATURE_NAME
|
|-- PRO_E_SHUT_SRF_REF_TYPE
|
|-- PRO_E_SHUT_SRF_SRF_REFS
| |
| |-- PRO_E_STD_SURF_COLLECTION_APPL
|
|-- PRO_E_SHUT_SRF_COLL_CRV_CMP
| |
| |-- PRO_E_SHUT_SRF_ARR_COLL_CRV
| |
| |-- PRO_E_STD_CURVE_COLLECTION_APPL
|
|-- PRO_E_SHUT_SRF_CAP_SRFS
| |
| |-- PRO_E_STD_SURF_COLLECTION_APPL
|
|-- PRO_E_SHUT_SRF_CLOSE_ALL
```

The following table describes the elements in the element tree for the shut-off surface feature.

| Element ID              | Data Type              | Description                                                                                                |
|-------------------------|------------------------|------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE      | PRO_VALUE_TYPE_INT     | Specifies the type of the feature. The valid value for this element is <code>PRO_MOLD_SHUTOFF_SRF</code> . |
| PRO_E_STD_FEATURE_NAME  | PRO_VALUE_TYPE_WSTRING | Specifies the name of the feature.                                                                         |
| PRO_E_SHUT_SRF_REF_TYPE | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the                                                                           |

| Element ID                                  | Data Type                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                             |                                       | <p>type of references to be selected for the shut off surface. Select either surface references or curve references. The valid values for this element are defined in the enumerated type <code>ProShutSrfRefType</code>:</p> <ul style="list-style-type: none"> <li>• <code>PRO_SHUT_SRF_SRF_REF</code>— Specifies the references for a surface.</li> <li>• <code>PRO_SHUT_SRF_CRV_REF</code>— Specifies the references for a curve.</li> </ul>                                                                                    |
| <code>PRO_E_SHUT_SRF_SRF_REFS</code>        | Compound                              | Mandatory element. Specifies a compound element that contains the surface references.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>PRO_E_STD_SURF_COLLECTION_APPL</code> | <code>PRO_VALUE_TYPE_SELECTION</code> | Specifies the surfaces for which shut off surfaces need to be created. Select a single surface or multiple surfaces, if the reference type <code>PRO_E_SHUT_SRF_REF_TYPE</code> is set as <code>PRO_SHUT_SRF_SRF_REF</code> . If <code>PRO_E_SHUT_SRF_REF_TYPE</code> is set as <code>PRO_SHUT_SRF_CRV_REF</code> , then all the surfaces are automatically selected.                                                                                                                                                               |
| <code>PRO_E_SHUT_SRF_COLL_CRV_CMP</code>    | Compound                              | Specifies a compound element for curve chains. Chains enable you to perform operations on all of the selected curves in that chain or on multiple chains simultaneously by either including or excluding them from creating shut off surfaces.                                                                                                                                                                                                                                                                                      |
| <code>PRO_E_SHUT_SRF_ARR_COLL_CRV</code>    | Array                                 | <p>Specifies an array of curve chain loops that can be included or excluded from creating shut off surfaces. By default all the selected surfaces are included while creating the shut off surfaces.</p> <p> <b>Note</b></p> <p>The selected loops are excluded while creating shut off surfaces only if the element <code>PRO_E_SHUT_SRF_CLOSE_ALL</code> is set to <code>PRO_SHUT_SRF_SHUT_ALL</code> and this element becomes optional.</p> |

| Element ID                      | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_STD_CURVE_COLLECTION_APPL | PRO_VALUE_TYPE_SELECTION | <p>Specifies the reference chain loops to be included or excluded while creating shut off surfaces. Select both open and closed chain loops as reference. By default all the selected reference chain loops are included while creating the shut off surfaces. The reference chain loops are excluded only if the value of the element PRO_E_SHUT_SRF_CLOSE_ALL is set to the value True.</p> <p> <b>Note</b></p> <p>You can specify only one-sided edges as curve chain loops if the element PRO_E_SHUT_SRF_REF_TYPE is set to PRO_SHUT_SRF_CRV_REF.</p> |
| PRO_E_SHUT_SRF_CAP_SRFS         | Compound                 | Optional element. Specifies a compound element for cap surface references.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_STD_SURF_COLLECTION_APPL  | PRO_VALUE_TYPE_SELECTION | <p>Specifies the selection of reference surfaces for capping open loops. This is an optional element and you can select single or multiple surfaces as reference.</p> <p> <b>Note</b></p> <ul style="list-style-type: none"> <li>You can select multiple surfaces only if the datum plane is not selected.</li> <li>Select a reference surface only if open curve-chain loops are selected.</li> </ul>                                                                                                                                                  |
| PRO_E_SHUT_SRF_CLOSE_ALL        | PRO_VALUE_TYPE_BOOLEAN   | Specifies an option to include all loops while creating shut off surfaces. The valid value for this element is PRO_SHUT_SRF_SHUT_ALL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Element Trees: Manufacturing Round and Chamfer

The following table describes the elements in the element tree for the Round and Chamfer feature.

| Element ID                  | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE          | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_MILL.                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_STD_FEATURE_NAME      | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name for the Creo NC sequence. The default value is Engraving_1.                                                                                                                                                                                                                                                                                                                                                     |
| PRO_E_SEQ_TYPE              | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of Creo NC sequence. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_SEQ_ROUND_MILL— For round sequence.</li> <li>PRO_SEQ_CHAMFER_MILL— For chamfer sequence.</li> </ul>                                                                                                                                                                                                     |
| PRO_E_MFG_OPER_REF          | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the operation feature selection.                                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_SEQ_CSYS              | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the datum coordinate system that will be used as the sequee coordinate system for the Creo NC sequence.                                                                                                                                                                                                                                                                                                                 |
| PRO_E_RETR_SURF             | Compound                 | Mandatory compound element. Specifies retract definition. For more information, refer to the section <a href="#">Retract Elements on page 1657</a> .                                                                                                                                                                                                                                                                                                 |
| PRO_E_MFG_SUB_SPINDLE_OPT   | PRO_VALUE_TYPE_INT       | Optional Element. Specifies the type of spindle assigned to the sequence. This element can be used when two parts are machined during the same operation in different spindles, that is in the main spindle and in the sub spindle. The valid values for this element are defined by the enumerated type ProSubSpindleOpt. For more information on the values of ProSubSpindleOpt, refer to the section <a href="#">Spindle Types on page 1674</a> . |
| PRO_E_MFG_TOOL_REF_COMPOUND | Compound                 | Mandatory compound element. Specifies tool reference definition. For more information, refer to the section <a href="#">Tool Reference on page 1660</a> .                                                                                                                                                                                                                                                                                            |
| PRO_E_MFG_TOOL_ADAPTER_NAME | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the tool adapter model name.                                                                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_MFG_PARAM_SITE_       | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Element ID                  | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME                        |                          | <p>name of the site file with default values for manufacturing parameters.</p> <p> <b>Note</b></p> <p>The site file name will be ignored if the site does not exist in the manufacturing model.</p>                                                                                               |
| PRO_E_MFG_PARAM_ARR         | Array                    | Mandatory element. Defines an array of manufacturing parameters. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> .                                                                                                                                                                                                                |
| PRO_E_MACH_SURFS            | Compound                 | Mandatory compound element. Specifies the machining surfaces compound definition. For more information, refer to the section <a href="#">Element Trees: Machining Surfaces on page 1556</a> .                                                                                                                                                                                      |
| PRO_E_MFG_CUT_START_PNT_REF | PRO_VALUE_TYPE_SELECTION | <p>Optional element. Select a datum point, or a point on the bottom edges of the machining surfaces.</p> <p> <b>Note</b></p> <p>This element is applicable only when the machining surfaces form a closed loop. It allows to start machining at the location nearest to the selected point.</p> |
| PRO_E_CHECK_SURF_COLL       | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the check surfaces collection. For more information, refer to the section <a href="#">Checking Surfaces on page 1671</a> .                                                                                                                                                                                                                             |
| PRO_E_TOOL_MTN_ARR          | Array                    | Optional element. Specifies an array of tool motions.                                                                                                                                                                                                                                                                                                                              |
| PRO_E_TOOL_MTN              | Compound                 | <p>Optional compound element. Specifies the tool motion compound specifications. The applicable tool motion type for this element are:</p> <ul style="list-style-type: none"> <li>• PRO_TM_TYPE_ROUND_MILLING— For Round Sequence. For more information, refer to the section <a href="#">Tool Motion — Round Milling on page 1763</a>.</li> </ul>                                 |

| Element ID | Data Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| PRO_E_MFG_START_PNT        | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to start the machining at the specified position.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| PRO_E_MFG_END_PNT          | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to end the machining at the specified position.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_MFG_PREREQUISITE_ARR | Array                    | Optional element. This array specifies the Ids of the prerequisite seques. For more information, refer to the section <a href="#">Sequence Prerequisites on page 1666</a> .                                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_MFG_PROCESS_REF      | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the referee selections such as part, feature, curve, surface, datum plane, axis, point, and datum coordinate. It allows you to create additional geometric references to be used only in special process application. This element supports multiple selections.                                                                                                                                                                                                                                           |
| PRO_E_MFG_FEAT_VIEW_NAME   | PRO_VALUE_TYPE_WSTRING   | <p>Optional element. Specifies the name of the view. This element allows you to associate a specific view with the machining step.</p> <p> <b>Note</b></p> <p>This element is used only in special process application.</p>                                                                                                                                                                                                                       |
| PRO_E_MFG_SIMP_REP_NAME    | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Element ID              | Data Type              | Description                                                                                                                                                                                                                                                                                                       |
|-------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         |                        | <p>simplified representation name. This element allows you to associate the specific simplified representation with the machining step.</p> <p> <b>Note</b></p> <p>This element is used only in special process application.</p> |
| PRO_E_MFG_TIME_ESTIMATE | PRO_VALUE_TYPE_DOUBLE  | <p>Optional element. Specifies the time estimated for the machining step.</p> <p> <b>Note</b></p> <p>This element is used only in special process application.</p>                                                               |
| PRO_E_MFG_COST_ESTIMATE | PRO_VALUE_TYPE_DOUBLE  | <p>Optional element. Specifies the cost estimate for the machining step.</p> <p> <b>Note</b></p> <p>This element is used only in special process application.</p>                                                                |
| PRO_E_MFG_TIME_ACTUAL   | PRO_VALUE_TYPE_DOUBLE  | <p>Optional element. Specifies the actual time for the machining step.</p> <p> <b>Note</b></p> <p>This element is used only in special process application.</p>                                                                |
| PRO_E_MFG_COMMENTS      | PRO_VALUE_TYPE_WSTRING | Specifies the sequence comments.                                                                                                                                                                                                                                                                                  |

## Element Trees: Engraving Step

This section describes how to construct and access the element tree for a engraving step. It also describes how to create, redefine, and access the properties of these features.

### The Engraving Step Element Tree

This section describes how to construct and access the element tree for a engraving step. It also describes how to create, redefine, and access the properties of these features.

The element tree for the Engraving Step feature is documented in the header file `ProMfgFeatEngraving.h` and is as shown in the following figure:

## Element Tree for Engraving feature

The following table describes the elements in the element tree for the Engraving feature.

| Element ID                 | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE         | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_MILL.                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_STD_FEATURE_NAME     | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name for the Creo NC sequence. The default value is Engraving_1.                                                                                                                                                                                                                                                                                                                                              |
| PRO_E_NCSEQ_TYPE           | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of Creo NC sequence. The valid value for this element is PRO_NCSEQ_GROOVE_MILL.                                                                                                                                                                                                                                                                                                                         |
| PRO_E_MFG_OPER_REF         | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the operation feature selection.                                                                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_MFG_SEQ_NUM_AXES_OPT | PRO_VALUE_TYPE_INT       | Specifies the number of controlled axes. The valid values for this element are: <ul style="list-style-type: none"> <li>3— Default value.</li> <li>4— Used for machining with tool axis parallel to the plane specified in PRO_E_MFG_4_AXIS_PLANE. This is applicable if work center allows 4-axis, or 5-axis machining.</li> <li>5— Used for 5-axis machining. This is applicable if work center allows 5-axis machining.</li> </ul>          |
| PRO_E_NCSEQ_CSYS           | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the datum coordinate system that will be used as the coordinate system for the Creo NC sequence.                                                                                                                                                                                                                                                                                                                 |
| PRO_E_RETR_SURF            | Compound                 | Mandatory compound element. Specifies retract definition. For more information, refer to the section <a href="#">Retract Elements on page 1657</a> .                                                                                                                                                                                                                                                                                          |
| PRO_E_MFG_SUB_SPINDLE_OPT  | PRO_VALUE_TYPE_INT       | Optional Element. Specifies the type of spindle assigned to the sequence. This element can be used when two parts are machined during the same operation in different spindles, that is in the main spindle and in the sub spindle. The valid values for this element are defined by the enumerated type ProSubSpindleOpt. For more information on the values of ProSubSpindleOpt, refer to the section <a href="#">Spindle Types on page</a> |

| Element ID                      | Data Type                | Description                                                                                                                                                                                                                                                                                                     |
|---------------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 |                          | <a href="#">1674</a> .                                                                                                                                                                                                                                                                                          |
| PRO_E_MFG_TOOL_REF_COMPOUND     | Compound                 | Mandatory compound element. Specifies tool reference definition. For more information, refer to the section <a href="#">Tool Reference on page 1660</a> .                                                                                                                                                       |
| PRO_E_MFG_TOOL_ADAPTER_NAME     | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the tool adapter model name.                                                                                                                                                                                                                                                        |
| PRO_E_MFG_PARAM_SITE_NAME       | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name of the site file with default values for manufacturing parameters.<br><br> <b>Note</b><br><br>The site file name will be ignored if the site does not exist in the manufacturing model. |
| PRO_E_MFG_PARAM_ARR             | Array                    | Mandatory element. Defines an array of manufacturing parameters. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> .                                                                                                                                             |
| PRO_E_MFG_MACH_CRVS             | Compound                 | Mandatory compound element. Specifies the machining curves compound definition.                                                                                                                                                                                                                                 |
| PRO_E_STD_CURVE_COLLECTION_APPL | Chain Collection         | Specifies the curve collection.<br><br> <b>Note</b><br><br>This element is mandatory if the element PRO_E_MFG_CURVE_FEAT is not set.                                                                                       |
| PRO_E_MFG_CURVE_FEAT            | PRO_VALUE_TYPE_SELECTION | Specifies the curve feature selection. This element supports multiple selections.<br><br> <b>Note</b><br><br>This element is mandatory if the element PRO_E_STD_CURVE_COLLECTION_APPL is not set.                          |
| PRO_E_MFG_NORM_SRFS             | Compound                 | Optional element. Specifies the normal surfaces compound definition.                                                                                                                                                                                                                                            |
| PRO_E_STD_SURF_COLLECTION_APPL  | Surface Collection       | Specifies the normal surfaces collection and is used for tool axis                                                                                                                                                                                                                                              |

| Element ID             | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        |                          | control.<br><br> <b>Note</b> <ul style="list-style-type: none"> <li>This element is mandatory if the element PRO_E_STD_CURVE_COLLECTION_APPL is set with curves.</li> <li>This element is ignored for 3-axis machining.</li> </ul>                                                                                                         |
| PRO_E_MFG_NORM_GEOM    | PRO_VALUE_TYPE_SELECTION | Specifies the normal surface selection and is used for tool axis control.<br><br> <b>Note</b> <ul style="list-style-type: none"> <li>This element is mandatory if the element PRO_E_STD_CURVE_COLLECTION_APPL is set with edges.</li> <li>This element is ignored for 3-axis machining.</li> </ul>                                         |
| PRO_E_MFG_4_AXIS_PLANE | PRO_VALUE_TYPE_SELECTION | Specifies the selection of datum plane or planar surface.<br><br> <b>Note</b> <ul style="list-style-type: none"> <li>This element is mandatory for 4-axis machining, when the element PRO_E_MFG_SEQ_NUM_AXES_OPT is set to 4.</li> <li>This element is ignored for 3-axis and 5-axis machining.</li> </ul>                               |
| PRO_E_TOOL_MTN_ARR     | Array                    | Optional element. Specifies an array of tool motions.                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_TOOL_MTN         | Compound                 | Mandatory compound element. Specifies the tool motion compound specifications. The applicable tool motion type for this element are: <ul style="list-style-type: none"> <li>PRO_TM_TYPE_GROOVE_MILLING. For more information, refer to the section <a href="#">Tool Motion — Groove Milling on page 1762</a>.</li> <li>PRO_TM_TYPE_FOLLOW_CURVE. For more information, refer to the section <a href="#">Tool</a></li> </ul> |

| PRO_E_MFG_TIME_ACTUAL | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the actual time for the machining step.<br><br> <b>Note</b><br>This element is used only in special process application. |
| PRO_E_MFG_COMMENTS    | PRO_VALUE_TYPE_WSTRING | Specifies the sequence comments.                                                                                                                                                                                                      |

## Element Trees: Manufacturing Cutline Milling Sequence

This section describes how to construct and access the element tree for a cutline milling sequence. It also describes how to create, redefine, and access the properties of these features.

### The Cutline Milling Element Tree

This section describes how to construct and access the element tree for a cutline milling sequence. It also describes how to create, redefine, and access the properties of these features.

The element tree for the cutline milling sequence is documented in the header file `ProMfgFeatCutlineMilling.h`, and is as shown in the following figure:

## Element Tree for Cutline Milling feature

| Element ID             | Data Type              | Description                                                                                              |
|------------------------|------------------------|----------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE     | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_MILL. |
| PRO_E_STD_FEATURE_NAME | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the name for the Creo NC sequence.                                           |

| Element ID                  | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                             |                          | The default value is Cutline_Milling_1.                                                                                                                                                                                                                                                                                                                                                                                                              |
| PRO_E_NCSEQ_TYPE            | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of Creo NC sequence. The valid value for this element is PRO_NCSEQ_CUTLINE_MILL.                                                                                                                                                                                                                                                                                                                               |
| PRO_E_MFG_OPER_REF          | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the operation feature selection.                                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_MFG_SEQ_NUM_AXES_OPT  | PRO_VALUE_TYPE_INT       | Specifies the number of controlled axes. The valid values for this element are: <ul style="list-style-type: none"> <li>3—Default value.</li> <li>4—Used for machining with tool axis parallel to the plane specified in PRO_E_MFG_4_AXIS_PLANE. This is applicable if work center allows 4-axis, or 5-axis machining.</li> <li>5—Used for 5-axis machining. This is applicable if work center allows 5-axis machining.</li> </ul>                    |
| PRO_E_NCSEQ_CSYS            | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the datum coordinate system that will be used as the coordinate system for the Creo NC sequence.                                                                                                                                                                                                                                                                                                                        |
| PRO_E_RETR_SURF             | Compound                 | Mandatory compound element. Specifies retract compound definition. For more information, refer to the section <a href="#">Retract Elements on page 1657</a> .                                                                                                                                                                                                                                                                                        |
| PRO_E_MFG_SUB_SPINDLE_OPT   | PRO_VALUE_TYPE_INT       | Optional Element. Specifies the type of spindle assigned to the sequence. This element can be used when two parts are machined during the same operation in different spindles, that is in the main spindle and in the sub spindle. The valid values for this element are defined by the enumerated type ProSubSpindleOpt. For more information on the values of ProSubSpindleOpt, refer to the section <a href="#">Spindle Types on page 1674</a> . |
| PRO_E_MFG_TOOL_REF_COMPOUND | Compound                 | Mandatory compound element. Specifies tool reference compound definition. For more information, refer to the section <a href="#">Tool Reference on page 1660</a> .                                                                                                                                                                                                                                                                                   |

| Element ID                       | Data Type                | Description                                                                                                                                                                                                                                                                                                                   |
|----------------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_TOOL_ADAPTER_NAME      | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the tool adapter model name.                                                                                                                                                                                                                                                                      |
| PRO_E_MFG_PARAM_SITE_NAME        | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name of the site file with default values for manufacturing parameters.<br><br> <b>Note</b><br>The site file name will be ignored if the site does not exist in the manufacturing model.                   |
| PRO_E_MFG_PARAM_ARR              | Array                    | Mandatory element. Defines an array of manufacturing parameters. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> .                                                                                                                                                           |
| PRO_E_MACH_SURFS                 | Compound                 | Mandatory compound element. Specifies the machining surfaces compound definition. For more information, refer to the section <a href="#">Element Trees: Machining Surfaces on page 1556</a> .                                                                                                                                 |
| PRO_E_CUTLINE_TP_OPTIONS         | Compound                 | Optional element. Specifies tool path options.                                                                                                                                                                                                                                                                                |
| PRO_E_CUTLINE_TP_TOOL_CENTER_OPT | PRO_VALUE_TYPE_INT       | Optional element. Specifies the tool center curve option.                                                                                                                                                                                                                                                                     |
| PRO_E_CUTLINE_CUT_DEFINITION     | Compound                 | Mandatory element. Specifies the cutline array compound definition. For more information on the sub elements, For more information, refer to the section <a href="#">Element Tree for PRO_E_CUTLINE_CUT_DEFINITION on page 1625</a> .                                                                                         |
| PRO_E_MFG_SURF_SIDE_COMPOUND     | Compound                 | Optional element. Specifies the surface side definition. For more information, refer to the section <a href="#">Manufacturing Surface Side on page 1549</a> .                                                                                                                                                                 |
| PRO_E_MFG_4_AXIS_PLANE           | PRO_VALUE_TYPE_SELECTION | Specifies the selection of datum plane or planar surface.<br><br> <b>Note</b><br>This element is mandatory for 4-axis machining, when the element PRO_E_MFG_SEQ_NUM_AXES_OPT is set to 4 and is ignored for 3-axis and 5-axis machining. |

| Element ID              | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

For more information, refer to the section <a href="#">Exit Along Tool Axis on page 1676</a>.</li> </ul> |
| PRO_E_MFG_START_PNT        | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to start the machining at the specified position.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| PRO_E_MFG_END_PNT          | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to end the machining at the specified position.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_MFG_PREREQUISITE_ARR | Array                    | Optional element. This array specifies the Ids of the prerequisite sequences. For more information, refer to the section <a href="#">Sequence Prerequisites on page 1666</a> .                                                                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_MFG_PROCESS_REF      | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the reference selections such as part, feature, curve, surface, datum plane, axis, point, and datum coordinate. It allows you to create additional geometric references to be used only in special process application. This element supports multiple selections.                                                                                                                                                                                                                                                                               |
| PRO_E_MFG_FEAT_VIEW_NAME   | PRO_VALUE_TYPE_WSTRING   | <p>Optional element. Specifies the name of the view. This element allows you to associate a specific view with the machining step.</p> <p> <b>Note</b></p> <p>This element is used only in special process application.</p>                                                                                                                                                                                                                                                               |
| PRO_E_MFG_SIMP_REP_NAME    | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the simplified representation name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Element ID              | Data Type              | Description                                                                                                                                                                                                                                                                         |
|-------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         |                        | <p>This element allows you to associate the specific simplified representation with the machining step.</p> <p> <b>Note</b></p> <p>This element is used only in special process application.</p> |
| PRO_E_MFG_TIME_ESTIMATE | PRO_VALUE_TYPE_DOUBLE  | <p>Optional element. Specifies the time estimated for the machining step.</p> <p> <b>Note</b></p> <p>This element is used only in special process application.</p>                               |
| PRO_E_MFG_COST_ESTIMATE | PRO_VALUE_TYPE_DOUBLE  | <p>Optional element. Specifies the cost estimate for the machining step.</p> <p> <b>Note</b></p> <p>This element is used only in special process application.</p>                                |
| PRO_E_MFG_TIME_ACTUAL   | PRO_VALUE_TYPE_DOUBLE  | <p>Optional element. Specifies the actual time for the machining step.</p> <p> <b>Note</b></p> <p>This element is used only in special process application.</p>                                |
| PRO_E_MFG_COMMENTS      | PRO_VALUE_TYPE_WSTRING | Specifies the sequence comments.                                                                                                                                                                                                                                                    |

## Element Tree for PRO\_E\_CUTLINE\_CUT\_DEFINITION

The element tree for PRO\_E\_CUTLINE\_CUT\_DEFINITION is as shown in the figure below:

```

|-- PRO_E_CUTLINE_CUT_DEFINITION
|
| |-- PRO_E_CUTLINE_ALT_SRFS
| | |-- PRO_E_STD_SURF_COLLECTION_APPL
| | |-- PRO_E_CUTLINE_USE_ALT_SRFS
| |
| |-- PRO_E_CUTLINE_AUTO_OUTER_OPT
| |-- PRO_E_CUTLINE_INNER_POINT
| |-- PRO_E_CUTLINE_INNER_FIRST_OPT
| |-- PRO_E_CUTLINE_REF_ARR
| |-- PRO_E_CUTLINE_SYNC_ARR
|

```

The following table lists the sub elements of the element PRO\_E\_CUTLINE\_CUT\_DEFINITION defined in the header file ProMfgFeatCutlineMilling.h.

| Element ID                     | Data Type                | Description                                                                                                                                                                                                                                                                         |
|--------------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_CUTLINE_ALT_SRFS         | Compound                 | Optional element. Specifies the cutline alternate surface compound definition.                                                                                                                                                                                                      |
| PRO_E_STD_SURF_COLLECTION_APPL | Surface Collection       | Optional element. Specifies the cutline alternate surface collection.                                                                                                                                                                                                               |
| PRO_E_CUTLINE_USE_ALT_SRFS     | PRO_VALUE_TYPE_INT       | Optional element. Specifies the cutline alternate surface option definition.                                                                                                                                                                                                        |
| PRO_E_CUTLINE_AUTO_OUTER_OPT   | PRO_VALUE_TYPE_INT       | Specifies the auto cutline option definition. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_FALSE—Specifies that cutlines are being defined manually.</li> <li>PRO_B_TRUE—Specifies that cutlines are being defined automatically.</li> </ul> |
| PRO_E_CUTLINE_INNER_POINT      | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the auto cutline inner point selection.                                                                                                                                                                                                                 |
| PRO_E_CUTLINE_INNER_FIRST_OPT  | PRO_VALUE_TYPE_INT       | Specifies the auto cutline inner first option definition. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_FALSE—Specifies that outer auto cutline is first.</li> </ul>                                                                          |

| Element ID             | Data Type | Description                                                                                              |
|------------------------|-----------|----------------------------------------------------------------------------------------------------------|
|                        |           | <ul style="list-style-type: none"> <li>PRO_B_TRUE—Specifies that inner auto cutline is first.</li> </ul> |
| PRO_E_CUTLINE_REF_ARR  | Array     | Mandatory element. Specifies an array of cutlines.                                                       |
| PRO_E_CUTLINE_SYNC_ARR | Array     | Optional element. Specifies an array of cutline synchronization lines.                                   |

### Element Tree for PRO\_E\_CUTLINE\_REF\_ARR

The element tree for PRO\_E\_CUTLINE\_REF\_ARR is as shown in the figure below:

The following table lists the sub elements of the element PRO\_E\_CUTLINE\_REF\_ARR defined in the header file ProMfgFeatCutlineMilling.h.

| Element ID             | Data Type          | Description                                                                                                                                                                                                                                                                                                                         |
|------------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_CUTLINE_REF_ITEM | Compound           | <p>Specifies the cutline compound definition.</p> <p> <b>Note</b></p> <p>This element is mandatory if the element PRO_E_CUTLINE_AUTO_OUTER_OPT is set to PRO_B_FALSE and is not used if PRO_E_CUTLINE_AUTO_OUTER_OPT is set to PRO_B_TRUE.</p> |
| PRO_E_CUTLINE_ID       | PRO_VALUE_TYPE_INT | Mandatory element. Specifies the cutline id.                                                                                                                                                                                                                                                                                        |

| Element ID                        | Data Type                | Description                                                              |
|-----------------------------------|--------------------------|--------------------------------------------------------------------------|
| PRO_E_STD_CURVE_COLLECTION_APPL   | Chain Collection         | Mandatory element. Specifies the outline chain collection.               |
| PRO_E_NCD_CURVE_POINT             | Compound                 | Optional element. Specifies the outline start point compound definition. |
| PRO_E_NCD_CURVE_POINT_REF         | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the outline start point reference.           |
| PRO_E_NCD_CURVE_POINT_OFFSET_TYPE | PRO_VALUE_TYPE_INT       | Optional element. Specifies the outline start point offset type.         |
| PRO_E_NCD_CURVE_POINT_OFFSET      | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the outline start point offset definition.   |
| PRO_E_CUTLINE_PROJ_PLN            | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the outline project plane definition.        |

### Element Tree for PRO\_E\_CUTLINE\_SYNC\_ARR

The element tree for PRO\_E\_CUTLINE\_SYNC\_ARR is as shown in the figure below:

The following table lists the sub elements of the element PRO\_E\_CUTLINE\_SYNC\_ARR defined in the header file ProMfgFeatCutlineMilling.h.

| Element ID              | Data Type              | Description                                                             |
|-------------------------|------------------------|-------------------------------------------------------------------------|
| PRO_E_CUTLINE_SYNC_ITEM | Compound               | Optional element. Specifies the outline synch line compound definition. |
| PRO_E_CUTLINE_SYNC_ID   | PRO_VALUE_TYPE_INT     | Optional element. Specifies the outline synch line id.                  |
| PRO_E_CUTLINE_SYNC_NAME | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the outline synch line name.                |

| Element ID                      | Data Type             | Description                                                                                                                                                                                                                                                                                                            |
|---------------------------------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_CUTLINE_SYNC_TYPE         | PRO_VALUE_TYPE_INT    | Optional element. Specifies the cutline synch line type. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_E_CUTLINE_SYNC_TYPE_POINTS—Specifies the synch between points on the cutlines.</li> <li>PRO_E_CUTLINE_SYNC_TYPE_REF—Specifies the synch on the reference chains.</li> </ul> |
| PRO_E_CUTLINE_SYNC_POINT_ARR    | Array                 | Optional element. Specifies an array of cutline synch points.                                                                                                                                                                                                                                                          |
| PRO_E_CUTLINE_SYNC_POINT        | Compound              | Optional element. Specifies the cutline synch point compound definition.                                                                                                                                                                                                                                               |
| PRO_E_CUTLINE_SYNC_POINT_REF_ID | PRO_VALUE_TYPE_INT    | Optional element. Specifies the cutline synch point reference ID.                                                                                                                                                                                                                                                      |
| PRO_E_CUTLINE_SYNC_POINT_RATIO  | PRO_VALUE_TYPE_DOUBLE | Optional element. Specifies the cutline synch point ratio.                                                                                                                                                                                                                                                             |
| PRO_E_STD_CURVE_COLLECTION_APPL | Chain Collection      | Optional element. Specifies the cutline synch line chain collection.                                                                                                                                                                                                                                                   |

## Element Tree for PRO\_E\_MFG\_AXIS\_DEF\_COMP

The element tree for PRO\_E\_MFG\_AXIS\_DEF\_COMP is as shown in the figure below:

|                              |                          |                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_AXIS_DEF_TYPE      | PRO_VALUE_TYPE_INT       | <p>Mandatory element. Specifies the type of the axis definition. The valid values for this element are defined in the enumerated type ProAxisDefType and are as follows:</p> <ul style="list-style-type: none"> <li>PRO_AXIS_DEF_TYPE_UNDEF</li> <li>PRO_AXIS_DEF_BY_PIVOT_REF</li> <li>PRO_AXIS_DEF_BY_LOCATIONS</li> <li>PRO_AXIS_DEF_BY_TWO_CONTOURS</li> <li>PRO_AXIS_DEF_BY_NORM_SURF</li> </ul> |
| PRO_E_MFG_AXIS_DEF_PIVOT_REF | PRO_VALUE_TYPE_SELECTION | <p>Specifies the selection of the single reference. You can select either a point or an axis.</p> <p> <b>Note</b></p> <p>This element is mandatory, only if the element PRO_E_MFG_AXIS_DEF_TYPE is set to the value PRO_AXIS_DEF_BY_PIVOT_REF. This element is ignored in all other cases.</p>                     |
| PRO_E_MFG_AXIS_DEF_NORM_SRF  | Compound                 | <p>Normal Surface compound element.</p> <p> <b>Note</b></p> <p>This element is mandatory, only if the element PRO_E_MFG_AXIS_DEF_TYPE is set to the value PRO_AXIS_DEF_BY_NORM_SURF. This element is ignored in all other cases.</p>                                                                             |

|                                 |                          |                                                                                                                                                                                                                                                                                                                                |
|---------------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_AXIS_DEF_LOCATION_ARR | Array                    | <p>Specifies an array of locations.</p> <p> <b>Note</b></p> <p>This element is mandatory, only if the element PRO_E_MFG_AXIS_DEF_TYPE is set to the value PRO_AXIS_DEF_BY_LOCATIONS. This element is ignored in all other cases.</p>          |
| PRO_E_MFG_AXIS_DEF_LOCATION     | Compound                 | <p>Mandatory element. Specifies the compound element for the location axis definition.</p>                                                                                                                                                                                                                                     |
| PRO_E_MFG_AXIS_DEF_ORIGIN_REF   | PRO_VALUE_TYPE_SELECTION | <p>Specifies the selection of the single reference. You can either select a point on a curve or an edge.</p>                                                                                                                                                                                                                   |
| PRO_E_MFG_AXIS_DEF_ORIENT_COMP  | Compound                 | <p>Mandatory element. Specifies the orientation compound element.</p>                                                                                                                                                                                                                                                          |
| PRO_E_MFG_AXIS_DEF_ORIENT_REF   | PRO_VALUE_TYPE_SELECTION | <p>Specifies the single reference selection. You can select either a point or an axis.</p> <p> <b>Note</b></p> <p>This element is mandatory, if the elements PRO_E_MFG_AXES_DEF_ANGLE_X and PRO_E_MFG_AXES_DEF_ANGLE_Y are not defined.</p> |
| PRO_E_MFG_AXES_DEF_ANGLE_X      | PRO_VALUE_TYPE_DOUBLE    | <p>Specifies the lead angle. The valid range for this element is from —90 to +90.</p> <p> <b>Note</b></p> <p>This element is mandatory, if the element PRO_E_MFG_AXIS_DEF_ORIENT_REF is not defined.</p>                                    |
| PRO_E_MFG_AXES_DEF_ANGLE_Y      | PRO_VALUE_TYPE_DOUBLE    | <p>Specifies the tilt angle. The valid range for this element is from —90 to +90.</p> <p> <b>Note</b></p> <p>This element is mandatory, if the element PRO_E_MFG_AXIS_DEF_ORIENT_REF is not defined.</p>                                    |

|                                  |                          |                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_AXIS_DEF_LOC_FLIP_OPT  | PRO_VALUE_TYPE_INT       | <p>Mandatory element. Specifies the flip direction at a location. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_B_TRUE—Specifies that the direction will be reversed.</li> <li>PRO_B_FALSE—Specifies that the direction will remain the same.</li> </ul>                                         |
| PRO_E_MFG_AXIS_DEF_CURVE_COMP    | Compound                 | <p>Specifies the compound element for the pivot curve.</p> <p> <b>Note</b></p> <p>This element is mandatory, if the element PRO_E_MFG_AXIS_DEF_TYPE is set to the value PRO_AXIS_DEF_BY_TWO_CONTOURS. This element is ignored in all other cases.</p> |
| PRO_E_STD_CURVE_COLLECTION_APPL  | Chain Collection         | Mandatory element. Specifies a general compound element for chain collection.                                                                                                                                                                                                                                                            |
| PRO_E_MFG_AXIS_DEF_SYNC_ARR      | Array                    | Optional element. Specifies the synchronization array.                                                                                                                                                                                                                                                                                   |
| PRO_E_MFG_AXIS_DEF_SYNC_COMP     | Compound                 | Optional element. Specifies the synchronization compound element.                                                                                                                                                                                                                                                                        |
| PRO_E_MFG_AXIS_DEF_SYNC_PNT_1    | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the single reference selection. Select a point on the trajectory curve.                                                                                                                                                                                                                                     |
| PRO_E_MFG_AXIS_DEF_SYNC_PNT_2    | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the single reference selection. Select a point on the pivot curve.                                                                                                                                                                                                                                          |
| PRO_E_MFG_AXIS_DEF_SYNC_FLIP_OPT | PRO_VALUE_TYPE_INT       | <p>Mandatory element. Specifies the flip direction. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_B_TRUE—Specifies that the tool motion is flipped in the reverse direction.</li> <li>PRO_B_FALSE—Specifies that the direction will remain the same.</li> </ul>                                  |
| PRO_E_MFG_AXIS_DEF_FLIP_OPT      | PRO_VALUE_TYPE_INT       | <p>Specifies the flip direction. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_B_TRUE—Specifies that the direction will be reversed.</li> <li>PRO_B_FALSE—Specifies that the direction will remain the same.</li> </ul>                                                                          |

## Element Trees: Manufacturing Drill Group Feature

This section describes how to construct and access the element tree for a Drill Group feature. It also describes how to create, redefine, and access the properties of these features.

### The Drill Group Feature Element Tree

The element tree for the drill group feature is documented in the header file `PromfgFeatDrillGroup.h`, and is as shown in the following figure:

```

User's Guide

| Element ID                    | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE            | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_OPERATION.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_STD_FEATURE_NAME        | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name for the NC feature. The default value is DRILL_GROUP_1.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_DRILL_GRP_CSYS          | PRO_VALUE_TYPE_SELECTION | Specifies the selection of datum coordinate system.<br><br> <b>Note</b><br><br>This element is not supported for the Creo Parametric 2.0 release.                                                                                                                                                                                                                                                                                                                 |
| PRO_E_DRILL_GRP_AXES_COMPOUND | Compound                 | Mandatory element. This compound element specifies information about location of holes to be drilled.<br><br> <b>Note</b><br><br>You can use this element only when at least one of the following child elements are defined: <ul style="list-style-type: none"> <li>• PRO_E_DRILL_GRP_AXES_INDIV</li> <li>• PRO_E_DRILL_GRP_AXES_PATTERN</li> <li>• PRO_E_DRILL_GRP_SURFACES</li> <li>• PRO_E_DRILL_GRP_DIAM_ARR</li> <li>• PRO_E_DRILL_GRP_PARAM_ARR</li> </ul> |
| PRO_E_DRILL_GRP_AXES_EXCL     | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the selection of axes of holes to be excluded for machining. This element supports multiple selections.                                                                                                                                                                                                                                                                                                                                                                                                                |
| PRO_E_DRILL_GRP_AXES_PATTERN  | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the selection of axes of patterned holes. This element supports multiple selections.                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Element ID                     | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|                                |                          |  <b>Note</b><br>If a pattern leader is selected, all the holes in the pattern will be collected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PRO_E_DRILL_GRP_RULES_COMPOUND | Compound                 | Optional element. This compound element specifies the information about hole search rules.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_DRILL_GRP_SURFACES       | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the selection of surfaces or quilts with holes. This element supports multiple selections.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| PRO_E_DRILL_GRP_DIAM_TYPE_OPT  | PRO_VALUE_TYPE_INT       | Optional element. Specifies the type of hole diameters that can be collected in the element PRO_E_DRILL_GRP_DIAM_ARR. The type of hole diameter is specified using the enumerated data type ProHolesetDiamType. The valid values are: <ul style="list-style-type: none"> <li>PRO_HSET_ALL_DIAMS—This is the default value. Specifies that diameters of both solid surfaces and cosmetic threads can be collected.</li> </ul>  <b>Note</b><br>If the element PRO_E_DRILL_GRP_DIAM_TYPE_OPT is not defined, then by default, the hole diameter of type PRO_HSET_ALL_DIAMS is used. <ul style="list-style-type: none"> <li>PRO_HSET_HOLE_DIAMS—Specifies that diameters only of solid surfaces can be collected.</li> <li>PRO_HSET_THREAD_DIAMS—Specifies that diameters only of cosmetic threads can be collected.</li> </ul> |
| PRO_E_DRILL_GRP_DIAM_ARR       | Array                    | Optional element. Specifies an array of diameters of holes to be machined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_DRILL_GRP_DIAM_COMPOUND  | Compound                 | Optional element. Specifies a compound definition of a hole diameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_DRILL_GRP_DIAM           | PRO_VALUE_TYPE_DOUBLE    | Specifies the diameter of the hole                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Element ID                     | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                |                        | <p>to be machined.</p> <p> <b>Note</b></p> <p>This element is a mandatory child of PRO_E_DRILL_GRP_DIAM_COPMPOUND element.</p>                                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_DRILL_GRP_PARAM_RULE_OPT | PRO_VALUE_TYPE_INT     | <p>Specifies the type of query that must be used to search for holes to machine.</p> <p>The query type is specified using the enumerated data type ProHsetParamRuleOpt. The valid values are:</p> <ul style="list-style-type: none"> <li>PRO_HSET_BOOL_OPER_OR—Collects holes that satisfy at least one of the search conditions set for a parameter.</li> <li>PRO_HSET_BOOL_OPER_AND—Collects holes that satisfy all the search conditions set for a parameter.</li> </ul> <p>The search conditions and parameters are defined in the elements PRO_E_DRILL_GRP_PARAM*.</p> |
| PRO_E_DRILL_GRP_PARAM_ARR      | Array                  | Optional element. Specifies an array of search conditions to collect the holes for machining.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_DRILL_GRP_PARAM_COMPOUND | Compound               | <p>Optional element. Specifies a compound definition of a condition to match the hole features with the user defined parameters.</p> <p> <b>Note</b></p> <p>In Creo Parametric, each condition defines expression with user defined parameter name on the left side of the expression and value on the right side for comparison.</p>                                                                                                                                                    |
| PRO_E_DRILL_GRP_PARAM_NAME     | PRO_VALUE_TYPE_WSTRING | Specifies the name of the user                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Element ID                      | Data Type             | Description                                                                                                                                                                                                                                                                                        |
|---------------------------------|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 |                       | <p>defined parameter.</p> <p> <b>Note</b></p> <p>This element is a mandatory child of PRO_E_DRILL_GRP_PARAM_COMPOUND element.</p>                                                                               |
| PRO_E_DRILL_GRP_PARAM_DATA_TYPE | PRO_VALUE_TYPE_INT    | <p>Specifies the data type of specified value using the enumerated type ProParamvalueType.</p> <p> <b>Note</b></p> <p>This element is a mandatory child of PRO_E_DRILL_GRP_PARAM_COMPOUND element.</p>          |
| PRO_E_DRILL_GRP_PARAM_OPER      | PRO_VALUE_TYPE_INT    | <p>Specifies the type of the expression operator using the enumerated type ProDrillParamOper.</p> <p> <b>Note</b></p> <p>This element is a mandatory child of PRO_E_DRILL_GRP_PARAM_COMPOUND element.</p>     |
| PRO_E_DRILL_GRP_PARAM_VAL_INT   | PRO_VALUE_TYPE_INT    | <p>Specifies the value of type double.</p> <p> <b>Note</b></p> <p>This element is a mandatory child of PRO_E_DRILL_GRP_PARAM_COMPOUND element for double data type and is ignored for other data types.</p>   |
| PRO_E_DRILL_GRP_PARAM_VAL_DBL   | PRO_VALUE_TYPE_DOUBLE | <p>Specifies the value of type integer.</p> <p> <b>Note</b></p> <p>This element is a mandatory child of PRO_E_DRILL_GRP_PARAM_COMPOUND element for integer data type and is ignored for other data types.</p> |

| Element ID                     | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_DRILL_GRP_PARAM_VAL_WSTR | PRO_VALUE_TYPE_WSTRING   | <p>Specifies the value of type string.</p> <p> <b>Note</b></p> <p>This element is a mandatory child of PRO_E_DRILL_GRP_PARAM_COMPOUND element for string data type and is ignored for other data types.</p>                                                                                                                                                                                  |
| PRO_E_DRILL_GRP_PARAM_VAL_BOOL | PRO_VALUE_TYPE_INT       | <p>Specifies the value of type ProBoolean.</p> <p> <b>Note</b></p> <p>This element is a mandatory child of PRO_E_DRILL_GRP_PARAM_COMPOUND element for ProBoolean data type and is ignored for other data types.</p>                                                                                                                                                                          |
| PRO_E_DRILL_GRP_AXES_INDIV     | PRO_VALUE_TYPE_SELECTION | <p>Specifies the selection of datum axes. This element supports multiple selections.</p> <p> <b>Note</b></p> <p>This element is mandatory if none of the following elements are defined:</p> <ul style="list-style-type: none"> <li>• PRO_E_DRILL_GRP_AXES_PATTERN</li> <li>• PRO_E_DRILL_GRP_SURFACES</li> <li>• PRO_E_DRILL_GRP_DIAM_ARR</li> <li>• PRO_E_DRILL_GRP_PARAM_ARR</li> </ul> |

## Manufacturing Volume Milling Feature

This section describes how to construct and access the element tree for a Volume Milling feature. It also describes how to create, redefine, and access the properties of this feature.

---

## The Volume Milling Feature Element Tree

This section describes how to construct and access the element tree for a Volume Milling feature. It also describes how to create, redefine, and access the properties of this feature.

The element tree for the Volume Milling feature is documented in the header file `ProMfgFeatVolMilling.h`, and is as shown in the following figure:

```

## Element Tree for Volume Milling feature

The following table describes the elements in the element tree for the Volume Milling feature.

| Element ID                  | Data Type                | Description                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE          | PRO_VALUE_TYPE_INT       | Specifies the type of the feature. The valid value for this element is PRO_FEAT_MILL.                                                                                                                                                                                                                                                                  |
| PRO_E_STD_FEATURE_NAME      | PRO_VALUE_TYPE_WSTRING   | Specifies the default name for the feature.                                                                                                                                                                                                                                                                                                            |
| PRO_E_NCSEQ_TYPE            | PRO_VALUE_TYPE_INT       | Specifies the feature form and should be of type PRO_NCSEQ_VOL_MILL only.                                                                                                                                                                                                                                                                              |
| PRO_E_MFG_OPER_REF          | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the operation feature selection.                                                                                                                                                                                                                                                                                          |
| PRO_E_NCSEQ_CSYS            | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the datum coordinate system that will be used as the coordinate system for the Creo NC sequence.                                                                                                                                                                                                                          |
| PRO_E_RETR_SURF             | Compound                 | Mandatory compound element. Specifies retract definition. For more information, refer to the section <a href="#">Retract Elements on page 1657</a> .                                                                                                                                                                                                   |
| PRO_E_MFG_SUB_SPINDLE_OPT   | PRO_VALUE_TYPE_INT       | Optional Element. Specifies the type of spindle assigned to the sequence. The default value for this element is PRO_MFG_MAIN_SPINDLE. The valid values for this element are defined by the enumerated type ProSubSpindleOpt. For more information on the values of ProSubSpindleOpt, refer to the section <a href="#">Spindle Types on page 1674</a> . |
| PRO_E_MFG_TOOL_REF_COMPOUND | Compound                 | Mandatory compound element. Specifies tool reference definition. For more information, refer to the section <a href="#">Tool Reference on page 1660</a> .                                                                                                                                                                                              |
| PRO_E_MFG_TOOL_ADAPTER_NAME | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the tool adapter model name.                                                                                                                                                                                                                                                                                               |
| PRO_E_MFG_PARAM_SITE_NAME   | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name of the site file with default values for manufacturing parameters.                                                                                                                                                                                                                                                |

| Element ID                       | Data Type                | Description                                                                                                                                                                                |
|----------------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                  |                          |  <b>Note</b><br>The site file name will be ignored if the site does not exist in the manufacturing model. |
| PRO_E_MFG_PARAM_ARR              | Array                    | Mandatory element. Defines an array of manufacturing parameters. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> .                        |
| PRO_E_MFG_WIN_VOL_REF_COMPOUND   | Compound                 | Mandatory element. Specifies the machining reference compound specification.                                                                                                               |
| PRO_E_MFG_WIN_VOL_REF            | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the selection of mill window or mill volume feature.                                                                                                          |
| PRO_E_MFG_CMP_CLOSED_LOOPS       | Compound                 | Optional element. Specifies the closed loop compound specification.                                                                                                                        |
| PRO_E_MFG_CLOSED_LOOP_ARR        | Array                    | Optional element. Specifies an array of closed loop specifications.                                                                                                                        |
| PRO_E_MFG_CLOSED_LOOP_REF_ITEM   | Compound                 | Optional element. Specifies the closed loop specification.                                                                                                                                 |
| PRO_E_STD_CURVE_COLLECTION_APPL  | Chain Collection         | Optional element. Specifies an excluded surfaces compound specification for chain collection.                                                                                              |
| PRO_E_MFG_WIN_VOL_EXCL_SURF_COMP | Compound                 |                                                                                                                                                                                            |
| PRO_E_STD_SURF_COLLECTION_APPL   | Surface Collection       | Optional element. Specifies surface collection for the creation of the volume milling sequence.                                                                                            |
| PRO_E_MFG_APPR_WALLS_SURF_COMP   | Compound                 | Optional element. Specifies the approach walls surfaces compound specification. Use this element only if mill volume is selected as a machining reference.                                 |
| PRO_E_STD_SURF_COLLECTION_APPL   | Surface Collection       | Optional element. Specifies surface collection for the creation of the volume milling sequence.                                                                                            |
| PRO_E_MFG_APPR_WALLS_CHAIN_COMP  | Compound                 | Optional element. Specifies the approach walls chain compound specification. Use this element only if mill volume is selected as a machining reference.                                    |
| PRO_E_STD_CURVE_COLLECTION_APPL  | Chain Collection         | Optional element. Specifies the chain collection for the creation of the volume milling sequence.                                                                                          |
| PRO_E_MFG_MILL_VOL_TOP           | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the                                                                                                                                                            |

| Element ID                     | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SURF_REF                       |                          | selection of the top surface. Use this element only if mill volume is selected as a machining reference.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| PRO_E_SCALLOP_SURF_COLL        | Compound                 | Optional element. Specifies the scallop surfaces compound definition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PRO_E_STD_SURF_COLLECTION_APPL | Surface Collection       | Optional element. Specifies the collection of the scallop surfaces.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| PRO_E_CHECK_SURF_COLL          | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the check surfaces compound definition. The element tree for the Checking Surfaces is defined in the header file <code>ProMfgElemCheckSurf.h</code> . For more information, refer to the section <a href="#">Checking Surfaces on page 1671</a> for more information on the element tree.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PRO_E_TOOL_MTN_ARR             | Array                    | Mandatory element. Specifies an array of tool motions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| PRO_E_MFG_START_PNT | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to start the machining at the specified position.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_MFG_END_PNT   | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the datum point selection. It allows to end the machining at the specified position.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Element ID                 | Data Type                | Description                                                                                                                                                                                                                                                                                                                                    |
|----------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_PREREQUISITE_ARR | Array                    | Optional element. This array specifies the Ids of the prerequisite sequences. For more information, refer to the section <a href="#">Sequence Prerequisites on page 1666</a> .                                                                                                                                                                 |
| PRO_E_MFG_PROCESS_REF      | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the reference selections such as part, feature, curve, surface, datum plane, axis, point, and datum coordinate. It allows you to create additional geometric references to be used only in special process application. This element supports multiple selections.                                                 |
| PRO_E_MFG_FEAT_VIEW_NAME   | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the name of the view. This element allows you to associate a specific view with the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                        |
| PRO_E_MFG_SIMP_REP_NAME    | PRO_VALUE_TYPE_WSTRING   | Optional element. Specifies the simplified representation name. This element allows you to associate the specific simplified representation with the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application. |
| PRO_E_MFG_TIME_ESTIMATE    | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the time estimated for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                                                                               |
| PRO_E_MFG_COST_ESTIMATE    | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the cost estimate for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application.                                                                                                |

| Element ID            | Data Type              | Description                                                                                                                                                                                                                               |
|-----------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_TIME_ACTUAL | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the actual time for the machining step.<br><br> <b>Note</b><br><br>This element is used only in special process application. |
| PRO_E_MFG_COMMENTS    | PRO_VALUE_TYPE_WSTRING | Specifies the sequence comments.                                                                                                                                                                                                          |

## Element Trees: Skirt Feature

This section describes how to construct and access the element tree for a Skirt Surface Extension feature. It also describes how to create, redefine, and access the properties of these features.

### Skirt Surface Extension Feature Element Tree

The element tree for the skirt surface extension feature is documented in the header file `ProMoldSkirtExt.h`, and is as shown in the following figure:

## Element Tree for Skirt Surface Extension feature

The following table describes the elements in the element tree for the Skirt Extension feature.

| Element ID                    | Data Type                | Description                                                                                                                                                                                                                                                 |
|-------------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE            | PRO_VALUE_TYPE_INT       | Specifies the type of the feature. The valid value for this element is PRO_FEAT_DATUM_SURF.                                                                                                                                                                 |
| PRO_E_FEATURE_FORM            | PRO_VALUE_TYPE_INT       | Specifies the feature form and should be of type PRO_SKIRT_EXT only.                                                                                                                                                                                        |
| PRO_E_STD_FEATURE_NAME        | PRO_VALUE_TYPE_WSTRING   | Specifies the default name for the feature. The default value for this element is Skirt_Extension_1                                                                                                                                                         |
| PRO_E_SKIRT_REF_MODEL         | PRO_VALUE_TYPE_SELECTION | Mandatory element. Select the reference model used for creating the parting extension surface. The valid reference for this element is a single PRO_PART.                                                                                                   |
| PRO_E_SKIRT_BOUNDARY_REF      | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specify the boundary reference for trimming the outer limits of the skirt surface. The valid reference for this element is either a single PRO_PART or a single PRO_QUILT.                                                               |
| PRO_E_SKIRT_PULL_DIR_COMPOUND | Compound                 | Specifies the reference for the view direction. The valid reference for this element is PRO_E_DIRECTION_COMPOUND. This element is optional, if the default pull direction exists. The default pull direction is used as a reference for the view direction. |
| PRO_E_SKIRT_EXT_SET_ARR       | Array                    | Mandatory element. Specifies an array element which contain a set of PRO_E_SKIRT_EXT_SET_COMPOUND elements.                                                                                                                                                 |
| PRO_E_SKIRT_EXT_SET_COMPOUND  | Compound                 | Mandatory element. Specify one element of this type for each compound set PRO_E_SKIRT_EXT_SET_COMPOUND contained in PRO_E_SKIRT_EXT_SET_ARR. Each set provides information about the skirt extension set.                                                   |
| PRO_E_SKIRT_EXT_SET_REF_IDX   | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the reference index, which is unique for each compound set PRO_E_SKIRT_EXT_SET_COMPOUND.                                                                                                                                       |
| PRO_E_SKIRT_EXT_SET_TYPE      | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of extension used for the skirt feature creation. This element defines the direction of the extension. The valid values for this element are defined by the enumerated type ProSkirtExtType and are as                |

| Element ID                       | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                  |                          | <p>follows:</p> <ul style="list-style-type: none"> <li>PRO_SKIRT_EXT_TYPE_NORMAL—Specifies that the skirt surface extension will be created normal to the pull direction and will end in a direction normal to the curve. The extension is created between the edge and the boundary reference.</li> <li>PRO_SKIRT_EXT_TYPE_PARALLEL—Specifies that the skirt surface extension will be created parallel to the pull direction.</li> <li>PRO_SKIRT_EXT_TYPE_TANGENT—Specifies that the skirt extension is created tangent to the model surface of the selected reference model.</li> <li>PRO_SKIRT_EXT_TYPE_USER—Specifies that the skirt surface extension is created in the user-defined direction.</li> <li>PRO_SKIRT_EXT_TYPE_NORMAL_TO_BNDRY—Specifies that the skirt extension is created normal to the pull direction and will end in a direction normal to the boundary.</li> </ul> |
| PRO_E_SKIRT_EXT_SET_CURVE_COMP   | Compound                 | Mandatory element. This element specifies the collection of extension curves.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_STD_CURVE_COLLECTION_APPL  | PRO_VALUE_TYPE_SELECTION | Specifies the selection of the curves for the skirt surface extension.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_SKIRT_EXT_SET_DIR_COMPOUND | Compound                 | Specifies the direction reference for building the geometry of the extension. This element is mandatory, only if the element PRO_E_SKIRT_EXT_SET_TYPE is set to the value PRO_SKIRT_EXT_TYPE_USER.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| PRO_E_DIRECTION_COMPOUND         | Compound                 | <p>Specifies the direction reference for the extension of surfaces. The valid references for this element are:</p> <ul style="list-style-type: none"> <li>Straight Edge</li> <li>Straight Curve</li> <li>Planar Surface</li> <li>Datum Plane</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| PRO_E_SKIRT_EXT_SET_NEXT_DIR_OPT | PRO_VALUE_TYPE_INT    | <p>Optional element. Specifies an option to switch between the tangent or parallel extension solutions. In tangent extensions, this element enables you to switch between the two available tangent extension solutions, whereas in parallel extensions, this element flips the direction of the extension. The valid values for this element are defined by the enumerated type <code>ProSkirtExtNextDirOpt</code> and are as follows:</p> <ul style="list-style-type: none"> <li><code>PRO_SKIRT_EXT_NEXT_DIR_DEFAULT</code>—This is the default value for tangent and parallel extensions. Tangent extensions, use the default base geometry whereas parallel extensions, extend along the view direction.</li> <li><code>PRO_SKIRT_EXT_NEXT_DIR_ALTERNATE</code>—In case of tangent extension, the other base geometry is used to create the extension. For parallel extensions, the extension is opposite to the view direction.</li> </ul> |
| PRO_E_SKIRT_SHUTOFF_EXT_COMPOUND | Compound              | Mandatory element. This element provides information about the shut-off extension options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_SKIRT_SHUTOFF_EXT_TYPE     | PRO_VALUE_TYPE_INT    | <p>Mandatory element. Specifies the type of the extension shut-off used during the skirt feature creation. The valid values for this element are defined by the enumerated type <code>ProSkirtShutoffExtType</code> and are as follows:</p> <ul style="list-style-type: none"> <li><code>PRO_SKIRT_EXT_SHUTOFF_BY_DIST</code>—Defines the shut-off extension by a specified distance.</li> <li><code>PRO_SKIRT_EXT_SHUTOFF_BY_BOUND</code>—Defines the shut-off extension till the selected boundary.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_SKIRT_SHUTOFF_EXT_DIST     | PRO_VALUE_TYPE_DOUBLE | Specifies the shut-off extension distance. This element is                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Element ID                     | Data Type                | Description                                                                                                                                                                                                                                                                 |
|--------------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                |                          | mandatory only if the element PRO_E_SKIRT_SHUTOFF_EXT_TYPE is set to the value PRO_SKIRT_EXT_SHUTOFF_BY_DIST.                                                                                                                                                               |
| PRO_E_SKIRT_SHUTOFF_CURVE_COMP | Compound                 | Specifies the selected boundary for the shut-off extension. This element is mandatory only if the element PRO_E_SKIRT_SHUTOFF_EXT_TYPE is set to the value PRO_SKIRT_EXT_SHUTOFF_BY_BOUND.                                                                                  |
| PRO_E_SKIRT_DRAFT_ANGLE        | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the draft angle to define the shut-off extension. The default value for this element is zero degrees.                                                                                                                                           |
| PRO_E_SKIRT_SHUTOFF_PLANE_REF  | PRO_VALUE_TYPE_SELECTION | Specifies a parting plane on which the shut-off surface extension is to be created. It defines how far the drafted surface will be extended. This element is mandatory only if the element PRO_E_SKIRT_SHUTOFF_EXT_TYPE is set to the value PRO_SKIRT_EXT_SHUTOFF_BY_BOUND. |
| PRO_E_SKIRT_CREATE_TRANS_OPT   | PRO_VALUE_TYPE_INT       | Optional element. Specify a value to create transitions across different sets of skirt extensions.                                                                                                                                                                          |

## Skirt Fill Feature

The element tree for the skirt fill feature is documented in the header file ProMoldSkirtFill.h, and is as shown in the following figure:

## Element Tree for Skirt Fill feature

```

```

The following table describes the elements in the element tree for the Skirt Fill feature.

| Element ID             | Data Type              | Description                                                                                   |
|------------------------|------------------------|-----------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE     | PRO_VALUE_TYPE_INT     | Specifies the type of the feature. The valid value for this element is PRO_FEAT_DATUM_SURF.   |
| PRO_E_FEATURE_FORM     | PRO_VALUE_TYPE_INT     | Specifies the feature form and should be of type PRO_SKIRT_FILL only.                         |
| PRO_E_STD_FEATURE_NAME | PRO_VALUE_TYPE_WSTRING | Specifies the default name of the feature. The default value for this element is Skirt_Fill_1 |
| PRO_E_SKIRT_REF_MODEL  | PRO_VALUE_TYPE_        | Mandatory element. Select the                                                                 |

| Element ID                       | Data Type          | Description                                                                                                                                                                                                                                                                                                    |
|----------------------------------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                  | SELECTION          | reference model used for creating the skirt surface fill feature. The valid reference for this element is a single PRO_PART                                                                                                                                                                                    |
| PRO_E_SKIRT_PULL_DIR_COMPOUND    | Compound           | Specifies the reference for the view direction. The valid reference for this element is PRO_E_DIRECTION_COMPOUND. This element is optional, if the default pull direction exists. The default pull direction is used as a reference for the view direction.                                                    |
| PRO_E_DIRECTION_COMPOUND         | Compound           | Specifies the direction reference for the skirt surface. The valid references for this element are: <ul style="list-style-type: none"> <li>• Straight Edge</li> <li>• Straight Curve</li> <li>• Planar Surface</li> <li>• Datum Plane</li> <li>• Datum axis</li> <li>• Datum Coordinate System Axis</li> </ul> |
| PRO_E_SKIRT_FILL_SET_ARR         | Array              | Mandatory element. Specifies an array element which contains a set of PRO_E_SKIRT_FILL_SET_COMPOUND elements.                                                                                                                                                                                                  |
| PRO_E_SKIRT_FILL_SET_COMPOUND    | Compound           | Mandatory element. Specify one element of this type for each compound set PRO_E_SKIRT_FILL_SET_COMPOUND contained in PRO_E_SKIRT_FILL_SET_ARR. Each set gives provides information about the skirt fill set.                                                                                                   |
| PRO_E_SKIRT_FILL_SET_REF_IDX     | PRO_VALUE_TYPE_INT | Mandatory element. Specifies the reference index, which is a unique value for each compound set PRO_E_SKIRT_FILL_SET_COMPOUND.                                                                                                                                                                                 |
| PRO_E_SKIRT_FILL_CURVES_COMPOUND | Compound           | Mandatory element. Specifies the collection of skirt fill closure curves.                                                                                                                                                                                                                                      |
| PRO_E_STD_CURVE_COLLECTION_APPL  | Compound           | Specifies the selection of the curves for the skirt surface fill feature.                                                                                                                                                                                                                                      |
| PRO_E_SKIRT_FILL_TYPE            | PRO_VALUE_TYPE_INT | Mandatory element. Specify the type of closure to be used for closing inner loops or holes in a skirt parting surface. The valid values for this element are defined by the enumerated type ProSkirtFillType and are as                                                                                        |

| Element ID                     | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                |                          | <p>follows:</p> <ul style="list-style-type: none"> <li>• PRO_SKIRT_FILL_STANDARD—This is the default closure type.</li> <li>• PRO_SKIRT_FILL_MID_PLANE—Specifies the closure from the middle plane.</li> <li>• PRO_SKIRT_FILL_MID_SURF—Specifies the closure from the middle surface.</li> <li>• PRO_SKIRT_FILL_CAP_PLANE—Specifies the closure from the capping plane.</li> <li>• PRO_SKIRT_FILL_CAP_SURF—Specifies the closure from the capping surface.</li> <li>• PRO_SKIRT_FILL_NEAREST_PLANE—Specifies the closure from the nearest plane.</li> </ul> |
| PRO_E_SKIRT_FILL_PLANE         | PRO_VALUE_TYPE_SELECTION | Select a planar surface. This element is mandatory, if the element PRO_E_SKIRT_FILL_TYPE is set to the value PRO_SKIRT_FILL_MID_PLANE and PRO_SKIRT_FILL_CAP_PLANE.                                                                                                                                                                                                                                                                                                                                                                                         |
| PRO_E_SKIRT_FILL_SURF_COMPOUND | Compound                 | Select any surface. You can select all the surfaces except the reference model geometry. This element is mandatory, if the element PRO_E_SKIRT_FILL_TYPE is set to the value PRO_SKIRT_FILL_MID_SURF and PRO_SKIRT_FILL_CAP_SURF.                                                                                                                                                                                                                                                                                                                           |
| PRO_E_SKIRT_FILL_LOOP_OFFSET   | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the loop offset. This element is used only when the element PRO_E_SKIRT_FILL_TYPE is set to the value PRO_SKIRT_FILL_MID_PLANE or PRO_SKIRT_FILL_CAP_PLANE.                                                                                                                                                                                                                                                                                                                                                                     |

## Sub-Element Trees: Creo NC Steps

This section describes how to construct and access the sub-element trees that are used in the creation of Creo NC features.

---

## Retract Elements

The element `PRO_E_RETR_SURF` is documented in the header file `ProMfgElemRetract.h`, and is as shown in the following figure.

### Element tree for `PRO_E_RETR_SURF` element

```
-- PRO_E_RETR_SURF
|
|-- PRO_E_RETR_SURF_TYPE
|
|-- PRO_E_RETR_SURF_REF
|
|-- PRO_E_RETR_SURF_ORIENT
|
|-- PRO_E_RETR_SURF_VALUE
```

The following table lists the contents of `PRO_E_RETR_SURF` element.

| Element ID           | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_RETR_SURF_TYPE | PRO_VALUE_TYPE_INT       | <p>Mandatory element. Specifies the type of retract surface. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_RETR_SURF_UNDEFINED—Specifies that the retract surface type is not defined. This value is applicable only for manufacturing operations.</li> <li>PRO_RETR_SURF_PLANE—Specifies that the retract surface defined is a planar surface.</li> <li>PRO_RETR_SURF_CYLINDER—Specifies that the retract surface defined is a cylindrical surface.</li> <li>PRO_RETR_SURF_SPHERE—Specifies that the retract surface defined is a spherical surface.</li> <li>PRO_RETR_SURF_REVOLVED—Specifies that the retract surface defined is a revolved surface.</li> </ul> <p> <b>Note</b></p> <p>The values PRO_RETR_SURF_CYLINDER, PRO_RETR_SURF_SPHERE, and PRO_RETR_SURF_REVOLVED are not applicable for 3-axis sequences and operations with 3-axis workcell.</p> |
| PRO_E_RETR_SURF_REF  | PRO_VALUE_TYPE_SELECTION | <p>Mandatory element. Specifies the selection of retract surface. The type of reference depends on values specified for the element PRO_E_RETR_SURF_TYPE. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>Plane retract: Planar retract includes datum plane, planar surface, planar quilt and coordinate system.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Element ID             | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        |                    |  <b>Note</b><br><p>For 3-axis sequence (operation):</p> <ul style="list-style-type: none"> <li>○ Planar surface must be normal to Z axis of the sequence (operation) coordinate system.</li> <li>○ Z axis of selected datum coordinate system must be aligned with Z axis of sequence (operation) coordinate system.</li> </ul> <ul style="list-style-type: none"> <li>• Cylinder retract: Cylinder retract includes datum axis and coordinate system.</li> <li>• Sphere retract: It includes datum point and coordinate system.</li> <li>• Revolved surface retract: It includes revolved quilts.</li> </ul> |
| PRO_E_RETR_SURF_ORIENT | PRO_VALUE_TYPE_INT | <p>Specifies the orientation of the axis for the retract cylinder if coordinate system is selected as retract reference</p> <p>The valid values for this element are:</p> <ul style="list-style-type: none"> <li>• PRO_RETR_SURF_X_DIR</li> <li>• PRO_RETR_SURF_Y_DIR</li> <li>• PRO_RETR_SURF_Z_DIR</li> </ul>  <b>Note</b><br><p>This element is mandatory if coordinate system is selected for cylindrical retract reference and is ignored in all other cases.</p>                                                                                                                                      |

| Element ID            | Data Type             | Description                                                                                                                                                   |
|-----------------------|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_RETR_SURF_VALUE | PRO_VALUE_TYPE_DOUBLE | Mandatory element. Specifies the offset value for the planar retract. For cylindrical and spherical retracts, this element specifies the value of the radius. |

## Tool Reference

The element PRO\_E\_MFG\_TOOL\_REF\_COMPOUND is documented in the header file ProMfgElemToolRef.h, and is as shown in the following figure.

### Element tree for PRO\_E\_MFG\_TOOL\_REF\_COMPOUND element

```

PRO_E_MFG_TOOL_REF_COMPOUND
|
|-- PRO_E_MFG_TOOL_REF_HEAD_NUM
|
|-- PRO_E_MFG_TOOL_REF_POCKET
|
|-- PRO_E_MFG_TOOL_REF_ID

```

The following table lists the contents of PRO\_E\_MFG\_TOOL\_REF\_COMPOUND element.

| Element ID                  | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_TOOL_REF_HEAD_NUM | PRO_VALUE_TYPE_INT     | <p>Mandatory element. Head (turret) number. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_MFG_TOOL_HEAD_1— Specifies that the tool is placed in the head 1.</li> <li>PRO_MFG_TOOL_HEAD_2— Specifies that the tool is placed in the head 2.</li> <li>PRO_MFG_TOOL_HEAD_3— Specifies that the tool is placed in the head 3.</li> <li>PRO_MFG_TOOL_HEAD_4— Specifies that the tool is placed in the head 4.</li> </ul> <p> <b>Note</b></p> <p>You can specify the tools in head 1 for all types of workcells. Tools in head 2 can be specified for lathe and mill-turn workcells and tools in heads 3 and 4 can be specified for mill-turn workcells.</p> |
| PRO_E_MFG_TOOL_REF_POCKET   | PRO_VALUE_TYPE_INT     | Mandatory element. This element defines the position of the tool in the turret head.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PRO_E_MFG_TOOL_REF_ID       | PRO_VALUE_TYPE_WSTRING | Mandatory element. Specifies the tool Id.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Manufacturing Parameters

The element PRO\_E\_MFG\_PARAM\_ARR is documented in the header file ProMfgElemParam.h, and is as shown in the following figure.

## Element tree for PRO\_E\_MFG\_PARAM\_ARR element

```
-- PRO_E_MFG_PARAM_ARR
|
|-- PRO_E_MFG_PARAM_COMPOUND
|
|-- PRO_E_MFG_PRM_NAME
|
|-- PRO_E_MFG_PRM_ATTR
|
|-- PRO_E_MFG_PRM_VAL_DBL
|
|-- PRO_E_MFG_PRM_VAL_STR
```

The element PRO\_E\_MFG\_PARAM\_ARR contains the compound element PRO\_E\_MFG\_PARAM\_COMPOUND that defines the name, attribute, and value of the parameter. You must define this element for parameters, such as, CUT\_FEED and SPINDLE\_SPEED, which do not have a default value. Refer to the Creo NC Manufacturing Help for more information on Creo NC Parameters.

The following table lists the contents of PRO\_E\_MFG\_PARAM\_ARR element.

| Element ID         | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_PRM_NAME | PRO_VALUE_TYPE_WSTRING | Specifies the untranslated parameter name from the list predefined names.<br><br> <b>Note</b><br><br>This element is a mandatory child of PRO_E_MFG_PARAM_COMPOUND element.                                                                                                                                                                                              |
| PRO_E_MFG_PRM_ATTR | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the option to define logic for parameter value assignment. The values for this element are defined by ProMfgParamAttr. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_MFG_PRM_ATTR_DEFAULT—The value from PRO_E_MFG_PRM_VAL_DBL or PRO_E_MFG_PRM_VAL_STR is going to be assigned to the corresponding manufacturing parameter.</li> <li>PRO_MFG_PRM_ATTR_AUTOMATIC—Default value</li> </ul> |

| Element ID            | Data Type             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       |                       | <p>(supplied by Creo NC) is going to be assigned to the corresponding manufacturing parameter. Use PRO_MFG_PRM_ATTR_DEFAULT to set param value to dash (if applicable). Value from PRO_E_MFG_PRM_VAL_DBL or PRO_E_MFG_PRM_VAL_STR is ignored.</p> <ul style="list-style-type: none"> <li>PRO_MFG_PRM_ATTR_MODIFIED—Value from site or parent sequence (for tool motion parameters) is going to be assigned to the corresponding manufacturing parameter. Value from PRO_E_MFG_PRM_VAL_DBL or PRO_E_MFG_PRM_VAL_STR is going to be used only if site with corresponding name does not exist in manufacturing model (The site name is specified by PRO_E_MFG_PARAM_SITE_NAME element in sequence elem tree).</li> <li>PRO_MFG_PRM_ATTR_INHERITED—Value will be assigned automatically: either from site (if exists), or from system defaults. The Value from PRO_E_MFG_PRM_VAL_DBL or PRO_E_MFG_PRM_VAL_STR is ignored.</li> </ul> <p> <b>Note</b></p> <p>This element is a mandatory child of PRO_E_MFG_PARAM_COMPOUND element.</p> |

|                                    |

The following table lists the contents of PRO\_E\_MFG\_CMP\_MILL\_WIND element

| Element ID                 | Data Type                | Description                                                        |
|----------------------------|--------------------------|--------------------------------------------------------------------|
| PRO_E_MFG_MILL_WIND        | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the selection of mill window feature. |
| PRO_E_MFG_CMP_CLOSED_LOOPS | Compound                 | Optional element. Specifies closed loop compound specification.    |
| PRO_E_MFG_EXCL_SRF_COLL    | Compound<br>:D           | Optional element. Defines the                                      |

| Element ID                      | Data Type                | Description                                                                                                                                                                                                                                                                                                        |
|---------------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 |                          | <p>excluded surfaces.</p> <p> <b>Note</b></p> <p>Specify a value for this element only for finishing and corner finishing sequences.</p>                                                                                        |
| PRO_E_STD_SURF_COLLECTION_APPL  | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the surface collection.                                                                                                                                                                                                                                                                |
| PRO_E_MFG_SURF_SIDE_COMPOUND    | Compound                 | Optional element. Specifies the surface side compound specification. This element is used as a sub element of PRO_E_MFG_CMP_MILL_WIND only when you click <b>Adjust geometry collection within window</b> and select <b>Quilt</b> during the Mill Window feature definition in the Creo Parametric user interface. |
| PRO_E_MFG_SURF_SIDE_TOLERANCE   | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the tolerance used for the grouping of quilts.                                                                                                                                                                                                                                         |
| PRO_E_MFG_SURF_SIDE_FLIP_QUILTS | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the selection of quilts with changed normal. This element supports multiple selections.                                                                                                                                                                                                |

## PRO\_E\_MFG\_CMP\_CLOSED\_LOOPS Element

The elements under the compound element PRO\_E\_MFG\_CMP\_CLOSED\_LOOPS are described in this section .

### Element tree for PRO\_E\_MFG\_CMP\_CLOSED\_LOOPS element

|  | -- PRO_E_MFG_CLOSED_LOOP_ID        |

| Element ID                      | Data Type              | Description                                                                                                                                                                                                                   |
|---------------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_CLOSED_LOOP_ARR       | Array                  | Optional element. Specifies an array of closed loop specifications.                                                                                                                                                           |
| PRO_E_MFG_CLOSED_LOOP_REF_ITEM  | Compound               | Optional element. Specifies the closed loop specification.                                                                                                                                                                    |
| PRO_E_STD_CURVE_COLLECTION_APPL | PRO_VALUE_TYPE_POINTER | Specifies the chain collection.<br><br> <b>Note</b><br>This element is a mandatory child of PRO_E_MFG_CLOSED_LOOP_REF_ITEM compound element. |

## Sequence Prerequisites

The element PRO\_E\_MFG\_PREREQUISITE\_ARR is documented in the header file ProMfgElemPrerequisite.h, and is shown in the following figure.

### Element tree for PRO\_E\_MFG\_PREREQUISITE\_ARR element

The following table lists the contents of PRO\_E\_MFG\_PREREQUISITE\_ARR element.

| Element ID                      | Data Type          | Description                                                                                                |
|---------------------------------|--------------------|------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_PREREQUISITE_COMPOUND | Compound           | Compound element. A compound element which defines the prerequisites for the step.                         |
| PRO_E_MFG_PREREQUISITE_ID       | PRO_VALUE_TYPE_INT | Mandatory child of PRO_E_MFG_PREREQUISITE_COMPOUND element. Specifies the Id of the prerequisite sequence. |

---

## Element Trees: Tool Setup

### The Tool Setup Feature Element Tree:

The element tree for the milling roughing sequence is documented in the header file `ProMfgElemToolSetup.h`, and is as shown in the following figure:

Specifies the tool setup array.                                                                                                                                                                                                                                                         |
| PRO_E_MFG_WCELL_TOOL_SETUP      | Compound               | Optional element. Specifies the tool setup compound specification.                                                                                                                                                                                                                                        |
| PRO_E_MFG_WCELL_TOOL_POCKET_NUM | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the tool position in head (turret).                                                                                                                                                                                                                                          |
| PRO_E_MFG_WCELL_TOOL_ID         | PRO_VALUE_TYPE_WSTRING | Mandatory feature. Specifies the tool ID.<br><br> <b>Note</b><br>Tool with such ID should exist in manufacturing model.                                                                                                  |
| PRO_E_MFG_WCELL_TOOL_OUTPUT_TIP | PRO_VALUE_TYPE_INT     | Optional element, if not defined or if the value is set to 1. Specifies the tip number.<br><br> <b>Note</b><br>The tool tip number should not be greater than the number of children in PRO_E_MFG_TOOL_TIP_ARR.          |
| PRO_E_MFG_TOOL_TIP_ARR          | Array                  | Optional element. Specifies an array of tips.                                                                                                                                                                                                                                                             |
| PRO_E_MFG_TOOL_TIP_COMPOUND     | Compound               | Optional element. This compound element defines the tip specification.                                                                                                                                                                                                                                    |
| PRO_E_MFG_TOOL_TIP_REGISTER     | PRO_VALUE_TYPE_INT     | Optional element. Specifies the tip register number.                                                                                                                                                                                                                                                      |
| PRO_E_MFG_TOOL_TIP_COMMENT      | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the tip comment.                                                                                                                                                                                                                                                              |
| PRO_E_MFG_TOOL_TIP_OFFSET_Z     | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the offset value for the tool tip in the Z-direction.                                                                                                                                                                                                                         |
| PRO_E_MFG_TOOL_TIP_OFFSET_X     | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the offset value for the tool tip in the X-direction.                                                                                                                                                                                                                         |
| PRO_E_MFG_TOOL_TIP_OFFSET_ANGLE | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the tip angle offset value.                                                                                                                                                                                                                                                   |
| PRO_E_MFG_TOOL_TIP_FLASH_OPT    | PRO_VALUE_TYPE_INT     | Optional element, if the element is not defined or the value of the element is set to PRO_B_FALSE. Specifies the enabling/disabling of the flash option of the tool tip. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE—Enables flashing capability.</li> </ul> |

| Element ID                       | Data Type              | Description                                                                                                                                                                                                                                                                                           |
|----------------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                  |                        | <ul style="list-style-type: none"> <li>PRO_B_FALSE—Disables flashing capability.</li> </ul>                                                                                                                                                                                                           |
| PRO_E_MFG_TOOL_TIP_FLSH_REGISTER | PRO_VALUE_TYPE_INT     | <p>Optional element. Specifies the register number for alternate tip for the flash tool.</p> <p> <b>Note</b></p> <p>This element is ignored if the element PRO_E_MFG_TOOL_TIP_FLASH_OPT is set to PRO_B_FALSE.</p> |
| PRO_E_MFG_TOOL_TIP_FLSH_COMMENT  | PRO_VALUE_TYPE_WSTRING | <p>Optional element. Specifies the flash tool alternate tip comments.</p> <p> <b>Note</b></p> <p>This element is ignored if the element PRO_E_MFG_TOOL_TIP_FLASH_OPT is set to PRO_B_FALSE.</p>                    |
| PRO_E_MFG_TOOL_TIP_FLSH_OFFSET_Z | PRO_VALUE_TYPE_DOUBLE  | <p>Optional element. Specifies the flash tool alternate tip Z offset.</p> <p> <b>Note</b></p> <p>This element is ignored if the element PRO_E_MFG_TOOL_TIP_FLASH_OPT is set to PRO_B_FALSE.</p>                  |
| PRO_E_MFG_TOOL_TIP_FLSH_OFFSET_X | PRO_VALUE_TYPE_DOUBLE  | <p>Optional element. Specifies the flash tool alternate tip X offset.</p> <p> <b>Note</b></p> <p>This element is ignored if the element PRO_E_MFG_TOOL_TIP_FLASH_OPT is set to PRO_B_FALSE.</p>                  |

## Element Trees: CMM Probe Setup

### The CMM probe Setup Element Tree:

The element tree for the CMM probe setup is documented in the header file `ProMfgElemToolSetupCmm.h`, and is as shown in the following figure:

#### Element Tree for CMM Probe Setup

```
-- PRO_E_MFG_CMM_TOOL_SETUP_ARR
|
|-- PRO_E_MFG_CMM_TOOL_SETUP
| |
| |-- PRO_E_MFG_CMM_TOOL_POCKET_NUM
| |
| |-- PRO_E_MFG_CMM_TOOL_TOOL_ID
| |
| |-- PRO_E_MFG_CMM_TOOL_TIP_NUM
| |
| |-- PRO_E_MFG_CMM_TOOL_REGISTER
| |
| |-- PRO_E_MFG_CMM_TOOL_COMMENT
| |
| |-- PRO_E_MFG_CMM_TOOL_PITCH_ANGLE
| |
| |-- PRO_E_MFG_CMM_TOOL_ROLL_ANGLE
```

The following table describes the elements in the element tree for the CMM probe setup feature.

| Element ID                    | Data Type              | Description                                                                                                                                                                                                     |
|-------------------------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_CMM_TOOL_SETUP_ARR  | Array                  | Optional element. Specifies the CMM probes setup array.                                                                                                                                                         |
| PRO_E_MFG_CMM_TOOL_SETUP      | Compound               | Optional element. This compound element defines the probe setup compound specification.                                                                                                                         |
| PRO_E_MFG_CMM_TOOL_POCKET_NUM | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the probe position in tool magazine.                                                                                                                                               |
| PRO_E_MFG_CMM_TOOL_TOOL_ID    | PRO_VALUE_TYPE_WSTRING | Mandatory element. Specifies the Probe ID.<br><br> <b>Note</b><br><br>Tool with such ID should exist in manufacturing model. |
| PRO_E_MFG_CMM_TOOL_TIP_NUM    | PRO_VALUE_TYPE_INT     | Optional element, if not defined or if the value is set to 1. Specifies the tip number by identifying it                                                                                                        |

| Element ID                     | Data Type              | Description                                        |
|--------------------------------|------------------------|----------------------------------------------------|
|                                |                        | from the array.                                    |
| PRO_E_MFG_CMM_TOOL_REGISTER    | PRO_VALUE_TYPE_INT     | Optional element. Specifies the register number.   |
| PRO_E_MFG_CMM_TOOL_COMMENT     | PRO_VALUE_TYPE_WSTRING | Optional element. Specifies the probe comments.    |
| PRO_E_MFG_CMM_TOOL_PITCH_ANGLE | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the pitch angle value. |
| PRO_E_MFG_CMM_TOOL_ROLL_ANGLE  | PRO_VALUE_TYPE_DOUBLE  | Optional element. Specifies the roll angle value.  |

## Checking Surfaces

The element `PRO_E_CHECK_SURF_COLL` is documented in the header file `ProMfgElemCheckSurf.h`, and is shown in the following figure.

### Element tree for `PRO_E_CHECK_SURF_COLL` element

```
-- PRO_E_CHECK_SURF_COLL
|
|-- PRO_E_ADD_REF_PARTS
|
|-- PRO_E_USE_MILL_STK
|
|-- PRO_E_STD_SURF_COLLECTION_APPL
```

The following table lists the contents of `PRO_E_CHECK_SURF_COLL` element.

| Element ID                     | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_ADD_REF_PARTS            | PRO_VALUE_TYPE_INTEGER | <p>Optional element. This element is used to check the reference parts for collisions. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>TRUE—All reference parts surfaces will be checked for collisions.</li> <li>FALSE—Reference parts surfaces will not be added for collision checking.</li> </ul> <p> <b>Note</b></p> <p>The FALSE value will be used if element does not exist.</p>                                                                                                                             |
| PRO_E_USE_MILL_STK             | PRO_VALUE_TYPE_INTEGER | <p>Optional element. This element is used to apply the stock allowance parameters of mill surface to the surfaces being checked. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>TRUE— Mill surface stock allowance parameter will be applied to check surfaces. Value of stock allowance is defined by sequence manufacturing parameter.</li> <li>FALSE—Mill surface stock allowance parameter will not be applied.</li> </ul> <p> <b>Note</b></p> <p>The FALSE value will be used if element does not exist.</p> |
| PRO_E_STD_SURF_COLLECTION_APPL | Surface Collection     | Optional element. Specifies the collection of selected surfaces to be checked for collisions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Approach and Exit

The element tree for the approach and exit parameters is defined in the header file `ProMfgElemApproachExit.h`, and is as shown in the following figure:

### Element tree for `PRO_E_MFG_CMP_APPROACH_EXIT` element

The following table lists the contents of `PRO_E_MFG_CMP_APPROACH_EXIT` element.

| Element ID                              | Data Type                             | Description                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------------|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>PRO_E_MFG_CMP_APPROACH</code>     | Compound                              | Optional element. This compound element specifies approach compound. It combines approach axis and first slice only.                                                                                                                                                                                                                                                                                   |
| <code>PRO_E_MFG_APPROACH_AXIS</code>    | <code>PRO_VALUE_TYPE_SELECTION</code> | Optional element. Specifies the selection of a vertical datum axis.                                                                                                                                                                                                                                                                                                                                    |
| <code>PRO_E_MFG_FIRST_SLICE_ONLY</code> | <code>PRO_VALUE_TYPE_INT</code>       | Specifies the flag value for the approach motion. The valid values for this element are: <ul style="list-style-type: none"> <li>• True</li> <li>• False</li> </ul> <div>  <b>Note</b><br/> This element is mandatory if the element <code>PRO_E_MFG_APPROACH_AXIS</code> is set. It is not used otherwise. </div> |
| <code>PRO_E_MFG_CMP_EXIT</code>         | Compound                              | This compound element specifies an exit compound. It combines exit axis and last slice only.                                                                                                                                                                                                                                                                                                           |

| Element ID                | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_EXIT_AXIS       | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the selection of a vertical datum axis.                                                                                                                                                                                                                                                                                                              |
| PRO_E_MFG_LAST_SLICE_ONLY | PRO_VALUE_TYPE_INT       | <p>Specifies the flag value for the exit motion. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>• True</li> <li>• False</li> </ul> <p> <b>Note</b></p> <p>This element is mandatory if the element PRO_E_MFG_EXIT_AXIS is set. It is not used otherwise.</p> |

## Spindle Types

This section describes the types of spindles, which can be used while creating a sequence feature. The types of spindles are defined by the enumerated type `ProSubSpindleOpt` and are as follows:

- `PRO_MFG_MAIN_SPINDLE`—Specifies that the sequence feature is created for the part in the main spindle.
- `PRO_MFG_SUB_SPINDLE`—Specifies that the sequence feature is created for the part in the sub-spindle.

Two parts can be machined during the same operation using the main spindle and the sub spindle.

## Tool Motions

This section describes how to construct and access the sub-element trees for various Tool Motion types that are used in the creation of Creo NC features.

## Approach Along Tool Axis

This section describes how to construct and access the sub-element trees for various Tool Motion types that are used in the creation of Creo NC features.

The element `PRO_E_TOOL_MTN` is a member of `PRO_E_TOOL_MTN_ARR` array and is documented in the header file `ProMfgElemToolMtnAlongAxisAppr.h`, and is as shown in the following figure:

---

```
-- PRO_E_TOOL_MTN
|
|-- PRO_E_TOOL_MTN_REF_ID
|
|-- PRO_E_TOOL_MTN_TYPE
|
|-- PRO_E_TOOL_MTN_FEED_TYPE
|
|-- PRO_E_MFG_PARAM_ARR
```

The following table describes the elements in the element tree for the approach along tool axis feature.

| Element ID               | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN_TYPE      | PRO_VALUE_TYPE_INT | Mandatory element. Species the tool motion type . The valid value for this element is PRO_TM_TYPE_ALONG_AXIS_APPROACH.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| PRO_E_TOOL_MTN_FEED_TYPE | PRO_VALUE_TYPE_INT | Optional element. Specifies the type of feed for the tool motion using the enumerated data type ProToolMtnFeedType. The valid value for this element are: <ul style="list-style-type: none"> <li>PRO_TM_FEED_FREE— Specifies a free feed type. Free feed specifies the rate at which the tool moves in the transverse motion, that is, the non-cutting motion.</li> <li>PRO_TM_FEED_CUT— Specifies a cut feed type. Cut feed specifies the rate at which the tool moves into the workpiece.</li> <li>PRO_TM_FEED_PLUNGE— Specifies a plunge feed type. Plunge feed specifies the rate at which the tool approaches and plunges into the workpiece.</li> <li>PRO_TM_FEED_APPROACH— Specifies an approach feed type. Approach feed specifies the rate at which the tool approaches the workpiece.</li> </ul> |
| PRO_E_MFG_PARAM_ARR      | Array              | Mandatory element. Specifies an array of manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file ProMfgElemParam.h. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Exit Along Tool Axis

The element PRO\_E\_TOOL\_MTN is a member of PRO\_E\_TOOL\_MTN\_ARR array and is documented in the header file ProMfgElemToolMtnAlongAxisExit.h, and is as shown in the following figure:

---

```
-- PRO_E_TOOL_MTN
|
|-- PRO_E_TOOL_MTN_REF_ID
|
|-- PRO_E_TOOL_MTN_TYPE
|
|-- PRO_E_TOOL_MTN_FEED_TYPE
|
|-- PRO_E_MFG_PARAM_ARR
```

The following table describes the elements in the element tree for the approach along tool axis feature.

| Element ID               | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN_TYPE      | PRO_VALUE_TYPE_INT | Mandatory element. Species the tool motion type . The valid value for this element is PRO_TM_TYPE_ALONG_AXIS_EXIT.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| PRO_E_TOOL_MTN_FEED_TYPE | PRO_VALUE_TYPE_INT | Optional element. Specifies the type of feed for the tool motion using the enumerated data type ProToolMtnFeedType. The valid value for this element are: <ul style="list-style-type: none"> <li>PRO_TM_FEED_FREE— Specifies a free feed type. Free feed specifies the rate at which the tool moves in the transverse motion, that is, the non-cutting motion.</li> <li>PRO_TM_FEED_CUT— Specifies a cut feed type. Cut feed specifies the rate at which the tool moves into the workpiece.</li> <li>PRO_TM_FEED_RETRACT— Specifies a retract feed type. Retract feed specifies the rate at which the tool moves away from the workpiece.</li> <li>PRO_TM_FEED_EXIT— Specifies an exit feed type. Exit feed specifies the rate at which the tool leaves the workpiece.</li> </ul> |
| PRO_E_MFG_PARAM_ARR      | Array              | Mandatory element. Specifies an array of manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file ProMfgElemParam.h. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Tool Motion — Follow Curve

The element PRO\_E\_TOOL\_MTN is a compound element that allows you to specify the tool motion parameters.

This element is a member of PRO\_E\_TOOL\_MTN\_ARR array and is documented in the header file ProMfgElemToolMtnFollowCrv.h, and is shown in the following figure.

## Element tree for PRO\_E\_TOOL\_MTN element

```
-- PRO_E_TOOL_MTN
|
|-- PRO_E_TOOL_MTN_REF_ID
|
|-- PRO_E_TOOL_MTN_TYPE
|
|-- PRO_E_TOOL_MTN_FEED_TYPE
|
|-- PRO_E_MFG_PARAM_ARR
|
|-- PRO_E_TOOL_MTN_CRV_REF
|
|-- PRO_E_TOOL_MTN_CRV_DIR
```

The following table lists the contents of PRO\_E\_TOOL\_MTN element.

| Element ID               | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN_TYPE      | PRO_VALUE_TYPE_INT | Mandatory element. Species the tool motion type . The valid value for this element is PRO_TM_TYPE_FOLLOW_CURVE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_TOOL_MTN_FEED_TYPE | PRO_VALUE_TYPE_INT | Optional element. Specifies the type of feed for the tool motion using the enumerated data type ProToolMtnFeedType. The valid value for this element are: <ul style="list-style-type: none"> <li>PRO_TM_FEED_FREE— Specifies a free feed type. Free feed specifies the rate at which the tool moves in the transverse motion, that is, the non-cutting motion.</li> <li>PRO_TM_FEED_CUT— Specifies a cut feed type. Cut feed specifies the rate at which the tool moves into the workpiece.</li> <li>PRO_TM_FEED_APPROACH— Specifies an approach feed type. Approach feed specifies the rate at which the tool approaches the workpiece.</li> <li>PRO_TM_FEED_EXIT— Specifies an exit feed type. Exit feed specifies the rate at</li> </ul> |

| Element ID             | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        |                          | which the tool leaves the workpiece.                                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_MFG_PARAM_ARR    | Array                    | Mandatory element. Specifies an array of manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file <code>ProMfgElemParam.h</code> . For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree.                                                        |
| PRO_E_TOOL_MTN_CRV_REF | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the selection of the curve feature.                                                                                                                                                                                                                                                                                                                     |
| PRO_E_TOOL_MTN_CRV_DIR | PRO_VALUE_TYPE_INT       | <p>Mandatory element. Specifies the direction of the working for the curve feature. The direction is defined by the enumerated data type <code>ProMfgCrvDir</code> in <code>ProMfgOptions.h</code>.</p> <p>The valid values for this element are:</p> <ul style="list-style-type: none"> <li>• <code>PRO_MFG_DIR_OPPOSITE</code></li> <li>• <code>PRO_MFG_DIR_SAME</code></li> </ul> |

## Tool Motion — Go To Point

The element `PRO_E_TOOL_MTN` is a member of `PRO_E_TOOL_MTN_ARR` array and is documented in the header file `ProMfgElemToolMtnGotoPnt.h`, and is shown in the following figure.

## Element tree for PRO\_E\_TOOL\_MTN element

```

The following table lists the contents of PRO\_E\_TOOL\_MTN element.

| Element ID               | Data Type          | Description                                                                                                                                                         |
|--------------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN_TYPE      | PRO_VALUE_TYPE_INT | Mandatory element. Specifies the tool motion type . The valid value for this element is PRO_TM_TYPE_GOTO_POINT. The value for this element is defined by ProTmType. |
| PRO_E_TOOL_MTN_FEED_TYPE | PRO_VALUE_TYPE_INT | Optional element. Specifies the type of feed for the tool motion using the enumerated data type ProToolMtnFeedType. The                                             |

| Element ID             | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        |                          | <p>valid value for this element are:</p> <ul style="list-style-type: none"> <li>• <b>PRO_TM_FEED_FREE</b>—Specifies a free feed type. Free feed specifies the rate at which the tool moves in the transverse motion, that is, the non-cutting motion.</li> <li>• <b>PRO_TM_FEED_CUT</b>—Specifies a cut feed type. Cut feed specifies the rate at which the tool moves into the workpiece.</li> <li>• <b>PRO_TM_FEED_PLUNGE</b>—Specifies a plunge feed type. Plunge feed specifies the rate at which the tool approaches and plunges into the workpiece.</li> <li>• <b>PRO_TM_FEED_RETRACT</b>—Specifies a retract feed type. Retract feed specifies the rate at which the tool moves away from the workpiece.</li> <li>• <b>PRO_TM_FEED_APPROACH</b>—Specifies an approach feed type. Approach feed specifies the rate at which the tool approaches the workpiece.</li> <li>• <b>PRO_TM_FEED_EXIT</b>—Specifies an exit feed type. Exit feed specifies the rate at which the tool leaves the workpiece.</li> <li>• <b>PRO_TM_FEED_THREAD</b>—Specifies a thread feed type. Thread feed specifies the feed rate for the tapping step.</li> </ul> |
| PRO_E_MFG_PARAM_ARR    | Array                    | Mandatory element. Specifies an array of manufacturing parameters. See the Creo NC online help for more information on manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file <code>ProMfgElemParam.h</code> . For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_TOOL_MTN_PNT_REF | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the datum point reference.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Element ID                      | Data Type             | Description                                                                                                                                                                                                                                                                |
|---------------------------------|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN_OFFSET           | Compound              | Optional element. This compound element specifies the definition for the various tool motion offset parameters.                                                                                                                                                            |
| PRO_E_TOOL_MTN_X_OFFSET         | PRO_VALUE_TYPE_DOUBLE | Optional element. Specifies the offset along X-axis. This element can range from negative to positive values. The valid range values for this element are from -MAX_DIM_VALUE to MAX_DIM_VALUE.                                                                            |
| PRO_E_TOOL_MTN_Y_OFFSET         | PRO_VALUE_TYPE_DOUBLE | Optional element. Specifies the offset along Y-axis. This element can range from negative to positive values. The valid range values for this element are from -MAX_DIM_VALUE to MAX_DIM_VALUE.                                                                            |
| PRO_E_TOOL_MTN_Z_OFFSET         | PRO_VALUE_TYPE_DOUBLE | Optional element. Specifies the offset along Z-axis. This element can range from negative to positive values. The valid range values for this element are from -MAX_DIM_VALUE to MAX_DIM_VALUE.                                                                            |
| PRO_E_TOOL_MTN_AXIS_MOVES       | PRO_VALUE_TYPE_INT    | Mandatory if the element PRO_E_TOOL_MTN_OFFSET is defined. Specifies the attributes for the axis moves.                                                                                                                                                                    |
| PRO_E_MFG_TM_TOOL_AXIS_COMPOUND | Compound              | Optional element. This compound element specifies the tool axis.                                                                                                                                                                                                           |
| PRO_E_MFG_TM_TOOL_AXIS_OPT      | PRO_VALUE_TYPE_INT    | Optional element. This element specifies the tool axis options using the enumerated type ProTmToolAxisOpt. The valid values for this element are: <ul style="list-style-type: none"> <li>• PRO_TM_ALONG_Z</li> <li>• PRO_TM_USE_PREV</li> <li>• PRO_TM_AXIS_SEL</li> </ul> |

| Element ID                      | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_TM_TOOL_AXIS_REF      | PRO_VALUE_TYPE_SELECTION | <p>This element specifies the axis selection.</p> <p> <b>Note</b></p> <p>This element is mandatory if the element PRO_E_MFG_TM_TOOL_AXIS_OPT is set to PRO_TM_AXIS_SEL.</p>                                                                                                   |
| PRO_E_MFG_TM_TOOL_AXIS_FLIP_OPT | PRO_VALUE_TYPE_INT       | <p>Specifies the flip options. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>• TRUE</li> <li>• FALSE</li> </ul> <p> <b>Note</b></p> <p>This element is mandatory if the element PRO_E_MFG_TM_TOOL_AXIS_OPT is set to PRO_TM_AXIS_SEL.</p> |

## Tool Motion — Go Delta

The PRO\_E\_TOOL\_MTN element is a member of PRO\_E\_TOOL\_MTN\_ARR array and is documented in the header file `ProMfgElemToolMtnGoDelta.h`, and is shown in the following figure.

## Element tree for PRO\_E\_TOOL\_MTN element

The following table lists the contents of PRO\_E\_TOOL\_MTN element.

| Element ID               | Data Type          | Description                                                                                                                                                                                                                                                                                                                                           |
|--------------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN_TYPE      | PRO_VALUE_TYPE_INT | Mandatory element. Species the Tool motion type . The valid value for this element is TPRO_TM_TYPE_GO_DELTA. The value for this element is defined by ProTmType.                                                                                                                                                                                      |
| PRO_E_TOOL_MTN_FEED_TYPE | PRO_VALUE_TYPE_INT | Optional element. Specifies the type of feed for the tool motion using the enumerated data type ProToolMtnFeedType. The valid value for this element are: <ul style="list-style-type: none"> <li>PRO_TM_FEED_FREE— Specifies a free feed type. Free feed specifies the rate at which the tool moves in the transverse motion, that is, the</li> </ul> |

| Element ID            | Data Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       |           | <p>non-cutting motion.</p> <ul style="list-style-type: none"> <li>• PRO_TM_FEED_CUT— Specifies a cut feed type. Cut feed specifies the rate at which the tool moves into the workpiece.</li> <li>• PRO_TM_FEED_PLUNGE— Specifies a plunge feed type. Plunge feed specifies the rate at which the tool approaches and plunges into the workpiece.</li> <li>• PRO_TM_FEED_RETRACT— Specifies a retract feed type. Retract feed specifies the rate at which the tool moves away from the workpiece.</li> <li>• PRO_TM_FEED_APPROACH— Specifies an approach feed type. Approach feed specifies the rate at which the tool approaches the workpiece.</li> <li>• PRO_TM_FEED_EXIT— Specifies an exit feed type. Exit feed specifies the rate at which the tool leaves the workpiece.</li> <li>• PRO_TM_FEED_THREAD— Specifies a thread feed type. Thread feed specifies the feed rate for the tapping step.</li> </ul> |
| PRO_E_MFG_PARAM_ARR   | Array     | Mandatory element. Specifies an array of manufacturing parameters. See the Creo NC online help for more information on manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file ProMfgElemParam.h. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| PRO_E_TOOL_MTN_OFFSET | Compound  | Optional element. This compound                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Element ID                      | Data Type             | Description                                                                                                                                                                                                                                                                                                                                                           |

The valid values for this element are:</p> <ul style="list-style-type: none"> <li>• TRUE</li> <li>• FALSE</li> </ul> <p> <b>Note</b></p> <p>This element is mandatory if the element PRO_E_MFG_TM_TOOL_AXIS_OPT is set to PRO_TM_AXIS_SEL.</p> |

## Tool Motion — Go Home

The PRO\_E\_TOOL\_MTN element is a member of PRO\_E\_TOOL\_MTN\_ARR array and is documented in the header file ProMfgElemToolMtnGoHome.h, and is shown in the following figure.

### Element tree for PRO\_E\_TOOL\_MTN element

```
-- PRO_E_TOOL_MTN
|
|-- PRO_E_TOOL_MTN_REF_ID
|
|-- PRO_E_TOOL_MTN_TYPE
|
|-- PRO_E_TOOL_MTN_FEED_TYPE
|
|-- PRO_E_MFG_PARAM_ARR
|
|-- PRO_E_TOOL_MTN_AXIS_REF
```

The following table lists the contents of PRO\_E\_TOOL\_MTN element.

| Element ID               | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN           | Compound           | Compound element. This element specifies the tool motion definition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_TOOL_MTN_FEED_TYPE | PRO_VALUE_TYPE_INT | Optional element. Specifies the type of feed for the tool motion using the enumerated data type <code>ProToolMtnFeedType</code> . The valid value for this element are: <ul style="list-style-type: none"> <li>• <code>PRO_TM_FEED_FREE</code>— Specifies a free feed type. Free feed specifies the rate at which the tool moves in the transverse motion, that is, the non-cutting motion.</li> <li>• <code>PRO_TM_FEED_CUT</code>— Specifies a cut feed type. Cut feed specifies the rate at which the tool moves into the workpiece.</li> <li>• <code>PRO_TM_FEED_RETRACT</code>— Specifies a retract feed type. Retract feed specifies the rate at which the tool moves away from the workpiece.</li> <li>• <code>PRO_TM_FEED_EXIT</code>— Specifies an exit feed type. Exit feed specifies the rate at which the tool leaves the workpiece.</li> </ul> |
| PRO_E_TOOL_MTN_TYPE      | PRO_VALUE_TYPE_INT | Mandatory element. Specifies the tool motion type . The valid value for this element is <code>PRO_TM_TYPE_GOHOME</code> . The value for this element is defined by <code>ProTmType</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Element ID              | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_PARAM_ARR     | Array                    | Mandatory element. Specifies an array of manufacturing parameters. See the Creo NC online help for more information on manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file ProMfgElemParam.h. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree. |
| PRO_E_TOOL_MTN_AXIS_REF | PRO_VALUE_TYPE_SELECTION | <p>Specifies the axis selection. This element is optional for 5-axis Creo NC sequences.</p> <p> <b>Note</b></p> <p>By default, Z-axis of the Creo NC sequence is used to define the constraint plane. For 5-axis Creo NC sequences, you can select an alternative axis.</p>                                  |

## Tool Motion — Lead In

The element PRO\_E\_TOOL\_MTN is a member of PRO\_E\_TOOL\_MTN\_ARR array and is documented in the header file ProMfgElemToolMtnLeadIn.h, and is shown in the following figure.

## Element tree for PRO\_E\_TOOL\_MTN element

```
-- PRO_E_TOOL_MTN
|
|-- PRO_E_TOOL_MTN_REF_ID
|
|-- PRO_E_TOOL_MTN_TYPE
|
|-- PRO_E_TOOL_MTN_FEED_TYPE
|
|-- PRO_E_MFG_PARAM_ARR
|
|-- PRO_E_MFG_APPR_EXIT_DIR
|
|-- PRO_E_TOOL_MTN_AXIS_REF
```

The following table lists the contents of PRO\_E\_TOOL\_MTN element.

| Element ID               | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN           | Compound           | Compound element. This element specifies the tool motion definition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| PRO_E_TOOL_MTN_TYPE      | PRO_VALUE_TYPE_INT | Mandatory element. Species the tool motion type. The valid value for this element is PRO_TM_TYPE_LEAD_IN. The value for this element is defined by ProTmType.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_TOOL_MTN_FEED_TYPE | PRO_VALUE_TYPE_INT | Optional element. Specifies the type of feed for the tool motion using the enumerated data type ProToolMtnFeedType. The valid value for this element are: <ul style="list-style-type: none"> <li>PRO_TM_FEED_FREE—Specifies a free feed type. Free feed specifies the rate at which the tool moves in the transverse motion, that is, the non-cutting motion.</li> <li>PRO_TM_FEED_CUT—Specifies a cut feed type. Cut feed specifies the rate at which the tool moves into the workpiece.</li> <li>PRO_TM_FEED_APPROACH—Specifies an approach feed type. Approach feed specifies the rate at which</li> </ul> |

| Element ID              | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         |                          | the tool approaches the workpiece.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_MFG_PARAM_ARR     | Array                    | <p>Mandatory element. Specifies an array of manufacturing parameters. The values which are used to define this element are:</p> <ul style="list-style-type: none"> <li>ENTRY_ANGLE</li> <li>TANGENT_LEAD_STEP</li> <li>NORMAL_LEAD_STEP</li> <li>LEAD_RADIUS</li> </ul> <p>The element tree for the manufacturing parameter is defined in the header file <code>ProMfgElemParam.h</code>. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree.</p> |
| PRO_E_MFG_APPR_EXIT_DIR | PRO_VALUE_TYPE_INT       | <p>Mandatory element. Specifies the direction for the normal approach type of tool exit. The direction is defined by the enumerated data type <code>ProTmSideDir</code> in <code>ProMfgOptions.h</code>. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_TM_DIR_RIGHT_SIDE</li> <li>PRO_TM_DIR_LEFT_SIDE</li> </ul>                                                                                                                                                                                |
| PRO_E_TOOL_MTN_AXIS_REF | PRO_VALUE_TYPE_SELECTION | <p>Mandatory element. Specifies the axis selection.</p> <p> <b>Note</b></p> <p>This element is optional for 5-axis Creo NC sequences. By default Z-axis of the Creo NC sequence is used to define the constraint plane. For 5-axis Creo NC sequences a user can select an alternative axis.</p>                                                                                                                                                       |

## Tool Motion — Go Retract

The element `PRO_E_TOOL_MTN` is a member of `PRO_E_TOOL_MTN_ARR` array and is documented in the header file `ProMfgElemToolMtnGoRetr.h`, and is shown in the following figure.

### Element tree for `PRO_E_TOOL_MTN` element

The following table lists the contents of `PRO_E_TOOL_MTN` element.

| Element ID                       | Data Type                       | Description                                                                                                                                                                                   |
|----------------------------------|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>PRO_E_TOOL_MTN</code>      | Compound                        | Compound element. This element specifies Tool motion definition.                                                                                                                              |
| <code>PRO_E_TOOL_MTN_TYPE</code> | <code>PRO_VALUE_TYPE_INT</code> | Mandatory element. Species the Tool motion type . The valid value for this element is <code>PRO_TM_TYPE_GO_RETRACT</code> . The value for this element is defined by <code>ProTmType</code> . |

| Element ID               | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN_FEED_TYPE | PRO_VALUE_TYPE_INT | <p>Optional element. Specifies the type of feed for the tool motion using the enumerated data type <code>ProToolMtnFeedType</code>. The valid value for this element are:</p> <ul style="list-style-type: none"> <li>• <code>PRO_TM_FEED_FREE</code>— Specifies a free feed type. Free feed specifies the rate at which the tool moves in the transverse motion, that is, the non-cutting motion.</li> <li>• <code>PRO_TM_FEED_CUT</code>— Specifies a cut feed type. Cut feed specifies the rate at which the tool moves into the workpiece.</li> <li>• <code>PRO_TM_FEED_RETRACT</code>— Specifies a retract feed type. Retract feed specifies the rate at which the tool moves away from the workpiece.</li> <li>• <code>PRO_TM_FEED_EXIT</code>— Specifies an exit feed type. Exit feed specifies the rate at which the tool leaves the workpiece.</li> </ul> |
| PRO_E_MFG_PARAM_ARR      | Array              | <p>Mandatory element. Specifies an array of manufacturing parameters. See the Creo NC online help for more information on manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file <code>ProMfgElemParam.h</code>. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Tool Motion — Normal Approach

The element `PRO_E_TOOL_MTN` is a member of `PRO_E_TOOL_MTN_ARR` array and is documented in the header file `ProMfgElemToolMtnNormAppr.h`, and is shown in the following figure.

## Element tree for PRO\_E\_TOOL\_MTN element

```
-- PRO_E_TOOL_MTN
|
|-- PRO_E_TOOL_MTN_REF_ID
|
|-- PRO_E_TOOL_MTN_TYPE
|
|-- PRO_E_TOOL_MTN_FEED_TYPE
|
|-- PRO_E_MFG_PARAM_ARR
|
|-- PRO_E_TOOL_MTN_OFFSET
| |
| |-- PRO_E_TOOL_MTN_X_OFFSET
| |
| |-- PRO_E_TOOL_MTN_Y_OFFSET
| |
| |-- PRO_E_TOOL_MTN_Z_OFFSET
|
|-- PRO_E_MFG_APPR_EXIT_DIR
|
|-- PRO_E_TOOL_MTN_AXIS_REF
```

The following table lists the contents of PRO\_E\_TOOL\_MTN element.

| Element ID               | Data Type          | Description                                                                                                                                                                                                                                                                                                                                           |
|--------------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN           | Compound           | Compound element. This element specifies the tool motion definition.                                                                                                                                                                                                                                                                                  |
| PRO_E_TOOL_MTN_TYPE      | PRO_VALUE_TYPE_INT | Mandatory element. Species the tool motion type. The valid value for this element is PRO_TM_TYPE_NORMAL_APPROACH. The value for this element is defined by ProTmType.                                                                                                                                                                                 |
| PRO_E_TOOL_MTN_FEED_TYPE | PRO_VALUE_TYPE_INT | Optional element. Specifies the type of feed for the tool motion using the enumerated data type ProToolMtnFeedType. The valid value for this element are: <ul style="list-style-type: none"> <li>PRO_TM_FEED_FREE— Specifies a free feed type. Free feed specifies the rate at which the tool moves in the transverse motion, that is, the</li> </ul> |

| Element ID              | Data Type             | Description                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         |                       | <p>non-cutting motion.</p> <ul style="list-style-type: none"> <li>PRO_TM_FEED_CUT—Specifies a cut feed type. Cut feed specifies the rate at which the tool moves into the workpiece.</li> <li>PRO_TM_FEED_APPROACH—Specifies an approach feed type. Approach feed specifies the rate at which the tool approaches the workpiece.</li> </ul>                                                                    |
| PRO_E_MFG_PARAM_ARR     | Array                 | <p>Mandatory element. Specifies an array of manufacturing parameters. The element APPROACH_DIST is used to specify the approach distance.</p> <p>The element tree for the manufacturing parameter is defined in the header file <code>ProMfgElemParam.h</code>. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree.</p> |
| PRO_E_TOOL_MTN_OFFSET   | Compound              | Optional element. This compound element specifies the offset value.                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_TOOL_MTN_X_OFFSET | PRO_VALUE_TYPE_DOUBLE | Optional element. Specifies the offset along X-axis. This element can range from negative to positive values. The valid range values for this element are from <code>-MAX_DIM_VALUE</code> to <code>MAX_DIM_VALUE</code> .                                                                                                                                                                                     |
| PRO_E_TOOL_MTN_Y_OFFSET | PRO_VALUE_TYPE_DOUBLE | Optional element. Specifies the offset along Y-axis. This element can range from negative to positive values. The valid range values for this element are from <code>-MAX_DIM_VALUE</code> to <code>MAX_DIM_VALUE</code> .                                                                                                                                                                                     |
| PRO_E_TOOL_MTN_Z_OFFSET | PRO_VALUE_TYPE_DOUBLE | Optional element. Specifies the offset along Z-axis. This element can range from negative to positive values. The valid range values for this element are from <code>-MAX_DIM_VALUE</code> to <code>MAX_DIM_VALUE</code> .                                                                                                                                                                                     |

| Element ID              | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_APPR_EXIT_DIR | PRO_VALUE_TYPE_INT       | <p>Mandatory element. Specifies the direction for the normal approach type of tool exit. The direction is defined by the enumerated data type <code>ProTmSideDir</code> in <code>ProMfgOptions.h</code>. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>• <code>PRO_TM_DIR_RIGHT_SIDE</code></li> <li>• <code>PRO_TM_DIR_LEFT_SIDE</code></li> </ul> |
| PRO_E_TOOL_MTN_AXIS_REF | PRO_VALUE_TYPE_SELECTION | <p>Mandatory element. Specifies the axis selection.</p> <p> <b>Note</b></p> <p>This element is optional for 5-axis Creo NC sequences. By default Z-axis of the Creo NC sequence is used to define the constraint plane. For 5-axis Creo NC sequences a user can select an alternative axis.</p>      |

## Tool Motion — Normal Exit

The element `PRO_E_TOOL_MTN` is a member of `PRO_E_TOOL_MTN_ARR` array and is documented in the header file `ProMfgElemToolMtnNormExit.h`, and is shown in the following figure.

## Element tree for PRO\_E\_TOOL\_MTN element

|                             |
|-----------------------------|
| -- PRO_E_TOOL_MTN           |
| -- PRO_E_TOOL_MTN_REF_ID    |
| -- PRO_E_TOOL_MTN_TYPE      |

This element specifies the Tool motion definition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| PRO_E_TOOL_MTN_TYPE      | PRO_VALUE_TYPE_INT | Mandatory element. Tool motion type . The valid value for this element is PRO_TM_TYPE_NORMAL_EXIT. The value for this element is defined by ProTmType.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PRO_E_TOOL_MTN_FEED_TYPE | PRO_VALUE_TYPE_INT | Optional element. Specifies the type of feed for the tool motion using the enumerated data type ProToolMtnFeedType. The valid value for this element are: <ul style="list-style-type: none"> <li>PRO_TM_FEED_FREE— Specifies a free feed type. Free feed specifies the rate at which the tool moves in the transverse motion, that is, the non-cutting motion.</li> <li>PRO_TM_FEED_CUT— Specifies a cut feed type. Cut feed specifies the rate at which the tool moves into the workpiece.</li> <li>PRO_TM_FEED_EXIT— Specifies an exit feed type. Exit feed specifies the rate at which the tool leaves the workpiece.</li> </ul> |

| Element ID              | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_PARAM_ARR     | Array                    | <p>Mandatory element. Specifies an array of manufacturing parameters. The element EXIT_DISTANCE is used to specify the exit distance.</p> <p>The element tree for the manufacturing parameter is defined in the header file <code>ProMfgElemParam.h</code>. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree</p> |
| PRO_E_MFG_APPR_EXIT_DIR | PRO_VALUE_TYPE_INT       | <p>Mandatory element. Specifies the direction of orientation for the approach or exit tool motion. The direction of the orientation is defined by the enumerated data type <code>ProTmSideDir</code> in <code>ProMfgOptions.h</code>. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_TM_DIR_RIGHT_SIDE</li> <li>PRO_TM_DIR_LEFT_SIDE</li> </ul>                    |
| PRO_E_TOOL_MTN_AXIS_REF | PRO_VALUE_TYPE_SELECTION | <p>Mandatory element. Specifies the axis selection.</p> <p> <b>Note</b></p> <p>This element is optional for 5-axis Creo NC sequences. By default Z-axis of the Creo NC sequence is used to define the constraint plane. For 5-axis Creo NC sequences a user can select an alternative axis.</p>                      |

## Tool Motion — Lead Out

The element `PRO_E_TOOL_MTN` is a member of `PRO_E_TOOL_MTN_ARR` array and is documented in the header file `ProMfgElemToolMtnLeadOut.h`, and is shown in the following figure.

## Element tree for PRO\_E\_TOOL\_MTN element

```
-- PRO_E_TOOL_MTN
|
|-- PRO_E_TOOL_MTN_REF_ID
|
|-- PRO_E_TOOL_MTN_TYPE
|
|-- PRO_E_TOOL_MTN_FEED_TYPE
|
|-- PRO_E_MFG_PARAM_ARR
|
|-- PRO_E_MFG_APPR_EXIT_DIR
|
|-- PRO_E_TOOL_MTN_AXIS_REF
```

The following table lists the contents of PRO\_E\_TOOL\_MTN element.

| Element ID               | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN_TYPE      | PRO_VALUE_TYPE_INT | Mandatory element. Species the tool motion type . The valid value for this element is PRO_TM_TYPE_LEAD_OUT. The value for this element is defined by ProTmType.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| PRO_E_TOOL_MTN_FEED_TYPE | PRO_VALUE_TYPE_INT | Optional element. Specifies the type of feed for the tool motion using the enumerated data type ProToolMtnFeedType. The valid value for this element are: <ul style="list-style-type: none"> <li>PRO_TM_FEED_FREE— Specifies a free feed type. Free feed specifies the rate at which the tool moves in the transverse motion, that is, the non-cutting motion.</li> <li>PRO_TM_FEED_CUT— Specifies a cut feed type. | PRO_E_MFG_PARAM_ARR     | Array                    | <p>Mandatory element. Specifies an array of manufacturing parameters. The following parameters are used to define the helical approach motion:</p> <ul style="list-style-type: none"> <li>ENTRY_ANGLE</li> <li>CLEAR_DIST</li> <li>NORMAL_LEAD_STEP</li> <li>LEAD_RADIUS</li> </ul> <p>The element tree for the manufacturing parameter is defined in the header file <code>ProMfgElemParam.h</code>. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree.</p> |
| PRO_E_MFG_APPR_EXIT_DIR | PRO_VALUE_TYPE_INT       | <p>Mandatory element. Specifies the direction of orientation for approach or exit tool motion. The direction of orientation is defined by the enumerated data type <code>ProTmSideDir</code> in <code>ProMfgOptions.h</code>. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_TM_DIR_RIGHT_SIDE</li> <li>PRO_TM_DIR_LEFT_SIDE</li> </ul>                                                                                                                                                                       |
| PRO_E_TOOL_MTN_AXIS_REF | PRO_VALUE_TYPE_SELECTION | <p>Mandatory element. Specifies the axis selection.</p> <p> <b>Note</b></p> <p>This element is optional for 5-axis Creo NC sequences. By default Z-axis of the Creo NC sequence is used to define the constraint plane. For 5-axis Creo NC sequences a user can select an alternative axis.</p>                                                                                                                                                                 |

## Tool Motion — Helical Exit

The element `PRO_E_TOOL_MTN` is a member of `PRO_E_TOOL_MTN_ARR` array and is documented in the header file `ProMfgElemToolMtnHelExit.h`, and is shown in the following figure.

### Element tree for `PRO_E_TOOL_MTN` element

```
-- PRO_E_TOOL_MTN
|
| -- PRO_E_TOOL_MTN_REF_ID
|
| -- PRO_E_TOOL_MTN_TYPE
|
| -- PRO_E_TOOL_MTN_FEED_TYPE
|
| -- PRO_E_MFG_PARAM_ARR
|
| -- PRO_E_MFG_APPR_EXIT_DIR
|
| -- PRO_E_TOOL_MTN_AXIS_REF
```

The following table lists the contents of `PRO_E_TOOL_MTN` element.

| Element ID                            | Data Type                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>PRO_E_TOOL_MTN_TYPE</code>      | <code>PRO_VALUE_TYPE_INT</code> | Mandatory element. Species the tool motion type. The valid value for this element is <code>PRO_TM_TYPE_HELICAL_EXIT</code> . The value for this element is defined by <code>ProTmType</code> .                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>PRO_E_TOOL_MTN_FEED_TYPE</code> | <code>PRO_VALUE_TYPE_INT</code> | Optional element. Specifies the type of feed for the tool motion using the enumerated data type <code>ProToolMtnFeedType</code> . The valid value for this element are: <ul style="list-style-type: none"><li><code>PRO_TM_FEED_FREE</code>— Specifies a free feed type. Free feed specifies the rate at which the tool moves in the transverse motion, that is, the non-cutting motion.</li><li><code>PRO_TM_FEED_CUT</code>— Specifies a cut feed type. Cut feed specifies the rate at which the tool moves into the workpiece.</li><li><code>PRO_TM_FEED_RETRACT</code>—</li></ul> |

## Tool Motion — Go To Surface

The element `PRO_E_TOOL_MTN` is a member of `PRO_E_TOOL_MTN_ARR` array and is documented in the header file `ProMfgElemToolMtnGotoSrf.h`, and is shown in the following figure.

### Element tree for `PRO_E_TOOL_MTN` element

```
-- PRO_E_TOOL_MTN
|
|-- PRO_E_TOOL_MTN_REF_ID
|
|-- PRO_E_TOOL_MTN_TYPE
|
|-- PRO_E_TOOL_MTN_FEED_TYPE
|
|-- PRO_E_MFG_PARAM_ARR
|
|-- PRO_E_TOOL_MTN_SRF_REF
```

The following table lists the contents of PRO\_E\_TOOL\_MTN element.

| Element ID               | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree. |
| PRO_E_TOOL_MTN_SRF_REF | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the selection of a surface.                                                                                                                                                                                                                                                                                                                                      |

## Tool Motion — Go To Axis

The element PRO\_E\_TOOL\_MTN is a member of PRO\_E\_TOOL\_MTN\_ARR array and is documented in the header file ProMfgElemToolMtnGotoAxis.h, and is shown in the following figure.

### Element tree for PRO\_E\_TOOL\_MTN element

```
-- PRO_E_TOOL_MTN
|
|-- PRO_E_TOOL_MTN_REF_ID
|
|-- PRO_E_TOOL_MTN_TYPE
|
|-- PRO_E_TOOL_MTN_FEED_TYPE
|
|-- PRO_E_MFG_PARAM_ARR
|
|-- PRO_E_TOOL_MTN_GOTO_AXIS_REF
```

The following table lists the contents of PRO\_E\_TOOL\_MTN element.

| Element ID               | Data Type          | Description                                                                                                                                                      |
|--------------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN_TYPE      | PRO_VALUE_TYPE_INT | Mandatory element. Species the tool motion type . The valid value for this element is PRO_TM_TYPE_GOTO_AXIS. The value for this element is defined by ProTmType. |
| PRO_E_TOOL_MTN_FEED_TYPE | PRO_VALUE_TYPE_INT | Optional element. Specifies the type of feed for the tool motion                                                                                                 |

| Element ID                                | Data Type                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------------------|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                           |                                       | <p>using the enumerated data type <code>ProToolMtnFeedType</code>. The valid value for this element are:</p> <ul style="list-style-type: none"> <li>• <code>PRO_TM_FEED_FREE</code>—Specifies a free feed type. Free feed specifies the rate at which the tool moves in the transverse motion, that is, the non-cutting motion.</li> <li>• <code>PRO_TM_FEED_CUT</code>—Specifies a cut feed type. Cut feed specifies the rate at which the tool moves into the workpiece.</li> <li>• <code>PRO_TM_FEED_PLUNGE</code>—Specifies a plunge feed type. Plunge feed specifies the rate at which the tool approaches and plunges into the workpiece.</li> <li>• <code>PRO_TM_FEED_RETRACT</code>—Specifies a retract feed type. Retract feed specifies the rate at which the tool moves away from the workpiece.</li> <li>• <code>PRO_TM_FEED_APPROACH</code>—Specifies an approach feed type. Approach feed specifies the rate at which the tool approaches the workpiece.</li> <li>• <code>PRO_TM_FEED_EXIT</code>—Specifies an exit feed type. Exit feed specifies the rate at which the tool leaves the workpiece.</li> </ul> |
| <code>PRO_E_MFG_PARAM_ARR</code>          | Array                                 | Mandatory element. Specifies an array of manufacturing parameters. See the Creo NC online help for more information on manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file <code>ProMfgElemParam.h</code> . For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>PRO_E_TOOL_MTN_GOTO_AXIS_REF</code> | <code>PRO_VALUE_TYPE_SELECTION</code> | Mandatory element. Specifies the axis selection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Tool Motion — Tangent Approach

The compound element `PRO_E_TOOL_MTN` is a member of `PRO_E_TOOL_MTN_ARR` array and is documented in the header file `ProMfgElemToolMtnTanAppr.h`, and is shown in the following figure.

### Element tree for `PRO_E_TOOL_MTN` element

```
-- PRO_E_TOOL_MTN
|
| -- PRO_E_TOOL_MTN_REF_ID
|
| -- PRO_E_TOOL_MTN_TYPE
|
| -- PRO_E_TOOL_MTN_FEED_TYPE
|
| -- PRO_E_MFG_PARAM_ARR
|
| -- PRO_E_TOOL_MTN_OFFSET
| |
| | -- PRO_E_TOOL_MTN_X_OFFSET
| |
| | -- PRO_E_TOOL_MTN_Y_OFFSET
| |
| | -- PRO_E_TOOL_MTN_Z_OFFSET
|
| -- PRO_E_TOOL_MTN_AXIS_REF
```

The following table lists the contents of `PRO_E_TOOL_MTN` element.

| Element ID                            | Data Type                       | Description                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>PRO_E_TOOL_MTN_TYPE</code>      | <code>PRO_VALUE_TYPE_INT</code> | Mandatory element. Species the tool motion type . The valid value for this element is <code>PRO_TM_TYPE_TANGENT_APPROACH</code> .                                                                                                                                                                                                                                                                  |
| <code>PRO_E_TOOL_MTN_FEED_TYPE</code> | <code>PRO_VALUE_TYPE_INT</code> | Optional element. Specifies the type of feed for the tool motion using the enumerated data type <code>ProToolMtnFeedType</code> . The valid value for this element are: <ul style="list-style-type: none"><li><code>PRO_TM_FEED_FREE</code>— Specifies a free feed type. Free feed specifies the rate at which the tool moves in the transverse motion, that is, the non-cutting motion.</li></ul> |

| Element ID              | Data Type             | Description                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         |                       | <ul style="list-style-type: none"> <li>PRO_TM_FEED_CUT—Specifies a cut feed type. Cut feed specifies the rate at which the tool moves into the workpiece.</li> <li>PRO_TM_FEED_APPROACH—Specifies an approach feed type. Approach feed specifies the rate at which the tool approaches the workpiece.</li> </ul>                                                             |
| PRO_E_MFG_PARAM_ARR     | Array                 | Mandatory element. Specifies an array of manufacturing parameters. The parameter APPROACH_DIST specifies the approach distance. The element tree for the manufacturing parameter is defined in the header file ProMfgElemParam.h. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree. |
| PRO_E_TOOL_MTN_OFFSET   | Compound              | Optional element. This compound element specifies the tool motion offset.                                                                                                                                                                                                                                                                                                    |
| PRO_E_TOOL_MTN_X_OFFSET | PRO_VALUE_TYPE_DOUBLE | Optional element. Specifies the offset value along the X-axis. This element can range from negative to positive values. The valid range values for this element are from -MAX_DIM_VALUE to MAX_DIM_VALUE.                                                                                                                                                                    |
| PRO_E_TOOL_MTN_Y_OFFSET | PRO_VALUE_TYPE_DOUBLE | Optional element. Specifies the offset value along the Y-axis. This element can range from negative to positive values. The valid range values for this element are from -MAX_DIM_VALUE to MAX_DIM_VALUE.                                                                                                                                                                    |

| Element ID              | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN_Z_OFFSET | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the offset value along the Z-axis. This element can range from negative to positive values. The valid range values for this element are from -MAX_DIM_VALUE to MAX_DIM_VALUE                                                                                                                                                                                                                             |
| PRO_E_TOOL_MTN_AXIS_REF | PRO_VALUE_TYPE_SELECTION | Specifies the axis selection.<br><br> <b>Note</b> <ul style="list-style-type: none"> <li>• This element is optional for 5-axis Creo NC sequences</li> <li>• Z-axis of the Creo NC sequence is used to define the constraint plane. This is the default value.</li> <li>• For 5-axis Creo NC sequences you can select an alternative axis</li> </ul> |

## Tool Motion — Tangent Exit

The compound element PRO\_E\_TOOL\_MTN is a member of PRO\_E\_TOOL\_MTN\_ARR array and is documented in the header file ProMfgElemToolMtnTanExit.h, and is shown in the following figure.

### Element tree for PRO\_E\_TOOL\_MTN element

The following table lists the contents of PRO\_E\_TOOL\_MTN element.

| Element ID               | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN_TYPE      | PRO_VALUE_TYPE_INT | Mandatory element. Species the tool motion type . The valid value for this element is PRO_TM_TYPE_TANGENT_EXIT.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_TOOL_MTN_FEED_TYPE | PRO_VALUE_TYPE_INT | Optional element. Specifies the type of feed for the tool motion using the enumerated data type ProToolMtnFeedType. The valid value for this element are: <ul style="list-style-type: none"><li>• PRO_TM_FEED_FREE— Specifies a free feed type. Free feed specifies the rate at which the tool moves in the transverse motion, that is, the non-cutting motion.</li><li>• PRO_TM_FEED_CUT— Specifies a cut feed type. Cut feed specifies the rate at which the tool moves into the workpiece.</li><li>• PRO_TM_FEED_EXIT— Specifies an exit feed type. Exit feed specifies the rate at which the tool leaves the workpiece.</li></ul> |

| Element ID              | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_PARAM_ARR     | Array                    | Mandatory element. Specifies an array of manufacturing parameters. The parameter APPROACH_DIST specifies the approach distance. The element tree for the manufacturing parameter is defined in the header file ProMfgElemParam.h. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree.                                                                  |
| PRO_E_TOOL_MTN_AXIS_REF | PRO_VALUE_TYPE_SELECTION | <p>Specifies the axis selection.</p> <p> <b>Note</b></p> <ul style="list-style-type: none"> <li>• This element is optional for 5-axis Creo NC sequences.</li> <li>• Z-axis of the Creo NC sequence is used to define the constraint plane. This is the default value.</li> <li>• For 5-axis Creo NC sequences you can select an alternative axis.</li> </ul> |

---

## Tool Motion — Area and Groove Turning

The element `PRO_E_TOOL_MTN` is a member of `PRO_E_TOOL_MTN_ARR` array and is documented in the header file `ProMfgElemToolMtnAreaTurn.h` and `ProMfgElemToolMtnGrooveTurn.h` respectively, and is as shown in the following figure:

**Element tree for `PRO_E_TOOL_MTN` element:**

The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_TM_TURN_CORNER_TYPE_SHARP</li> <li>PRO_TM_TURN_CORNER_TYPE_FILLET</li> <li>PRO_TM_TURN_CORNER_TYPE_CHAMFER</li> </ul>                                                                                                                                                                                                                                                             |
| PRO_E_TOOL_MTN_TURN_<br>CORNER_ARR       | Array              | Optional element. Specifies the corner conditions array.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| PRO_E_TOOL_MTN_TURN_                     | Compound           | This compound element defines                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Element ID                      | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CORNER                          |                          | the elements related to the corner                                                                                                                                                                                                                                                                                                                                                                                   |
| PRO_E_TOOL_MTN_TURN_CORNER_TYPE | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the corner type. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_TM_TURN_CORNER_TYPE_SHARP</li> <li>PRO_TM_TURN_CORNER_TYPE_FILLET</li> <li>PRO_TM_TURN_CORNER_TYPE_CHAMFER</li> </ul>                                                                                                                                                                |
| PRO_E_TOOL_MTN_TURN_PREV_ENT_ID | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the previous entity id.                                                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_TOOL_MTN_TURN_NEXT_ENT_ID | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the next entity id.                                                                                                                                                                                                                                                                                                                                                                     |
| PRO_E_TOOL_MTN_TURN_CORNER_VAL  | PRO_VALUE_TYPE_DOUBLE    | Specifies the fillet radius or chamfer dimension. This element can range from negative to positive values. The valid range values for this element are from -MAX_DIM_VALUE to MAX_DIM_VALUE<br><br> <b>Note</b><br>This element is mandatory if corner type is PRO_TM_TURN_CORNER_TYPE_FILLET or PRO_TM_TURN_CORNER_TYPE_CHAMFER. |
| PRO_E_TURN_STK_ALLW_PROF_ARR    | Array                    | Specifies an array for profile stock allowance.                                                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_TURN_STK_ALLW_ROUGH_ARR   | Array                    | Specifies an array for rough stock allowance.                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_TURN_STK_ALLOWANCE        | Compound                 | Specifies the compound element for stock allowance. For more information, refer to the section <a href="#">Specifying the Stock Allowance on page 1719</a> .                                                                                                                                                                                                                                                         |
| PRO_E_TOOL_MTN_TURN_STK_BND_REF | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies reference to the workpiece or stock boundary.                                                                                                                                                                                                                                                                                                                                           |
| PRO_E_TOOL_MTN_TURN_EXT         | Compound                 | Mandatory element. This compound element specifies extensions.                                                                                                                                                                                                                                                                                                                                                       |

| Element ID                | Data Type          | Description                                                                                                                                                                                                                     |
|---------------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN_TURN_S_EXT | PRO_VALUE_TYPE_INT | Mandatory element. Specifies the start extension. The valid values for this element are: <ul style="list-style-type: none"> <li>EXT_POS_Z</li> <li>EXT_NEG_Z</li> <li>EXT_POS_Y</li> <li>EXT_NEG_Y</li> <li>EXT_NONE</li> </ul> |
| PRO_E_TOOL_MTN_TURN_E_EXT | PRO_VALUE_TYPE_INT | Mandatory element. Specifies the end extension. The valid values for this element are: <ul style="list-style-type: none"> <li>EXT_POS_Z</li> <li>EXT_NEG_Z</li> <li>EXT_POS_Y</li> <li>EXT_NEG_Y</li> <li>EXT_NONE</li> </ul>   |

## Specifying the Stock Allowance

The element `PRO_E_TURN_STK_ALLOWANCE` is used to specify the stock allowance and is documented in the header files

`ProMfgElemToolMtnAreaTurn.h`,  
`ProMfgElemToolMtnGrooveTurn.h` and  
`ProMfgElemToolMtnProfTurn.h`.

The following figure shows the element `PRO_E_TURN_STK_ALLOWANCE`:

|                                     |
|-------------------------------------|
|                                     |
| -- PRO_E_TURN_STK_ALLOWANCE         |
|                                     |
| -- PRO_E_TURN_STK_ALLW_FIRST_ENT_ID |
|                                     |
| -- PRO_E_TURN_STK_ALLW_LAST_ENT_ID  |
|                                     |
| -- PRO_E_TURN_STK_ALLOWANCE_VAL     |

The following table lists the contents of `PRO_E_TURN_STK_ALLOWANCE` element.

| Element ID               | Data Type          | Description                                         |
|--------------------------|--------------------|-----------------------------------------------------|
| PRO_E_TURN_STK_ALLOWANCE | Compound           | Specifies the compound element for stock allowance. |
| PRO_E_TURN_STK_ALLW_     | PRO_VALUE_TYPE_INT | Specifies the ID of the first entity                |

---

| Element ID                          | Data Type             | Description                                                                           |
|-------------------------------------|-----------------------|---------------------------------------------------------------------------------------|
| FIRST_ENT_ID                        |                       | of the turn profile segment with stock allowance.                                     |
| PRO_E_TURN_STK_ALLW_<br>LAST_ENT_ID | PRO_VALUE_TYPE_INT    | Specifies the ID of the last entity of the turn profile segment with stock allowance. |
| PRO_E_TURN_STK_<br>ALLOWANCE_VAL    | PRO_VALUE_TYPE_DOUBLE | Specifies the value of the stock allowance.                                           |

---

## Tool Motion — Profile Turning

The element `PRO_E_TOOL_MTN` is a member of `PRO_E_TOOL_MTN_ARR` array and is documented in the header file `ProMfgElemToolMtnProfTurn.h`, and is as shown in the following figure:

### Element tree for `PRO_E_TOOL_MTN` element:

```
-- PRO_E_TOOL_MTN

| PRO_E_TOOL_MTN_TYPE               | PRO_VALUE_TYPE_INT       | Mandatory element. Species the Tool motion type. The valid value for this element is PRO_TM_TYPE_PROF_TURNING. The value for this element is defined by ProTmType.                                                                                                                                                                                                                                 |
| PRO_E_MFG_PARAM_ARR               | Array                    | Mandatory element. Specifies an array of manufacturing parameters. See the Creo NC online help for more information on manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file ProMfgElemParam.h. For more information, refer to the section <a href="#">pecifying the Stock Allowance on page 1719</a> for more information on the element tree. |
| PRO_E_TOOL_MTN_TURN_PROF          | Compound                 | This compound element specifies the turning profile definition.                                                                                                                                                                                                                                                                                                                                    |
| PRO_E_TOOL_MTN_TURN_PROF_REF      | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the turning profile reference.                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_TOOL_MTN_TURN_PROF_S_VAL    | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the start point offset. This element can range from negative to positive values. The valid range values for this element are from -MAX_DIM_VALUE to MAX_DIM_VALUE.                                                                                                                                                                                                     |
| PRO_E_TOOL_MTN_TURN_PROF_E_VAL    | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the end point offset. This element can range from negative to positive values. The valid range values for this element are from -MAX_DIM_VALUE to MAX_DIM_VALUE.                                                                                                                                                                                                       |
| PRO_E_TOOL_MTN_TURN_PROF_S_REF    | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the start point adjustment reference.                                                                                                                                                                                                                                                                                                                                  |
| PRO_E_TOOL_MTN_TURN_PROF_E_REF    | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the end point adjustment reference.                                                                                                                                                                                                                                                                                                                                    |
| PRO_E_TOOL_MTN_TURN_PROF_S_ORIENT | PRO_VALUE_TYPE_INT       | Specifies the orientation of the axis when coordinate system is selected as the start point adjustment. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_TM_TURN_CSYS_X</li> <li>PRO_TM_TURN_CSYS_Y</li> </ul>                                                                                                                                                    |

| Element ID                               | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                          |                    | <ul style="list-style-type: none"> <li>PRO_TM_TURN_CSYS_Z</li> </ul> <p> <b>Note</b></p> <p>This element is mandatory if coordinate system is selected for cylindrical retract reference and is ignored in all other cases.</p>                                                                                                                                                                                                     |
| PRO_E_TOOL_MTN_TURN_<br>PROF_E_ORIENT    | PRO_VALUE_TYPE_INT | <p>Specifies the orientation of the axis when coordinate system is selected as the ending point. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_TM_TURN_CSYS_X</li> <li>PRO_TM_TURN_CSYS_Y</li> <li>PRO_TM_TURN_CSYS_Z</li> </ul> <p> <b>Note</b></p> <p>This element is mandatory if coordinate system is selected for cylindrical retract reference and is ignored in all other cases.</p> |
| PRO_E_TOOL_MTN_TURN_<br>PROF_OFFSET_CUT  | PRO_VALUE_TYPE_INT | <p>Mandatory element. Specifies the offset from turn profile by the tool radius. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_B_TRUE</li> <li>PRO_B_FALSE</li> </ul>                                                                                                                                                                                                                                                                                                          |
| PRO_E_TOOL_MTN_TURN_<br>DFLT_CORNER_TYPE | PRO_VALUE_TYPE_INT | <p>Mandatory element. Specifies the corner type. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_TM_TURN_CORNER_TYPE_SHARP</li> <li>PRO_TM_TURN_CORNER_TYPE_FILLET</li> <li>PRO_TM_TURN_CORNER_TYPE_CHAMFER</li> </ul>                                                                                                                                                                                                                                                           |
| PRO_E_TOOL_MTN_TURN_<br>CORNER_ARR       | Array              | Optional element. Specifies the corner conditions array.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| PRO_E_TOOL_MTN_TURN_<br>CORNER           | Compound           | This compound element defines the elements related to the corner.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_TOOL_MTN_TURN_<br>CORNER_TYPE      | PRO_VALUE_TYPE_INT | <p>Mandatory element. Specifies the corner type. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_TM_TURN_CORNER_TYPE_SHARP</li> <li>PRO_TM_TURN_CORNER_TYPE_FILLET</li> <li>PRO_TM_TURN_CORNER_TYPE_CHAMFER</li> </ul>                                                                                                                                                                                                                                                           |

|---------------------------------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 |                       | TYPE_FILLET<br>• PRO_TM_TURN_CORNER_TYPE_CHAMFER                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_TOOL_MTN_TURN_PREV_ENT_ID | PRO_VALUE_TYPE_INT    | Mandatory element. Specifies the previous entity id.                                                                                                                                                                                                                                                                                                                                                                   |
| PRO_E_TOOL_MTN_TURN_NEXT_ENT_ID | PRO_VALUE_TYPE_INT    | Mandatory element. Specifies the next entity id.                                                                                                                                                                                                                                                                                                                                                                       |
| PRO_E_TOOL_MTN_TURN_CORNER_VAL  | PRO_VALUE_TYPE_DOUBLE | Specifies the fillet radius or chamfer dimension. This element can range from negative to positive values. The valid range values for this element are from -MAX_DIM_VALUE to MAX_DIM_VALUE<br><br> <b>Note</b><br><br>This element is mandatory if corner type is PRO_TM_TURN_CORNER_TYPE_FILLET or PRO_TM_TURN_CORNER_TYPE_CHAMFER. |
| PRO_E_TURN_STK_ALLW_PROF_ARR    | Array                 | Specifies an array for profile stock allowance.                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_TURN_STK_ALLW_ROUGH_ARR   | Array                 | Specifies an array for rough stock allowance.                                                                                                                                                                                                                                                                                                                                                                          |
| PRO_E_TURN_STK_ALLOWANCE        | Compound              | Specifies the compound element for stock allowance. For more information, refer to the section <a href="#">Specifying the Stock Allowance</a> on page 1719.                                                                                                                                                                                                                                                            |

## Tool Motion — Curve Trajectory

The compound element PRO\_E\_TOOL\_MTN is a member of PRO\_E\_TOOL\_MTN\_ARR array and is documented in the header file ProMfgElemToolMtnCrvTraj.h, and is shown in the following figure.

## Element tree for PRO\_E\_TOOL\_MTN element

The following table lists the contents of PRO\_E\_TOOL\_MTN element.

| Element ID                        | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN_TYPE               | PRO_VALUE_TYPE_INT       | Mandatory element. Species the tool motion type . The valid value for this element is PRO_TM_TYPE_CURVE_TRAJECTORY.                                                                                                                                                                                                                                                                    |
| PRO_E_MFG_PARAM_ARR               | Array                    | Mandatory element. Specifies an array of manufacturing parameters. See the Creo NC help for more information on manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file ProMfgElemParam.h. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree. |
| PRO_E_MFG_TRAJ_CRV                | Compound                 | Mandatory element. Specifies the machining curves compound definition.                                                                                                                                                                                                                                                                                                                 |
| PRO_E_STD_CURVE_COLLECTION_APPL   | Curve Collection         | Mandatory element. Specifies the curve collection.                                                                                                                                                                                                                                                                                                                                     |
| PRO_E_NCD_CURVE_POINT             | Compound                 | Optional element. Specifies the compound Start Point definition.<br><br> <b>Note</b><br><br>This element is applicable for closed loops only.                                                                                                                                                       |
| PRO_E_NCD_CURVE_POINT_REF         | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the start point vertex definition to offset from.                                                                                                                                                                                                                                                                                                          |
| PRO_E_NCD_CURVE_POINT_OFFSET_TYPE | PRO_VALUE_TYPE_INT       | Optional element. Specifies the start point offset type definition. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_CURVE_POINT_OFFSET_TYPE_RATIO—Specifies the offset by parameter.</li> <li>PRO_CURVE_POINT_OFFSET_TYPE_REAL—Specifies the offset by length.</li> </ul>                                                                            |
| PRO_E_NCD_CURVE_POINT_OFFSET      | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the start point offset definition.                                                                                                                                                                                                                                                                                                                         |
| PRO_E_MFG_HELICAL_CUT_OPT         | PRO_VALUE_TYPE_INT       | Optional element. Specifies the helical cut option. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE—Specifies that helical option and parameters will be applied.</li> </ul>                                                                                                                                                                  |

| Element ID                 | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            |                          | <ul style="list-style-type: none"> <li>PRO_B_FALSE—Specifies that helical option and parameters will not be applied.</li> </ul>                                                                                                                                                                                                                                                                    |
| PRO_E_MFG_START_HEIGHT     | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the selection of start height surface.                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_MFG_HEIGHT           | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the multiple selections of height surfaces.                                                                                                                                                                                                                                                                                                                            |
| PRO_E_MFG_OFFSET           | Compound                 | Optional element. Specifies the offset compound definition.                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_MFG_OFFSET_CUT       | PRO_VALUE_TYPE_INT       | <p>Optional element. Specifies the offset cut. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_B_TRUE—Tool offset will be applied.</li> <li>PRO_B_FALSE—Tool offset will not be applied.</li> </ul>                                                                                                                                                          |
| PRO_E_MFG_MAT_REM_PREC_OPT | PRO_VALUE_TYPE_STRING    | <p>Specifies the value of the precision tab present in stock. The values for this element are defined by the enumerated value ProMatRemPrecOpt. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_PREC_OPT_AUTO</li> <li>PRO_PREC_OPT_HIGH</li> <li>PRO_PREC_OPT_MEDIUM</li> <li>PRO_PREC_OPT_LOW</li> </ul>                                                   |
| PRO_E_MFG_MAT_TO_RMV       | PRO_VALUE_TYPE_INT       | <p>Optional element. Specifies the material side. The values for this element are defined by the enumerated value ProMaterialRmvSide in the header file ProMfgOptions.h. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_MAT_RMV_LEFT—Specifies a cut on left from the curve.</li> <li>PRO_MAT_RMV_RIGHT—Specifies a cut on right from the curve.</li> </ul> |
| PRO_E_MFG_DRV_SRF_DIR      | PRO_VALUE_TYPE_INT       | <p>Optional element. Specifies the flip drive surface direction. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_B_FALSE—The default direction on the drive surface will be used.</li> <li>PRO_B_TRUE—The opposite direction on the drive surface will be used.</li> </ul>                                                                                   |
| PRO_E_CHECK_SURF_COLL      | Compound                 | Specifies the check surfaces                                                                                                                                                                                                                                                                                                                                                                       |

| Element ID                      | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 |                    | compound definition. The element tree for the Checking Surfaces is defined in the header file <code>ProMfgElemCheckSurf.h</code> . For more information, refer to the section <a href="#">Checking Surfaces on page 1671</a> for more information on the element tree.                                                                                                                                        |
| PRO_E_MFG_AXIS_DEF_COMP         | Compound           | Optional element. Specifies the compound element for the axis definition.                                                                                                                                                                                                                                                                                                                                     |
| PRO_E_MFG_TRAJ_CORNER_COND      | Compound           | Optional element. Specifies the compound element for the corner condition.                                                                                                                                                                                                                                                                                                                                    |
| PRO_E_MFG_TRAJ_CORNER_DFLT_TYPE | PRO_VALUE_TYPE_INT | Specifies the default corner type. The valid values for this element are defined in the enumerated type <code>ProTmTrajCornerType</code> and are as follows: <ul style="list-style-type: none"> <li>PRO_TM_TRAJ_CORNER_TYPE_SHARP</li> <li>PRO_TM_TRAJ_CORNER_TYPE_FILLET</li> <li>PRO_TM_TRAJ_CORNER_TYPE_CHAMFER</li> <li>PRO_TM_TRAJ_CORNER_TYPE_LOOP</li> <li>PRO_TM_TRAJ_CORNER_TYPE_STRAIGHT</li> </ul> |
| PRO_E_MFG_TRAJ_CORNER_ARR       | Array              | Optional element. Specifies an array for the corner condition.                                                                                                                                                                                                                                                                                                                                                |
| PRO_E_MFG_TRAJ_CORNER           | Compound           | Optional element. Specifies the corner condition item.                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_MFG_TRAJ_CORNER_TYPE      | PRO_VALUE_TYPE_INT | Specifies the default corner type. The valid values for this element are defined in the enumerated type <code>ProTmTrajCornerType</code> and are as follows: <ul style="list-style-type: none"> <li>PRO_TM_TRAJ_CORNER_TYPE_SHARP</li> <li>PRO_TM_TRAJ_CORNER_TYPE_FILLET</li> <li>PRO_TM_TRAJ_CORNER_TYPE_CHAMFER</li> <li>PRO_TM_TRAJ_CORNER_TYPE_LOOP</li> <li>PRO_TM_TRAJ_CORNER_TYPE_STRAIGHT</li> </ul> |
| PRO_E_MFG_TRAJ_CORNER_PREV_ID   | PRO_VALUE_TYPE_INT | Mandatory element. Specifies the previous Id for the corner.                                                                                                                                                                                                                                                                                                                                                  |

| Element ID                    | Data Type             | Description                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_TRAJ_CORNER_NEXT_ID | PRO_VALUE_TYPE_INT    | Mandatory element. Specifies the next Id for the corner.                                                                                                                                                                                                                                                                                                          |
| PRO_E_MFG_TRAJ_CORNER_VAL     | PRO_VALUE_TYPE_DOUBLE | <p>Specifies the fillet radius or the chamfer dimension. The valid range for this element is from 0 to MAX_DIM_VALUE.</p> <p> <b>Note</b></p> <p>This element is mandatory if the corner type is set to PRO_TM_TRAJ_CORNER_TYPE_FILLET or PRO_TM_TRAJ_CORNER_TYPE_CHAMFER.</p> |

## Element Tree for PRO\_E\_MFG\_AXIS\_DEF\_COMP

The element tree for PRO\_E\_MFG\_AXIS\_DEF\_COMP is as shown in the figure below:

### Element tree for PRO\_E\_MFG\_AXIS\_DEF\_COMP element

The following table lists the contents of PRO\_E\_MFG\_AXIS\_DEF\_COMP element.

| Element ID                       | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_AXIS_DEF_COMP          | Compound                 | Optional element. Specifies the compound element for the axis definition.                                                                                                                                                                                                                                                                                                                      |
| PRO_E_MFG_AXIS_DEF_TYPE          | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the type of the axis definition. The valid values for this element are defined in the enumerated type ProAxisDefType and are as follows: <ul style="list-style-type: none"> <li>PRO_AXIS_DEF_TYPE_UNDEF</li> <li>PRO_AXIS_DEF_BY_PIVOT_REF</li> <li>PRO_AXIS_DEF_BY_LOCATIONS</li> <li>PRO_AXIS_DEF_BY_TWO_CONTOURS</li> <li>PRO_AXIS_DEF_BY_NORM_SURF</li> </ul> |
| PRO_E_MFG_AXIS_DEF_PIVOT_REF     | PRO_VALUE_TYPE_SELECTION | Specifies the selection of the single reference. You can select either a point or an axis. <p> <b>Note</b></p> <p>This element is mandatory, only if the element PRO_E_MFG_AXIS_DEF_TYPE is set to the value PRO_AXIS_DEF_BY_PIVOT_REF. This element is ignored in all other cases.</p>                   |
| PRO_E_MFG_AXIS_DEF_NORM_SRF_COMP | Compound                 | Specifies the normal surface                                                                                                                                                                                                                                                                                                                                                                   |

| Element ID                    | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               |                          | <p>compound element.</p> <p> <b>Note</b></p> <p>This element is mandatory, only if the element PRO_E_MFG_AXIS_DEF_TYPE is set to the value PRO_AXIS_DEF_BY_NORM_SURF. This element is ignored in all other cases.</p>                                                                                                                                                 |
| PRO_E_MFG_AXIS_DEF_NORM_SRF   | PRO_VALUE_TYPE_SELECTION | <p>Specifies the selection of multiple references. You can select surface, quilt or feature.</p> <p> <b>Note</b></p> <p>The quilt or feature must represent a Mill surface, if selected.</p> <p>This element is mandatory, only if the element PRO_E_MFG_AXIS_DEF_TYPE is set to the value PRO_AXIS_DEF_BY_NORM_SURF. This element is ignored in all other cases.</p> |
| PRO_E_MFG_AXDEF_NORM_SURF_DIR | PRO_VALUE_TYPE_INT       | <p>Specifies the normal surface direction. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_B_TRUE—Specifies that the direction opposite to the normal to the surface is selected for the element PRO_E_MFG_AXIS_DEF_NORM_SRF.</li> <li>PRO_B_FALSE—Specifies that same direction as the normal to the surface is selected for the element PRO_E_MFG_AXIS_DEF_NORM_SRF.</li> </ul>                                |

| Element ID                      | Data Type                | Description                                                                                                                                                                                                                                                                                                               |
|---------------------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 |                          | SRF.<br><br> <b>Note</b><br><br>This element is mandatory, only if the element PRO_E_MFG_AXIS_DEF_TYPE is set to the value PRO_AXIS_DEF_BY_NORM_SURF. This element is ignored in all other cases.                                      |
| PRO_E_MFG_AXIS_DEF_LOCATION_ARR | Array                    | Specifies an array of locations.<br><br> <b>Note</b><br><br>This element is mandatory, only if the element PRO_E_MFG_AXIS_DEF_TYPE is set to the value PRO_AXIS_DEF_BY_LOCATIONS. This element is ignored in all other cases.          |
| PRO_E_MFG_AXIS_DEF_LOCATION     | Compound                 | Mandatory element. Specifies the compound element for the location axis definition.                                                                                                                                                                                                                                       |
| PRO_E_MFG_AXIS_DEF_ORIGIN_REF   | PRO_VALUE_TYPE_SELECTION | Specifies the selection of the single reference. You can either select a point on a curve or an edge.                                                                                                                                                                                                                     |
| PRO_E_MFG_AXIS_DEF_ORIENT_COMP  | Compound                 | Mandatory element. Specifies the orientation compound element.                                                                                                                                                                                                                                                            |
| PRO_E_MFG_AXIS_DEF_ORIENT_REF   | PRO_VALUE_TYPE_SELECTION | Specifies the single reference selection. You can select either a point or an axis.<br><br> <b>Note</b><br><br>This element is mandatory, if the elements PRO_E_MFG_AXES_DEF_ANGLE_X and PRO_E_MFG_AXES_DEF_ANGLE_Y are not defined. |
| PRO_E_MFG_AXES_DEF_ANGLE_X      | PRO_VALUE_TYPE_DOUBLE    | Specifies the lead angle. The valid range for this element is from —90                                                                                                                                                                                                                                                    |

| Element ID                      | Data Type             | Description                                                                                                                                                                                                                                                                                                                       |
|---------------------------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 |                       | to +90.<br><br> <b>Note</b><br><br>This element is mandatory, if the element PRO_E_MFG_AXIS_DEF_ORIENT_REF is not defined.                                                                                                                       |
| PRO_E_MFG_AXES_DEF_ANGLE_Y      | PRO_VALUE_TYPE_DOUBLE | Specifies the tilt angle. The valid range for this element is from —90 to +90.<br><br> <b>Note</b><br><br>This element is mandatory, if the element PRO_E_MFG_AXIS_DEF_ORIENT_REF is not defined.                                                |
| PRO_E_MFG_AXIS_DEF_LOC_FLIP_OPT | PRO_VALUE_TYPE_INT    | Mandatory element. Specifies the flip direction at a location. The valid values for this element are: <ul style="list-style-type: none"> <li>• PRO_B_TRUE—Specifies that the direction will be reversed.</li> <li>• PRO_B_FALSE—Specifies that the direction will remain the same.</li> </ul>                                     |
| PRO_E_MFG_AXIS_DEF_LOC_ALIGN_Z  | PRO_VALUE_TYPE_INT    | Mandatory element. Specifies the alignment of the tool axis with the Z axis of the step coordinate system. Specify the value PRO_B_TRUE to this element.                                                                                                                                                                          |
| PRO_E_MFG_AXIS_DEF_CURVE_COMP   | Compound              | Specifies the compound element for the pivot curve.<br><br> <b>Note</b><br><br>This element is mandatory, if the element PRO_E_MFG_AXIS_DEF_TYPE is set to the value PRO_AXIS_DEF_BY_TWO_CONTOURS. This element is ignored in all other cases. |
| PRO_E_STD_CURVE_COLLECTION_APPL | Chain Collection      | Mandatory element. Specifies a general compound element for chain collection.                                                                                                                                                                                                                                                     |
| PRO_E_MFG_AXIS_DEF_             | Array                 | Optional element. Specifies the                                                                                                                                                                                                                                                                                                   |

| Element ID                       | Data Type                | Description                                                                                                                                                                                                                                                                                      |
|----------------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SYNC_ARR                         |                          | synchronization array.                                                                                                                                                                                                                                                                           |
| PRO_E_MFG_AXIS_DEF_SYNC_COMP     | Compound                 | Optional element. Specifies the synchronization compound element.                                                                                                                                                                                                                                |
| PRO_E_MFG_AXIS_DEF_SYNC_PNT_1    | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the single reference selection. Select a point on the trajectory curve.                                                                                                                                                                                             |
| PRO_E_MFG_AXIS_DEF_SYNC_PNT_2    | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the single reference selection. Select a point on the pivot curve.                                                                                                                                                                                                  |
| PRO_E_MFG_AXIS_DEF_SYNC_FLIP_OPT | PRO_VALUE_TYPE_INT       | Mandatory element. Specifies the flip direction. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE—Specifies that the tool motion is flipped in the reverse direction.</li> <li>PRO_B_FALSE—Specifies that the direction will remain the same.</li> </ul> |
| PRO_E_MFG_AXIS_DEF_FLIP_OPT      | PRO_VALUE_TYPE_INT       | Specifies the flip direction. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE—Specifies that the direction will be reversed.</li> <li>PRO_B_FALSE—Specifies that the direction will remain the same.</li> </ul>                                         |

## Tool Motion — Surface Trajectory

The compound element PRO\_E\_TOOL\_MTN is a member of PRO\_E\_TOOL\_MTN\_ARR array and is documented in the header file `ProMfgElemToolMtnSrfTraj.h`, and is shown in the following figure.

## Element tree for PRO\_E\_TOOL\_MTN element

The following table lists the contents of PRO\_E\_TOOL\_MTN element.

| Element ID                     | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN_TYPE            | PRO_VALUE_TYPE_INT       | Mandatory element. Species the tool motion type. The valid value for this element is PRO_TM_TYPE_SURF_TRAJECTORY.                                                                                                                                                                                                                                                                                             |
| PRO_E_MFG_PARAM_ARR            | Array                    | Mandatory element. Specifies an array of manufacturing parameters. See the Creo NC help for more information on manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file ProMfgElemParam.h. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree.                        |
| PRO_E_MFG_TRAJ_SRFS            | Compound                 | Specifies the drive surfaces compound definition.                                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_STD_SURF_COLLECTION_APPL | Surface Collection       | Mandatory element. Specifies the drive surfaces collection.                                                                                                                                                                                                                                                                                                                                                   |
| PRO_E_MFG_CUT_START_PNT_REF    | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the selection of a datum point or a point on the bottom edges of the machining surfaces. It allows the machining to start at the location which is nearest to the selected point.<br><br> <b>Note</b><br><br>This element is applicable only when the machining surfaces form a closed loop. |
| PRO_E_MFG_HELICAL_CUT_OPT      | PRO_VALUE_TYPE_INT       | Optional element. Specifies the helical cut option. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE—Specifies that helical option and parameters will be applied.</li> <li>PRO_B_FALSE—Specifies that helical option and parameters will not be applied.</li> </ul>                                                                                                  |
| PRO_E_MFG_START_HEIGHT         | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the selection of start height surface.                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_MFG_HEIGHT               | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the multiple selections of height surfaces.                                                                                                                                                                                                                                                                                                                                      |
| PRO_E_MFG_OFFSET               | Compound                 | Optional element. Specifies the offset compound definition.                                                                                                                                                                                                                                                                                                                                                   |
| PRO_E_MFG_OFFSET_CUT           | PRO_VALUE_TYPE_INT       | Optional element. Specifies the                                                                                                                                                                                                                                                                                                                                                                               |

| Element ID              | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         |                    | offset cut. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE—Tool offset will be applied.</li> <li>PRO_B_FALSE—Tool offset will not be applied.</li> </ul>                                                                                                                                                                                                 |
| PRO_E_MFG_MAT_TO_RMV    | PRO_VALUE_TYPE_INT | Optional element. Specifies the material side. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_MFG_DIR_SAME—Default side will be used.</li> <li>PRO_MFG_DIR_OPPOSITE—The default side will be flipped.</li> </ul>                                                                                                                                                |
| PRO_E_MFG_DRV_SRF_DIR   | PRO_VALUE_TYPE_INT | Optional element. Specifies the flip drive Surface direction. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_FALSE—The default direction on the drive surface will be used.</li> <li>PRO_B_TRUE—The opposite direction on the drive surface will be used.</li> </ul>                                                                                          |
| PRO_E_CHECK_SURF_COLL   | Compound           | Optional element. Specifies the check surfaces compound definition. The element tree for the Checking Surfaces is defined in the header file <code>ProMfgElemCheckSurf.h</code> . For more information, refer to the section <a href="#">Checking Surfaces on page 1671</a> for more information on the element tree.                                                                              |
| PRO_E_MFG_AXIS_DEF_COMP | Compound           | Optional element. Specifies the compound element for the axis definition.                                                                                                                                                                                                                                                                                                                          |
| PRO_E_MFG_AXIS_DEF_TYPE | PRO_VALUE_TYPE_INT | Mandatory element. Specifies the type of the axis definition. The valid values for this element are defined in the enumerated type <code>ProAxisDefType</code> and are as follows: <ul style="list-style-type: none"> <li>PRO_AXIS_DEF_TYPE_UNDEF</li> <li>PRO_AXIS_DEF_BY_PIVOT_REF</li> <li>PRO_AXIS_DEF_BY_LOCATIONS</li> <li>PRO_AXIS_DEF_BY_TWO_CONTOURS</li> <li>PRO_AXIS_DEF_BY_</li> </ul> |

| Element ID                      | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 |                          | NORM_SURF                                                                                                                                                                                                                                                                                                                                                                         |
| PRO_E_MFG_AXIS_DEF_PIVOT_REF    | PRO_VALUE_TYPE_SELECTION | <p>Specifies the selection of the single reference. You can select either a point or an axis.</p> <p> <b>Note</b></p> <p>This element is mandatory, only if the element PRO_E_MFG_AXIS_DEF_TYPE is set to the value PRO_AXIS_DEF_BY_PIVOT_REF. This element is ignored in all other cases.</p> |
| PRO_E_MFG_AXIS_DEF_NORM_SRF     | Compound                 | <p>Specifies the normal surface compound element.</p> <p> <b>Note</b></p> <p>This element is mandatory, only if the element PRO_E_MFG_AXIS_DEF_TYPE is set to the value PRO_AXIS_DEF_BY_NORM_SURF. This element is ignored in all other cases.</p>                                             |
| PRO_E_MFG_AXIS_DEF_LOCATION_ARR | Array                    | <p>Specifies an array of locations.</p> <p> <b>Note</b></p> <p>This element is mandatory, only if the element PRO_E_MFG_AXIS_DEF_TYPE is set to the value PRO_AXIS_DEF_BY_LOCATIONS. This element is ignored in all other cases.</p>                                                         |
| PRO_E_MFG_AXIS_DEF_LOCATION     | Compound                 | Mandatory element. Specifies the compound element for the location axis definition.                                                                                                                                                                                                                                                                                               |
| PRO_E_MFG_AXIS_DEF_ORIGIN_REF   | PRO_VALUE_TYPE_SELECTION | Specifies the selection of the single reference. You can either select a point on a curve or an edge.                                                                                                                                                                                                                                                                             |
| PRO_E_MFG_AXIS_DEF_ORIENT_COMP  | Compound                 | Mandatory element. Specifies the orientation compound element.                                                                                                                                                                                                                                                                                                                    |
| PRO_E_MFG_AXIS_DEF_ORIENT_REF   | PRO_VALUE_TYPE_SELECTION | Specifies the single reference selection. You can select either a                                                                                                                                                                                                                                                                                                                 |

| Element ID                      | Data Type             | Description                                                                                                                                                                                                                                                                                                                              |
|---------------------------------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 |                       | <p>point or an axis.</p> <p> <b>Note</b></p> <p>This element is mandatory, if the elements PRO_E_MFG_AXES_DEF_ANGLE_X and PRO_E_MFG_AXES_DEF_ANGLE_Y are not defined.</p>                                                                               |
| PRO_E_MFG_AXES_DEF_ANGLE_X      | PRO_VALUE_TYPE_DOUBLE | <p>Specifies the lead angle. The valid range for this element is from — 90 to +90.</p> <p> <b>Note</b></p> <p>This element is mandatory, if the element PRO_E_MFG_AXIS_DEF_ORIENT_REF is not defined.</p>                                               |
| PRO_E_MFG_AXES_DEF_ANGLE_Y      | PRO_VALUE_TYPE_DOUBLE | <p>Specifies the tilt angle. The valid range for this element is from — 90 to +90.</p> <p> <b>Note</b></p> <p>This element is mandatory, if the element PRO_E_MFG_AXIS_DEF_ORIENT_REF is not defined.</p>                                             |
| PRO_E_MFG_AXIS_DEF_LOC_FLIP_OPT | PRO_VALUE_TYPE_INT    | <p>Mandatory element. Specifies the flip direction at a location. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>• PRO_B_TRUE—Specifies that the direction will be reversed.</li> <li>• PRO_B_FALSE—Specifies that the direction will remain the same.</li> </ul>                                     |
| PRO_E_MFG_AXIS_DEF_CURVE_COMP   | Compound              | <p>Specifies the compound element for the pivot curve.</p> <p> <b>Note</b></p> <p>This element is mandatory, if the element PRO_E_MFG_AXIS_DEF_TYPE is set to the value PRO_AXIS_DEF_BY_TWO_CONTOURS. This element is ignored in all other cases.</p> |

| Element ID                      | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_STD_CURVE_COLLECTION_APPL | Chain Collection         | Mandatory element. Specifies a general compound element for chain collection.                                                                                                                                                                                                                                                                                                                                 |
| PRO_E_MFG_AXIS_DEF_SYNC_ARR     | Array                    | Optional element. Specifies the synchronization array.                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_MFG_AXIS_DEF_SYNC_COMP    | Compound                 | Optional element. Specifies the synchronization compound element.                                                                                                                                                                                                                                                                                                                                             |
| PRO_E_MFG_AXIS_DEF_SYNC_PNT_1   | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the single reference selection. Select a point on the trajectory curve.                                                                                                                                                                                                                                                                                                          |
| PRO_E_MFG_AXIS_DEF_SYNC_PNT_2   | PRO_VALUE_TYPE_SELECTION | Mandatory element. Specifies the single reference selection. Select a point on the pivot curve.                                                                                                                                                                                                                                                                                                               |
| PRO_E_MFG_AXIS_DEF_FLIP_OPT     | PRO_VALUE_TYPE_INT       | Specifies the flip direction. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE—Specifies that the direction will be reversed.</li> <li>PRO_B_FALSE—Specifies that the direction will remain the same.</li> </ul>                                                                                                                                                      |
| PRO_E_MFG_TRAJ_CORNER_COND      | Compound                 | Optional element. Specifies the compound element for the corner condition.                                                                                                                                                                                                                                                                                                                                    |
| PRO_E_MFG_TRAJ_CORNER_DFLT_TYPE | PRO_VALUE_TYPE_INT       | Specifies the default corner type. The valid values for this element are defined in the enumerated type <code>ProTmTrajCornerType</code> and are as follows: <ul style="list-style-type: none"> <li>PRO_TM_TRAJ_CORNER_TYPE_SHARP</li> <li>PRO_TM_TRAJ_CORNER_TYPE_FILLET</li> <li>PRO_TM_TRAJ_CORNER_TYPE_CHAMFER</li> <li>PRO_TM_TRAJ_CORNER_TYPE_LOOP</li> <li>PRO_TM_TRAJ_CORNER_TYPE_STRAIGHT</li> </ul> |
| PRO_E_MFG_TRAJ_CORNER_ARR       | Array                    | Optional element. Specifies an array for the corner condition.                                                                                                                                                                                                                                                                                                                                                |
| PRO_E_MFG_TRAJ_CORNER           | Compound                 | Optional element. Specifies the corner condition item.                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_MFG_TRAJ_CORNER_TYPE      | PRO_VALUE_TYPE_INT       | Specifies the default corner type. The valid values for this element are defined in the enumerated type <code>ProTmTrajCornerType</code> and are as follows: <ul style="list-style-type: none"> <li>PRO_TM_TRAJ_CORNER_TYPE_SHARP</li> </ul>                                                                                                                                                                  |

| Element ID                    | Data Type             | Description                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               |                       | <ul style="list-style-type: none"> <li>PRO_TM_TRAJ_CORNER_TYPE_FILLET</li> <li>PRO_TM_TRAJ_CORNER_TYPE_CHAMFER</li> <li>PRO_TM_TRAJ_CORNER_TYPE_LOOP</li> <li>PRO_TM_TRAJ_CORNER_TYPE_STRAIGHT</li> </ul>                                                                                                                                                       |
| PRO_E_MFG_TRAJ_CORNER_PREV_ID | PRO_VALUE_TYPE_INT    | Mandatory element. Specifies the previous Id for the corner.                                                                                                                                                                                                                                                                                                    |
| PRO_E_MFG_TRAJ_CORNER_NEXT_ID | PRO_VALUE_TYPE_INT    | Mandatory element. Specifies the next Id for the corner.                                                                                                                                                                                                                                                                                                        |
| PRO_E_MFG_TRAJ_CORNER_VAL     | PRO_VALUE_TYPE_DOUBLE | <p>Specifies the fillet radius or the chamfer dimension. The valid range for this element is from 0 to MAX_DIM_VALUE.</p> <p> <b>Note</b></p> <p>This element is mandatory if the corner type is set to PRO_TM_TRAJ_CORNER_TYPE_FILLET or PRO_TM_TRAJ_CORNER_TYPE_CHAMFER.</p> |

## Tool Motion — Ramp Approach

The compound element PRO\_E\_TOOL\_MTN is a member of PRO\_E\_TOOL\_MTN\_ARR array and is documented in the header file ProMfgElemToolMtnRampAppr.h, and is shown in the following figure.

## Element tree for PRO\_E\_TOOL\_MTN element

```
-- PRO_E_TOOL_MTN
|
|-- PRO_E_TOOL_MTN_REF_ID
|
|-- PRO_E_TOOL_MTN_TYPE
|
|-- PRO_E_TOOL_MTN_FEED_TYPE
|
|-- PRO_E_MFG_PARAM_ARR
|
|-- PRO_E_MFG_APPR_EXIT_DIR
```

The following table lists the contents of PRO\_E\_TOOL\_MTN element.

| Element ID               | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN_TYPE      | PRO_VALUE_TYPE_INT | Mandatory element. Species the tool motion type. The valid value for this element is PRO_TM_TYPE_RAMP_APPROACH.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_TOOL_MTN_FEED_TYPE | PRO_VALUE_TYPE_INT | Optional element. Specifies the type of feed for the tool motion using the enumerated data type ProToolMtnFeedType. The valid value for this element are: <ul style="list-style-type: none"> <li>PRO_TM_FEED_FREE—Specifies a free feed type. Free feed specifies the rate at which the tool moves in the transverse motion, that is, the non-cutting motion.</li> <li>PRO_TM_FEED_CUT—Specifies a cut feed type. Cut feed specifies the rate at which the tool moves into the workpiece.</li> <li>PRO_TM_FEED_PLUNGE—Specifies a plunge feed type. Plunge feed specifies the rate at which the tool approaches and plunges into the workpiece.</li> <li>PRO_TM_FEED_APPROACH—Specifies an approach feed type. Approach feed specifies the rate at which the tool approaches the workpiece.</li> </ul> |

| Element ID              | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_PARAM_ARR     | Array              | <p>Mandatory element. Specifies an array of manufacturing parameters. Elements that define the ramp exit motion are:</p> <ul style="list-style-type: none"> <li>EXIT_DIST</li> <li>EXIT_ANGLE</li> <li>RAMP_ANGLE</li> </ul> <p>See the Creo NC help for more information on manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file <code>ProMfgElemParam.h</code>. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree.</p> |
| PRO_E_MFG_APPR_EXIT_DIR | PRO_VALUE_TYPE_INT | <p>Mandatory element. Specifies the direction for the ramp approach type of tool exit. The direction is defined by the enumerated data type <code>ProTmSideDir</code> in <code>ProMfgOptions.h</code>. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>PRO_TM_DIR_RIGHT_SIDE</li> <li>PRO_TM_DIR_LEFT_SIDE</li> </ul>                                                                                                                                                                                                              |

## Tool Motion — Ramp Exit

The compound element `PRO_E_TOOL_MTN` is a member of `PRO_E_TOOL_MTN_ARR` array and is documented in the header file `ProMfgElemToolMtnRampExit.h`, and is shown in the following figure.

## Element tree for PRO\_E\_TOOL\_MTN element

```
-- PRO_E_TOOL_MTN
|
|-- PRO_E_TOOL_MTN_REF_ID
|
|-- PRO_E_TOOL_MTN_TYPE
|
|-- PRO_E_TOOL_MTN_FEED_TYPE
|
|-- PRO_E_MFG_PARAM_ARR
|
|-- PRO_E_MFG_APPR_EXIT_DIR
```

The following table lists the contents of PRO\_E\_TOOL\_MTN element.

| Element ID               | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

The valid value for this element is PRO_TM_TYPE_PROFILE_MILL_CUT.                                                                                                                                                                                                                                                                     |
| PRO_E_TOOL_MTN_PROFILE_TYPE | PRO_VALUE_TYPE_INT | Specifies the type of the tool motion profile. The values for this element are defined by Pro_MillProfCutType.                                                                                                                                                                                                                                                                         |
| PRO_E_MFG_PARAM_ARR         | Array              | Mandatory element. Specifies an array of manufacturing parameters. See the Creo NC help for more information on manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file ProMfgElemParam.h. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree. |
| PRO_E_MFG_CMP_APPROACH_EXIT | Compound           | Optional element. Specifies approach and exit compound definition. For more information, refer to the section <a href="#">Approach and Exit on page 1673</a> for more information on the element tree.                                                                                                                                                                                 |

| Element ID             | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MFG_START_HEIGHT | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the starting height and selection of a horizontal surface.<br><br> <b>Note</b><br><br>This element is mandatory if the element PRO_E_TOOL_MTN_PROFILE_TYPE is set to PRO_E_MILL_CUT_FROM_TO. This element is ignored otherwise.                                         |
| PRO_E_MFG_HEIGHT       | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the height and enables single surface selection.<br><br> <b>Note</b><br><br>This element is mandatory if the element PRO_E_TOOL_MTN_PROFILE_TYPE is set to PRO_E_MILL_CUT_FROM_TO, PRO_E_MILL_CUT_UPTO and PRO_E_MILL_CUT_ONE_SLICE. This element is ignored otherwise. |

## Tool Motion — Auto Cut

The compound element PRO\_E\_TOOL\_MTN is a member of PRO\_E\_TOOL\_MTN\_ARR array and is documented in the header file ProMfgElemToolMtnAutoCut.h, and is shown in the following figure.

### Element tree for PRO\_E\_TOOL\_MTN element

|                          |
|--------------------------|
| -- PRO_E_TOOL_MTN        |
|                          |
| -- PRO_E_TOOL_MTN_REF_ID |
|                          |
| -- PRO_E_TOOL_MTN_TYPE   |
|                          |
| -- PRO_E_MFG_PARAM_ARR   |

The following table lists the contents of PRO\_E\_TOOL\_MTN element.

| Element ID          | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN_TYPE | PRO_VALUE_TYPE_INT | Mandatory element. Species the tool motion type. The valid value for this element is PRO_TM_TYPE_AUTOMATIC_CUT.                                                                                                                                                                                                                                                                        |
| PRO_E_MFG_PARAM_ARR | Array              | Mandatory element. Specifies an array of manufacturing parameters. See the Creo NC help for more information on manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file ProMfgElemParam.h. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree. |

## Tool Motion — CL Command

The compound element PRO\_E\_TOOL\_MTN is a member of PRO\_E\_TOOL\_MTN\_ARR array and is documented in the header file ProMfgElemToolMtnClCmd.h, and is shown in the following figure.

### Element tree for PRO\_E\_TOOL\_MTN element

```

-- PRO_E_TOOL_MTN
|
|-- PRO_E_TOOL_MTN_REF_ID
|
|-- PRO_E_TOOL_MTN_TYPE
|
|-- PRO_E_TOOL_MTN_CL_CMD
| |
| |-- PRO_E_TOOL_MTN_CL_CMD_LOC_TYPE
| |
| |-- PRO_E_TOOL_MTN_CL_CMD_STR
| |
| |-- PRO_E_TOOL_MTN_CL_CMD_PARAM
| |
| |-- PRO_E_TOOL_MTN_CL_CMD_GEOM_REF
| |
| |-- PRO_E_TOOL_MTN_CL_CMD_SRF_OPT
| |
| |-- PRO_E_TOOL_MTN_CL_CMD_ON_EXIST_PNT
|
|-- PRO_E_TOOL_MTN_PARENT_REF_ID

```

The following table lists the contents of PRO\_E\_TOOL\_MTN element.

| Element ID                     | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN_TYPE            | PRO_VALUE_TYPE_INT | Mandatory element. Species the tool motion type. The valid value for this element is PRO_TM_TYPE_CL_COMMAND.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PRO_E_TOOL_MTN_CL_CMD          | Compound           | This compound element defines elements related to CL command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| PRO_E_TOOL_MTN_PARENT_REF_ID       | PRO_VALUE_TYPE_INT | <p>Specifies the tool motion id of the tool motion referred by the cl command tool motion.</p> <p> <b>Note</b></p> <p>This element is mandatory for PRO_CL_CMD_LOC_TYPE_SEL.</p>                                                                                                                                                  |

## Tool Motion — Follow Cut

The compound element PRO\_E\_TOOL\_MTN is a member of PRO\_E\_TOOL\_MTN\_ARR array and is documented in the header file ProMfgElemToolMtnFollowCut.h. The Follow Cut tool Motion follows the following types of tool motions in an array:

- PRO\_TM\_TYPE\_CURVE\_TRAJECTORY
- PRO\_TM\_TYPE\_AREA\_TURNING
- PRO\_TM\_TYPE\_GROOVE\_TURNING
- PRO\_TM\_TYPE\_PROF\_TURNING
- PRO\_TM\_TYPE\_SURF\_TRAJECTORY
- PRO\_TM\_TYPE\_EDGE\_TRAJECTORY

## Element tree for PRO\_E\_TOOL\_MTN element

```

|
|-- PRO_E_TOOL_MTN_REF_ID
|
|-- PRO_E_TOOL_MTN_TYPE
|
|-- PRO_E_MFG_PARAM_ARR
|
|-- PRO_E_TOOL_MTN_PARENT_REF_ID
|
|-- PRO_E_TOOL_MTN_TRIM_VAL_OPT
|
|-- PRO_E_TOOL_MTN_TRIM_START_VAL
|
|-- PRO_E_TOOL_MTN_TRIM_END_VAL
|
|-- PRO_E_TOOL_MTN_TRIM_FLIP_DIR
```

The following table lists the contents of PRO\_E\_TOOL\_MTN element.

| Element ID                  | Data Type          | Description                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN_TYPE         | PRO_VALUE_TYPE_INT | Mandatory element. Specifies the tool motion type. The valid value for this element is PRO_TM_TYPE_TRIM. The value for this element is defined by ProTmType.                                                                                                                                                                                                        |
| PRO_E_MFG_PARAM_ARR         | Array              | Specifies an array of manufacturing parameters. See the Creo NC help for more information on manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file ProMfgElemParam.h. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree. |
| PRO_E_TOOL_MTN_TRIM_VAL_OPT | PRO_VALUE_TYPE_INT | Mandatory element. Specifies the value options. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_TM_TRIM_VAL_PARAM—The input value is a ratio parameter.</li> <li>PRO_TM_TRIM_VAL_</li> </ul>                                                                                                                                      |

| Element ID                    | Data Type             | Description                                                                                                                                                                                                                                                                                                                             |
|-------------------------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               |                       | DIST—The input value is a distance.                                                                                                                                                                                                                                                                                                     |
| PRO_E_TOOL_MTN_TRIM_START_VAL | PRO_VALUE_TYPE_DOUBLE | Mandatory element. Specifies the start parameter on tool path. The range specifies by this element is from [0., 1.].                                                                                                                                                                                                                    |
| PRO_E_TOOL_MTN_TRIM_END_VAL   | PRO_VALUE_TYPE_DOUBLE | Mandatory element. Specifies the end parameter on tool path. The range specifies by this element is from [0., 1.].<br><br> <b>Note</b><br><br>The value for the element PRO_E_TOOL_MTN_TRIM_END_VAL must be greater than PRO_E_TOOL_MTN_TRIM_START_VAL |
| PRO_E_TOOL_MTN_TRIM_FLIP_DIR  | PRO_VALUE_TYPE_INT    | Mandatory element. Specifies the direction of the tool motion. The valid values for this element are: <ul style="list-style-type: none"> <li>PRO_B_TRUE—Specifies reversed direction.</li> <li>PRO_B_FALSE—Specifies same direction.</li> </ul>                                                                                         |

## Tool Motion — Plunge

The element PRO\_E\_TOOL\_MTN is a member of PRO\_E\_TOOL\_MTN\_ARR array and is documented in the header file ProMfgElemToolMtnPlunge.h, and is as shown in the following figure:

```

-- PRO_E_TOOL_MTN
|
| -- PRO_E_TOOL_MTN_REF_ID
|
| -- PRO_E_TOOL_MTN_TYPE
|
| -- PRO_E_TOOL_MTN_FEED_TYPE
|
| -- PRO_E_MFG_PARAM_ARR
|
| -- PRO_E_TOOL_MTN_OFFSET
| |
| | -- PRO_E_TOOL_MTN_X_OFFSET
| |
| | -- PRO_E_TOOL_MTN_Y_OFFSET
| |
| | -- PRO_E_TOOL_MTN_Z_OFFSET
|
| -- PRO_E_TOOL_MTN_AXIS_REF

```

The following table describes the elements in the element tree for the approach along tool axis feature.

|                          |                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_TOOL_MTN_TYPE      | PRO_VALUE_TYPE_INT | Mandatory element. Species the tool motion type . The valid value for this element is <a href="#">Tool Motion — Plunge on page 1756</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| PRO_E_TOOL_MTN_FEED_TYPE | PRO_VALUE_TYPE_INT | Optional element. Specifies the type of feed for the tool motion using the enumerated data type <code>ProToolMtnFeedType</code> . The valid value for this element are: <ul style="list-style-type: none"> <li>• <code>PRO_TM_FEED_FREE</code>— Specifies a free feed type. Free feed specifies the rate at which the tool moves in the transverse motion, that is, the non-cutting motion.</li> <li>• <code>PRO_TM_FEED_CUT</code>— Specifies a cut feed type. Cut feed specifies the rate at which the tool moves into the workpiece.</li> <li>• <code>PRO_TM_FEED_PLUNGE</code>— Specifies a plunge feed type. Plunge feed specifies the rate</li> </ul> |

|                         |                          |                                                                                                                                                                                                                                                                                                                               |
|-------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         |                          | at which the tool approaches and plunges into the workpiece.                                                                                                                                                                                                                                                                  |
| PRO_E_MFG_PARAM_ARR     | Array                    | Mandatory element. Specifies an array of manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file <code>ProMfgElemParam.h</code> . For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree. |
| PRO_E_TOOL_MTN_OFFSET   | Compound                 | Optional element. This compound element specifies the offset value.                                                                                                                                                                                                                                                           |
| PRO_E_TOOL_MTN_X_OFFSET | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the offset along X-axis. This element can range from negative to positive values. The valid range values for this element are from <code>-MAX_DIM_VALUE</code> to <code>MAX_DIM_VALUE</code> .                                                                                                    |
| PRO_E_TOOL_MTN_Y_OFFSET | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the offset along Y-axis. This element can range from negative to positive values. The valid range values for this element are from <code>-MAX_DIM_VALUE</code> to <code>MAX_DIM_VALUE</code> .                                                                                                    |
| PRO_E_TOOL_MTN_Z_OFFSET | PRO_VALUE_TYPE_DOUBLE    | Optional element. Specifies the offset along Z-axis. This element can range from negative to positive values. The valid range values for this element are from <code>-MAX_DIM_VALUE</code> to <code>MAX_DIM_VALUE</code> .                                                                                                    |
| PRO_E_TOOL_MTN_AXIS_REF | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the axis selection.<br><br> <b>Note</b><br>By default Z-axis of the Creo NC sequence is used to define the constraint plane.                                                                                   |

## Tool Motion — Chamfer Milling

The element `PRO_E_TOOL_MTN` is a member of `PRO_E_TOOL_MTN_ARR` array and is documented in the header file `ProMfgElemToolMtnChamferMill.h`, and is shown in the following figure.

### Element tree for `PRO_E_TOOL_MTN` element

```
-- PRO_E_TOOL_MTN
|
| -- PRO_E_TOOL_MTN_REF_ID
|
| -- PRO_E_TOOL_MTN_TYPE
|
| -- PRO_E_MFG_PARAM_ARR
```

The following table lists the contents of `PRO_E_TOOL_MTN` element.

| Element ID                       | Data Type                       | Description                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>PRO_E_TOOL_MTN_TYPE</code> | <code>PRO_VALUE_TYPE_INT</code> | Mandatory element. Specifies the tool motion type . The valid value for this element is <code>PRO_TM_TYPE_CHAMFER_MILLING</code> . The value for this element is defined by <code>ProTmType</code> .                                                                                                                                                                                                 |
| <code>PRO_E_MFG_PARAM_ARR</code> | Array                           | Mandatory element. Specifies an array of manufacturing parameters. See the Creo NC help for more information on manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file <code>ProMfgElemParam.h</code> . For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree. |

## Tool Motion — Cutline Milling

The element `PRO_E_TOOL_MTN` is a member of `PRO_E_TOOL_MTN_ARR` array and is documented in the header file `ProMfgElemToolMtnCutlineMill.h`, and is shown in the following figure.

### Element tree for `PRO_E_TOOL_MTN` element

The following table lists the contents of `PRO_E_TOOL_MTN` element.

| Element ID                       | Data Type                       | Description                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>PRO_E_TOOL_MTN_TYPE</code> | <code>PRO_VALUE_TYPE_INT</code> | Mandatory element. Specifies the tool motion type . The valid value for this element is <code>PRO_TM_TYPE_CUTLINE_MILLING</code> . The value for this element is defined by <code>ProTmType</code> .                                                                                                                                                                                                 |
| <code>PRO_E_MFG_PARAM_ARR</code> | Array                           | Mandatory element. Specifies an array of manufacturing parameters. See the Creo NC help for more information on manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file <code>ProMfgElemParam.h</code> . For more information, refer to the <a href="#">section Manufacturing Parameters on page 1661</a> for more information on the element tree. |

## Tool Motion — Face Milling

The element `PRO_E_TOOL_MTN` is a member of `PRO_E_TOOL_MTN_ARR` array and is documented in the header file `ProMfgElemToolMtnFaceMill.h`, and is shown in the following figure.

### Element tree for `PRO_E_TOOL_MTN` element

```
-- PRO_E_TOOL_MTN
|
|-- PRO_E_TOOL_MTN_REF_ID
|
|-- PRO_E_TOOL_MTN_TYPE
|
|-- PRO_E_MFG_PARAM_ARR
|
|-- PRO_E_MFG_CMP_APPROACH_EXIT
```

The following table lists the contents of `PRO_E_TOOL_MTN` element.

| Element ID                               | Data Type                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>PRO_E_TOOL_MTN_TYPE</code>         | <code>PRO_VALUE_TYPE_INT</code> | Mandatory element. Specifies the tool motion type . The valid value for this element is <code>PRO_TM_TYPE_FACE_MILLING</code> . The value for this element is defined by <code>ProTmType</code> .                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>PRO_E_MFG_PARAM_ARR</code>         | Array                           | Optional element. Specifies an array of manufacturing parameters. See the Creo NC help for more information on manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file <code>ProMfgElemParam.h</code> . For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree.<br><br> <b>Note</b><br><br>This element is inherited from Creo NC Sequence if not specified. |
| <code>PRO_E_MFG_CMP_APPROACH_EXIT</code> | Compound                        | Optional element. Specifies the approach and exit compound definition. For more information, refer to the section <a href="#">Approach and Exit on page 1673</a> .                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Tool Motion — Groove Milling

The element `PRO_E_TOOL_MTN` is a member of `PRO_E_TOOL_MTN_ARR` array and is documented in the header file `ProMfgElemToolMtnGrooveMill.h`, and is shown in the following figure.

### Element tree for `PRO_E_TOOL_MTN` element

The following table lists the contents of `PRO_E_TOOL_MTN` element.

| Element ID                       | Data Type                       | Description                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>PRO_E_TOOL_MTN_TYPE</code> | <code>PRO_VALUE_TYPE_INT</code> | Mandatory element. Specifies the tool motion type . The valid value for this element is <code>PRO_TM_TYPE_GROOVE_MILLING</code> . The value for this element is defined by <code>ProTmType</code> .                                                                                                                                                                                                  |
| <code>PRO_E_MFG_PARAM_ARR</code> | Array                           | Mandatory element. Specifies an array of manufacturing parameters. See the Creo NC help for more information on manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file <code>ProMfgElemParam.h</code> . For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree. |

---

## Tool Motion — Round Milling

The element `PRO_E_TOOL_MTN` is a member of `PRO_E_TOOL_MTN_ARR` array and is documented in the header file `ProMfgElemToolMtnRoundMill.h`, and is shown in the following figure.

### Element tree for `PRO_E_TOOL_MTN` element

```
-- PRO_E_TOOL_MTN
|
|-- PRO_E_TOOL_MTN_REF_ID
|
|-- PRO_E_TOOL_MTN_TYPE
|
|-- PRO_E_MFG_PARAM_ARR
```

The following table lists the contents of `PRO_E_TOOL_MTN` element.

| Element ID                       | Data Type                       | Description                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>PRO_E_TOOL_MTN_TYPE</code> | <code>PRO_VALUE_TYPE_INT</code> | Mandatory element. Specifies the tool motion type . The valid value for this element is <code>PRO_TM_TYPE_ROUND_MILLING</code> . The value for this element is defined by <code>ProTmType</code> .                                                                                                                                                                                                   |
| <code>PRO_E_MFG_PARAM_ARR</code> | Array                           | Mandatory element. Specifies an array of manufacturing parameters. See the Creo NC help for more information on manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file <code>ProMfgElemParam.h</code> . For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree. |

## Tool Motion — Thread Milling

The element `PRO_E_TOOL_MTN` is a member of `PRO_E_TOOL_MTN_ARR` array and is documented in the header file `ProMfgElemToolMtnThreadMill.h`, and is shown in the following figure.

### Element tree for `PRO_E_TOOL_MTN` element

The following table lists the contents of `PRO_E_TOOL_MTN` element.

| Element ID                       | Data Type                       | Description                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>PRO_E_TOOL_MTN_TYPE</code> | <code>PRO_VALUE_TYPE_INT</code> | Mandatory element. Specifies the tool motion type . The valid value for this element is <code>PRO_TM_TYPE_THREAD_MILLING</code> . The value for this element is defined by <code>ProTmType</code> .                                                                                                                                                                                                  |
| <code>PRO_E_MFG_PARAM_ARR</code> | Array                           | Mandatory element. Specifies an array of manufacturing parameters. See the Creo NC help for more information on manufacturing parameters. The element tree for the manufacturing parameter is defined in the header file <code>ProMfgElemParam.h</code> . For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> for more information on the element tree. |

## Tool Motion — Volume Mill Cut

The element `PRO_E_TOOL_MTN` is a member of `PRO_E_TOOL_MTN_ARR` array and is documented in the header file `ProMfgElemToolMtnVolMillCut.h`, and is shown in the following figure.

### Element tree for `PRO_E_TOOL_MTN` element

```
-- PRO_E_TOOL_MTN
|
|-- PRO_E_TOOL_MTN_REF_ID
|
|-- PRO_E_TOOL_MTN_TYPE
|

The following table lists the contents of `PRO_E_TOOL_MTN` element.

| Element ID                               | Data Type                       | Description                                                                                                                                                                       |
|------------------------------------------|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>PRO_E_TOOL_MTN_TYPE</code>         | <code>PRO_VALUE_TYPE_INT</code> | Mandatory element. Specify the tool motion type as <code>PRO_TM_TYPE_VOLUME_MILLING</code> . The value for this element is defined by the enumerated <code>typeProTmType</code> . |
| <code>PRO_E_TOOL_MTN_PROFILE_TYPE</code> | <code>PRO_VALUE_TYPE_INT</code> | Specifies the tool motion profile type. The enumerated type <code>ProMillProfCutType</code> defines the valid values for this element                                             |

| Element ID                               | Data Type                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                          |                                       | <p>which are as follows:</p> <ul style="list-style-type: none"> <li>• <code>PRO_E_MILL_CUT_FULL_DEPTH</code>— Specifies that the entire depth of the mill cut is machined.</li> <li>• <code>PRO_E_MILL_CUT_FROM_TO</code>— Specifies that the machining depth is limited by the specified start and the end references.</li> <li>• <code>PRO_E_MILL_CUT_UPTO</code>— Specifies that the machining depth is limited by the specified end reference.</li> <li>• <code>PRO_E_MILL_CUT_ONE_SLICE</code>— Specifies the machining of a single slice cut.</li> </ul> |
| <code>PRO_E_MFG_PARAM_ARR</code>         | Array                                 | Optional element. Defines an array of manufacturing parameters. For more information, refer to the section <a href="#">Manufacturing Parameters on page 1661</a> . This element is inherited from the Creo NC Sequence, if not specified.                                                                                                                                                                                                                                                                                                                      |
| <code>PRO_E_MFG_CMP_APPROACH_EXIT</code> | Compound                              | Specifies the approach and exit motions. This optional element is defined in the header file <code>ProMfgElemApproachExit.h</code> . For more information, refer to the section <a href="#">Approach and Exit on page 1673</a> .                                                                                                                                                                                                                                                                                                                               |
| <code>PRO_E_MFG_START_HEIGHT</code>      | <code>PRO_VALUE_TYPE_SELECTION</code> | <p>Optional element. Select the horizontal surface from where machining will begin.</p> <p> <b>Note</b></p> <p>This element is mandatory only if the element <code>PRO_E_TOOL_MTN_PROFILE_TYPE</code> is set to <code>PRO_E_MILL_CUT_FROM_TO</code>.</p>                                                                                                                                                                                                                    |
| <code>PRO_E_MFG_HEIGHT</code>            | <code>PRO_VALUE_TYPE_SELECTION</code> | Select a single surface where the                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Element ID                     | Data Type                | Description                                                                                                                                                                                                                                                                                                 |
|--------------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                |                          | <p>machining will begin.</p> <p> <b>Note</b></p> <p>This element is mandatory only if the element PRO_E_TOOL_MTN_PROFILE_TYPE is set to PRO_E_MILL_CUT_FROM_TO, or PRO_E_MILL_CUT_UPTO, or PRO_E_MILL_CUT_ONE_SLICE.</p> |
| PRO_E_VOL_MILL_REGION_ARR      | Array                    | Optional element. Specifies an array of region specifications. Define this element to overwrite the default order of machining of different areas                                                                                                                                                           |
| PRO_E_VOL_MILL_REGION          | Compound                 | Specifies a compound element that defines the volume milling region.                                                                                                                                                                                                                                        |
| PRO_E_VOL_MILL_REGION_SKIP_OPT | PRO_VALUE_TYPE_INT       | <p>Specifies the skipping option for the region. The valid values for this element are:</p> <ul style="list-style-type: none"> <li>• PRO_B_TRUE—Specifies that the region will be skipped while machining.</li> <li>• PRO_B_FALSE—Specifies that the region will not be skipped while machining.</li> </ul> |
| PRO_E_VOL_MILL_AP_REF          | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the selection of a vertical datum axis, or a datum point. This element defines a location for the region to make an approach move.                                                                                                                                              |
| PRO_E_VOL_MILL_EX_REF          | PRO_VALUE_TYPE_SELECTION | Optional element. Specifies the selection of a vertical datum axis, or a datum point. This element defines a location for the region to make an exit move.                                                                                                                                                  |

---

# Production Applications: Process Planning

## Production Applications: Process Planning

This section describes how to use the Creo TOOLKIT functions for assembly process operations. It assumes that you are familiar with the functionality of Manufacturing Process Planning for ASSEMBLIES.

### Process Step Objects

Function Introduced:

- **ProProcstepInit()**

Process steps are represented by the object `ProProcstep`, which is an instance of `ProModelitem`. The object `ProProcstep` describes the contents and ownership of a assembly process step.

The declaration is as follows:

```
typedef struct pro_model_item
{
 ProType type;
 int id;
 ProMdl owner;
} ProProcstep;
```

To create a new process step handle, use the function `ProProcstepInit()`.

### Visiting Process Steps

Function Introduced:

- **ProProcstepVisit()**

The function `ProProcstepVisit()` enables you to visit all the process steps in the specified solid. For a detailed explanation of visiting functions, see the section [Visit Functions on page 67](#) in the [Fundamentals on page 30](#) section.

### Process Step Access

Functions Introduced:

- **ProProcstepActiveGet()**
- **ProProcstepActiveSet()**
- **ProProcstepNumberGet()**

These functions access the process step objects.

---

The functions `ProProcstepActiveGet()` and `ProProcstepActiveSet()` enable you to get and set the current active process step.

The function `ProProcstepNumberGet()` retrieves the process step number for the specified solid and process step.

## Creating Process Steps

To create an assembly process step, use the function `ProFeatureCreate()`. As with any other type of feature, you use the element tree to create a process step feature.

This section describes the basic principles of programmatic process step creation. The section [Element Trees: Principles of Feature Creation on page 771](#) is a necessary background for this topic; therefore, you should read that section first.

The element tree for a process step feature is documented in the header file `ProProcstep.h` and has a fairly simple structure, as shown in the following figure. You can also create a copy of the feature element tree of an existing process step feature by calling the function `ProFeatureElementtreeExtract()` with an input feature of type `ProProcstep`.

The following figure shows the element tree of a process step feature.

## Element Tree of Process Step Feature

## Feature Elements

The following table describes the tree elements in more detail.

| Element ID              | Data Type                | Description                                            |
|-------------------------|--------------------------|--------------------------------------------------------|
| PRO_E_FEATURE_TYPE      | PRO_VALUE_TYPE_INT       | PRO_FEAT_PROCESS_STEP                                  |
| PRO_E_PROCESS_STEP_TYPE | PRO_VALUE_TYPE_INT       | See <a href="#">Types of Process Step on page 1771</a> |
| PRO_E_COMPONENTS        | PRO_VALUE_TYPE_SELECTION | Step components                                        |
| PRO_E_DESCRIPTION       | PRO_VALUE_TYPE_WSTRING   | Step description                                       |
| PRO_E_POSITION          | PRO_VALUE_TYPE_TRANSFORM | Position transformation                                |
| PRO_E_GEN_STEP_TYPE     | PRO_VALUE_TYPE_WSTRING   | General step type                                      |
| PRO_E_GEN_STEP_REFS     | PRO_VALUE_TYPESELECTION_ | General step references                                |
| PRO_E_SIMPLFD_REP       | PRO_VALUE_TYPE_INT       | Simplified representation identifier                   |
| PRO_E_EXPLODE_STATE     | PRO_VALUE_TYPE_INT       | Explode state identifier                               |
| PRO_E_TIME_ESTIMATE     | PRO_VALUE_TYPE_DOUBLE    | Time estimate (greater than 0.0)                       |
| PRO_E_COST_ESTIMATE     | PRO_VALUE_TYPE_DOUBLE    | Cost estimate (any value)                              |

---

## Types of Process Step

The types of process step are as follows:

- `PRO_PROCSTEP_ASSEMBLE`—Step to assemble components
- `PRO_PROCSTEP_DISASSEMBLE`—Step to disassemble components
- `PRO_PROCSTEP_REASSEMBLE`—Step to reassemble components
- `PRO_PROCSTEP_REPOSITION`—Step to reposition components
- `PRO_PROCSTEP_GENERAL`—General step (default or user-defined types)

## Optional Elements

The following elements in the tree are optional for all types of process step:

- `PRO_E_DESCRIPTION`
- `PRO_E_SIMPLFD_REP`
- `PRO_E_EXPLODE_STATE`
- `PRO_E_TIME_ESTIMATE`
- `PRO_E_COST_ESTIMATE`

For a detailed explanation of explode states and related functions, see the section [Exploded Assemblies on page 1115](#) in the [Assembly: Basic Assembly Access on page 1115](#) section.

## General Process Steps

The following two elements are used for general process steps (type `PRO_PROCSTEP_GENERAL`) only:

- `PRO_E_GEN_STEP_TYPE`—Default types, as well as user-defined types
- `PRO_E_GEN_STEP_REFS`—The following are valid reference types:
  - `PRO_PART`
  - `PRO_FEATURE`
  - `PRO_SURFACE`
  - `PRO_EDGE`
  - `PRO_CURVE`
  - `PRO_AXIS`
  - `PRO_CSYS`
  - `PRO_POINT`

---

## Reposition Process Steps

The element `PRO_E_POSITION` is used for reposition process steps. It defines the transformation of the repositioned components.

# Production Applications: NC Process Manager

## Production Applications: NC Process Manager

### Overview

The Process Manager functionality is based on the Process Table, which lists all the manufacturing process objects, such as workcells, operations, fixture setups, tooling, and NC sequences.

The Process Table lets you create new manufacturing objects and modify properties of existing ones. You can create new Holemaking and some milling steps directly in the Process Table. Steps of other types, that is, NC Sequences created outside the Process Manager, are also listed in the Process Table. You can manipulate the NC Sequences like any other steps, for example, reorder or duplicate them. However, customizations done to the toolpath outside the Process Table will be lost as a result of manipulation.

You can also define manufacturing templates based on existing Milling and Holemaking steps, and use these templates to create manufacturing steps in a different model.

You can add manufacturing templates as annotations to the reference part. This way, when you bring a reference part into a manufacturing model, the annotation can be automatically extracted into the manufacturing process to create the necessary steps, complete with tooling, parameters, and geometric references.

### Accessing the Process Manager

You can access the Process Manager in Creo Parametric in the Manufacturing Mode via Creo TOOLKIT as follows:

- When the process manager dialog box is not active.
- When the process manager dialog box is active.

---

## Accessing the Process Manager when the Dialog Box is not Active

You can access and modify the contents of the process manager without opening the Process Manager User Interface or while editing a manufacturing model in Creo Parametric.

Functions Introduced:

- **ProMfgProactableEnable()**
- **ProMfgProactableDisable()**

The function `ProMfgProactableEnable()` ensures that the process manager database is prepared for access or modification by Creo TOOLKIT functions. The application must call the function `ProMfgProactableEnable()` before using the process manager APIs discussed in the following sections.

The function `ProMfgProactableDisable()` enables Creo Parametric to perform cleanup of data that was loaded while calling the function `ProMfgProactableEnable()`.

## Accessing the Process Manager User Interface

You can add new items to the Process Manager User Interface using a Creo TOOLKIT application. The Creo TOOLKIT application should register the new user interface items in Creo Parametric before you open the Process Manager dialog box. Once the dialog box is opened, Creo Parametric automatically adds the registered menu buttons and menus to the dialog box.

Functions Introduced:

- **ProMfgproactableMenuAdd()**
- **ProMfgproactablePushbuttonAdd()**
- **ProMfgproactableItemAccessFunction**
- **ProMfgproactableItemActionFunction**
- **ProMfgproactableSelecteditemsGet()**
- **ProMfgproactableSelecteditemsSet()**
- **ProMfgproactableDisplayUpdate()**

The function `ProMfgproactableMenuAdd()` adds a new menu or submenu to an existing menu in the process manager user interface.

The function `ProMfgproactablePushbuttonAdd()` adds a new button at the end of the existing menu in the Process Manager user interface. When adding a new menu button, you must supply two callback functions whose signature matches `ProMfgproactableItemAccessFunction` and `ProMfgproactableItemActionFunction` respectively.

---

The function whose signature matches

`ProMfgproctableItemAccessFunction` sets the access state for the button in the process manager dialog box. The function whose signature is similar to `ProMfgproctableItemActionFunction` provides the implementation for the new menu button.

Use the functions `ProMfgproctableSelecteditemsGet()` and `ProMfgproctableSelecteditemsSet()` in the context of menu buttons added to the Process Manager. These functions provide access to the steps, operations and workcells that are currently selected by the user in the Process Manager dialog box. This information can guide the application as to which items it should modify. Select the appropriate type of table for the selected item to be able to determine the subtype of the process item.

These functions can be used out of context of the menu addition APIs as well.

The function `ProMfgproctableDisplayUpdate()` refreshes the Process Manager dialog box. It allows the application to update the contents of the process table after some changes have been made during a custom menu button action.

## Manufacturing Process Items

This section gives you more information on the handles that are provided to enable access to process item data.

## Steps, Operations and Workcells

An NC sequence is an assembly feature that represents a single tool path. NC sequences listed in the Process Table are called steps.

An operation is a series of NC sequences performed in a particular workcell and using a particular coordinate system for output of Cutter Location data.

A workcell is a machine tool definition and is stored in the assembly.

The object `ProMfgprocItem` will be used for all functions that operate on steps, operations, and workcells. This item is a derivative of `ProModelitem` and is defined as

```
typedef struct pro_model_item
{
 ProType type;
 int id;
 ProMdl owner;
}ProMfgprocItem;
```

For all three item types, the `ProType` field should be `PRO_NC_PROCESS_ITEM`.

---

## Step Models

The Step Model object represents the default properties of steps in the process manager and is a derivative of the `ProModelItem` and is defined as typedef `struct pro_model_item`.

```
{
ProType type;
int id;
ProMdl owner;
}ProMfgprocItem;
```

Step objects have a step id, the Mfg owner, and the ProType field as `PRO_NC_PROCESS_MODEL`.

## Determining the Subtype of a Process Item

Function Introduced:

- **ProMfgprocitemSubtypeGet()**

The function `ProMfgprocitemSubtypeGet()` returns the subtype of a manufacturing process item. It could be one of the following:

- `PRO_MFGPROCITEM_STEP`—Specifies if the subtype is a step.
- `PRO_MFGPROCITEM_OPERATION`—Specifies if the subtype is an operation.
- `PRO_MFGPROCITEM_WORKCELL`—Specifies if the subtype is a workcell.

## Accessing Details of Process Items

Although a `ProMfgprocItem` is not a feature, it shares many properties with Creo TOOLKIT features. In fact, process items generally map one-to-one with a specified manufacturing feature. Because of this, many of the process item's properties can be accessed via the corresponding manufacturing feature element tree. Also, new items may be created by populating the element tree for the new step, operation or workcell.

## Visiting Steps, Operations and Workcells

Functions Introduced:

- **ProMfgProctableVisit()**
- **ProMfgprocitemVisitAction()**
- **ProMfgprocitemFilterAction()**

---

The function `ProMfgProctableVisit()` enables you to visit the steps, workcells, and operations in a process table. As with other Creo TOOLKIT visit functions, specify the visit action and visit filter functions. For more information on Visit Functions, refer to the section [Fundamentals on page 30](#).

## Creating Steps, Operations, and Workcells

Functions Introduced:

- **ProMfgprocitemCreate()**
- **ProMfgprocitemFromTemplateCreate()**

Use the function `ProMfgprocitemCreate()` to create a new step, operation, or workcell in the process table. The input arguments of this function are:

- *model*—Specifies the manufacturing model in which to create the new item.
- *table\_type*—Specifies the type of table where the item will reside. The valid values are:
  - `PRO_MFGPROCTABLE_PROCESS`—Specifies the process table.
  - `PRO_MFGPROCTABLE_WORKCELLS`—Specifies the workcell table.
- *elem\_tree*—Specifies the manufacturing feature element tree used to enumerate the properties of the new manufacturing item. To create a step you must fill one of the following element trees:
  - Milling and Drilling—The element tree documented in header file `ProNcseq.h`.
  - Fixture—The element tree documented in header file `ProFixture.h`.
  - Assembly setup step—The element tree documented in header file `ProFixture.h`.

To create an Operation you must fill out the element tree documented in header file `ProMfgoper.h`.

To create a Workcell you must fill the element tree documented in header file `ProWcell.h`.

- *predecessor*—Specifies the step or operation immediately before the new manufacturing item in the process table. When creating workcells, this can be `NULL`.

The function `ProMfgprocitemCreate()` returns the new manufacturing item.

Use the function `ProMfgprocitemFromTemplateCreate()` to create a new manufacturing step or workcell from a predefined template. A template is an XML file containing information necessary to create the manufacturing step or workcell, such as:

- 
- Resources, that is, workcells, tools, and fixtures
  - Ordered operations
  - Ordered steps and their reference information such as manufacturing templates and manufacturing criteria.
  - Retract plane for a step or an operation, as a distance calculated from the step coordinate system.

## Accessing the Properties of Manufacturing Process Items

The functions described below enable you to access the properties of process items.

Functions Introduced:

- **ProMfgprocitemFeatureGet()**
- **ProMfgprocitemElemtreeGet()**
- **ProMfgprocitemElemtreeFree()**
- **ProMfgprocitemAnnotationGet()**
- **ProMfgprocitemReorderlimitsGet()**
- **ProMfgprocitemNextitemGet()**
- **ProMfgprocitemPreviousitemGet()**
- **ProMfgprocitemHolesetdepthGet()**
- **ProMfgprocitemHolesetdepthtypeGet()**
- **ProMfgprocitemHolesetdepthSet()**
- **ProMfgprocitemDefaultfixturesetupstepGet()**

The function `ProMfgprocitemFeatureGet()` returns the feature referenced by the process item. If the item is related to an actual manufacturing feature, some of the access functions that follow will not be supported. The properties of the item can be obtained by reading the feature's properties and element tree.

The function `ProMfgprocitemElemtreeGet()` obtains the element tree for a manufacturing item. This tree should be freed using `ProMfgprocitemElemtreeFree()`.

The function `ProMfgprocitemAnnotationGet()` returns the annotation element that created the process item.

---

The function `ProMfgprocitemReorderlimitsGet()` identifies the limits where the specified process item may be moved in the process table. The top limit represents the first process item after which you can insert the step. The lower limit, if any, represents the first process item that must come after the step in the process sequence.

The limits of reorder are based on step dependencies and priority and prerequisite rules. The input argument *options* specifies the checks to determine the position of reordering the process item elements. The valid values are:

- `PRO_MFGPROCORDER_CHECK_PARENT_CHILD`
- `PRO_MFGPROCORDER_CHECK_PREREQUISITES`
- `PRO_MFGPROCORDER_CHECK_PRIORITIES`

The function `ProMfgprocitemNextitemGet()` returns the process item following the specified item in the process table.

The function `ProMfgprocitemPreviousitemGet()` returns the process item preceding the specified process item in the process table.

The function `ProMfgprocitemHolesetdepthtypeGet()` returns the type of holeset and holeset end reference contained in the manufacturing process step.

The output argument *end\_type* can have the following values:

- `PRO_MFGSTEP_HOLESETEND_REFERENCE`—Specifies the end reference surface for the hole depth.
- `PRO_MFGSTEP_HOLESETEND_ALONG_AXIS`—Specifies the end reference by entering a depth value along the hole axis.

The function `ProMfgprocitemHolesetdepthGet()` returns the process item holeset depth for a holeset of type `BLIND` and end reference type of `ALONG AXIS`.

The function `ProMfgprocitemHolesetdepthSet()` sets the holeset depth for a step. This function supports steps with only one holeset. The holeset type must be `BLIND` and the end reference type will be changed to `ALONG AXIS` after using this function.

The function `ProMfgprocitemDefaultfixturesetupstepGet()` returns the fixture setup defined for the specified operation.

## Modifying Process Items

Functions Introduced:

- **`ProMfgprocitemRedefine()`**
- **`ProMfgprocitemDelete()`**
- **`ProMfgprocitemReorder()`**

---

Use the function `ProMfgprocitemRedefine()` to redefine the manufacturing item created using an element tree.

The function `ProMfgprocitemDelete()` deletes the specified step, operation, or workcell from the manufacturing table.

The function `ProMfgprocitemReorder()` reorders a step or operation within the process table.

## Parameters

Several categories of parameters are accessible for items in the process manager table:

- Manufacturing parameters
- AE parameters
- Step parameters
- Template parameters
- Special parameters
- Global Parameters

## Manufacturing Parameters

You can access the manufacturing parameters by reading or writing the manufacturing feature or step element tree.

## Annotation Element Parameters

You can access the annotation element parameters by getting the parent Annotation Element via `ProMfgprocitemAnnotationGet()` and reading parameters from that object. Refer to the section Parameters for details on how to read parameters from items such as annotation elements.

## Step Parameters and Relations

Step Parameters are parameters assigned to the step object. You can define parameters and relations to a particular step in the process table.

You can access these parameters by reading them directly from the step object using the standard parameter functions.

Refer to the section Parameters for details on how to read parameters from items.

## Template Parameters

Template parameters are inherited from the step's process template.

Function Introduced:

- **ProMfgprocitemTemplateparamGet()**

The function `ProMfgprocitemTemplateparamGet()` obtains a template parameter value for the process item.

## Special Parameters

Other special parameters are properties of steps and can include the extract status, machining time, the template name, and so on. Some of these properties may be also accessible via the step element tree.

Functions Introduced:

- **ProMfgprocitemPropertyGet()**
- **ProMfgprocitemPropertySet()**

The function `ProMfgprocitemPropertyGet()` returns the value of the special property of the process manager step or operation. The special property can be as follows:

- `PRO_MFGPROP_EXTRACT_STATUS`—Specifies the extraction priority of the step.
- `PRO_MFGPROP_ACTUAL_MACHINING_TIME`—Specifies the machining time of a step.
- `PRO_MFGPROP_ACTUAL_MACHINING_LENGTH`— Specifies the machining distance of a step.
- `PRO_MFGPROP_TEMPLATE_NAME`—Specifies the name of the manufacturing template used.
- `PRO_MFGPROP_GROUP_LEVEL_1`—Specifies a merge group created by merging several Holmaking steps together, to optimize the tool path.
- `PRO_MFGPROP_GROUP_LEVEL_2`—Specifies a merge group created by merging `PRO_MFGPROP_GROUP_LEVEL_1` type merge groups together.

`ProMfgprocitemPropertyGet()` returns string values for `PRO_MFGPROP_GROUP_LEVEL_1` and `PRO_MFGPROP_GROUP_LEVEL_2` depending on the location of the process manager step in the merged group. The following table lists all the possible values taken by the special properties.

| Step Location                                          | Value returned for              | Value returned for |
|--------------------------------------------------------|---------------------------------|--------------------|
| If the step is a merge leader, but not a merge member. | "*leader"                       | Empty string       |
| If the step is both a merge leader                     | Name of the parent merge leader | "*leader"          |

| Step Location                                                                      | Value returned for              | Value returned for              |
|------------------------------------------------------------------------------------|---------------------------------|---------------------------------|
| and merge member.                                                                  |                                 |                                 |
| If the step is merge member, but not a merge leader.                               |                                 |                                 |
| Case 1: It is a two level merge. For example, the parent itself is a merge member. | Name of the top merge leader    | Name of the parent merge leader |
| Case 2: It is a one level merge                                                    | Name of the parent merge leader | Empty string                    |
| If the step is neither merge leader nor a merge member.                            | Empty string                    | Empty string                    |

The function `ProMfgprocitemPropertySet()` sets the value of the special property of the process manager step or operation.

## Global Parameters and Relations

Function Introduced:

- **ProMfgProctablemodelGet()**

The function `ProMfgProctablemodelGet()` obtains the process model that provides access to the manufacturing global parameters.

You can use this function to specify parameters and relations to all or selected steps in the process table. The `modelitem` handle returned by this function can be used to access the Global parameters of the process table.

## Manufacturing Features

Functions Introduced:

- **ProMfgproctableFeaturesCreate()**
- **ProMfgproctableFeaturesDelete()**

The function `ProMfgproctableFeaturesCreate()` creates features for items in the process manufacturing table.

The function `ProMfgproctableFeaturesDelete()` deletes all existing manufacturing features from the Creo Parametric model while keeping everything in the process manager unchanged.

## Import and Export of Process Table Contents

Functions Introduced:

- **ProMfgProctableWrite()**
- **ProMfgProctableSynchronize()**

---

The function `ProMfgProctableWrite()` exports the contents of the manufacturing process table to CSV format. The input arguments of the function are:

- *mfg*—Specifies the manufacturing model.
- *table\_type*—Specifies the type of table to be generated as output. The valid values are:
  - `PRO_MFGPROCTABLE_PROCESS`
  - `PRO_MFGPROCTABLE_WORKCELLS`
- *view\_name*—Specifies the view name in the setup file; pass `NULL` to use the current view.
- *output\_file*—Specifies the full path and name of the output file.

The function `ProMfgProctableSynchronize()` synchronizes the manufacturing table with the input CSV file.

## Notification

Function Introduced:

- **ProMfgproctableExtractionPostAction**

The notification `ProMfgproctableExtractionPostAction` identifies when the user has extracted the process table in order to form manufacturing features. It provides the path to the extraction log file, which can be examined by the application for further information.

## Example 1: To Add Menu Button to The Manufacturing Process Table

The sample code in `PTMfgProcTable.c` located at `<creo_toolkit_loadpoint>\<datecode>\Common Files\protoolkit\protk_appls\pt_mfg_proctable\pt_mfg_proctable_src` enables you to add the Highlight Prereq and the Update Speed and Feed options respectively, to the **Tools** menu in the Manufacturing Process Table.

The image above displays the Highlight Prereq and Update Feed & Speed menu buttons added to the **Tools** menu in the Manufacturing Process Table. When you click the Highlight Prereq option the function `PTMfgProactableItemActionPreReq` is invoked. The following example deals with this function in detail.

## Example 2: To Highlight the Pre-requisites for the Selected Step in The Manufacturing Process Table

The sample code in `PTMfgProcTable.c` located at `<creo_toolkit_loadpoint>\<datecode>\Common Files\protookit\protk_appls\pt_mfg_proactable\pt_mfg_proactable_src` demonstrates how to highlight the pre-requisites for the selected step in the Manufacturing Process Table.

| Manufacturing Process Table          |                 |                   |          |         |        |
|--------------------------------------|-----------------|-------------------|----------|---------|--------|
| File Edit View Insert Tools Features |                 |                   |          |         |        |
|                                      | Name            | Type              | Workcell | Tool    | Axes   |
|                                      | OP010           | OPERATION         | TOYODA   |         |        |
|                                      | DRILL_DEPTH     | STANDARD DRILLING |          | DRILL5  | 3 Axes |
|                                      | DRILL_DEPTH_000 | STANDARD DRILLING |          | DRILL5  | 3 Axes |
|                                      | DRILL_TEST      | STANDARD DRILLING |          | DRILL5  | 3 Axes |
|                                      | DRILL_DEPTH_001 | STANDARD DRILLING |          | DRILL5  | 3 Axes |
|                                      | DRILL_DEPTH_002 | STANDARD DRILLING |          | DRILL5  | 3 Axes |
|                                      | DRILL_DEPTH_003 | STANDARD DRILLING |          | DRILL5  | 3 Axes |
|                                      | DRILL_REF       | STANDARD DRILLING |          | DRILL10 | 3 Axes |
|                                      | DRILL_REF_000   | STANDARD DRILLING |          | DRILL10 | 3 Axes |
|                                      | DRILL_REF_001   | STANDARD DRILLING |          | DRILL10 | 3 Axes |
|                                      | DRILL_REF_002   |                   |          |         |        |

### Example 3: To Update Feed and Spindle Speed

The sample code in `PTMfgProcTable.c` located at `<creo_toolkit_loadpoint>\<datecode>\Common Files\protoolkit\protk_appls\pt_mfg_proctable\pt_mfg_proctable_src` demonstrates how to change the cut feed and the spindle speed for the specified tool.

When you click the **Update Speed and Feed** options in the **Tools** menu in the Manufacturing Process Table, the function `PTMfgProctableItemFeedSpeed` is invoked.

| Feed/Speed database access                                                  |        |
|-----------------------------------------------------------------------------|--------|
| MATERIAL :                                                                  |        |
| TOOL_ID :                                                                   | DRILL5 |
| CUT_FEED                                                                    | 200.0  |
| SPINDLE_SPEED                                                               | 3050.0 |
| <input type="button" value="Update"/> <input type="button" value="Cancel"/> |        |

---

The sample code in `PTMfgProcTable.c` located at `<creo_toolkit_loadpoint>\<datecode>\Common Files\protoolkit\protk_appls\pt_mfg_proctable\pt_mfg_proctable_src` describes the following action functions

- `PTMfgElemtreeWalkthroughAction()`
- `PTMfgUsrUpdateAction()`
- `PTMfgUsrCancelAction()`
- `PTMfgElemtreePreReqAction()`
- `PTMfgDialogCreate()`
- `PTMfgProcitemElemtreeGet()`
- `PTTestMfgProcItemVisit()`
- `PTMfgParameterVisit()`
- `PTMfgProcitemToolNameGet()`

## Example 4: To Add a Submenu to the Manufacturing Process Table

The following example enables you to add a menu and submenu to an existing menu option in the Manufacturing Process Table.

```
#include <ProMenuBar.h>
#include <ProMfgproctable.h>
#include <ProMfg.h>
#include <ProMdl.h>
#include <ProMessage.h>
#include <ProUtil.h>
ProName submenulabel;
ProName help;
ProName submenubutton;
ProError APITestCommand (ProMfg mfg, char* button_name,
ProAppData appdata);
ProStringToWstring (submenulabel, "MyNewSubmenu");
ProStringToWstring (submenubutton, "SubmenuButton");
ProStringToWstring (help, "SubmenuHelp");
status = ProMfgproctableMenuAdd ("APITestMenu",
submenulabel, "Insert");
PT_TEST_LOG_SUCC("ProMfgproctableMenuAdd")
status = ProMfgproctablePushbuttonAdd ("APITestMenu",
"APITestMain",
submenubutton,
help, NULL, APITestCommand, NULL);
PT_TEST_LOG_SUCC("ProMfgproctablePushbuttonAdd");
ProError APITestCommand (ProMfg mfg, char* button_name,
ProAppData appdata) {
printf("Just some output\n");
return PRO_TK_NO_ERROR;
```

## Production Applications: Cabling

### Production Applications: Cabling

This section describes the Creo TOOLKIT cabling functions.

### Cabling

This section describes the functions in Creo TOOLKIT that access the contents of a cabling harness created using the cabling module in Creo Parametric. The explanations in this section assume a knowledge of cabling and the fundamental concepts of Creo TOOLKIT, especially assemblies.

Be careful with the terminology of cabling. You can route three kinds of objects to make electrical connections within a harness: wires, cables, and bundles. The generic word for all three is cable. Unless otherwise specified, the explanations in the following sections use the word cable, in its generic sense, to include wires, cables, and bundles.

Creo TOOLKIT uses the object type `ProCable` to refer to any type of cable object. The data object has the same structure as `ProModelitem`.

```
typedef struct pro_model_item {
 ProMdl owner;
 int id;
 prototype type;
} ProCable;
```

### Creating a Harness

Function Introduced:

- **ProHarnessCreate()**

---

`ProCable` operates on a Creo Parametric assembly. Cables can belong to one or more harness. A harness is a special Creo Parametric part designed to contain cables.

A harness cannot be retrieved into Creo Parametric Part mode. It appears in the cabling assembly as an assembly component. A harness is identified by the Creo Parametric object handle `ProHarness`.

The function `ProHarnessCreate()` creates a new harness in the specified assembly.

## Finding a Harness

Function Introduced:

- **`ProAssemblyHarnessesCollect()`**
- **`ProAssemblyHarnessesTopCollect()`**
- **`ProAsmcompIsHarness()`**
- **`ProCablingIsHarness()`**
- **`ProHarnessSubharnessesCollect()`**

The function `ProAssemblyHarnessesCollect()` returns an array of handles to any harness that is part of a specified assembly and its sub-assemblies.

The function `ProAssemblyHarnessesTopCollect()` returns an array of handles to the harnesses present in the specified top level assembly.

Use the function `ProAsmcompIsHarness()` to identify if the specified component is a harness part. This function returns the value `TRUE`, if the component is a harness. The function `ProCablingIsHarness()` identifies if the specified model is a harness part.

Use the function `ProHarnessSubharnessesCollect()` to collect all the sub harnesses in the specified input harness part.

## Finding the Cables in a Harness

Functions Introduced:

- **`ProHarnessCablesCollect()`**
- **`ProCableHarnessesGet()`**
- **`ProInputFileRead()`**

The function `ProHarnessCablesCollect()` provides an array of names of cables that exist in the specified harness. The output of the function includes cables that have not yet been routed.

---

Each cable can be created in, and routed through, several harnesses. The function `ProCableHarnessesGet()` provides an array of the handles to the harnesses below the current assembly that contain a cable with the specified name.

Use function `ProInputFileRead()` with argument `PRO_WIRELIST_TYPE` to read files in Mentor Graphics LCABLE format. This function does not create wires, but provides parameters from a wire list for use when creating in a harness assembly a wire with the same name as that in the LCABLE file.

## Harness Parameters

Functions Introduced:

- **`ProCablelocationAttachToHarnessComponentGet()`**
- **`ProCablelocationIsAttachToHarness()`**

Use the function

`ProCablelocationAttachToHarnessComponentGet()` to get the component on which the attach to harness location is dependent.

Use the function `ProCablelocationIsAttachToHarness()` to identify if the specified location is a cabling attach to harness location.

## Importing Neutral Wire List Files

The PTC neutral wire format contains logical information for cabling. It contains information about the reference designator, pin-to-pin connection, and parameter values of connectors, pins, spools, wires, and cables.

Functions Introduced:

- **`ProCablingNeutralwirelistImport()`**

The function `ProCablingNeutralwirelistImport()` allows you to import and load the PTC neutral wire list file (`.nwf`) in the current session. Specify the name of the file along with its extension and full path as the input argument *filename*.

## Managing Spools

Functions Introduced:

- **`ProAssemblySpoolsCollect()`**
- **`ProSpoolCreate()`**
- **`ProInputFileRead()`**
- **`ProOutputFileMdlnameWrite()`**

---

Function `ProAssemblySpoolsCollect()` returns a list of all spools defined in the specified assembly.

Use function `ProSpoolCreate()` to create a new spool of a given cable and sheath type in the specified assembly.

Use function `ProInputFileRead()` with argument `PRO_SPOOL_FILE` to create new spools or update existing ones. Function `ProOutputFileMdlnameWrite()` with the same argument to export a spool file.

## Spool Parameters

Functions Introduced:

- **ProSpoolParameterGet()**
- **ProSpoolParametersCollect()**
- **ProSpoolParameterDelete()**
- **ProSpoolParametersSet()**
- **ProSpoolsFromLogicalGet()**
- **ProSpoolsFromLogicalCreate()**
- **ProSpoolCablesLengthGet()**
- **ProSubharnessCablesCollect()**

Function `ProSpoolParameterGet()` retrieves a single parameter for the specified spool. This function supports only single-valued parameters. If you specify a multivalued parameter, the function returns `PRO_TK_E_NOT_FOUND`.

Function `ProSpoolParametersCollect()` retrieves all parameters of the specified spool, both single- and multi-valued parameters.

Use `ProSpoolParameterDelete()` to remove a single parameter from the specified spool. This function deletes both single- and multi-valued parameters.

Function `ProSpoolParametersSet()` sets all parameters of the specified spool, both single- and multi-valued parameters. This function overwrites existing parameter values with values in the input parameter array.

Function `ProSpoolsFromLogicalGet()` returns a list of spool names in the specified assembly for which data has been imported from a logical reference but which have not yet been created. Use function `ProSpoolsFromLogicalCreate()` to create instances of spools for which logical data exists. Refer to the Creo Parametric Cabling Help and Creo Parametric Harness Help for more information on logical references.

Use the function `ProSpoolCablesLengthGet()` to get the total length of all the cables present in the specified input harness, using the specified spool.

---

Use the function `ProSubharnessCablesCollect ()` to retrieve an array of all the cables present in the specified sub harness.

## Finding Harness Connectors

Functions Introduced:

- **ProAssemblyConnectorsGet()**
- **ProConnectorsFromLogicalGet()**
- **ProAsmcompIsConnector()**

Each connector in a cabling assembly is a Creo Parametric part that is a component of that assembly. A connector can be at any level in the assembly hierarchy. Each connector is identified by its assembly component path (`ProAsmcompPath`).

The function `ProAssemblyConnectorGet ()` provides an array of member identifier tables identifying the connectors in the specified assembly. The function allocates the memory for these tables.

Function `ProConnectorsFromLogicalGet ()` returns a list of connector names in the specified assembly for which data has been imported from a logical reference but which have not yet been created. Refer to the Creo Parametric Cabling Help and Creo Parametric Harness Help for more information on logical references.

Use the function `ProAsmcompIsConnector ()` to identify if the specified component is a cabling connector. This function returns the value `TRUE`, if the component is a cabling connector.

## Connectors Parameters

Functions Introduced:

- **ProConnectorEntryPortsGet()**
- **ProConnectorParamsCollect()**
- **ProConnectorDesignate()**
- **ProConnectorWithAllParamsDesignate()**
- **ProConnectorUndesignate()**
- **ProConnectorParamGet()**
- **ProConnectorParamDelete()**
- **ProConnectorParamsSet()**
- **ProConnectorsFromLogicalGet()**
- **ProOutputFileMdlnameWrite()**

- **ProInputFileRead()**
- **ProConnectorRefModelNameGet()**
- **ProCableCurvesGet()**

Each connector contains a set of entry ports to which cables can be connected. Each entry port is modeled by a coordinate system datum that belongs to the part that models the connector. The function `ProConnectorEntryPortsGet()` returns a `ProArray` of datum coordinate systems representing the entry ports in the specified connector. The connector is identified by its component path (its `memb_id_tab`).

The function `ProConnectorParamsCollect()` provides an array of the user parameters for the connector. However, this array contains only single-valued parameters that refer to the connector itself, not the parameters that describe the entry ports.

To access parameters on the connector entry ports, you must call the function `ProOutputFileMdlnameWrite()` with the option `PRO_CONNECTOR_PARAMS_FILE`. This writes a text file to disk, which is the same format as the file you edit when using the ProCable command **Connector, Modify Parameters, Mod Param**.

The following example shows a sample connector parameters file. Refer to the Creo Parametric Cabling Help on the parameters.

The function `ProConnectorRefModelNameGet()` retrieves the reference model name of the specified cable connector. The function returns the output argument `p_ref_model_name` as a `wchar_t*` string.

Use the function `ProCableCurvesGet()` to retrieve the trajectory entities for the specified feature. The input arguments are:

- *cbl\_feat*—Specify the cable for which the `ProCurves` is returned using the object `ProCable`.
- *inc\_bundle*—Returns the `ProCurve` function for the bundles through which the cable is passed using the `ProBoolean` object.

The output argument *p\_curves* is a `ProArray` of the curves.

## Connector Parameters File

```
! Enter or modify parameters for the connector. You may use the
help

Note that this file is not free-format. Each parameter name and value is followed by a tab character, and each empty value is represented by a tab character. Therefore, the line in the example that assigns the first parameter, SIGNAL, contains three tab characters between the value of the PIN\_ID and the value of ENTRY\_PORT: the first tab belongs to the PIN\_ID value, and next two tabs provide null values for SIGNAL\_NAME and SIGNAL\_VALUE.

The function `ProInputFileRead()` imports a file in this format, so you can use it in conjunction with `ProOutputFileMdlnameWrite()` to edit the parameters on connectors and their entry ports. To identify the connector, both functions use the following arguments:

- *arg1*—Represents the `memb_id_tab`
- *arg2*—Represents the `memb_num`

The function `ProConnectorDesignate()` designates a component in the assembly as a cabling connector. It takes as input the component path that identifies the part in the cabling assembly, and an optional name that will be the reference descriptor (REF\_DES) of the connector.

---

When a new connector has been designated, it has only the two parameters REF\_DES and MODEL\_NAME. The MODEL\_NAME is set to be the name of the part designated, and the REF\_DES is set to the value provided as input to the function ProConnectorDesignate(), if any, or to the MODEL\_NAME otherwise. After you designate a connector, you must call ProOutputFileMdlnameWrite() and ProInputFileRead() to set up the necessary parameters.

The function ProConnectorWithAllParamsDesignate() designates a component in the assembly as a cabling connector using all the logical parameters. The input arguments are:

- *p\_connector*—Specifies the component path that identifies the part in the cabling assembly.
- *name*—Specifies the reference descriptor (REF\_DES) of the connector. The argument can be NULL when the designation is not from a logical reference.
- *from\_logical*—Specifies if the component must be designated using logical references.

To undesignate a connector, call the function ProConnectorUndesignate().

Function ProConnectorParamGet() retrieves a single parameter for the specified connector. This function supports only single-valued parameters. If you specify a multivalued parameter, the function returns PRO\_TK\_E\_NOT\_FOUND.

Use function ProConnectorParamDelete() to remove a single parameter from the specified connector. This function deletes both single- and multi-valued parameters.

Function ProConnectorParamsCollect() retrieves all parameters of the specified connector. This function supports both single- and multi-valued parameters.

Function ProConnectorParamsSet() sets all parameters of the specified connector. This function overwrites all existing parameter values with the values in the input parameter array. This function supports both single- and multi-valued parameters.

Function ProConnectorsFromLogicalGet() returns a list of connector names in the specified assembly for which data has been imported from a logical reference but which have not yet been created. Refer to the Creo Parametric Cabling Help and Creo Parametric Harness Help for more information on logical references.

## Managing Cables and Bundles

Functions Introduced:

- **ProCableCreate()**

- 
- **ProCableAndConductorsCreate()**
  - **ProBundleCreate()**
  - **ProBundleCablesCollect()**
  - **ProCablesegmentInfoIsInBundle()**
  - **ProNetworkCreate()**
  - **ProNetworkGet()**
  - **ProCablingSchematicsLayerNamesGet()**
  - **ProCablingSchematicswirelistImport()**

Use the functions `ProCableCreate()` and `ProCableAndConductorsCreate()` to create a new cable or wire in a specified harness. The type of cable created corresponds to the spool type. This function creates all required parameters with default values. If the cable or wire name has already been imported from a wire list, then parameters from that reference are used instead of default values.

---

 **Note**

The function `ProCableAndConductorsCreate()` also creates conductors if needed. Pass the value of the input argument *create\_conductors* as `PRO_B_TRUE` to create conductors.

---

Use function `ProBundleCreate()` to create a new bundle in a specified harness. The type of bundle corresponds with the spool type. This function creates all required parameters with default values.

Use the function `ProCablesegmentInfoIsInBundle()` to identify if the specified cable segment runs into a bundle. This function returns the name of the bundle only if the specified cable segment runs into a bundle.

A network is a series of locations that defines default paths to automate the process to route cables. While routing a cable through a network, the application routes the cable along the network using the shortest calculated path. Cables can only enter and exit a network path through a network location.

Use the function `ProNetworkCreate()` to create a new network in the specified harness.

The function `ProNetworkGet()` gets the network for the specified harness.

The input argument *harness* is specified using the handle `ProHarness`. The output argument *p\_cable* is the handle to the new network and specified using the class `ProCable`.

---

A wire list contains information about the reference designator, pin-to-pin connection information, and parameter values of connectors, pins, spools, wires, and cables.

Use the function `ProCablingSchematicswirelistImport()` to import the Creo Schematics wire list from the specified file. The input arguments are as follows:

- *p\_assem*—Input assembly specified using the object `ProAssembly`.
- *filename*—Full path to the input file name including the extension
- *layer\_names*—Pointer to the array of layer names in the file and is specified using the class `ProName`.

The function `ProCablingSchematicslayerNamesGet()` gets the Creo Schematics layer list from the specified file. The input argument *filename* is the full path to the input file name including the extension. The output argument *layer\_names* is the pointer to the array of layer names in the file and is specified using the class `ProName`

## Cable Parameters

Functions Introduced:

- **ProCableParameterGet()**
- **ProCableParameterDelete()**
- **ProCableParametersCollect()**
- **ProCableParametersSet()**
- **ProCableparammemberFree()**
- **ProCableparamproarrayFree()**
- **ProCablesFromLogicalGet()**
- **ProCablesFromLogicalCreate()**
- **ProCablesFromLogicalAllCreate()**
- **ProCableLocationsOnSegEndGet()**
- **ProOutputFileMdlnameWrite()**
- **ProInputFileRead()**
- **ProCableTessellationGet()**
- **ProCablesegmentInfoIsNew()**
- **ProCablesegmentInfoPointsGet()**
- **ProCablesegmentInfosGet()**

---

Function `ProCableParameterGet()` retrieves a single parameter for the specified cable. This function supports only single-valued parameters. If you specify a multivalued parameter, the function returns `PRO_TK_E_NOT_FOUND`.

Use `ProCableParameterDelete()` to remove a single parameter from the specified cable. This function deletes both single- and multi-valued parameters.

Function `ProCableParametersCollect()` retrieves all parameters of the specified cable. This function supports both single- and multi-valued parameters.

Function `ProCableParametersSet()` sets all parameters of the specified cable. This function overwrites all existing parameter values with the values in the input parameter array. This function supports both single- and multi-valued parameters.

Function `ProCableparammemberFree()` releases the memory assigned to the `ProCableparam` object. Function `ProCableparamproarrayFree()` releases the memory assigned to the array of `ProCableparam` objects. The `ProCableparam` object stores the names and values of cable parameters.

Function `ProCablesFromLogicalGet()` returns a list of cable names in the specified assembly for which data has been imported from a logical reference but which have not yet been created.

Use function `ProCablesFromLogicalCreate()` to create instances of cables for which logical data exists.

The function `ProCablesFromLogicalAllCreate()` creates cables and conductors from logical references. Cables are created using the spool features. If a cable already has a spool feature defined for it, then such cables are created using the existing spools in the model. If the spool feature is not defined for a cable, then this function also creates spools for such cables.

Refer to the *Creo Parametric Cabling Help* and *Creo Parametric Harness Help* for more information on logical references.

The function `ProCableLocationsOnSegEndGet()` returns the start and end location of each segment for the specified cable. The locations are returned as a `ProArray`.

The functions `ProOutputFileMdlnameWrite()` and `ProInputFileRead()` can be used with the option `PRO_CABLE_PARAMS_FILE` to export and import (and therefore edit) parameters on the specified cable.

Use the function `ProCableTessellationGet()` to get the tessellation for the specified input cable. Specify the following parameters as input arguments to create the surface tessellation:

- `cable`—Specify the input cable on which the tessellation is to be created.

- `input_data`—Specify the input data used for the tessellation such as `AngleControl`, `ChordHeight`, `StepSize` and so on. You can choose the options to use when generating a tessellation for the input cable.

---

### **Note**

You must set the configuration option `display_thick_cables` to yes before using this API.

---

Use the function `ProCablesegmentInfoIsNew()` to identify if the specified cable segment with location information is connected to the previous segment.

Use the function `ProCablesegmentInfoPointsGet()` to get an array of points, tangents and location Ids for the specified cable segment.

Use the function `ProCablesegmentInfosGet()` to collect cable segments with location Ids of the cable segments present within the specified cable.

The following example shows a sample cable parameters file. Like the file for connector parameters, the parameter names and values are separated by tab characters.

## Cable Parameters File

```
! Enter or modify parameters for the cable.
! You can use the help functionality of Pro/TABLE
! to enter pre-defined parameters.
! Cable Name
NAME WIRE_2
! Spool Name
SPOOL 24Y
! Modify the "DIRECTION" parameter for the end type of this cable.
!
REF_DES ENTRY_PORT DIRECTION
END_TYPE MOTOR ENTRY1 FROM
END_TYPE XCONN2 ENTRY1 TO
```

## Cable Identifiers and Types

Functions Introduced:

- **`ProCableByNameGet()`**
- **`ProCableNameGet()`**
- **`ProCableTypeGet()`**

The functions `ProCableByNameGet()` and `ProCableNameGet()` provide the handle of a cable given its name. The functions also return the cable name when supplied with the handle.

---

The function `ProCableTypeGet ()` provides the type of a named cable. The possible types are as follows:

- A wire—A single conductor
- A cable—With several conductors
- A bundle—A collection of other wires, cables, and bundles

## Cable Cosmetic Features

Functions Introduced:

- **`ProCableCosmeticFeatureCreate()`**
- **`ProCableCosmeticFeatureTypeGet()`**
- **`ProCableCosmeticDistanceGet()`**
- **`ProCablelocationMaxDiameterGet()`**
- **`ProCablelocationHeightDimensionGet()`**
- **`ProCableTapeWindsGet()`**
- **`ProCableTapeWindsSet()`**
- **`ProCableTapeFeatSpoolGet()`**
- **`ProFeatureIsCableCosmetic()`**
- **`ProCableCosmeticfeatureEntityGet()`**
- **`ProCableCosmeticfeatureThicknessGet()`**
- **`ProCableCosmeticfeatureReferencethicknessGet()`**

The function `ProCableCosmeticFeatureCreate ()` creates a cabling cosmetic feature. The types of cabling cosmetic features are tie wraps, markers, and tape. The selected cable location or cable segment point to use for the feature creation. If creating a tape feature, this must contain a cable location. If creating a marker, this must contain a point on the cable segment. If creating a tie wrap, this could be a cable location or a point on a cable segment.

Use the function `ProCableCosmeticFeatureTypeGet ()` to retrieve the type of the specified cosmetic feature. The enumerated data type `ProCableCosmeticType` is used to define the types of cosmetic features.

The function `ProCableCosmeticDistanceGet ()` retrieves the position of a cosmetic feature relative to the start or end of a cable segment. The output arguments are listed below:

- *p\_offset*—Distance of the cosmetic feature from the start or end of a segment.
- *p\_start*—Boolean value which indicates if the distance is measured from the start position of a segment.

---

Use the function `ProCablelocationMaxDiameterGet()` to retrieve the maximum diameter of the location for the specified harness.

Use the function `ProCablelocationHeightDimensionGet()` to retrieve the height dimension for the specified cable location. The function returns the error `PRO_TK_BAD_CONTEXT` if the specified location does not have a height dimension.

The functions `ProCableTapeWindsGet()` and `ProCableTapeWindsSet()` provide access to the number of winds in a tape cosmetic feature.

The function `ProCableTapeFeatSpoolGet()` returns the spool for the specified tape feature.

Use the function `ProFeatureIsCableCosmetic()` to check if the specified feature is a cabling cosmetic feature. Cabling cosmetic feature comprises of tie wraps, markers, and tape. For more information on cabling cosmetic feature, refer to the Creo Parametric Help.

Use the function `ProCableCosmeticfeatureEntityGet()` to get the entity for the cabling cosmetic feature. This function returns a line entity for the tie wrapper and tape types of cosmetic features, and spline entity is returned if the cosmetic feature is of the a marker type.

Use the function `ProCableCosmeticfeatureThicknessGet()` to get the thickness of the specified input cable cosmetic feature.

Use the function `ProCableCosmeticfeatureReferencethicknessGet()` to obtain the thickness of the reference cable which is wrapped by the input cable cosmetic feature.

## Cable Connectivity

Function Introduced:

- **ProCableLogicalEndsGet()**

The function `ProCableLogicalEndsGet()` identifies the entry ports and their owning connectors to which the specified cable should be connected. This function depends on the connector parameters `SIGNAL` and `PIN_ASSIGN`. A cable connects logically to an entry port if the connector has a `PIN_ASSIGN` parameter that relates a `PIN_ID` value to that `CABLE_NAME`, and a `SIGNAL` parameter that relates the same `PIN_ID` value to that `ENTRY_PORT` name.

In the sample connector parameters file, the cable `WIRE_2` connects to connector `MOTOR`, entry port `ENTRY1`.

A cable can have logical ends, even if it has not yet been routed.

The output of the function `ProCableLogicalEndsGet()` is in the form of two `Pro/Selection` structures for the coordinate system datums that represent the entry ports.

## Cable Routing Locations

Functions Introduced:

- **`ProCableLocationsCollect()`**
- **`ProHarnessLocationsCollect()`**
- **`ProCablelocationTypeGet()`**
- **`ProCablelocationPointGet()`**
- **`ProCablelocationCablesGet()`**

The locations through which a cable is routed are identified by `ProCableLocation` structures, which are of the same structure as `ProModelItem`. The `ProCableLocationsCollect()` function provides an array of the structures for the locations through which the specified cable is routed. The function `ProHarnessLocationsCollect()` provides an array of the structures for the locations in a specified harness.

The function `ProCablelocationTypeGet()` gives the type of a specified location. The following table lists the valid location types.

| Location Type                    | Equivalent Command in the CBL ROUTE Menu |
|----------------------------------|------------------------------------------|
| <code>PRO_LOC_CONNECTOR</code>   | <b>Connector</b>                         |
| <code>PRO_LOC_POINT</code>       | <b>Pnt/Vertex</b>                        |
| <code>PRO_LOC_FREE</code>        | <b>Free</b>                              |
| <code>PRO_LOC_DEPENDENT</code>   | <b>Dependent</b>                         |
| <code>PRO_LOC_AXIS</code>        | <b>Along Axis</b>                        |
| <code>PRO_LOC_USE_DIR</code>     | <b>Use Dir</b>                           |
| <code>PRO_LOC_OFFSET</code>      | <b>Offset</b>                            |
| <code>PRO_LOC_SPLICE</code>      | <b>Splice</b>                            |
| <code>PRO_LOC_LOC</code>         | <b>Location</b>                          |
| <code>PRO_LOC_OFFSET_CSYS</code> | <b>Coordinate Offset</b>                 |
| <code>PRO_LOC_OFFSET_AXIS</code> | <b>Axis Offset</b>                       |

The function `ProCablelocationPointGet()` provides the XYZ coordinates of the location in the coordinate system of the harness.

The function `ProCablelocationCablesGet()` provides an array of the names of cables routed through the specified location.

## Cable Geometry

Functions Introduced:

- 
- **ProCableLengthGet()**
  - **ProCableSegmentsGet()**
  - **ProCablesegmentPointsGet()**
  - **ProCablesegmentIsInBundle()**
  - **ProCablesegmentIsNew()**

The function `ProCableLengthGet()` provides the length of the specified wire within a specified harness.

The functions `ProCableSegmentsGet()` and `ProCablesegmentPointsGet()` provide the geometry of a named wire, bundle, or cable within a specified harness part. The geometry of a wire or cable is divided into a number of segments, each of which represents a region where the wire or cable is bundled with other wires and cables. The geometry of each such segment is described by a series of three-dimensional locations and tangent vectors.

The function `ProCablesegmentIsInBundle()` determines whether a cable segment runs into a bundle.

The function `ProCablesegmentIsNew()` determines whether the cable segment is connected to a previous cable segment.

## Measuring Harness Clearance

Function Introduced:

- **ProCableClearanceCompute()**

The function `ProCableClearanceCompute()` determines the minimum distance between two items in a harness. The items can be of any of the following types, in any combination:

- Part
- Surface
- Cable
- Cable location

The inputs identify the two items in terms of `ProSelection` structures. The function outputs a flag to show whether the two items interfere, and, if they do not interfere, the function also returns the three-dimensional locations of the two nearest points.

## Cable Routing

Functions Introduced:

- **ProCableRoutingStart()**
- **ProCableThruLocationRoute()**
- **ProCableRoutingEnd()**
- **ProCablelocationrefAlloc()**
- **ProCablelocationrefFree()**

To Route a Group of Cables Through a Sequence of Locations:

1. Call `ProCableRoutingStart()` to identify the cables to be routed.
2. Call `ProCablelocationrefAlloc()` to create a routing reference location structure.
3. Call `ProCableThruLocationRoute()` for each location through which to route the cables.
4. Call `ProCablelocationrefFree()` to free the location reference.
5. Call `ProCableRoutingEnd()` to complete the routing.
6. Call `ProSolidRegenerate()` to make Creo Parametric calculate the resulting cable geometry and create the necessary cable features.

#### **Note**

You must also call the function `ProWindowRepaint()` to see the new cables.

After the call to `ProCableRoutingStart()`, the information about the routing in progress is contained in an opaque data structure `ProRouting` that `ProCableRoutingStart()` provides. This pointer is then given as an input to the functions `ProCableThruLocationRoute()` and `ProCableRoutingEnd()`.

The inputs to `ProCableRoutingStart()` are the cabling assembly and harness handles, and an array of cables.

The input to `ProCableThruLocationRoute()` is a structure of type `ProCablelocationref`, which contains all the necessary information about the location through which to route the cables.

The following table shows the possible values of the `type` field, and the values that other fields need for each type.

| type             | refs                                           | axis_flip                  | offsets |
|------------------|------------------------------------------------|----------------------------|---------|
| PROLOC_CONNECTOR | The coordinate system datum for the entry port | —                          | —       |
| PROLOC_POINT     | The datum point                                | —                          | —       |
| PROLOC_AXIS      | The axis                                       | 0 or 1 to show the routing | —       |

| type          | refs                                                        | axis_flip | offsets                                     |
|---------------|-------------------------------------------------------------|-----------|---------------------------------------------|
|               |                                                             | direction |                                             |
| PROLOC_OFFSET | The coordinate system datum to define the offset directions | —         | Offset distances from the previous location |
| PROLOC_LOC    | An existing routing location                                | —         | —                                           |

The function `ProCableThruLocationRoute()` also outputs an array of the structures for the locations created as a result of the call. (The function usually creates a single location, but creates two in the case of routing through an axis.)

As input, the `ProCableRoutingEnd()` function takes only the *void\** for the routing data.

## Deleting Cable Sections

Function Introduced:

- **ProCableSectionsDelete()**

The function `ProCableSectionsDelete()` deletes the section of cables that lies between designated locations. `ProCableSectionsDelete()` does not delete loom bundle cable sections.

## Production Applications: Piping

### Production Applications: Piping

This section contains information about the Piping API functions. The functions in this section allow a Creo TOOLKIT application to create, read, and write pipe linestock information. These APIs also support analysis of pipeline connectivity as built with the Creo Parametric module Piping.

### Piping Terminology

Creo TOOLKIT supports Piping. Piping uses specific terminology. This section defines this terminology.

A *pipeline* is set of interconnecting pipes and fitments. A pipeline consists of an extension which terminates at open ends (that is, ends with no further pipeline items are attached), non-open ends (that is, ends with equipment such as nozzles or other pipelines), or junctions. A pipeline also contains extensions that branch from extensions which branch from it, then others which branch from those, and so on.

A pipeline extension is a non-branching sequence of pipeline items.

---

A `pipeline feature` is a feature which names the pipeline to show its grouping. All other features in the pipeline refer to this feature. A pipeline feature does not contain any geometry of its own.

At a `branch (or junction)`, pipes are grouped into extensions such that the extension which continues across the branch has a continuous direction of flow, and, if that criterion leaves a choice, has the smallest change of direction possible for that branch. Other pipes which join that branch then form the end points of other extensions.

A member of an extension is a terminator, a series, or a junction.

A `terminator` is the open or non-open ends of the pipeline.

A `series` is a non-branching sequence of pipeline objects.

A `junction` is an assembly component or a datum point which represents a part which joins three or more pipe segments.

A `stubin` is a datum point which joints three or more series.

A `segment` is a section of pipe, either straight or arced. If arced, the segment is manufactured by taking a straight section of tube and bending it.

A `fitting` is a component that connects two pipe segments, for example, to form a corner where space does not allow a bent pipe segment, or to represent an item such as a valve

A `pipeline object` is a segment, a fitting, or a stubin.

A `pipeline network` is a data structure which contains references to pipeline objects. The objects are structured to show their connectivity and sequence in relation to the flow.

## Linestock Management Functions

This section presents functions for management of linestock.

### Linestocks

Functions introduced:

- **ProAssemblyLnstksCollect()**
- **ProPipelineLnstkGet()**
- **ProPipelineLnstkSet()**
- **ProLnstkCreate()**

```
typedef struct pro_lnstk
{
 ProName name;
 ProAssembly owner;
} ProLnstk;
```

---

The function `ProAssemblyLnstksCollect()` finds all the linestocks defined for a specified assembly.

The functions `ProPipelineLnstkGet()` and `ProPipelineLnstkSet()` get and set the default linestock for a specified pipeline feature.

The function `ProLnstkCreate()` creates a new linestock in the specified assembly.

## Linestock Parameters

Functions introduced:

- **ProLnstkParametersCollect()**
- **ProLnstkParametersSet()**
- **ProLnstkParameterAdd()**
- **ProLnstkParameterDelete()**

The parameters of a linestock differ from regular Creo Parametric parameters in that they may be organized hierarchically. The data structure `ProLnstkParam` contains the description of a linestock parameter and its member parameters, if any. Its declaration follows, along with those of its member types.

```
typedef enum
{
 PROLNSTKPRM_SINGLE,
 PROLNSTKPRM_MULTIPLE
} ProLnstkParamType;
typedef struct _pro_lnstk_param_memb_
{
 ProName name;
 ProParamvalue value;
} ProLnstkParamMemb;
typedef struct _pro_lnstk_param_
{
 ProName name;
 ProLnstkParamType param_type;
 union {
 ProParamvalue value;
 ProLnstkParamMemb *members;
 } lnstk_param_value;
} ProLnstkParam;
```

The function `ProLnstkParametersCollect()` finds all the parameters for a specified linestock.

The function `ProLnstkParametersSet()` sets the parameters on a specified linestock to a specific list.

The function `ProLnstkParameterAdd()` adds a new parameter to the list of parameters on a specified linestock.

---

The function `ProLnstkParameterDelete()` deletes a named parameter from a linestock.

The linestock parameters can be set using the following enumerated types:

- `ProLnstkPipeSection`—Specifies the type of the pipe section as **Hollow** or **Solid**.
- `ProLnstkPipeShape`—Specifies the type of the pipe shape as **Flexible** or **Straight**.
- `ProLnstkPipeCrnrType`—Specifies the type of the pipe corner as **Bend**, **Fitting**, or **Miter Cut**. Corners are not set for flexible pipes.
- `ProLnstkPipeXSection`—Specifies the cross section of the pipe as **Circular** or **Rectangular**.

For round pipes the value of `ProLnstkPipeXSection` is set to `PROLNSTKPIPEXSECT_CIRCULAR`. Use the function `ProLnstkParametersCollect()` to access the values of the following pipe section parameters:

- `OD`—Outer diameter of the pipe.
- `WALL_THICKNESS`—Wall thickness of the pipe.

For rectangular pipes the value of `ProLnstkPipeXSection` is set to `PROLNSTKPIPEXSECT_RECTANGULAR`. Use the function `ProLnstkParametersCollect()` to access the values of the following pipe section parameters:

- `RECTANGULAR_HEIGHT`—Height of the rectangular pipe.
- `RECTANGULAR_WIDTH`—Width of the rectangular pipe
- `RECTANGULAR_ANGLE`—Rotate angle of the pipe solid part around its reference entity. The angle is relevant only in square pipes.
- `WALL_THICKNESS`—Wall thickness of the pipe.

## Pipeline Features

The functions in this section are used to create and work with pipeline features. These functions also allow a Creo TOOLKIT application to create, read, and write line stock information.

Functions introduced:

- **`ProPipelineSpecDrivenCreate()`**
- **`ProPipelineCreateFromXML()`**
- **`ProPipelineCreate()`**
- **`ProPipelineParametersCollect()`**
- **`ProPipelineParametersSet()`**

- 
- **ProPipelineParameterAdd()**
  - **ProPipelineParameterDelete()**

The function `ProPipelineSpecDrivenCreate()` creates line stock and pipeline features according to the specification parameters defined in the structure `ProPipingSpecParams`. The pipeline feature is created using the newly created line stock feature. The name of the line stock feature is generated based on the specification parameters. The name of the pipeline feature is generated based on the specification parameter and the configuration option `pipeline_label_format`.

The input arguments are:

- *model*—Specifies the model where the pipeline feature must be created. The model must be Specification-Driven, or the configuration option `piping_design_method` must be set to *spec\_driven*.

The configuration option `piping_design_method` enables you to set the design mode for the piping project. To activate the Spec-Driven design mode set the value of the configuration option to *spec\_driven*. In this mode, the piping systems are created using the specified specifications. For Non Spec-Driven mode, set the value to *non\_spec\_driven*. In this mode, the piping systems are created manually without using project-specific data. To work in the User-Driven mode, set the value to *user\_driven*. This mode enables you to switch between Spec-Driven and Non Spec-Driven piping design modes. You can convert existing assemblies to required design mode at any time in the design process.

- *spec\_params*—Specifies the specification parameters. These parameters are defined in the structure `ProPipingSpecParams`. User must set the parameter values in the structure based on the values defined in the auto-selection file. Refer to the Creo Parametric Piping Help for more information on the auto-selection files.
- *Mnemonic*—Specifies the fluid or piping system. If the value is specified as `NULL`, then the default mnemonic defined in the Specification Directory file is used. The path and name of the Specification Directory file are set in the configuration option `piping_spec_dir_file`. If you pass an empty string, then no mnemonic value is assigned to the pipeline feature.
- *number*—Specifies a number which uniquely identifies the pipeline. If the value is specified as `NULL` or an empty string, then no number is assigned to the pipeline feature.
- *insulation*—Specifies the insulation for the pipeline. If the value is specified as `NULL`, then the default insulation defined in the Specification Directory file is used. The path and name of the Specification Directory file are set in the configuration option `piping_spec_dir_file`. If you pass an empty string, then the pipeline feature is created without insulation.

- *CreateSubAsm*—Specifies if the pipeline must be created as a new subassembly. The pipeline subassembly is created using the template model defined in the configuration option `pipeline_start_assembly_name`.
- *SubAsmName*—Specifies the name of the pipeline subassembly. If you pass the value of the argument as NULL or an empty string, then the name of the pipeline subassembly is generated based on the configuration option `pipeline_assembly_name_format`.
- *csys\_reference*—Specifies a coordinate system for the placement of the pipeline subassembly. If the value is specified as NULL, then the coordinate system of the model is used to place the subassembly.

The function `ProPipelineCreateFromXML()` creates line stock and pipeline features according to the schematic information defined in the XML file for the specified pipeline label. The name of the line stock feature is generated based on the specification parameters. The name of the pipeline feature is generated based on the specification parameter and the configuration option `pipeline_label_format`.

The input arguments are:

- *model*—Specifies the model where the pipeline feature must be created. The model must be Specification-Driven, or the configuration option `piping_design_method` must be set to *spec\_driven*. The model must be enabled for schematic-driven modeling. The configuration option `piping_schematic_driven` must be set to *yes*.

The configuration option `piping_schematic_driven` enables or disables the schematic-driven modeling mode for a piping project. The valid values are *yes* and *no*.

- *xml\_file*—Specifies the path to the XML file which contains schematic information for pipelines.
- *pipeline\_label*—Specifies the pipeline label for the XML file. The properties SPEC, SIZE, SCHEDULE, MNEMONIC, NUMBER, and INSULATION associated with a pipeline label are updated from the XML file. The property GRADE, that is, the material code is updated based on the other specification parameters. The property CATEGORY has its value set as *PIPE*.
- *insulation*—Specifies if the pipeline must be created with insulation. If the value is specified as TRUE, then the pipeline is created with insulation based on the parameter INSULATION defined in the XML file.
- *CreateSubAsm*—Specifies if the pipeline must be created as a new subassembly. The pipeline subassembly is created using the template model defined in the configuration option `pipeline_start_assembly_name`.
- *SubAsmName*—Specifies the name of the pipeline subassembly. If you pass the value of the argument as NULL or an empty string, then the name of the pipeline subassembly is generated based on the configuration option `pipeline_assembly_name_format`.

- 
- *csys\_reference*—Specifies a coordinate system for the placement of the pipeline subassembly. If the value is specified as `NULL`, then the coordinate system of the model is used to place the subassembly.

The function `ProPipelineCreate()` creates a Non Specification-Driven pipeline feature. The pipeline is created under the specified model. The input arguments are:

- *model*—Specifies the model where the pipeline feature must be created. The model must be Non Specification-Driven.
- *lnstk*—Specifies the line stock feature. The line stock feature must have the specified model as its parent.
- *pipeline\_name*—Specifies the name of the pipeline feature.

The function `ProPipelineParametersCollect()` retrieves all the parameters of the specified pipeline as a `ProArray`. Use the function `ProArrayFree` to release the memory assigned to the `ProArray` of parameters.

Use the function `ProPipelineParametersSet()` to set the parameters in the specified pipeline.

The function `ProPipelineParameterAdd()` adds the parameter in the specified pipeline.

The function `ProPipelineParameterDelete()` deletes the parameter in the specified pipeline.

In this section, we have explained only the configuration options which are required to work with the piping APIs. Refer to the Creo Parametric Piping Help for the complete list of piping configuration options and their detailed descriptions.

## Pipeline Connectivity Analysis

The functions in the section support analysis of pipeline connectivity.

### Networks

Functions introduced:

- **`ProPipelineNetworkEval()`**
- **`ProPipelineNetworkEvaluate()`**
- **`ProPnetworkFree()`**
- **`ProPnetworkLabelGet()`**
- **`ProPnetworkSizeGet()`**
- **`ProPnetworkSpecGet()`**

---

A pipeline is a collection of Creo Parametric piping features and components that are connected together. A pipeline feature is a single feature that unites all the features and components in a pipeline. All the features and components that belong to one pipeline reference the pipeline feature.

A network is a temporary data structure which is the result of analyzing the connectivity and topology of the features and components in a pipeline. The functions in this section allow a Creo TOOLKIT application to create and analyze the network for a pipeline, which would be the first step in, for example, an analysis of the fluid flow down the pipeline.

The network is a hierarchical data structure whose branches describe the various logical subdivisions into which the features and components of a pipeline divide themselves according to their connectivity.

A network is described by the opaque pointer `ProPnetwork`. The function `ProPipelineNetworkEval()` analyzes the features and components that belong to a pipeline (specified by its pipeline feature, belongs to the top model) and builds a network data structure.

The function `ProPipelineNetworkEvaluate()` analyzes the features and components that belong to a pipeline (specified by its pipeline feature and path) in the top level assembly or its sub assemblies and builds a network data structure.

The input arguments are:

- *p\_comp\_path* —Specify the path from the top model to the pipeline's model by using `ProAsmcomppath`.
- *pipeline* —The feature handle to the pipeline feature.

The output argument *network* is a handle to the network structure. It is an opaque pointer to a structure that is accessed by functions starting with `ProPnetwork`.

After the structure has been analyzed it should be freed using `ProPnetworkFree()`.

The functions `ProPnetworkLabelGet()`, `ProPnetworkSizeGet()`, and `ProPnetworkSpecGet()` get information about the pipeline described by a specified network.

## Extensions

Functions introduced

- **`ProPnetworkExtensionVisit()`**
- **`ProPextensionFlowGet()`**

---

A network contains a list of extensions. An extension is a non branching sequence of connected pipeline items. At a branch in a pipeline one extension is continuous across the branch and other extensions terminate at the branch. To decide which extension is continuous across the branch, the analysis performed by `ProPipelineNetworkEval()` uses the following rules:

- The extension must have a continuous direction of flow across the branch.
- Of all such possible extensions, the one chosen is the one that gives the smallest change of direction across the branch.

An extension is represented by the opaque pointer `ProPextension`. The function `ProPnetworkExtensionVisit()` visits all the extensions in a network.

The function `ProPextensionFlowGet()` tells you the flow direction in relation to the sequence of members in the extension.

## Members

Functions introduced:

- **`ProPextensionMemberVisit()`**
- **`ProPmemberTypeGet()`**

An extension is conceptually divided into objects called members, described by the opaque object `ProPmember`. The members in an extension divide it at the pipeline branches which the extension crosses.

There are three types of member:

- **Terminator**—The end of a pipeline, where it either opens or connects to an item outside the pipeline, described by the opaque object `ProPterminator`.
- **Junction**—The item that describes how the pipeline branches, described by the opaque object `ProPjunction`.
- **Series**—A non branching sequence of pipeline objects, described by the opaque object `ProPseries`.

The function `ProPextensionMemberVisit()` visits all the members in an extension, and the function `ProPmemberTypeGet()` reports which of the three types the member represents. Each of three types of member is in turn composed of one or more objects.

The following sections describe the analysis of the three types of members.

## Terminators

Functions introduced:

- **`ProPmemberTerminatorGet()`**

---

- **ProPterminatorTypeGet()**

The function `ProPmemberTerminatorGet()` outputs the `Pterminator` object, which represents the terminator in the specified member.

The function `ProPterminatorTypeGet()` tells you whether a terminator is an input or an output.

## Junctions

Functions introduced:

- **ProPmemberJunctionGet()**

The function `ProPmemberJunctionGet()` outputs the `Pjunction` object which represents the junction in the specified member.

## Series

Functions introduced:

- **ProPmemberSeriesGet()**

- **ProPseriesIdGet()**

The function `ProPmemberSeriesGet()` outputs the `Pseries` object which represents the series in the specified member.

The function `ProPseriesIdGet()` yields the integer id of the specified series.

## Objects

Functions introduced:

- **ProPterminatorObjectGet()**
- **ProPjunctionObjectGet()**
- **ProPseriesObjectVisit()**
- **ProPobjectTypeGet()**
- **ProSelectionPipelineGet()**
- **ProPobjectSegmentGet()**
- **ProPobjectFittingGet()**
- **ProPfittingAsmcompGet()**
- **ProPobjectStubinGet()**
- **ProPstubinPointGet()**
- **ProPobjectSelectionGet()**
- **ProPselectionSelectionGet()**

---

A Piping Object describes a single item in a pipeline and is represented by the opaque pointer `Pobject`.

The functions `ProPterminatorObjectGet()` and `ProPjunctionObjectGet()` output the single object used to represent a terminator or a junction. The function `ProPseriesObjectVisit()` visits all the objects that represent the contents of a series.

The function `ProPobjectTypeGet()` yields one of the following types:

- **Segment**—A single pipe segment, either bent or straight. Can only belong to a series.
- **Fitting**—An assembly component that connects two or more pipeline segments. Can belong to a **Series** (if it connects two segments) or a **Junction** (if it connects more than two segments).
- **Stubin**—A datum point that defines the location where two or more pipeline segments connect directly without a fitting. Can only belong to a **Junction**.
- **Selection**—An object that contains a `ProSelection` describing the item a pipeline terminator connects to. Can only belong to a **Terminator**.

The function `ProSelectionPipelineGet()` outputs the pipeline feature to which the specified pipeline selection belongs.

The function `ProPobjectSegmentGet()` outputs the **Segment** contained by an **Object** of the appropriate type. The **Segment** is described in the next section.

The function `ProPobjectFittingGet()` outputs the fitting contained by an object of the appropriate type. The fitting is represented by the opaque object `ProPfitting`. The assembly component that represents the fitting can be found using the function `ProPfittingAsmcompGet()`.

The function `ProPobjectStubinGet()` outputs the stubin contained by an object of the appropriate type. The stubin is represented by the opaque pointer `ProPstubin`. The function `ProPstubinPointGet()` yields the 3-D location of the stubin.

The function `ProPobjectSelectionGet()` outputs the selection contained by an object of type terminator. The function `ProPselectionSelectionGet()` provides the `ProSelection` object that the selection contains and identifies the item outside the pipeline to which the terminator connects.

## Segments

Functions introduced:

- **`ProPsegmentTypeGet()`**
- **`ProPsegmentLinestockGet()`**

- 
- **ProPsegmentLengthGet()**
  - **ProPsegmentCurvesGet()**

A segment is represented by the opaque pointer `ProPsegment`.

The function `ProPsegmentTypeGet()` tells you whether the segment is straight or bent.

The function `ProPsegmentLinestockGet()` outputs which linestock was used for this segment. Note that because the pipeline may contain fittings which cause a change in diameter, some segments in the pipeline may yield a different linestock from that provided by `ProPipelineLnstkGet()` for the pipeline itself.

The function `ProPsegmentLengthGet()` outputs the physical length of the segment.

The function `ProPsegmentCurvesGet()` outputs an array of `ProCurve` objects that describes the geometry of the centerline of the segment. The curves are always listed in the direction of flow.

## Connecting Pipeline Segments

You can connect disconnected segments of the same pipeline or entry ports using the pipe connect feature.

The element tree for the pipe connect feature is documented in the header file `ProPipConnect.h` and is shown in the following figure:

## Element Tree for Pipe Connect Feature

```

PRO_E_FEATURE_TREE

The following table describes the elements in the element tree for the pipe connect feature:

| Element ID              | Data Type              | Description                                                                                                   |
|-------------------------|------------------------|---------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE      | PRO_VALUE_TYPE_INT     | Mandatory element. Specifies the type of the feature. The valid value for this element is PRO_FEAT_PIPE_JOIN. |
| PRO_E_STD_PIPE_LINE_ENV | PRO_ELEM_TYPE_COMPOUND | This compound element defines the pipe options.                                                               |
| PRO_E_STD_PIPE_LINE_ID  | PRO_ELEM_TYPE_INT      | This element is mandatory, except the pipe route environment.                                                 |

| Element ID                      | Data Type            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 |                      | Specifies the ID of the pipeline.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| PRO_E_STD_PIPE_LINE_LNSTK       | PRO_ELEM_TYPE_INT    | Optional element. Specifies the line stock. The default line stock is taken from the related pipeline.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| PRO_E_STD_PIPE_LINE_CORNER_TYPE | PRO_ELEM_TYPE_OPTION | <p>Optional element. Specifies the type of corner for the connect feature. The segments in the connect feature are joined using corners. The types of corner are set in the line stock. The default type of corner is taken from the related pipeline.</p> <p>The valid values for types of corner are:</p> <ul style="list-style-type: none"> <li>PRO_PIPE_CORNER_TYPE_FITTING—Creates sharp corners. You can later add corner fittings. Fitted corners create breaks in a pipeline.</li> <li>PRO_PIPE_CORNER_TYPE_MITER—Creates a corner by adding a miter cut.</li> <li>PRO_PIPE_CORNER_TYPE_BEND—Creates each corner by bending the pipe.</li> </ul> |
| PRO_E_STD_PIPE_LINE_BEND_RAD    | PRO_ELEM_TYPE_DOUBLE | <p>Optional element. This element is relevant when the corner type is set to PRO_PIPE_CORNER_TYPE_BEND. Specifies the radius of the bend. The default bend radius is taken from the related pipeline.</p> <p>For Specification-Driven pipelines, the value of bend radius is defined in the line stock, which is related to the pipeline.</p>                                                                                                                                                                                                                                                                                                            |
| PRO_E_STD_PIPE_LINE_MITER_NUM   | PRO_ELEM_TYPE_INT    | Optional element. This element is relevant when the corner type is set to PRO_PIPE_CORNER_TYPE_MITER. Specifies the number of miter cuts. The default number of cuts is taken from the related pipeline.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Element ID                       | Data Type            | Description                                                                                                                                                                                                                                                                                                                                |
|----------------------------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                  |                      | For Specification-Driven pipelines, the number of miter cuts is defined in the line stock, which is related to the pipeline.                                                                                                                                                                                                               |
| PRO_E_STD_PIPE_LINE_MITER_LEN    | PRO_ELEM_TYPE_DOUBLE | Optional element. This element is relevant when the corner type is set to PRO_PIPE_CORNER_TYPE_MITER. Specifies the length of the miter cut. The default length is taken from the related pipeline.<br><br>For Specification-Driven pipelines, the length of the miter cut is defined in the line stock, which is related to the pipeline. |
| PRO_E_PIPE_CONNECT_FROM_MAIN_REF | PRO_ELEM_TYPE_SELECT | Mandatory element. Specifies the first end of the connect feature.                                                                                                                                                                                                                                                                         |
| PRO_E_PIPE_CONNECT_TO_MAIN_REF   | PRO_ELEM_TYPE_SELECT | Mandatory element. Specifies the second end of the connect feature.                                                                                                                                                                                                                                                                        |

| Element ID                     | Data Type            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_PIPE_CONNECT_DIMS_SCHEME | PRO_ELEM_TYPE_OPTION | <p>Optional element. Specifies the dimensioning scheme to be used to connect the two ends. The valid values are:</p> <ul style="list-style-type: none"> <li>PRO_PIPE_DIM_SCHEME_L1_L2—Sets an offset from both ends of the connect. This is the default option.</li> <li>PRO_PIPE_DIM_SCHEME_L1_A1—Sets an offset from the first end of the connect and the angle between the first segment and middle segment of the connect.</li> <li>PRO_PIPE_DIM_SCHEME_L1_A2—Sets an offset from the first selected end of the connect, and the angle between the middle segment and the second end.</li> <li>PRO_PIPE_DIM_SCHEME_L2_A1—Sets an offset from the second selected end of the connect, and the angle between the first segment and middle segment of the connect.</li> <li>PRO_PIPE_DIM_SCHEME_L2_A2—Sets an offset from the second selected end of the connect, and the angle between the middle segment and the second end.</li> <li>PRO_PIPE_DIM_SCHEME_A1_A2—Sets the angles between the end segments and the middle segment of the connect.</li> </ul> <p> <b>Note</b></p> <p>If length is missing, then its value is considered as 0. If angle is missing, then the default dimensioning scheme PRO_PIPE_DIM_SCHEME_L1_L2 is used. Here again, if length is missing, then its value is considered as 0.</p> |

| Element ID            | Data Type              | Description                                                                                                              |
|-----------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------|
|                       |                        | Refer to the Creo Parametric Piping help for more information on the segments and angles created by the connect feature. |
| PRO_E_PIPE_ROUTE_ENDS | PRO_ELEM_TYPE_COMPOUND | This compound element defines the offset and angle values for the ends in the connect feature.                           |

The two main elements of PRO\_E\_PIPE\_ROUTE\_ENDS are:

- PRO\_E\_PIPE\_ROUTE\_END\_FIRST—This compound element specifies the values for the first end of the connect feature.
- PRO\_E\_PIPE\_ROUTE\_END\_SECOND—This compound element specifies the values for the second end of the connect feature.

The following elements are common to the both the compound elements:

| Element ID                  | Data Type            | Description                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_PIPE_ROUTE_END_OPT    | PRO_ELEM_TYPE_OPTION | Optional element. Specifies the type of offset. The valid values are: <ul style="list-style-type: none"> <li>• PRO_PIPE_OFFSET_REFERENCE—Specifies that the offset is defined from an reference object. The reference object can be a datum plane or coordinate system, which is perpendicular to the end axis or coordinate axis.</li> <li>• PRO_PIPE_OFFSET_END—Specifies that the offset is defined from the selected end.</li> </ul> |
| PRO_E_PIPE_ROUTE_END_LENGTH | PRO_ELEM_TYPE_DOUBLE | Optional element. Specifies the value for offset lengths. Depending on the dimensioning scheme, specify the value length_1 for L1 and length_2 for L2. The default value is 0.0.                                                                                                                                                                                                                                                         |

| Element ID                   | Data Type            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_PIPE_ROUTE_END_REF     | PRO_ELEM_TYPE_SELECT | This element is mandatory if the type of offset is set to PRO_PIPE_OFFSET_REFERENCE. Specifies the reference object.                                                                                                                                                                                                                                                                                                                                                                                                   |
| PRO_E_PIPE_CONNECT_END_ANGLE | PRO_ELEM_TYPE_DOUBLE | <p>Optional element. Specifies the value for the segment angles. Depending on the dimensioning scheme, specify <code>angle_1</code> for A1 and <code>angle_2</code> for A2. The default value is 0.0.</p> <p> <b>Note</b></p> <p>If the angle is missing, then the dimensioning scheme <code>PRO_E_PIPE_CONNECT_DIMS_SCHEME</code> is changed to <code>PRO_PIPE_DIM_SCHEME_L1_L2</code>. The default values of L1 and L2 are 0.0.</p> |

## Production Applications: Welding

### Production Applications: Welding

Welding is an optional Creo Parametric module that allows you to model welds in assemblies. In addition, you can generate report tables about weld parameters and show welding symbols in assembly drawings. This section provides a brief overview of weld features. For more information, refer to the “Welding Design” module in the Creo Parametric Online Help.

### Read Access to Weld Features

The functions listed in this section provide access to basic information about existing weld features.

Functions introduced:

- **ProWeldTypeGet()**
- **ProWeldInfoGet()**
- **ProWeldIntermittenceGet()**
- **ProWeldSequenceIdGet()**
- **ProMdlIsSolidWeld()**

- **ProWeldGeomTypeGet()**
- **ProWeldRodGet()**
- **ProWeldRodNameGet()**
- **ProWeldCompoundGet()**
- **ProWeldFilletdataGet()**
- **ProWeldGroovedataGet()**
- **ProWeldPlugdataGet()**
- **ProWeldSlotdataGet()**
- **ProWeldSpotdataGet()**
- **ProWeldExtendedInfoToXMLExport()**

Use function `ProWeldTypeGet()` to output the type and subtype of the specified weld. Function `ProWeldInfoGet()` outputs the information you get by using the Creo Parametric command **Info**, in the **Weld** group, under the welding tab.

Function `ProWeldIntermittenceGet()` outputs information about an intermittent weld, describing the size, number, and location of the welds that form it.

Use function `ProWeldSequenceIdGet()` to obtain the sequence ID of a weld feature.

In Creo Simulate, you can add the welds created in Creo Parametric Welding application to models. During meshing, solid elements are created for solid weld objects while surface weld objects are compressed to shells. The function `ProMdlIsSolidWeld()` checks if the specified solid has been created from a solid weld.

Use the function `ProWeldGeomTypeGet()` to get the type of geometry representation for the specified weld. The types of geometry representations are defined in the enumerated data type `ProWeldGeomType`. The valid values are:

- `PRO_WELD_LIGHT`—Light welds reference existing curves or edges but have no geometry of their own. The welds are represented by the edge or surface geometry it references.
- `PRO_WELD_SURFACE`—Surface welds creates and shows the surface geometry. It is represented by surface geometry.
- `PRO_WELD_SOLID`—Solid welds and edge preparations are geometric models that offer mass properties such as volume and surface area.

Refer to the Creo Parametric Welding for more information.

Use function `ProWeldRodGet()` to provide the feature handle of the rod for the specified weld feature. Function `ProWeldRodNameGet()` gets the name of the specified weld rod feature.

---

`ProWeldCompoundGet()` outputs the list of welds in a compound weld.

Use functions `ProWeldFilletdataGet()`, `ProWeldGroovedataGet()`, `ProWeldPlugdataGet()`, `ProWeldSlotdataGet()`, and `ProWeldSpotdataGet()` to output data on a specific fillet, groove, plug, slot, or spot weld respectively.

Use the function `ProWeldExtendedInfoToXMLExport()` to print the information that is necessary to automatize the welding info file, in XML format.

## Customizing Weld Drawing Symbols

Functions introduced:

- **`ProDrawingWeldSympathGetAction()`**
- **`ProDrawingWeldGroupsGetAction()`**
- **`ProDrawingWeldSymtextGetAction()`**

This section describes three notification functions invoked by Creo Parametric when the user instantiates a weld symbol that documents a weld in drawing mode. Your callback functions can output information which is used to modify the weld symbol that appears on the drawing. The effect is to allow much greater customization of the appearance of the weld symbol than is possible without Creo TOOLKIT .

### Note

From Pro/ENGINEER Wildfire 5.0 onward, you can also create weld symbols in weld features as 3D Symbol Annotation Elements. Creo TOOLKIT allows you to access the Weld Symbol Annotation Elements using existing `ProAnnotation*` functions. For more information on the functions, refer the [Annotations: Annotation Features and Annotations on page 555](#) section.

---

Each callback has input arguments which identify the drawing, the weld assembly, the weld feature being annotated, and the path to the drawing symbol being used. The functions for read-access to welds, described in the previous section, would be used inside the callbacks to find out about the weld being annotated.

Refer to the [Event-driven Programming: Notifications on page 1974](#) section for more data on how to set a notification.

Weld symbol notification types are:

- `PRO_DRAWING_WELD_SYMPATH_GET`—allows the callback function to override the entire weld symbol by specifying the path and file name of a substitute symbol.

- 
- `PRO_DRAWING_WELD_GROUPIDS_GET`—allows the callback to selectively include or exclude symbol groups contained in the symbol. Additional inputs to the callback are a flag to show which way the symbol will point (left or right) and an array of the names of the groups in the symbol; the output is an array of booleans which select the groups to be included.
  - `PRO_DRAWING_WELD_SYMTTEXT_GET`—allows the callback to substitute for variable text in the symbol.

All three notifications can be set at the same time, allowing you to use your own set of generic symbols which are designed to be customized according to the weld type and properties.

### Example 1: Weld Callback Notification

The sample code in `UgWeld.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_weld` shows how to use weld callback notification functions.

## Creo Simulate: Items

### Creo Simulate: Items

This section describes how to access the properties of Creo Simulate items. The functions described in this section evaluate the model's structural characteristics and thermal profile and provide powerful tools for examining mechanism performance.

## Entering the Creo Simulate Environment

You can access the Creo Simulate functions in one of the following situations:

- When the Creo Parametric session is in the Creo Simulate user interface for a given model.
- When the application initializes the Creo Simulate environment for a given model.

Functions Introduced:

- **ProMechanicaEnter()**
- **ProMechanicaLeave()**
- **ProMechanicaIsActive()**

The function `ProMechanicaEnter()` allows you to enter the Creo Simulate environment to access information about the Creo Simulate items in a specified model. The model must be displayed in the window.

---

### **Note**

- You cannot call the function `ProMechanicaEnter()` from `user_initialize()`.
- Models created in Creo Simulate Lite mode, in both Structure and Thermal, are not supported by the Creo Parametric TOOLKIT functions. If you access a Creo Simulate Lite model in the Creo Simulate environment, the function `ProMechanicaEnter()` returns an error `PRO_TK_CANT_ACCESS`.

---

The function `ProMechanicaLeave()` exits the Creo Simulate environment entered using the previous function.

The function `ProMechanicaIsActive()` identifies whether the Creo Simulate environment is currently active. The environment might be active if the user has entered the Creo Simulate environment interactively, or if the function `ProMechanicaEnter()` has been called.

---

### **Note**

Only functions related to the Creo Simulate database must be called between the calls to the functions `ProMechanicaEnter()` and `ProMechanicaLeave()`. `ProMechanicaEnter()` must not be used to initialize the Creo Simulate User Interface.

---

## Entering the Creo Simulate Environment with Failed Features

You can open a model created in Creo Parametric with features that failed to regenerate in the Creo Simulate environment. The failed features appear on the Model Tree for the part.

You can use the functions described in this section to enter and run applications in the Creo Simulate environment on a model with failed features or components. You can also create simulation objects on geometry from failed features or components and regenerate the model.

## Selection of Creo Simulate Items

Creo TOOLKIT supports selection of certain Creo Simulate items. Refer to the section [User Interface: Selection on page 521](#) for details about selection in Creo Parametric. These items are selected using `ProSelect()` or are obtained from

the selection buffer while Creo Parametric is in the Creo Simulate Environment. The following table lists the selectable items and their `ProSelect()` filter strings:

| Item Type  | ProSelect() Filter String | Model Item Type           |
|------------|---------------------------|---------------------------|
| Load       | sim_load*                 | PRO_SIMULATION_LOAD       |
| Constraint | sim_load*                 | PRO_SIMULATION_CONSTRAINT |
| Beam       | sim_beam                  | PRO_SIMULATION_BEAM       |
| Spring     | sim_spring                | PRO_SIMULATION_SPRING     |
| Gap        | sim_gap                   | PRO_SIMULATION_GAP        |
| Mass       | sim_mass                  | PRO_SIMULATION_MASS       |
| Shell      | sim_shell                 | PRO_SIMULATION_SHELL      |
| Shell pair | sim_shlpair               | PRO_SIMULATION_SHELL_PAIR |
| Weld       | sim_weld                  | PRO_SIMULATION_WELD       |
| Interface  | sim_connect               | PRO_SIMULATION_INTERFACE  |

\*Interactive selection using this filter will by default allow the user to select both loads and constraints. Use the `ProSelect()` filters if you desire to only allow selection of one of these types.

## Example 1: Interactively Selecting and Deleting a Creo Simulate Item

The sample code in the file `PTMechExDelete.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_mech_examples/pt_mech_ex_src` shows how to select a Creo Simulate item interactively and delete it.

## Accessing Creo Simulate Items

The functions described in this section allow access to Creo Simulate items in Creo Parametric.

Functions Introduced:

- **ProSolidMechitemVisit()**
- **ProMechitemNameGet()**
- **ProMechitemStatusGet()**
- **ProMechitemFilterAction()**
- **ProMechitemVisitAction()**

The Creo Simulate item is a derivative of the structure `ProModelitem` and is defined as

```
typedef struct pro_model_item
{
 ProType type;
 int id;
 ProMdl owner;
}ProMechItem;
```

The function `ProSolidMechitemVisit()` traverses the Creo Simulate items in a specified model. This function allows you to specify the type of item to be located, or optionally all item types can be visited.

The function `ProMechitemNameGet()` returns the name of the Creo Simulate item.

The function `ProMechitemStatusGet()` returns the visibility status of the item in the current Creo Simulate environment.

The function `ProMechitemFilterAction()` is used to filter Creo Simulate items for visiting them.

The function `ProMechitemVisitAction()` is used to visit a Creo Simulate item.

## Creo Simulate Object References

References to specific Creo Simulate items are contained within the Creo Simulate object references structure. This structure is represented in Creo TOOLKIT by the opaque handle, `ProMechObjectref`.

Functions Introduced:

- **ProMechobjectrefAlloc()**
- **ProMechobjectrefTypeGet()**
- **ProMechobjectrefTypeSet()**
- **ProMechobjectrefIdGet()**
- **ProMechobjectrefIdSet()**
- **ProMechobjectrefPathGet()**
- **ProMechobjectrefPathSet()**
- **ProMechobjectrefFree()**
- **ProMechobjectrefProarrayFree()**

The function `ProMechobjectrefAlloc()` allocates memory for the Creo Simulate object references handle.

The function `ProMechobjectrefTypeGet()` returns the type of the specified Creo Simulate object. The output argument *type* is one of the `PRO_SIMULATION*` types.

---

The function `ProMechobjectrefTypeSet()` sets the type of the Creo Simulate object.

The function `ProMechobjectrefIdGet()` obtains the ID of the specified Creo Simulate object.

The function `ProMechobjectrefIdSet()` sets the ID of the specified Creo Simulate object.

The function `ProMechobjectrefPathGet()` returns the complete path of the Creo Simulate object reference from the root assembly to the part or assembly that owns the specified Creo Simulate object.

The function `ProMechobjectrefPathSet()` sets the complete path for the Creo Simulate object reference.

Use the function `ProMechobjectrefFree()` to release the memory assigned to the Creo Simulate object reference handle.

Use the function `ProMechobjectrefProarrayFree()` to release the memory assigned to a `ProArray` of Creo Simulate object reference handles.

## Geometric References

Creo Simulate items use a geometric reference structure to contain references to Creo Parametric geometry items. This structure is represented in Creo TOOLKIT by the opaque handle `ProMechGeomref`.

Functions Introduced:

- **`ProMechgeomrefAlloc()`**
- **`ProMechgeomrefTypeGet()`**
- **`ProMechgeomrefSubtypeGet()`**
- **`ProMechgeomrefIdGet()`**
- **`ProMechgeomrefPathGet()`**
- **`ProMechgeomrefFree()`**
- **`ProMechgeomrefProarrayFree()`**
- **`ProMechgeomrefTypeSet()`**
- **`ProMechgeomrefSubtypeSet()`**
- **`ProMechgeomrefIdSet()`**
- **`ProMechgeomrefPathSet()`**

The function `ProMechgeomrefAlloc()` allocates memory for the geometric entity. The function returns a handle to the geometric entity.

The function `ProMechgeomrefTypeGet()` returns the *type* for the specified geometric entity. The output argument *type* can have one of the following values:

- 
- PRO\_MECH\_POINT—Specifies a point.
  - PRO\_MECH\_EDGE—Specifies an edge.
  - PRO\_MECH\_SURFACE—Specifies a surface.
  - PRO\_MECH\_VERTEX—Specifies a vertex.
  - PRO\_MECH\_QUILT—Specifies a quilt.
  - PRO\_MECH\_BOUNDARY—Specifies a boundary. This type is valid for all surfaces.
  - PRO\_MECH\_CURVE—Specifies a curve.
  - PRO\_MECH\_MODEL—Specifies a model. This type is valid for all parts and assemblies.
  - PRO\_MECH\_AXIS—Specifies the axis.
  - PRO\_MECH\_COORD\_SYSTEM—Specifies the coordinate system.
  - PRO\_MECH\_LAYER—Specifies a layer.
  - PRO\_MECH\_VOLUME—Specifies a set of associated surfaces that visually represents an entity with volume.
  - PRO\_MECH\_INT\*—Specifies the datum reference features that store the design intent objects. Intent objects are families of associated points, curves, edges, or surfaces that logically define boundaries of geometry created or modified by a feature. The types of datum reference features available are:
    - PRO\_MECH\_INT\_PNT—Specifies intent datum point references.
    - PRO\_MECH\_INT\_CURVE—Specifies intent curve references.
    - PRO\_MECH\_INT\_EDGE—Specifies intent edge references.
    - PRO\_MECH\_INT\_SURFACE—Specifies intent surface references.
  - PRO\_MECH\_FEAT—Specifies the references to a Weld Feature. The weld feature should be of type:
    - Groove or Fillet
    - A surface weld
  - PRO\_MECH\_COSMETIC—Specifies a cosmetic entity that is created as a container for lattice beams or walls. The cosmetic entities are created by simplified lattice features, and also by features that intersect or copy the lattices, such as extrude and mirror features.
  - PRO\_MECH\_BODY—Specifies a body.

The function `ProMechgeomrefTypeSet()` sets the type of the geometric entity.

---

The function `ProMechgeomrefSubtypeGet()` returns the subtypes of the specified geometric entity. Only certain types of geometric entities require subtypes. The geometric entity types and their respective subtypes are as follows:

- `PRO_MECH_POINT`
  - `PRO_MECH_POINT_SINGLE`—Specifies the placement of a point at any location.
  - `PRO_MECH_POINT_FEATURE`—Specifies the placement of a point along a surface.
  - `PRO_MECH_POINT_PATTERN`—Specifies the placement of a point along a curve.
- `PRO_MECH_VERTEX`
  - `PRO_MECH_VERTEX_EDGE_START`—Specifies the start point of the referenced edge.
  - `PRO_MECH_VERTEX_EDGE_END`—Specifies the end point of the referenced edge.
- `PRO_MECH_COORD_SYSTEM`
  - `PRO_MECH_CSYS_CARTESIAN`—Specifies a Cartesian coordinate system.
  - `PRO_MECH_CSYS_CYLINDRICAL`—Specifies a cylindrical coordinate system.
  - `PRO_MECH_CSYS_SPHERICAL`—Specifies a spherical coordinate system.
- `PRO_MECH_SURFACE`
  - `PRO_MECH_SURFACE_NORMAL`—Specifies that the surface reference uses the standard normal direction.
  - `PRO_MECH_SURFACE_REVERSED`—Specifies that the surface reference uses the standard normal direction.
- `PRO_MECH_CURVE`
  - `PRO_MECH_CURVE_NORMAL`—Specifies that the curve proceeds in the default direction (from  $t=0$  to  $t=1$ ).
  - `PRO_MECH_CURVE_REVERSED`—Specifies that the curve reference uses the reverse direction of the curve.
- `PRO_MECH_EDGE`
  - `PRO_MECH_EDGE_SURF_0`
  - `PRO_MECH_EDGE_SURF_1`

- `PRO_MECH_FEAT`
  - `PRO_MECH_FEAT_3D_LATT`—Specifies a 3D lattice.
  - `PRO_MECH_FEAT_2P5D_LATT`—Specifies a 2.5D lattice.

The function `ProMechgeomrefSubtypeSet()` sets the subtypes for the specified geometric entity.

The function `ProMechgeomrefIdGet()` returns the ID of the specified entity.

The function `ProMechgeomrefIdSet()` sets the ID of the specified entity.

The function `ProMechgeomrefPathGet()` returns the complete path of the assembly-component references from the root assembly to the part or assembly that owns the specified geometric reference entity.

The function `ProMechgeomrefPathSet()` sets the complete path of the assembly-component references.

Use the function `ProMechgeomrefFree()` to free the geometric reference entity from the memory.

Use the function `ProMechgeomrefProarrayFree()` to free the array of geometric entities from the memory.

## Y-directions

Several types of Creo Simulate items require a Y-direction (indicating a direction governing the properties of the item). In Creo TOOLKIT, Y-directions are represented using the opaque handle `ProMechYDirection`. The functions described in this section provide access to the y-direction handle.

Functions Introduced:

- **`ProMechydirectionAlloc()`**
- **`ProMechydirectionTypeGet()`**
- **`ProMechydirectionCsysGet()`**
- **`ProMechydirectionCsysSet()`**
- **`ProMechydirectionReferenceGet()`**
- **`ProMechydirectionReferenceSet()`**
- **`ProMechydirectionVectorGet()`**
- **`ProMechydirectionVectorSet()`**
- **`ProMechydirectionFree()`**

The function `ProMechydirectionAlloc()` allocates memory for the y-direction handle.

---

The function `ProMechydirectionTypeGet()` returns the type of the y-direction. Pass the y-direction handle as the input to this function. The output value *type* can have the following values:

- `PRO_MECH_YDIR_VECTOR`—Specifies a direction vector.
- `PRO_MECH_YDIR_REF`—Specifies a referenced coordinate system.
- `PRO_MECH_YDIR_CSYS`—Specifies a world coordinate system.

The function `ProMechydirectionCsysGet()` returns the coordinate system if the specified y-direction handle is of type `PRO_MECH_YDIR_CSYS`.

The function `ProMechydirectionCsysSet()` sets the coordinate system for the specified y-direction handle. Calling this function changes the Y-direction type to the appropriate type and discards any data related to its previous type.

The function `ProMechydirectionReferenceGet()` returns the reference entity if the specified y-direction handle is of type `PRO_MECH_YDIR_REF`.

The function `ProMechydirectionReferenceSet()` sets the reference entity for the specified y-direction handle. Calling this function changes the Y-direction type to the appropriate type and discards any data related to its previous type.

The function `ProMechydirectionVectorGet()` returns the vector direction if the specified y-direction handle is of type `PRO_MECH_YDIR_VECTOR`.

The function `ProMechydirectionVectorSet()` sets the vector for the specified y-direction handle. Calling this function changes the Y-direction type to the appropriate type and discards any data related to its previous type.

Use the function `ProMechydirectionFree()` to free the y-direction handle.

## Functions

The functions described in this section provide access to the data and contents of Creo Simulate function items.

Function items use the `ProType` field in the `ProMechitem` structure as `PRO_SIMULATION_FUNCTION`.

Functions Introduced:

- **`ProMechfuncCsysGet()`**
- **`ProMechfuncCsysSet()`**
- **`ProMechfuncDataGet()`**
- **`ProMechfuncDataSet()`**
- **`ProMechfuncDescriptionGet()`**
- **`ProMechfuncDescriptionSet()`**

- 
- **ProMechfuncVartypeGet()**
  - **ProMechfuncVartypeSet()**
  - **ProMechfuncdataTypeGet()**
  - **ProMechfuncdataTypeSet()**
  - **ProMechfuncdataExpressionGet()**
  - **ProMechfuncdataExpressionSet()**
  - **ProMechfuncdataFuncvalueinterpGet()**
  - **ProMechfuncdataFuncvalueinterpSet()**
  - **ProMechfuncdataIndependentvarGet()**
  - **ProMechfuncdataIndepvarinterpGet()**
  - **ProMechfuncdataIndepvarinterpSet()**
  - **ProMechfuncdataMirrordeflectionflagGet()**
  - **ProMechfuncdataMirrordeflectionflagSet()**
  - **ProMechfuncdataFuncTableGet()**
  - **ProMechfuncdataFuncTableSet()**
  - **ProMechtableentryFunctionvalueGet()**
  - **ProMechtableentryFunctionvalueSet()**
  - **ProMechtableentryIndependentvarGet()**
  - **ProMechtableentryIndependentvarSet()**
  - **ProMechfuncdataAlloc()**
  - **ProMechtableentryAlloc()**
  - **ProMechtableentryFree()**
  - **ProMechtableentryProarrayFree()**
  - **ProMechfuncdataFree()**

The function **ProMechfuncCsysGet()** gets the reference co-ordinate system for the specified Creo Simulate function item. Use the function **ProMechfuncCsysSet()** to set the reference co-ordinate system for the specified Creo Simulate function item.

The function **ProMechfuncDataGet()** returns the handle to the function data of the Creo Simulate item. Use the function **ProMechfuncDataSet()** to set the value of the function data from the Creo Simulate function item

The function **ProMechfuncDescriptionGet()** returns the description of the Creo Simulate function item. Use the function **ProMechfuncDescriptionSet()** to set the function description of the Creo Simulate item

---

The function `ProMechfuncdataVartypeGet()` gets the function variation type of the Creo Simulate item. Use the function `ProMechfuncdataVartypeSet()` to set the function variation type for the Creo Simulate item.

The function variation types are defined by the enumerated type `ProMechfuncVarType`, which has the following values:

- `PRO_MECH_FUNC_UNIVERSAL`—Specifies the default function type for the load.
- `PRO_MECH_FUNC_COORD`—Specifies the load as a function of the current coordinate system.
- `PRO_MECH_FUNC_TIME`—Specifies the load as a function of time.
- `PRO_MECH_FUNC_TEMPERATURE`—Specifies the load as a function of temperature.
- `PRO_MECH_FUNC_DEFLECTION`—Specifies the load as a function of deflection.
- `PRO_MECH_FUNC_ARCLENGTH`—Specifies the load as a function of arc length.
- `PRO_MECH_FUNC_COORDS_TIME`—Specifies the load as a combination of spatial (function of current coordinate system) and temporal (function of time) functions.
- `PRO_MECH_FUNC_ARCLENGTH_TIME`—Specifies the load as a combination of spatial (function of arc length) and temporal (function of time) functions.

The function `ProMechfuncdataTypeGet()` determines the type of the function used to create the Creo Simulate item. Specify the handle to the function data as the input for this function.

The output argument *value* specifies the type of the function and can have the following values:

- `PRO_MECH_FUNCTION_SYMBOLIC`—Specifies a symbolic expression for a function.
- `PRO_MECH_FUNCTION_TABLE`—Specifies a function created using data from an interpolation table.

Use the function `ProMechfuncdataTypeSet()` to set the function type to be used to create the Creo Simulate item.

The function `ProMechfuncdataExpressionGet()` returns the symbolic expression for the specified symbolic function. Use the function `ProMechfuncdataExpressionSet()` to set the symbolic expression for the specified symbolic function.

---

The function `ProMechfuncdataFuncvalueinterpGet()` specifies the interpolation method used for the function value of the tabular function. The output argument *value* can have the following values:

- `PRO_MECH_TABLE_LINEAR`—This method linearly interpolates the variable between the values.
- `PRO_MECH_TABLE_LOGARITHMIC`—This method linearly interpolates the log of the variable between values.

Use the function `ProMechfuncdataFuncvalueinterpSet()` to set the interpolation method for the function value of the tabular function.

The function `ProMechfuncdataIndependentvarGet()` returns the type of the independent variable for the specified tabular function. The independent variable corresponds to the coordinate system axes and has the following values:

- `PRO_MECH_INDEP_VAR_X`—Specifies the value of the X-axis in the Cartesian coordinate system.
- `PRO_MECH_INDEP_VAR_Y`—Specifies the value of the Y-axis in Cartesian coordinate system
- `PRO_MECH_INDEP_VAR_Z`—Specifies the value of the Z-axis in the Cartesian or cylindrical coordinate system.
- `PRO_MECH_INDEP_VAR_R`—Specifies the value of the radius in a cylindrical or spherical coordinate system.
- `PRO_MECH_INDEP_VAR_THETA`—Specifies the value of the angle in a cylindrical or spherical coordinate system.
- `PRO_MECH_INDEP_VAR_PHI`—Specifies the value of the second angle in a spherical coordinate system.
- `PRO_MECH_INDEP_VAR_TIME`—Specifies the value of the time variable (for a time-dependent function).

Use the function `ProMechfuncdataIndependentvarSet()` to set the independent variable type for the specified tabular function.

The function `ProMechfuncdataIndepvarinterpGet()` specifies the interpolation method used for the independent variable of the tabular function. Use the function `ProMechfuncdataIndepvarinterpSet()` to set the interpolation method to be used for the independent variable of the tabular function.

The function `ProMechfuncdataMirrordeflectionflagGet()` gets the value of the mirror flag for negative deflections from the function data.

Use the function `ProMechfuncdataMirrordeflectionflagSet()` to set the value of the mirror flag for the negative deflections in the function data

---

The function `ProMechfuncdataFuncTableGet()` returns an array of table entries for the specified tabular function. Free the array of table entries using the function `ProMechtablentryProarrayFree()`. Use the function `ProMechfuncdataFuncTableSet()` to set an array of table entries for the specified tabular function.

The function `ProMechtablentryFunctionvalueGet()` returns the value of the specified function in the table entry. Use the function `ProMechtablentryFunctionvalueSet()` to set the value of the specified function in the table entry.

The function `ProMechtablentryIndependentvarGet()` returns the value for the specified independent variable in the table entry. Use the function `ProMechtablentryIndependentvarSet()` to set the value for the specified independent variable in the table entry.

Use the function `ProMechfuncdataFree()` to free the array containing the function data.

## Creo Simulate Expressions

Most of the `ProMech*Get()` functions described in the following sections return mathematical expressions of the type `ProMechExpression`. This mathematical expression specifies a numeric or relational value, which is expressed and stored as a string. Use the function `ProMathExpressionEvaluate()` to evaluate such a mathematical expression. Refer to the [Evaluating Mathematical Expressions for a Solid on page 109](#) section in the [Core: Solids, Parts, and Materials on page 95](#) section for more information on this function.

## Accessing the Properties used for Loads and Constraints

Loads and constraints use complicated structures to mirror the number and type of properties available in the user interface. Several structures recur in different types of loads and constraints, and are described by the following table:

| Property                                                                                            | Creo TOOLKIT Opaque Handle           |
|-----------------------------------------------------------------------------------------------------|--------------------------------------|
| Vectored value—Specifies a value applied in a specified direction.                                  | <code>ProMechvectoredvalue</code>    |
| Direction vector—Represents a defined direction.                                                    | <code>ProMechdirvector</code>        |
| Value—Specifies a scalar value potentially affected by a defined variation.                         | <code>ProMechvalue</code>            |
| Variation—Specifies the components of a defined variation (either by function or by interpolation). | <code>ProMechvariation</code>        |
| Interpolation point—Specifies an individual interpolation point used to define a variation.         | <code>ProMechinterpolationpnt</code> |

---

The types specified in the preceding table and the functions required to access these types are defined in the header file `ProMechValue.h` and `ProMechValueSet.h`.

Functions Introduced:

- **ProMechvectoredvalueAlloc**
- **ProMechvectoredvalueDirectiontypeGet()**
- **ProMechvectoredvalueDirectiontypeSet()**
- **ProMechvectoredvalueDirectionvectorGet()**
- **ProMechvectoredvalueDirectionvectorSet()**
- **ProMechvectoredvalueMagnitudeGet()**
- **ProMechvectoredvalueMagnitudeSet()**
- **ProMechvectoredvaluePointsGet()**
- **ProMechvectoredvaluePointsSet()**
- **ProMechvectoredvalueFree()**
- **ProMechdirvectorAlloc()**
- **ProMechdirvectorComponentsGet()**
- **ProMechdirvectorComponentsSet()**
- **ProMechdirvectorCsysGet()**
- **ProMechdirvectorCsysSet()**
- **ProMechdirvectorVariationGet()**
- **ProMechdirvectorVariationSet()**
- **ProMechdirvectorFree()**
- **ProMechvalueAlloc()**
- **ProMechvalueValueGet()**
- **ProMechvalueValueSet()**
- **ProMechvalueVariationGet()**
- **ProMechvalueVariationSet()**
- **ProMechvalueFree()**
- **ProMechvalueProarrayFree()**
- **ProMechvariationAlloc()**
- **ProMechvariationTypeGet()**
- **ProMechvariationFunctionidGet()**
- **ProMechvariationFunctionidSet()**
- **ProMechvariationInterpolationGet()**

- 
- **ProMechvariationInterpolationSet()**
  - **ProMechvariationFree()**
  - **ProMechinterpolationpntAlloc()**
  - **ProMechinterpolationpntPointGet()**
  - **ProMechinterpolationpntPointSet()**
  - **ProMechinterpolationpntMagnitudeGet()**
  - **ProMechinterpolationpntMagnitudeSet()**
  - **ProMechinterpolationpntProarrayFree()**
  - **ProMechinterpolationpntFree()**
  - **ProMechexternalfielddataAlloc()**
  - **ProMechexternalfielddataCsysGet()**
  - **ProMechexternalfielddataCsysSet()**
  - **ProMechexternalfielddataFileGet()**
  - **ProMechexternalfielddataFileSet()**
  - **ProMechexternalfielddataFree()**
  - **ProMechvariationExternalfielddataGet()**
  - **ProMechvariationExternalfielddataSet()**

The function `ProMechvectoredvalueAlloc()` allocates memory for the directed value.

The function `ProMechvectoredvalueDirectiontypeGet()` returns the method used to specify the direction for the vectored value. The output argument *type* can have one of the following values:

- `PRO_MECH_DIRECTION_BY_VECTOR`—The vector is defined by specifying a direction.
- `PRO_MECH_DIRECTION_BY_2_POINTS`—The direction of the vector is specified using two points.

The function `ProMechvectoredvalueDirectiontypeSet()` sets the direction for the vectored value.

The function `ProMechvectoredvalueDirectionvectorGet()` returns the direction of vector for the vectored load of type `PRO_MECH_DIRECTION_BY_VECTOR`.

The function `ProMechvectoredvalueDirectionvectorSet()` sets the direction vector.

---

The function `ProMechvectoredvalueMagnitudeGet()` specifies the magnitude of the vectored load. If the value of the magnitude is positive, the load acts in the same direction as the vector and if the value of the magnitude is negative, the load acts in the direction opposite to that of the vector.

The function `ProMechvectoredvalueMagnitudeSet()` sets the magnitude of the vectored load.

The function `ProMechvectoredvaluePointsGet()` returns an array of points that define the direction of the vector if type of the vector is `PRO_MECH_DIRECTION_BY_2_POINTS`. Use the function `ProMechvectoredvaluePointsSet()` to set the array of points.

Use the function `ProMechvectoredvalueFree()` to free the memory containing the directed value.

The function `ProMechdirvectorComponentsGet()` returns the components of the vector for each coordinate direction. Use the function `ProMechdirvectorComponentsSet()` to set the component values of the vector.

The function `ProMechdirvectorCsysGet()` returns the coordinate system used to calculate the vector. Use the function `ProMechdirvectorCsysSet()` to set the coordinate system.

The function `ProMechdirvectorVariationGet()` specifies the spatial or time-based variation applied to the direction vector. Use the function `ProMechdirvectorVariationSet()` to set the spatial variation to the direction vector.

The function `ProMechvalueValueGet()` returns the expression used to specify the load or constraint value. Use the function `ProMechvalueValueSet()` to set the load or constraint value.

The function `ProMechvalueVariationGet()` returns the spatial or time-based variation assigned to the specified value. Use the function `ProMechvalueVariationSet()` to set the spatial variation.

The function `ProMechvariationTypeGet()` returns the variation type for the specified variation handle. The output argument *type* can have one of the following values:

- `PRO_MECH_VARIATION_UNIFORM`—Specifies that the variation of the load is uniform over the entity.
- `PRO_MECH_VARIATION_INTERPOLATION`—Specifies that the load varies along the entity as defined by the interpolation points.
- `PRO_MECH_VARIATION_FUNCTION`—Indicates that the variation is defined by specifying a function that is used to vary the property.

---

The function `ProMechvariationFunctionidGet()` returns the function id for the specified variation handle if the variation is of type `PRO_MECH_VARIATION_FUNCTION`. The function id is always extracted from the same model from where the varied value was obtained. Use the function `ProMechvariationFunctionidSet()` to set the function id for the variation.

The function `ProMechvariationInterpolationGet()` returns an array of interpolation points for the specified variation handle if the variation is of type `PRO_MECH_VARIATION_INTERPOLATION`. Use the function `ProMechvariationInterpolationSet()` to set the interpolation points for the specified variation.

The function `ProMechinterpolationpntAlloc()` allocates memory for the interpolation points.

The function `ProMechinterpolationpntPointGet()` specifies the geometric entity associated with the specified interpolation point. Use the function `ProMechinterpolationpntPointSet()` to set the geometric entity.

The function `ProMechinterpolationpntMagnitudeGet()` returns the magnitude of the load at the specified interpolation point. Use the function `ProMechinterpolationpntMagnitudeSet()` to set the magnitude of the load.

Use the function `ProMechinterpolationpntFree()` to free the memory containing the interpolation point. Use `ProMechinterpolationpntProarrayFree()` as a shortcut to free an entire array of interpolation points.

The function `ProMechexternalfielddataAlloc()` allocates memory for the external data structure.

The function `ProMechexternalfielddataCsysGet()` returns the reference coordinate system for the external field data. Use the function `ProMechexternalfielddataCsysSet()` to set the reference coordinate system for the external field data.

The function `ProMechexternalfielddataFileGet()` returns the information related to the external (FEM Neutral Format) FNF file to be imported for the external field. Use the function `ProMechexternalfielddataFileSet()` to set the path to the fnf file.

The function `ProMechvariationExternalfielddataGet()` returns the external field assigned for variation of a value.

Use the function `ProMechvariationExternalfielddataSet` to set the external field assigned for variation of a value.

---

## Creo Simulate Loads

Loads are used to simulate forces that act on the model in the real world. Once you create the loads, you can examine the response of the mechanism to the loads.

### Accessing Creo Simulate Loads

The functions described in this section provide a handle to the to the different types of Creo Simulate loads. Loads use the `ProType` field in the `ProMechItem` structure as `PRO_SIMULATION_LOAD`.

Functions Introduced:

- **ProMechloadTypeGet()**
- **ProMechloadForcedataGet()**
- **ProMechloadPressuredataGet()**
- **ProMechloadBearingdataGet()**
- **ProMechloadCentrifugaldataGet()**
- **ProMechloadGravitydataGet()**
- **ProMechloadStructtempdataGet()**
- **ProMechloadMecttempdataGet()**
- **ProMechloadHeatdataGet()**
- **ProMechloadReferencesGet()**
- **ProMechloadLoadsetsGet()**

The function `ProMechLoadTypeGet()` returns the type of load contained in the structure `ProModelItem`.

The output argument *value* can have one of the following values:

- `PRO_MECH_LOAD_FORCE`—Specifies a force load. Use the function `ProMechloadForcedataGet()` to access the data and contents of the force load structure.
- `PRO_MECH_LOAD_PRESSURE`—Specifies a pressure load. Use the function `ProMechloadPressuredataGet()` to access the data and contents of the pressure load structure.
- `PRO_MECH_LOAD_BEARING`—Specifies a bearing load. Use the function `ProMechloadBearingdataGet()` to access the data and contents of the bearing load structure.
- `PRO_MECH_LOAD_CENTRIFUGAL`—Specifies a centrifugal load. Use the function `ProMechloadCentrifugaldataGet()` to access the data and contents of the centrifugal load structure.

- 
- `PRO_MECH_LOAD_GRAVITY`—Specifies a gravity load. Use the function `ProMechloadGravitydataGet()` to access the data and contents of the gravity load structure.
  - `PRO_MECH_LOAD_STRUCTURAL_TEMPERATURE`—Specifies a temperature load. Use the function `ProMechloadStructtempdataGet()` to access the data and contents of the temperature load.
  - `PRO_MECH_LOAD_MECH_TEMPERATURE`—Specifies a Mechanical temperature load. Use the function `ProMechloadMecttempdataGet()` to access the data and contents of the mechanical temperature load.
  - `PRO_MECH_LOAD_HEAT`—Specifies a heat load. Use the function `ProMechloadHeatdataGet()` to access the data and contents of the heat load.

---

 **Note**

From Creo Parametric onward, the load types `PRO_MECH_LOAD_GLOBAL_TEMPERATURE` and `PRO_MECH_LOAD_EXTERNAL_TEMPERATURE` have been deprecated. The functions `ProMechloadGlobaltempdataGet()` and `ProMechloadExttempdataGet()` have also been deprecated. The global temperature loads and external temperature are converted to equivalent structural temperature loads. Use the function `ProMechloadStructtempdataGet()` instead to access the data and contents of the temperature load.

---

The function `ProMechloadReferencesGet()` returns the geometric references. It specifies the geometric references used to define the load.

The function `ProMechloadLoadsetsGet()` returns the load set(s) that contain the given load. (Currently, Creo Simulate allows a load to be assigned to only one set).

## Modifying the Creo Simulate Loads

The functions in this section assign load data to a load in the model. The load should have been created already using `ProMechitemCreate()`. Changes made via these functions will not be reflected in the user interface until you call the function `ProMechitemUpdateComplete()`.

## Note

Once a load has been created and updated successfully, its load type cannot be changed.

---

The following is the procedure to create a new user-visible load:

1. Create the load using `ProMechitemCreate()`
2. Set the load references using `ProMechloadReferencesSet()`.
3. Set the load type-specific data using one of the `ProMechload*dataSet()` functions.
4. Assign the load to a load set using `ProMechloadLoadsetAssign()`.
5. Check the status of the load using `ProMechitemStatusGet()`.
6. Complete the load set using `ProMechitemUpdateComplete()`.

Functions Introduced:

- **ProMechloadForcedataSet()**
- **ProMechloadPressuredataSet()**
- **ProMechloadBearingdataSet()**
- **ProMechloadCentrifugaldataSet()**
- **ProMechloadGravitydataSet()**
- **ProMechloadStructtempdataSet()**
- **ProMechloadMecttempdataSet()**
- **ProMechloadHeatdataSet()**
- **ProMechloadReferencesSet()**
- **ProMechloadLoadsetAssign()**

Use the function `ProMechloadForcedataSet()` to set the data and the contents of the force load structure.

Use the function `ProMechloadPressuredataSet()` to set the data and contents of the pressure load structure.

Use the function `ProMechloadBearingdataSet()` to set the data and contents of the pressure load structure.

Use the function `ProMechloadCentrifugaldataSet()` to set the data and contents of the centrifugal load structure.

Use the function `ProMechloadGravitydataSet()` to set the data for the gravity load structure.

---

Use the function `ProMechloadStructtempdataSet()` to set the data of the temperature load.

Use the function `ProMechloadMecttempdataSet()` to set the data of the mechanical temperature load.

Use the function `ProMechloadHeatdataSet()` to set the data and contents of the heat load.

Use the function `ProMechloadReferencesSet()` to set the geometric references for the load. This must be a valid set of references for the load type.

Use the function `ProMechloadLoadsetAssign()` to assign a load to a particular loadset.

---

 **Note**

The functions `ProMechloadGlobaltempdataSet()` and `ProMechloadExttempdataSet()` have been deprecated. From Creo Parametric onward, the global temperature loads and external temperature are converted to equivalent structural temperature loads. Use the function `ProMechloadStructtempdataSet()` instead to set the data for the temperature load.

---

## Example 2: Modifying Magnitude of Force or Pressure Load

The sample code in the file `PTMechExMagChange.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_mech_examples/pt_mech_ex_src` shows how to modify the magnitude of a force or pressure load.

## Force and Moment Loads

The functions described in this section provide read access to the data and contents of Creo Simulate force loads.

Functions Introduced:

- **`ProMechforcedataAlloc()`**
- **`ProMechforcedataTypeGet()`**
- **`ProMechforcedataTypeSet()`**
- **`ProMechforcedataForceGet()`**
- **`ProMechforcedataAxialForceIgnoreflagGet()`**
- **`ProMechforcedataAxialForceIgnoreflagSet()`**

- **ProMechforcedataForceSet()**
- **ProMechforcedataMomentGet()**
- **ProMechforcedataAxialMomentIgnoreflagGet()**
- **ProMechforcedataAxialMomentIgnoreflagSet()**
- **ProMechforcedataMomentSet()**
- **ProMechforcedataRefpntGet()**
- **ProMechforcedataRefpntSet()**
- **ProMechforcedataFree()**

The function `ProMechforcedataAlloc()` allocates memory for the Creo Simulate force load data.

The function `ProMechforcedataTypeGet()` specifies the distribution of the load over the selected entity. The output argument *value* can have one of the following values:

- `PRO_MECH_FORCE_AT_POINT`—Specifies a total load applied to a single point.
- `PRO_MECH_FORCE_TOTAL`—Specifies a load distributed along the length or area of the entity such that the integral of the load over the selected entity equals the total prescribed value.
- `PRO_MECH_FORCE_TOTAL_AT_POINT`—Specifies a Total Load At Point (TLAP) load.
- `PRO_MECH_FORCE_PER_UNIT`—Specifies a load applied to each unit that makes up the selected entity.
- `PRO_MECH_FORCE_TLAP_UNASSOCIATED`—Specifies that the Total Load At Point (TLAP) loads are un-associated from the selected entities in the model.
- `PRO_MECH_FORCE_TBLAP`—Specifies a Total Bearing Load At Point (TBLAP) for cylindrical surfaces or curves.

Use function `ProMechforcedataTypeSet()` to set the type of the force load.

The function `ProMechforcedataForceGet()` returns the magnitude and direction of the force applied to a geometric entity.

The function `ProMechforcedataAxialForceIgnoreflagGet()` returns a boolean flag indicating whether the axial force is ignored in case of a Total Bearing Load At Point (TBLAP).

`ProMechforcedataAxialForceIgnoreflagSet()` sets a boolean flag indicating whether the axial force is to be applied in case of a Total Bearing Load At Point (TBLAP).

---

The function `ProMechforcedataForceSet()` sets the force component for the load data.

The function `ProMechforcedataMomentGet()` returns the magnitude and direction of the moment applied to a geometric entity.

`ProMechforcedataAxialMomentIgnoreflagGet()` returns a boolean flag indicating whether the axial moment applied is ignored in case of a Total Bearing Load At Point (TBLAP).

`ProMechforcedataAxialMomentIgnoreflagSet()` sets a boolean flag indicating whether the axial moment is to be applied in case of a Total Bearing Load At Point (TBLAP).

The function `ProMechforcedataMomentSet()` sets the moment component for the load data.

The function `ProMechforcedataRefpntGet()` returns the reference point for the specified load if the load was applied at a given point. Use the function `ProMechforcedataRefpntSet()` to set the reference point.

The function `ProMechforcedataFree()` frees the memory of the force load data handle.

## Pressure, Gravity, and Bearing Loads

The functions described in this section provide read access to the data and contents of the Creo Simulate pressure, gravity, and bearing loads.

Functions Introduced:

- **`ProMechpressuredataAlloc()`**
- **`ProMechpressuredataValueGet()`**
- **`ProMechpressuredataValueSet()`**
- **`ProMechpressuredataFree()`**
- **`ProMechbearingdataValueGet()`**
- **`ProMechbearingdataValueSet()`**
- **`ProMechbearingdataFree()`**
- **`ProMechgravitydataAlloc()`**
- **`ProMechgravitydataValueGet()`**
- **`ProMechgravitydataValueSet()`**
- **`ProMechgravitydataFree()`**

The function `ProMechpressuredataAlloc()` allocates memory for the Creo Simulate pressure load data.

The function `ProMechpressuredataValueGet()` returns the value of the pressure load.

---

The function `ProMechpressuredataValueSet()` sets the value of the pressure load.

The function `ProMechpressuredataFree()` frees the memory of the pressure load data handle.

The function `ProMechbearingdataValueGet()` returns the value of the bearing load.

The function `ProMechbearingdataValueSet()` sets the value of the bearing load.

The function `ProMechbearingdataFree()` frees the memory of the bearing load data handle.

The function `ProMechgravitydataAlloc()` allocates memory for the Creo Simulate gravity load data.

The function `ProMechgravitydataValueGet()` returns the value of the gravity load.

The function `ProMechgravitydataValueSet()` sets the value of the gravity load.

The function `ProMechgravitydataFree()` frees the memory of the gravity load data handle.

## Centrifugal Loads

A centrifugal load results due to the rigid body rotation of the model and is applied on the entire model. The functions described in this section provide read access to the data and structure of the Creo Simulate centrifugal loads.

Functions Introduced:

- **ProMechcentrifugaldataAlloc()**
- **ProMechcentrifugaldataVelocityGet()**
- **ProMechcentrifugaldataVelocitySet()**
- **ProMechcentrifugaldataAccelerationGet()**
- **ProMechcentrifugaldataAccelerationSet()**
- **ProMechcentrifugaldataFree()**

The function `ProMechcentrifugaldataAlloc()` allocates memory for the centrifugal load data.

The function `ProMechcentrifugaldataVelocityGet()` returns the magnitude and direction of the angular velocity of the centrifugal load.

The function `ProMechcentrifugaldataVelocitySet()` sets the value of the angular velocity of the centrifugal load.

---

The function `ProMechcentrifugaldataAccelerationGet()` returns the acceleration vector for the centrifugal load. The acceleration vector is the rate of change of the angular velocity vector, and represents a change in magnitude or direction of the angular velocity.

The function `ProMechcentrifugaldataAccelerationSet()` sets the acceleration vector for the centrifugal load.

The function `ProMechcentrifugaldataFree()` releases the memory assigned to the centrifugal load data.

## Temperature Loads

Temperature loads enable you to simulate a temperature change over your model. Temperature loads provide valuable information on how the structure of your model deforms due to a particular temperature change.

## Creo Simulate Temperature Loads

The functions described in this section provide access to the data and contents of Creo Simulate temperature loads.

Functions Introduced:

- **`ProMechtemperaturedataAlloc()`**
- **`ProMechtemperaturedataValueGet()`**
- **`ProMechtemperaturedataValueSet()`**
- **`ProMechtemperaturedataFree()`**

The function `ProMechtemperaturedataAlloc()` allocates memory for the temperature load data.

The function `ProMechtemperaturedataValueGet()` returns a structure that contains the value of the temperature and the spatial variation of the load.

The function `ProMechtemperaturedataValueSet()` sets the value of the temperature and the spatial variation of the load.

The function `ProMechtemperaturedataFree()` releases the memory assigned to the temperature load data.

## Structural Temperature Loads

Structural temperature loads are thermal loads resulting from a temperature change over a geometric entity or a set of geometric entities. This load is applied to curves or surfaces. If the model is an assembly, the structural load can be applied to specific assembly components.

---

The functions described in this section provide access to the data and contents of the Creo Simulate structural temperature loads.

Functions Introduced:

- **ProMechstructtempdataAlloc()**
- **ProMechstructtempdataValueGet()**
- **ProMechstructtempdataValueSet()**
- **ProMechstructtempdataReftempGet()**
- **ProMechstructtempdataReftempSet()**
- **ProMechstructtempdataFree()**

The function `ProMechstructtempdataAlloc()` allocates memory for the structural temperature load data.

The function `ProMechstructtempdataValueGet()` returns a structure containing the temperature applied to the load and the variation of the load.

The function `ProMechstructtempdataValueSet()` sets the value of the structural temperature data.

The function `ProMechstructtempdataReftempGet()` returns the reference temperature of the structural temperature object. The reference temperature is the stress-free temperature for the model.

The function `ProMechstructtempdataReftempSet()` sets the reference temperature of the structural temperature data.

The function `ProMechstructtempdataFree()` releases the memory assigned to structural temperature load data.

---

 **Note**

From Creo Parametric onward, the global and external temperature loads are converted to equivalent structural temperature loads. The functions previously available to access Creo Simulate global and external temperature loads have been deprecated. The structural temperature load functions supersede the global and external temperature load functions.

---

## Global Temperature Loads

A global temperature load specifies a thermal load resulting from a temperature change over the entire model.

---

From Creo Parametric onward, the global temperature loads are converted to equivalent structural temperature loads. The data structure `ProMechglobaltempdata` for global temperature loads in `ProMechLoad.h` has been deprecated. Functions previously available to access Creo Simulate global temperature load have also been deprecated. Use the structural temperature load data structure `ProMechstructtempdata` and the functions that access this data structure instead. For more information on structural load functions, see the section [Structural Temperature Loads on page 1847](#).

The following functions have been deprecated:

- `ProMechglobaltempdataAlloc()`
- `ProMechglobaltempdataReftempGet()`
- `ProMechglobaltempdataReftempSet()`
- `ProMechglobaltempdataValueGet()`
- `ProMechglobaltempdataValueSet()`
- `ProMechglobaltempdataFree()`

## MEC/T Temperature Loads

The MEC/T temperature load applies a temperature load across the entire model based on a temperature field developed from the results of a steady state or transient thermal analysis. The functions described in this section provide read and write access to the data and contents of the MEC/T temperature loads.

Functions Introduced:

- **`ProMechmecttempdataAlloc()`**
- **`ProMechmecttempdataAnalysisidGet()`**
- **`ProMechmecttempdataAnalysisidSet()`**
- **`ProMechmecttempdataLoadsetidGet()`**
- **`ProMechmecttempdataLoadsetidSet()`**
- **`ProMechmecttempdataLoadsetSet()`**
- **`ProMechmecttempdataLoadsetGet()`**
- **`ProMechmecttempdataReftempGet()`**
- **`ProMechmecttempdataReftempSet()`**
- **`ProMechmecttempdataTimestepGet()`**
- **`ProMechmecttempdataTimestepSet()`**
- **`ProMechmecttempdataDesignstudySet()`**
- **`ProMechmecttempdataDesignstudyGet()`**
- **`ProMechmecttempdataFree()`**

---

The function `ProMechmecttempdataAlloc()` allocates memory for the MEC/T temperature data structure.

The function `ProMechmecttempdataAnalysisidGet()` returns the ID of the thermal analysis defined for the model.

The function `ProMechmecttempdataAnalysisidSet()` sets the ID of the thermal analysis.

The function `ProMechmecttempdataLoadsetidGet()` returns the ID of the load set. The load set is applicable only if the MEC/T temperature load is coming from a steady state thermal analysis.

The function `ProMechmecttempdataLoadsetidSet()` sets the ID of the load set.

The function `ProMechmecttempdataLoadsetGet()` returns the load set in the form of the `ProMechObjectref` object for the MEC/T temperature data.

The function `ProMechmecttempdataLoadsetSet()` assigns the load set.

The function `ProMechmecttempdataReftempGet()` returns the reference temperature for the MEC/T temperature data.

The function `ProMechmecttempdataReftempSet()` sets the reference temperature.

The function `ProMechmecttempdataTimestepGet()` returns the time step value if the MEC/T temperature load is coming from a transient thermal analysis.

The function `ProMechmecttempdataTimestepSet()` sets the time step value.

The function `ProMechmecttempdataDesignstudyGet()` returns the name of the design study for the MEC/T temperature load.

The function `ProMechmecttempdataDesignstudySet()` assigns the design study name for the MEC/T temperature load.

The function `ProMechmecttempdataFree()` releases the memory assigned to the MEC/T temperature data structure.

## External Temperature Loads

An external temperature load involves importing an externally calculated or measured temperature field as a temperature load. The external temperature field must contain connectivity of a linear solid element mesh, node locations, and temperature values at the nodes.

From Creo Parametric onward, the external temperature loads are converted to equivalent structural temperature loads. The data structure `ProMechexttempdata` for external temperature loads in `ProMechLoad.h` has been deprecated. Functions previously available to access Creo Simulate

---

external temperature load have also been deprecated. Use the structural temperature load data structure `ProMechstructtempdata` and the functions that access this data structure instead. For more information on structural load functions, see the section [Structural Temperature Loads on page 1847](#)

The following functions are deprecated:

- `ProMechexttempdataAlloc()`
- `ProMechexttempdataReftempGet()`
- `ProMechexttempdataReftempSet()`
- `ProMechexttempdataFemneutralfileGet()`
- `ProMechexttempdataFemneutralfileSet()`
- `ProMechexttempdataFree()`

## Heat Loads

Heat loads are entity loads and can be placed on one or more points, edges, surfaces, components, or volumes. Heat loads provide local heat sources and sinks for the model and can be used to model internal heat generation or flux.

The functions described in this section provide access to the data and contents of the Creo Simulate heat loads.

Functions Introduced:

- **`ProMechheatdataAlloc()`**
- **`ProMechheatdataTypeGet()`**
- **`ProMechheatdataTypeSet()`**
- **`ProMechheatdataValueGet()`**
- **`ProMechheatdataValueSet()`**
- **`ProMechheatdataTemporalvariationGet()`**
- **`ProMechheatdataTemporalvariationSet()`**
- **`ProMechheatdataFree()`**

Functions Superseded:

- `ProMechheatdataTimefunctionidGet()`
- `ProMechheatdataTimefunctionidSet()`

The function `ProMechheatdataAlloc()` allocates memory for the heat load data.

The function `ProMechheatdataTypeGet()` returns the type of distribution for the heat load across the geometric entities. The output argument *type* can have one of the following values:

- `PRO_MECH_HEAT_TOTAL`—Specifies that the heat load is distributed along the length or area of the entity such that the integral of the load over the selected entity equals the total prescribed value.
- `PRO_MECH_HEAT_PER_UNIT`—Specifies that the heat load is applied to each unit that makes up the selected load.
- `PRO_MECH_HEAT_AT_POINT`—Specifies that the heat load is applied to a single point, a feature, or a pattern of points.
- `PRO_MECH_HEAT_NONE`—No heat load type is assigned.

The function `ProMechheatdataTypeSet()` sets the type of heat load.

The function `ProMechheatdataValueGet()` returns the total or distributed heat transfer rate, depending on the distribution option specified for the entities.

The function `ProMechheatdataValueSet()` sets the value of the heat load.

The function `ProMechheatdataTemporalvariationGet()` returns the time variation for the specified heat load.

`ProMechheatdataTemporalvariationSet()` sets the time variation for the specified heat load.

The functions `ProMechheatdataTimefunctionidGet()` and `ProMechheatdataTimefunctionidSet()` have been deprecated. Use the functions `ProMechheatdataTemporalvariationGet()` and `ProMechheatdataTemporalvariationSet()` instead.

The function `ProMechheatdataFree()` releases the memory assigned to the heat load data.

## Creo Simulate Load Sets

A load set is a collection of loads that act together on the model. The functions described in this section provide access to data and contents of the Creo Simulate load set items. Load sets use the `ProType` field in the `ProMechitem` structure as `PRO_SIMULATION_LOAD_SET`.

Functions Introduced:

- **`ProMechloadsetDescriptionGet()`**
- **`ProMechloadsetDescriptionSet()`**
- **`ProMechloadsetLoadsGet()`**
- **`ProMechloadsetTypeGet()`**
- **`ProMechloadLoadsetAssign()`**

The function `ProMechloadsetDescriptionGet()` returns the name and the description of the specified load set.

---

The function `ProMechloadsetDescriptionSet()` sets the description of the specified load set.

The function `ProMechloadsetLoadsGet()` returns an array containing the different loads that are included in the specified load set.

The function `ProMechloadsetTypeGet()` returns the type of the specified load set. The type can be as follows:

- `PRO_MECH_LOADSET_STRUCTURAL`—Specifies a structural load set.
- `PRO_MECH_LOADSET_THERMAL`—Specifies a thermal load set.

Use the function `ProMechloadLoadsetAssign()` to assign a load to a particular loadset.

## Creo Simulate Constraints

To perform analyses on the models you need to apply constraints to at least one area of the model. The constraints are associated with the model geometry and can be applied to a single geometric entity or to multiple entities.

## Accessing the Creo Simulate Constraints

The functions described in this section provide access to the data and contents of the Creo Simulate constraints item. Constraints use the `ProType` field in the `ProMechitem` structure as `PRO_SIMULATION_CONSTRAINTS`.

Functions Introduced:

- **`ProMechconstrTypeGet()`**
- **`ProMechconstrConvectiondataGet()`**
- **`ProMechconstrRadiationdataGet()`**
- **`ProMechconstrRadiationdataSet()`**
- **`ProMechconstrDisplacementdataGet()`**
- **`ProMechconstrSymmetrydataGet()`**
- **`ProMechconstrTemperaturedataGet()`**
- **`ProMechconstrThermalsymmetrydataGet()`**
- **`ProMechconstrReferencesGet()`**
- **`ProMechconstrConstrsetsGet()`**

The function `ProMechconstrTypeGet()` returns the type of constraint contained in the structure `ProModelItem`. The output can have one of the following values:

- `PRO_MECH_CONSTR_CONVECTION`—Specifies a linear convective heat exchange condition for one or more geometric or model entities for thermal

---

mode. Use the function `ProMechconstrConvectiondataGet()` to access the data and contents of this constraint type.

- `PRO_MECH_CONSTR_DISPLACEMENT`—Specifies a displacement constraint for structural mode. Use the function `ProMechconstrDisplacementdataGet()` to access the data and contents of this constraint type.
- `PRO_MECH_CONSTR_SYMMETRY`—Specifies cyclic symmetry for structural mode. Use the function `ProMechconstrSymmetrydataGet()` to access the data and contents of this constraint type.
- `PRO_MECH_CONSTR_RADIATION`—Specifies a thermal radiation exchange between the model surface and the surroundings. Use the function `ProMechconstrRadiationdataGet()` to access the data and contents of radiation constraint type from the Creo Simulate item. The function `ProMechconstrRadiationdataSet()` sets the handle to the data and contents of radiation constraint type from the Creo Simulate item.
- `PRO_MECH_CONSTR_TEMPERATURE`—Specifies a temperature boundary condition for one or more geometric or model entities for thermal mode. Use the function `to()` to access the data and contents of this constraint type.
- `PRO_MECH_CONSTR_SYMMETRY_THERM`—Specifies a cyclic symmetry thermal constraint for thermal mode. Use the function `ProMechconstrThermalsymmetrydataGet()` to access the data and contents of this constraint type.
- `PRO_MECH_CONSTR_INIT_TEMP`—Specifies the initial temperature boundary condition for one or more geometric entities for thermal mode.

The function `ProMechconstrReferencesGet()` returns the geometric references. It specifies the geometric references used to define the constraint.

The function `ProMechconstrConstrsetsGet()` returns the constraint set (s) that contain the given constraint. Currently, Creo Simulate allows a constraint to be assigned to only one set.

## Modifying the Creo Simulate Constraints

The functions in this section assign load data to a constraint in the model. The load should have been already created using `ProMechitemCreate()`. The changes made using these functions will not be reflected in the user interface until you call `ProMechitemUpdateComplete()`.

---

 **Note**

Once a constraint has been created and updated successfully, its constraint type cannot be changed.

---

The following is the procedure to create a new user-visible constraint:

1. Create the load using `ProMechitemCreate()`.
2. Set the constraint references using `ProMechconstrReferencesSet()`.
3. Set the constraint type-specific data using one of the `ProMechconstr*dataSet()` functions.
4. Assign the constraint to a constraint set using `ProMechconstrConstrsetAssign()`.
5. Check the status of the constraint using `ProMechitemStatusGet()`.
6. Complete the constraint using `ProMechitemUpdateComplete()`.

Functions Introduced:

- **`ProMechconstrConvectiondataSet()`**
- **`ProMechconstrDisplacementdataSet()`**
- **`ProMechconstrSymmetrydataSet()`**
- **`ProMechconstrTemperaturedataSet()`**
- **`ProMechconstrThermalsymmetrydataSet()`**
- **`ProMechconstrReferencesSet()`**
- **`ProMechconstrConstrsetAssign()`**

The function `ProMechconstrConvectiondataSet()` sets the convection constraint data.

The function `ProMechconstrDisplacementdataSet()` sets the displacement constraint data.

The function `ProMechconstrRadiationdataSet()` sets the value for the radiation constraint data.

The function `ProMechconstrSymmetrydataSet()` sets the value of the symmetry constraint data.

The function `ProMechconstrTemperaturedataSet()` sets the value of the temperature constraint data.

The function `ProMechconstrThermalsymmetrydataSet()` sets the value of the thermal symmetry constraint data.

---

The function `ProMechconstrReferencesSet()` sets the value of the constraint geometric references. This must be a valid set of references for the constraint type.

Use the function `ProMechconstrConstrsetAssign()` to assign a constraint to a constraint set.

## Convection Constraints

Convection constraints specify a boundary condition on the convective heat exchange between a moving fluid and geometric entities and/or element entities within your model.

The functions described in this section provide access to the data and contents of the Creo Simulate convection constraints. You can define the value of the convection constraint as a function of temperature.

Functions Introduced:

- **`ProMechconvectiondataAlloc()`**
- **`ProMechconvectiondataBulktempGet()`**
- **`ProMechconvectiondataBulktempSet()`**
- **`ProMechconvectiondataBulktempUnset()`**
- **`ProMechconvectiondataFilmcoefficientGet()`**
- **`ProMechconvectiondataFilmcoefficientSet()`**
- **`ProMechconvectiondataTemperaturedependenceGet()`**
- **`ProMechconvectiondataTemperaturedependenceSet()`**
- **`ProMechconvectiondataTemporalvariationGet()`**
- **`ProMechconvectiondataTemporalvariationSet()`**
- **`ProMechconvectiondataFree()`**

The function `ProMechconvectiondataAlloc()` allocates memory for the convection load data.

The function `ProMechconvectiondataBulktempGet()` returns the value of the bulk temperature. The bulk temperature specifies the temperature of the fluid in contact with the surface, during convective heat transfer through a surface.

The function `ProMechconvectiondataBulktempSet()` sets the value of the bulk temperature.

The function `ProMechconvectiondataFilmcoefficientGet()` returns the value of the film coefficient. The film coefficient specifies the constant of proportionality between the flux through the surface and the difference between the surface temperature and the bulk temperature, in convective heat transfer through a surface.

---

Use the function `ProMechconvectiondataFilmcoefficientSet()` to set the value of the film coefficient.

The function

`ProMechconvectiondataTemperaturedependenceGet()` returns the temperature variation of the convection constraint. The convection constraint is specified as a function of temperature. Use the function

`ProMechconvectiondataTemperaturedependenceSet()` to set the temperature variation for the convection constraint.

The function `ProMechconvectiondataTemporalvariationGet()`

returns the temporal variation for the convection constraint. Use the function `ProMechconvectiondataTemporalvariationSet()` to set the temporal variation of the convection constraint. The temporal variation specifies whether the convection condition is in steady state or a function of time

#### Note

The function `ProMechconvectiondataTimefunctionidGet()` and `ProMechconvectiondataTimefunctionidSet()` have been deprecated. Use the functions

`ProMechconvectiondataTemporalvariationGet()` and `ProMechconvectiondataTemporalvariationSet()` instead

---

The function `ProMechconvectiondataFree()` releases the memory assigned to the convection load data.

## Radiation Constraints

A thermal radiation exchanges heat between the model surface and the surroundings. Radiation does not take place between the model surfaces. You can define the value of the radiation constraint as a function of temperature.

The functions described in this section provide access to the data and contents of the Creo Simulate radiation constraints.

Functions Introduced:

- **`ProMechradiationdataAlloc()`**
- **`ProMechradiationdataAmbienttempExprGet()`**
- **`ProMechradiationdataAmbienttempExprSet()`**
- **`ProMechradiationdataEmissivityGet()`**
- **`ProMechradiationdataEmissivitySet()`**
- **`ProMechradiationdataTemperaturedependenceGet()`**

- **ProMechradiationdataTemperaturedependenceSet()**
- **ProMechradiationdataFree()**

The function `ProMechradiationdataAlloc()` allocates memory for the radiation load data.

The model emits and absorbs energy from the surroundings at a fixed ambient temperature. Use the function `ProMechradiationdataAmbienttempExprGet()` to get the value of the ambient temperature for the radiation constraint data. Use the function `ProMechradiationdataAmbienttempExprSet()` to set the value of the ambient temperature for the radiation constraint data.

The function `ProMechradiationdataEmissivityGet()` gets the emissivity value. Use the function `ProMechradiationdataEmissivitySet()` to set the emissivity value.

The function `ProMechradiationdataTemperaturedependenceGet()` returns the temperature variation of the radiation constraint. Use the function `ProMechradiationdataTemperaturedependenceSet()` to set the temperature variation of the radiation constraint.

The function `ProMechradiationdataFree()` releases the memory assigned to the radiation load data.

## Displacement Constraints

The functions described in this section provide access to the data and contents of the Creo Simulate displacement constraints.

Functions Introduced:

- **ProMechdisplacementdataAlloc()**
- **ProMechdisplacementdataTypeGet()**
- **ProMechdisplacementdataTypeSet()**
- **ProMechdisplacementdataCsysGet()**
- **ProMechdisplacementdataCsysSet()**
- **ProMechdisplacementdataRotationconstrsGet()**
- **ProMechdisplacementdataRotationconstrsSet()**
- **ProMechdisplacementdataTranslationconstrsGet()**
- **ProMechdisplacementdataTranslationconstrsSet()**
- **ProMechdisplacementdataFree()**
- **ProMechdisplacementregularconstrAlloc()**
- **ProMechdisplacementregularconstrTypeSet()**

- **ProMechdisplacementregularconstrTypeGet()**
- **ProMechdisplacementregularconstrValueSet()**
- **ProMechdisplacementregularconstrValueGet()**
- **ProMechdisplacementdataTranslationinterpretinradiansflagGet()**
- **ProMechdisplacementdataTranslationinterpretinradiansflagSet()**
- **ProMechdisplacementregularconstrFree()**
- **ProMechdisplacementregularconstrProarrayFree()**
- **ProMechdisplacementdataPinconstrSet()**
- **ProMechdisplacementdataPinconstrGet()**
- **ProMechdisplacementpinconstrAlloc()**
- **ProMechdisplacementdataPinangularconstrTypeSet()**
- **ProMechdisplacementdataPinangularconstrTypeGet()**
- **ProMechdisplacementdataPinaxialconstrTypeSet()**
- **ProMechdisplacementdataPinaxialconstrTypeGet()**
- **ProMechdisplacementpinconstrFree()**

The function `ProMechdisplacementdataAlloc()` allocates the memory for the displacement constraint data handle.

The function `ProMechdisplacementdataTypeGet()` returns the type of displacement constraint data. The types of displacement constraints are:

- `PRO_MECH_DISPLACEMENT_REGULAR`—Specifies an external limit on the movement of a portion of the model.
- `PRO_MECH_DISPLACEMENT_PLANE`—This constraint type allows full planar movement, but constrains any off-plane displacement.
- `PRO_MECH_DISPLACEMENT_PIN`—Creates a constraint along a cylindrical surface for 3D models.
- `PRO_MECH_DISPLACEMENT_BALL`—Creates a constraint along a spherical surface for 3D models.

Use the function `ProMechdisplacementdataTypeSet()` to set the displacement constraint data.

The function `ProMechdisplacementdataCsysGet()` returns the reference coordinate system for the displacement constraint. Use the function `ProMechdisplacementdataCsysSet()` to set the reference coordinate system for the displacement constraint.

---

The function `ProMechdisplacementdataRotationconstrsGet()` returns the rotational component of the displacement about the X, Y, and Z axis. Use the function `ProMechdisplacementdataRotationconstrsSet()` to set the rotational component of displacement.

The function `ProMechdisplacementdataTranslationconstrsGet()` returns the translational component of the displacement about the X, Y, and Z directions. Use the function `ProMechdisplacementdataTranslationconstrsSet()` to set the translational component of displacement.

The function `ProMechdisplacementregularconstrAlloc()` allocates memory for the regular displacement constraint data structure.

The method `ProMechdisplacementregularconstrTypeGet()` returns the type of setting for the displacement constraint. Valid values are:

- `PRO_MECH_DISPLACEMENT_FREE`—Allows freedom of movement in the specified direction.
- `PRO_MECH_DISPLACEMENT_FIXED`—Constrains the entity, preventing movement in the specified direction.
- `PRO_MECH_DISPLACEMENT_ENFORCED`—Specifies an enforced displacement or rotation in the specified direction.

The function `ProMechdisplacementregularconstrTypeSet()` sets the type of the displacement constraint.

The function `ProMechdisplacementregularconstrValueGet()` returns the variation settings of the displacement if the type of displacement constraint is `PRO_MECH_DISPLACEMENT_ENFORCED`. The variation settings are as follows:

- An enforced displacement value in length units for the translational component
- An enforced rotation in radians for the rotational component

Use the function `ProMechdisplacementregularconstrValueSet()` to set the variation settings of the displacement.

The function `ProMechdisplacementdataTranslationinterpretinradiansflagGet()` returns the value `true` if the angular translations are interpreted in radians. This is applicable only if the displacement is of type `PRO_MECH_DISPLACEMENT_REGULAR` and if cylindrical or spherical coordinate system is selected for the translations. Use the function `ProMechdisplacementdataTranslationinterpretinradiansflagSet()` to set the value of the flag `interpret angular translations in radians`.

The function `ProMechdisplacementregularconstrFree()` releases the memory assigned to the regular displacement constraint data handle.

---

The function `ProMechdisplacementregularconstrProarrayFree()` releases the memory assigned to an array of regular displacement constraints.

The function `ProMechdisplacementpinconstrAlloc()` allocates memory for the pin constraint data structure.

The function `ProMechdisplacementdataPinconstrGet()` returns the pin constraint data structure. The pin constraint can have the following properties:

- **Angular**—Allows you to control the rotation about the axis of the selected cylindrical surface.
- **Axial**—Allows you to control translation along the axis of the selected cylindrical surface.

The function `ProMechdisplacementdataPinconstrSet()` sets the value for the pin constraint data structure.

The function

`ProMechdisplacementdataPinangularconstrTypeGet()` returns the angular constraint type for the pin constraint. Use the function `ProMechdisplacementdataPinangularconstrTypeSet()` to set the angular constraint type. Valid values are:

- `PRO_MECH_DISPLACEMENT_FREE`—Allows freedom of movement in the specified direction.
- `PRO_MECH_DISPLACEMENT_FIXED`—Constrains the entity, preventing movement in the specified direction.

---

 **Note**

The angular constraint cannot be of type `PRO_MECH_DISPLACEMENT_ENFORCED`.

---

The function `ProMechdisplacementdataPinaxialconstrTypeGet()` returns the axial constraint type for the pin constraint.

Use the method

`ProMechdisplacementdataPinaxialconstrTypeSet()` to set the axial constraint for the pin constraint. Valid values are:

- `PRO_MECH_DISPLACEMENT_FREE`—Allows freedom of movement in the specified direction.
- `PRO_MECH_DISPLACEMENT_FIXED`—Constrains the entity, preventing movement in the specified direction.

---

 **Note**

The axial constraint cannot be of type `PRO_MECH_DISPLACEMENT_ENFORCED`.

---

Use the function `ProMechdisplacementpinconstrFree()` to free the memory containing the pin constraint data structure.

### Example 3: Copying and Assigning a Displacement Constraint to a New Reference

The sample code in the file `PTMechExCopy.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_mech_examples/pt_mech_ex_src` shows how to copy a displacement constraint and assign it to a new reference.

## Symmetry Constraints

A symmetry constraint allows you to analyze a section of a symmetric model that simulates the behavior of the whole part or assembly to which it belongs.

The functions described in this section provide read and write access to the data and contents of the Creo Simulate symmetry constraints.

Functions Introduced:

- **`ProMechsymmetrydataAlloc()`**
- **`ProMechsymmetrydataTypeGet()`**
- **`ProMechsymmetrydataTypeSet()`**
- **`ProMechsymmetrydataAxisGet()`**
- **`ProMechsymmetrydataAxisSet()`**
- **`ProMechsymmetrydataSide1Get()`**
- **`ProMechsymmetrydataSide1Set()`**
- **`ProMechsymmetrydataSide2Get()`**
- **`ProMechsymmetrydataSide2Set()`**
- **`ProMechsymmetrydataFree()`**

The function `ProMechsymmetrydataAlloc()` allocates the memory for the symmetry constraint data handle.

The function `ProMechsymmetrydataTypeGet()` returns the type of symmetry constraint. The argument *type* can have the following values:

- `PRO_MECH_SYMMETRY_CYCLIC`—Specifies a cyclic symmetry

- **PRO\_MECH\_SYMMETRY\_MIRROR**—Specifies a mirror symmetry

Use the function `ProMechsymmetrydataTypeSet()` to set the type of symmetry constraint.

The function `ProMechsymmetrydataAxisGet()` returns the axis of symmetry of the section. Use the function `ProMechsymmetrydataAxisSet()` to set the axis of symmetry.

The function `ProMechsymmetrydataSide1Get()` returns the first side of the cut section. Use the function `ProMechsymmetrydataSide1Set()` to set the geometric references of the first side.

The function `ProMechsymmetrydataSide2Get()` returns the second side of the cut section. Use the function `ProMechsymmetrydataSide2Set()` to set the geometric references of the second side.

The function `ProMechsymmetrydataFree()` releases the memory assigned to the symmetry constraint data handle.

## Creo Simulate Constraint Sets

A constraint set is a collection of constraints that act together, and at the same time, on the model. Constraint sets do not contain loads.

The functions referring to the Creo Simulate constraint sets use the structure `ProModelItem`. Constraint sets use the `ProType` field in the `ProMechitem` structure as `PRO_SIMULATION_CONSTR_SET`.

Functions Introduced:

- **ProMechconstrsetTypeGet()**
- **ProMechconstrsetDescriptionGet()**
- **ProMechconstrsetDescriptionSet()**
- **ProMechconstrsetConstrsGet()**
- **ProMechconstrConstrsetAssign()**

The function `ProMechconstrsetTypeGet()` returns the type of the constraint sets that are applied to the model. The types are as follows:

- **PRO\_MECH\_LOADSET\_STRUCTURAL**—Specifies a structural constraint set.
- **PRO\_MECH\_LOADSET\_THERMAL**—Specifies a thermal constraint set.

The function `ProMechconstrsetDescriptionGet()` returns the description of the constraint set. The function `ProMechconstrsetDescriptionSet()` enables you to change the description of the constraint set.

The function `ProMechconstrsetConstrsGet()` returns the constraints specified in the constraint set.

---

Use the function `ProMechconstrConstrsetAssign()` to assign a constraint to a constraint set.

## Creo Simulate Matrix Functions

The functions described in this section provide read and write access to the matrix data of the Creo Simulate mass properties, spring properties, beam orientation, and beam section items.

Functions Introduced:

- **ProMechMatrixAlloc()**
- **ProMechMatrixComponentGet()**
- **ProMechMatrixComponentSet()**
- **ProMechMatrixFree()**

The function `ProMechMatrixAlloc()` allocates memory for the Creo Simulate matrix handle.

The function `ProMechMatrixComponentGet()` gets the individual matrix component value at the given index values. The function `ProMathExpressionEvaluate()` is used to evaluate the expression.

The function `ProMechMatrixComponentSet()` sets the individual matrix component value at the given index values. You can also set an expression in the specified index value.

The function `ProMechMatrixFree()` releases the memory assigned for the Creo Simulate matrix handle.

## Creo Simulate Vector Functions

The functions described in this section provide read and write access to the vector data of the Creo Simulate a mass properties, spring properties, beam orientation, and beam section items.

Functions Introduced:

- **ProMechVectorAlloc()**
- **ProMechVectorComponentGet()**
- **ProMechVectorComponentSet()**
- **ProMechVectorFree()**

The function `ProMechVectorAlloc()` allocates memory for the Creo Simulate vector handle.

---

The function `ProMechVectorComponentGet()` gets the individual vector component value at the given index values. The function `ProMathExpressionEvaluate()` is used to evaluate the expression.

The function `ProMechVectorComponentSet()` sets the individual vector component value at the given index values. You can also set an expression in the specified index value.

The function `ProMechVectorFree()` releases the memory assigned for the Creo Simulate vector handle.

## Creo Simulate Beams

A beam is a one-dimensional idealization that, in three dimensions, represents a structure whose length is much greater than its other two dimensions.

The functions described in this section provide read and write access to the data and contents of Creo Simulate beam items. Beams use the `ProType` field in the `ProMechitem` structure as `PRO_SIMULATION_BEAM`.

Functions Introduced:

- **`ProMechbeamdataAlloc()`**
- **`ProMechbeamTypeGet()`**
- **`ProMechbeamMaterialIdGet()`**
- **`ProMechbeamMaterialIdSet()`**
- **`ProMechbeamReferencesGet()`**
- **`ProMechbeamReferencesSet()`**
- **`ProMechbeamBeamdataGet()`**
- **`ProMechbeamBeamdataSet()`**
- **`ProMechbeamTrussdataGet()`**
- **`ProMechbeamTrussdataSet()`**
- **`ProMechbeamsideAlloc()`**
- **`ProMechbeamdataCompcurvrelGet()`**
- **`ProMechbeamdataCompcurvrelSet()`**
- **`ProMechbeamdataSidesGet()`**
- **`ProMechbeamdataSidesSet()`**
- **`ProMechbeamsideOrientGet()`**
- **`ProMechbeamsideOrientSet()`**
- **`ProMechbeamsideReleaseGet()`**
- **`ProMechbeamsideReleaseSet()`**

- **ProMechbeamsideSectionGet()**
- **ProMechbeamsideSectionSet()**
- **ProMechbeamsideFree()**
- **ProMechbeamsideProarrayFree()**
- **ProMechbeamdataStressrecoveryGet()**
- **ProMechbeamdataStressrecoverySet()**
- **ProMechbeamdataXyshearGet()**
- **ProMechbeamdataXyshearSet()**
- **ProMechbeamdataXzshearGet()**
- **ProMechbeamdataXzshearSet()**
- **ProMechbeamdataYdirectionGet()**
- **ProMechbeamdataYdirectionSet()**
- **ProMechbeamdataFree()**
- **ProMechtrussdataAlloc()**
- **ProMechtrussdataSectionGet()**
- **ProMechtrussdataSectionSet()**
- **ProMechtrussdataFree()**

The function `ProMechbeamdataAlloc()` allocates the memory for the beam data handle.

The function `ProMechbeamTypeGet()` returns the types of beams.

The different types of beams are as follows:

- **PRO\_MECH\_BEAM\_BEAM**—Specifies a beam. Use the function `ProMechbeamBeamdataGet()` to access the data structure for the beam. Use the function `ProMechbeamBeamdataSet()` to modify the beam.
- **PROMECH\_BEAM\_TRUSS**—Specifies a truss. Use the function `ProMechbeamTrussdataGet()` to access the data structure for the truss. Use the function `ProMechbeamTrussdataSet()` to modify the truss.

The function `ProMechbeamMaterialIdGet()` returns the ID of the Creo Parametric material used to create the beam. Use the function `ProMechbeamMaterialIdSet()` to set the material ID for the beam.

The function `ProMechbeamReferencesGet()` returns the start and end points of the beam or a curve or surface of the beam. Use the function `ProMechbeamReferencesSet()` to set the beam references.

The function `ProMechbeamsideAlloc()` allocates the memory for the beam side data handle.

---

The function `ProMechbeamdataCompcurvrelGet()` returns a boolean that indicates whether the beam releases are applied only to the ends of the selected composite curve or to the ends of the individual curves. Use the function `ProMechbeamdataCompcurvrelSet()` to set whether the beam releases are to be applied only to the ends of the selected composite curve or to the ends of the individual curves.

The function `ProMechbeamdataSidesGet()` returns a structure containing the cross section properties for beam elements, the orientation properties for angle and offsets, and the degrees of freedom at each beam end. Use the function `ProMechbeamdataSidesSet()` to set the cross section properties and orientation properties of the beam data.

The function `ProMechbeamsideOrientGet()` returns the orientation ID for the specified beam elements. Use the function `ProMechbeamsideOrientSet()` to set the orientation ID.

The function `ProMechbeamsideReleaseGet()` returns the beam release ID for the specified beam elements. Use the function `ProMechbeamsideReleaseSet()` to set the beam release ID.

The function `ProMechbeamsideSectionGet()` returns the cross section ID for the specified beam elements. Use the function `ProMechbeamsideSectionSet()` to set the cross section ID.

The function `ProMechbeamsideFree()` releases the memory assigned to the beam side handle.

The function `ProMechbeamsideProarrayFree()` releases the memory assigned to a `ProArray` of beam side handles.

The function `ProMechbeamdataStressrecoveryGet()` returns a boolean that indicates whether stress recovery is included while creating the beam. If this option is specified as `true`, you can access the beam stress at a specific location on the beam section. Use the function `ProMechbeamdataStressrecoverySet()` to set the value of the boolean.

The function `ProMechbeamdataXyshearGet()` returns the shear relief coefficient due to taper for the XY planes. Use the function `ProMechbeamdataXyshearSet()` to set the shear relief coefficient relative to the XY plane.

The function `ProMechbeamdataXzshearGet()` returns the shear relief coefficient due to taper for the XZ planes. Use the function `ProMechbeamdataXzshearSet()` to set the shear relief coefficient relative to the XZ plane.

The function `ProMechbeamdataYdirectionGet()` returns the orientation of the XY plane of a beam by defining its Y-direction. Use the function `ProMechbeamdataYdirectionSet()` to set the Y-direction of the beam.

---

The function `ProMechbeamdataFree()` releases the memory assigned to the beam data handle.

The function `ProMechtrussdataAlloc()` allocates the memory for the truss data handle.

The function `ProMechtrussdataSectionGet()` returns the cross section ID for the specified truss elements. Use the function `ProMechtrussdataSectionSet()` to set the beam section ID for the truss data.

The function `ProMechtrussdataFree()` releases the memory assigned to the truss data handle.

## Creo Simulate Beams: Sections, Sketched Sections, and General Sections

The functions described in this section provide read and write access to the data and contents of the Creo Simulate beam sections, sketched beam sections, and general beam sections items.

Functions Introduced:

- **ProMechBeamsectionTypeGet()**
- **ProMechBeamsectionTypeSet()**
- **ProMechBeamsectionIntegerGet()**
- **ProMechBeamsectionIntegerSet()**
- **ProMechBeamsectionExpressionGet()**
- **ProMechBeamsectionExpressionSet()**
- **ProMechBeamsectionMatrixGet()**
- **ProMechBeamsectionMatrixSet()**
- **ProMechBeamsectionVectorGet()**
- **ProMechBeamsectionVectorSet()**

These functions use the enumerated type `ProMechBeamsectionPropertyType` to define the beam section property type.

```
typedef enum
{
 PRO_MECH_BEAMSECTION_SKETCHED_FEATURE_ID = 0, /* int */
 PRO_MECH_BEAMSECTION_SKETCHED_SHEARCENTER = 1, /*
ProMechVector (2) [Dy, Dz] */
 PRO_MECH_BEAMSECTION_SKETCHED_ORIENTTYPE = 2, /*
ProMechSketchedSectionOrient (int) */
```

---

```

 PRO_MECH_BEAMSECTION_SQUARE_DIMENSION = 3, /*

}
ProMechBeamsectionPropertyType;

```

The function `ProMechBeamsectionTypeGet()` returns the type of beam section. Use the function `ProMechBeamsectionTypeSet()` to set the type of beam section.

The types of beam sections are as follows:

- `PRO_MECH_BEAM_SECTION_SKETCHED`—Specifies a cross section created using either the sketch solid beam or sketch thin beam type. Use the enumerated type `ProMechBeamsectionPropertyType` to get and set the properties of the sketched beam section.
- `PRO_MECH_BEAM_SECTION_SQUARE`—Specifies a square beam section type. The cross section dimension is specified by the length of the sides of the square. Use the function `ProMechBeamsectionExpressionGet()` to get the square beam section data. Use the function

---

`ProMechBeamsectionExpressionSet()` to set the properties of the square beam section.

- `PRO_MECH_BEAM_SECTION_RECTANGLE`—Specifies a rectangular beam section type. The cross section dimension is specified by the height and width of the rectangle. Use the function `ProMechBeamsectionVectorGet()` to get the rectangular beam section data. Use the function `ProMechBeamsectionVectorSet()` to set the properties of the rectangular beam section
- `PRO_MECH_BEAM_SECTION_HOLLOW_RECTANGLE`—Specifies a hollow rectangular beam section type. The cross section dimension for this beam type is specified by the Outer height and width, and the inner height and width of the rectangle. Use the function `ProMechBeamsectionVectorGet()` to get the hollow beam section data. Use the function `ProMechBeamsectionVectorSet()` to set the properties of the hollow beam section.
- `PRO_MECH_BEAM_SECTION_CHANNEL`—Specifies a channel beam section type. The cross section dimension is specified by the flange width, flange thickness, web height, and web thickness. Use the function `ProMechBeamsectionVectorGet()` to get the channel section data. Use the function `ProMechBeamsectionVectorSet()` to set the properties of the channel beam section.
- `PRO_MECH_BEAM_SECTION_I_BEAM`—Specifies an L-section beam section type. The cross section dimension for this beam type is specified by the overall flange width, flange thickness, web height, and web thickness. Use the function `ProMechBeamsectionVectorGet()` to get the L-section data. Use the function `ProMechBeamsectionVectorSet()` to set the properties of the L-section beam type.
- `PRO_MECH_BEAM_SECTION_L_SECTION`—Specifies an L-section beam section type. The cross section dimension for this beam type is specified by the overall flange width, flange thickness, web height, and web thickness. Use the function `ProMechBeamsectionVectorGet()` to get the L-section data. Use the function `ProMechBeamsectionVectorSet()` to set the properties of the L-section beam type.
- `PRO_MECH_BEAM_SECTION_DIAMOND`—Specifies a diamond beam section type. The cross section dimension is specified by the width and height of the sides. Use the function `ProMechBeamsectionVectorGet()` to get the diamond beam section data. Use the function `ProMechBeamsectionVectorSet()` to set the properties of the diamond beam section.

- 
- `PRO_MECH_BEAM_SECTION_SOLID_CIRCLE`—Specifies a solid circle beam section type. The cross section dimension for this beam type is specified by the radius of the circular beam cross-section. Use the function `ProMechsectiondataCirclesectdataGet()` to access the solid circle beam section data structure. Use the function `ProMechsectiondataCirclesectdataSet()` to modify the solid circle beam section data structure.
  - `PRO_MECH_BEAM_SECTION_HOLLOW_CIRCLE`—Specifies a hollow circle beam section type. The cross section dimension for this beam type is specified by the outside radius and the inside radius of the hollow beam cross-section. Use the function `ProMechBeamsectionVectorGet()` to get the hollow circle beam section data. Use the `ProMechBeamsectionVectorSet()` to set the properties of the hollow circle beam section.
  - `PRO_MECH_BEAM_SECTION_SOLID_ELLIPSE`—Specifies a solid ellipse beam section type. The cross section dimension for this beam type is specified by the length of the major axis and the length of the minor axis. Use the function `ProMechBeamsectionVectorGet()` to get the solid ellipse beam data. Use the function `ProMechBeamsectionVectorSet()` to set the properties of the solid ellipse beam section.
  - `PRO_MECH_BEAM_SECTION_HOLLOW_ELLIPSE`—Specifies a hollow ellipse beam section type. The cross section dimension for this beam type is specified by the length of the major axis, length of the minor axis, and the inside major axis. Use the function `ProMechBeamsectionVectorGet()` to get the hollow ellipse beam data. Use the function `ProMechBeamsectionVectorSet()` to set the properties of the hollow ellipse beam section.
  - `PRO_MECH_BEAM_SECTION_GENERAL`—Specifies a general beam section type. A general beam section type does not have a predefined shape. Use the enumerated type `ProMechBeamsectionPropertyType` to get and set the properties of the general beam data.

The function `ProMechBeamsectionIntegerGet()` returns the integer value of the specified beam type property. Use the function `ProMechBeamsectionIntegerSet()` to set an integer value for the specified beam type. For example, you can get and set the beam sketch feature id, the type of orientation used for the sketched beam section, and so on.

The function `ProMechBeamsectionExpressionGet()` returns the expression of type `ProMechExpression` for the specified beam section type. To evaluate the expression use the function `ProMathExpressionEvaluate()`. The function `ProMechBeamsectionExpressionSet()` sets the expression of type

---

`ProMechExpression` for the specified beam section type. For example, you can get and set the section area, torsion stiffness (J parameter) of the beam section, and so on.

The function `ProMechBeamsectionExpressionGet()` returns the expression of type `ProMechExpression` for the specified beam section type. To evaluate the expression use the function `ProMathExpressionEvaluate()`. The function `ProMechBeamsectionExpressionSet()` sets the expression of type `ProMechExpression` for the specified beam section type. For example, you can get and set the section area, torsion stiffness (J parameter) of the beam section, and so on.

The function `ProMechBeamsectionMatrixGet()` returns the Creo Simulate matrix handle `ProMechMatrix`. Use the function `ProMechBeamsectionMatrixSet()` to set the handle to `ProMechMatrix`. The functions `ProMechMatrixComponentGet/Set` provide read and write access to the individual matrix components of the specified beam section property type. For example, you can get/set the values for moments of inertia `Ixx`, `Ixy`, and `Izz`. See the section [Creo Simulate Matrix Functions on page 1864](#) for more information on handling matrix components.

The function `ProMechBeamsectionMatrixGet()` automatically allocates memory for the Creo Parametric Creo Simulate matrix handle. Use the function `ProMechMatrixFree()` to free the assigned memory.

The function `ProMechBeamsectionVectorGet()` returns the Creo Simulate vector handle `ProMechVector`. Use the function `ProMechBeamsectionVectorSet()` to set the handle to `ProMechVector`. The functions `ProMechVectorComponentGet/Set` provide read and write access to the individual vector components of the specified beam section property type. For example, you can get/set the values for circular, square, channel, I-beam sections, and so on. See the section [Creo Simulate Vector Functions on page 1864](#), for more information on handling vector components.

The function `ProMechBeamsectionVectorGet()` automatically allocates the memory for the Creo Simulate vector handle. Use the function `ProMechVectorFree()` to free the memory.

## Creo Simulate Beam Sections

The functions described in this section provide read and write access to the data and contents of the Creo Simulate beam section items. Beam sections use the `ProType` field in the `ProMechitem` structure as `PRO_SIMULATION_BEAM_SECTION`.

Functions Introduced:

- **`ProMechsectiondataAlloc()`**

- **ProMechbeamsectionDataGet()**
- **ProMechbeamsectionDataSet()**
- **ProMechbeamsectionDescriptionGet()**
- **ProMechbeamsectionDescriptionSet()**
- **ProMechsectiondataFree()**

The beam section functions listed under Functions Superseded have been deprecated. Use the functions described in the section [Creo Simulate Beams: Sections, Sketched Sections, and General Sections on page 1868](#) instead.

Functions Superseded:

- **ProMechsectiondataSectiontypeGet()**
- **ProMechsectiondataNonstructcogGet()**
- **ProMechsectiondataNonstructcogSet()**
- **ProMechsectiondataNonstructmassGet()**
- **ProMechsectiondataNonstructmassSet()**
- **ProMechsectiondataNonstructmomentGet()**
- **ProMechsectiondataNonstructmomentSet()**
- **ProMechsectiondataWarpcoeffGet()**
- **ProMechsectiondataWarpcoeffSet()**
- **ProMechsectiondataChannelsectdataGet()**
- **ProMechsectiondataChannelsectdataSet()**
- **ProMechsectiondataCirclesectdataGet()**
- **ProMechsectiondataCirclesectdataSet()**
- **ProMechsectiondataDiamondsectdataGet()**
- **ProMechsectiondataDiamondsectdataSet()**
- **ProMechsectiondataEllipsesectdataGet()**
- **ProMechsectiondataEllipsesectdataSet()**
- **ProMechsectiondataGeneralsectdataGet()**
- **ProMechsectiondataGeneralsectdataSet()**
- **ProMechsectiondataHollowcirclesectdataGet()**
- **ProMechsectiondataHollowcirclesectdataSet()**
- **ProMechsectiondataHollowellipsesectdataGet()**
- **ProMechsectiondataHollowellipsesectdataSet()**
- **ProMechsectiondataHollowrectsectdataGet()**
- **ProMechsectiondataHollowrectsectdataSet()**

- 
- **ProMechsectiondataIbeamsectdataGet()**
  - **ProMechsectiondataIbeamsectdataSet()**
  - **ProMechsectiondataLsectionsectdataGet()**
  - **ProMechsectiondataLsectionsectdataSet()**
  - **ProMechsectiondataRectanglesectdataGet()**
  - **ProMechsectiondataRectanglesectdataSet()**
  - **ProMechsectiondataSketchedsectdataGet()**
  - **ProMechsectiondataSketchedsectdataSet()**
  - **ProMechsectiondataSquaresectdataGet()**
  - **ProMechsectiondataSquaresectdataSet()**

The function `ProMechsectiondataAlloc()` allocates the memory for the beam section data handle.

The function `ProMechbeamsectionDataGet()` provides access to the data structure containing the properties of the beam section data. Use the function `ProMechbeamsectionDataSet()` to set the properties of the beam section data.

The function `ProMechsectiondataSectiontypeGet()` returns the types of beam sections.

The types of beam sections are as follows:

- **PRO\_MECH\_BEAM\_SECTION\_SKETCHED**—Specifies a cross section created using either the sketch solid beam or sketch thin beam type. Use the function `ProMechsectiondataSketchedsectdataGet()` to access the sketched beam data structure. Use the function `ProMechsectiondataSketchedsectdataSet()` to set the properties of the sketched beam data structure.
- **PRO\_MECH\_BEAM\_SECTION\_SQUARE**—Specifies a square beam section type. The cross section dimension is specified by the length of the sides of the square. Use the function `ProMechsectiondataSquaresectdataGet()` to access the square section data structure. Use the function `ProMechsectiondataSquaresectdataSet()` to set the properties of the square section data structure.
- **PRO\_MECH\_BEAM\_SECTION\_RECTANGLE**—Specifies a rectangular beam section type. The cross section dimension is specified by the height and width of the rectangle. Use the function `ProMechsectiondataRectanglesectdataGet()` to access the rectangular section data structure. Use the function

---

`ProMechsectiondataRectanglesectdataSet()` to access the rectangular section data structure.

- **PRO\_MECH\_BEAM\_SECTION\_HOLLOW\_RECTANGLE**—Specifies a hollow rectangular beam section type. The cross section dimension for this beam type is specified by the Outer height and width, and the inner height and width of the rectangle. Use the function `ProMechsectiondataHollowrectsectdataGet()` to access the hollow section data structure. Use the function `ProMechsectiondataHollowrectsectdataSet()` to access the hollow section data structure.
- **PRO\_MECH\_BEAM\_SECTION\_CHANNEL**—Specifies a channel beam section type. The cross section dimension is specified by the flange width, flange thickness, web height, and web thickness. Use the function `ProMechsectiondataChannelsectdataGet()` to access the channel section data structure. Use the function `ProMechsectiondataChannelsectdataSet()` to access the channel section data structure.
- **PRO\_MECH\_BEAM\_SECTION\_I\_BEAM**—Specifies an I-beam section type. The cross section dimension for this beam type is specified by the flange width, flange thickness, web height, and web thickness. Use the function `ProMechsectiondataIbeamsectdataGet()` to access the I-beam section data structure. Use the function `ProMechsectiondataIbeamsectdataSet()` to access the I-beam section data structure.
- **PRO\_MECH\_BEAM\_SECTION\_L\_SECTION**—Specifies an L-section beam section type. The cross section dimension for this beam type is specified by the overall flange width, flange thickness, web height, and web thickness. Use the function `ProMechsectiondataLsectionsectdataGet()` to access the L-section data structure. Use the function `ProMechsectiondataLsectionsectdataSet()` to access the L-section data structure.
- **PRO\_MECH\_BEAM\_SECTION\_DIAMOND**—Specifies a diamond beam section type. The cross section dimension is specified by the width and height of the sides. Use the function `ProMechsectiondataDiamondsectdataGet()` to access the diamond beam section data structure. Use the function `ProMechsectiondataDiamondsectdataSet()` to modify the diamond beam section data structure.
- **PRO\_MECH\_BEAM\_SECTION\_SOLID\_CIRCLE**—Specifies a solid circle beam section type. The cross section dimension for this beam type is specified by the radius of the circular beam cross-section. Use the function

---

`ProMechsectiondataCirclesectdataGet()` to access the solid circle beam section data structure. Use the function `ProMechsectiondataCirclesectdataSet()` to modify the solid circle beam section data structure.

- **PRO\_MECH\_BEAM\_SECTION\_HOLLOW\_CIRCLE**—Specifies a hollow circle beam section type. The cross section dimension for this beam type is specified by the outside radius and the inside radius of the hollow beam cross-section. Use the function `ProMechsectiondataHollowcirclesectdataGet()` to access the hollow circle beam section data structure. Use the function `ProMechsectiondataHollowcirclesectdataSet()` to modify the hollow circle beam section data structure.
- **PRO\_MECH\_BEAM\_SECTION\_SOLID\_ELLIPSE**—Specifies a solid ellipse beam section type. The cross section dimension for this beam type is specified by the length of the major axis and the length of the minor axis. Use the function `ProMechsectiondataEllipsesectdataGet()` to access the solid ellipse beam data structure. Use the function `ProMechsectiondataEllipsesectdataSet()` to modify the solid ellipse beam data structure.
- **PRO\_MECH\_BEAM\_SECTION\_HOLLOW\_ELLIPSE**—Specifies a hollow ellipse beam section type. The cross section dimension for this beam type is specified by the length of the major axis, length of the minor axis, and the inside major axis. Use the function `ProMechsectiondataHollowellipsesectdataGet()` to access the hollow ellipse beam data structure. Use the function `ProMechsectiondataHollowellipsesectdataSet()` to access the hollow ellipse beam data structure.
- **PRO\_MECH\_BEAM\_SECTION\_GENERAL**—Specifies a general beam section type. A general beam section type does not have a predefined shape. Use the function `ProMechsectiondataGeneralsectdataGet()` to access the general beam data structure. Use the function `ProMechsectiondataGeneralsectdataSet()` to access the general beam data structure.

The function `ProMechbeamsectionDescriptionGet()` returns the description for the specified beam section. Use the function `ProMechbeamsectionDescriptionSet()` to set the description of the specified beam section.

The function `ProMechsectiondataNonstructcogGet()` returns the Y and Z coordinates of the non-structural mass center of gravity. A non-structural mass is a mass that responds to gravity, but does not strengthen the structure. Non-structural masses can have different moments of inertia and gravitational centers

---

than the specified beam. The function

`ProMechsectiondataNonstructcogSet()` sets the Y and Z coordinates of the non-structural mass center of gravity.

The function `ProMechsectiondataNonstructmassGet()` returns the non-structural mass per unit length. Use the function

`ProMechsectiondataNonstructmassSet()` to set the non-structural mass per unit length the beam section.

The function `ProMechsectiondataNonstructmomentGet()` returns the non-structural mass moment of inertia per unit length. Use the function

`ProMechsectiondataNonstructmomentSet()` to set the non-structural mass moment of inertia per unit length of the beam section.

The function `ProMechsectiondataWarpcoeffGet()` returns the warp coefficient of the beam section. Use the function

`ProMechsectiondataWarpcoeffSet()` to set the warp coefficient of the beam section.

The function `ProMechsectiondataFree()` releases the memory assigned to the beam section data.

## Sketched Beam Section

The sketched beam section functions described below have been deprecated. Use the functions described in the section [Creo Simulate Beams: Sections, Sketched Sections, and General Sections on page 1868](#) instead.

Functions Superseded:

- **`ProMechsketchedsctndataAlloc()`**
- **`ProMechsketchedsctndataFeatureidGet()`**
- **`ProMechsketchedsctndataOrienttypeGet()`**
- **`ProMechsketchedsctndataOrienttypeSet()`**
- **`ProMechsketchedsctndataShearcenterGet()`**
- **`ProMechsketchedsctndataShearcenterSet()`**
- **`ProMechsketchedsctndataFree()`**

The function `ProMechsketchedsctndataAlloc()` allocates the memory for the sketched beam section data handle.

The function `ProMechsketchedsctndataFeatureidGet()` returns the sketch feature id of the sketched beam section.

The function `ProMechsketchedsctndataOrienttypeGet()` returns the type of orientation for the sketched beam section. The beam orientation defines the Y direction of the beam, that is, how it rotates on the XY plane. The types of orientation is as follows:

- `PRO_MECH_BEAM_SECTION_SKET_XY_AS_YZ`—The beam section X and Y coordinates correspond to the beam Y and Z directions, respectively.
- `PRO_MECH_BEAM_SECTION_SKET_XY_AS_ZY`—The beam section X and Y coordinates correspond to the beam Z and Y directions, respectively.

Use the function `ProMechsketchedsctndataOrienttypeSet()` to set the type of orientation for the sketched beam section.

The function `ProMechsketchedsctndataShearcenterGet()` returns the shear center of the beam section. The shear center is the point on a beam section about which the section rotates under deflection. The function `ProMechsketchedsctndataShearcenterSet()` sets the shear center of the beam section.

The function `ProMechsketchedsctndataFree()` releases the memory assigned to sketched beam section data.

## General Beam Section

The general beam section functions described below have been deprecated. Use the functions described in the section [Creo Simulate Beams: Sections, Sketched Sections, and General Sections on page 1868](#) instead.

Functions Superseded:

- **`ProMechgeneralsctndataAlloc()`**
- **`ProMechgeneralsctndataAreaGet()`**
- **`ProMechgeneralsctndataAreaSet()`**
- **`ProMechgeneralsctndataAreaproductGet()`**
- **`ProMechgeneralsctndataAreaproductSet()`**
- **`ProMechgeneralsctndataMomentsGet()`**
- **`ProMechgeneralsctndataMomentsSet()`**
- **`ProMechgeneralsctndataShearcenterGet()`**
- **`ProMechgeneralsctndataShearcenterSet()`**
- **`ProMechgeneralsctndataShearfactorGet()`**
- **`ProMechgeneralsctndataShearfactorSet()`**
- **`ProMechgeneralsctndataTorsionstiffnessGet()`**
- **`ProMechgeneralsctndataTorsionstiffnessSet()`**
- **`ProMechgeneralsctndataStressrecoverypntsGet()`**
- **`ProMechgeneralsctndataStressrecoverypntsSet()`**
- **`ProMechgeneralsctndataFree()`**

---

The function `ProMechgeneralstndataAlloc()` allocates the memory for the general beam section data handle.

The function `ProMechgeneralstndataAreaGet()` returns the cross-sectional area for each beam section. Use the function `ProMechgeneralstndataAreaSet()` to set the cross-sectional area for the beam section.

The function `ProMechgeneralstndataAreaproductGet()` returns the area product of the moments of inertia. Use the function `ProMechgeneralstndataAreaproductSet()` to set the area product of inertia.

The function `ProMechgeneralstndataMomentsGet()` returns the second moments of area for each beam section. These properties describe the stiffness in bending about a beam's principle Y and Z axes. Use the function `ProMechgeneralstndataMomentsSet()` to set the second moments of area for each beam section.

The function `ProMechgeneralstndataShearcenterGet()` returns the Shear DY and Shear DZ values. These values specify the distance between shear center (the point on a beam section about which the section rotates under deflection) and the centroid of the beam section, with respect to the principal axes. Use the function `ProMechgeneralstndataShearcenterSet()` to set the Shear DY and Shear DZ values.

The function `ProMechgeneralstndataShearfactorGet()` returns the Shear FY and Shear FZ values for the beam section. These values represent the ratio of a beam's effective "shear area" to its true cross-sectional area for shear in the principal Y and Z directions. Use the function `ProMechgeneralstndataShearfactorSet()` to set the Shear FY and Shear FZ values for the beam section.

The function `ProMechgeneralstndataTorsionstiffnessGet()` returns the second polar moment of area for each beam section. This property describes the stiffness in torsion. Use the function `ProMechgeneralstndataTorsionstiffnessSet()` to set the torsion stiffness for each beam section.

The function `ProMechgeneralstndataStressrecoverypntsGet()` returns the stress recovery points of the beam section. Use the `ProMechgeneralstndataStressrecoverypntsSet()` to set the stress recovery points of the beam section.

The function `ProMechgeneralstndataFree()` releases the memory assigned to the sketched beam section data.

---

## Beam Orientations

The functions described in this section provide read and write access to the data and contents of the Creo Simulate beam orientations data structure. Beam orientations use the `ProType` field in the `ProMechItem` structure as `PRO_SIMULATION_BEAM_ORIENT`.

Functions Introduced:

- **`ProMechbeamorientDescriptionGet()`**
- **`ProMechbeamorientDescriptionSet()`**
- **`ProMechBeamorientExpressionGet()`**
- **`ProMechBeamorientExpressionSet()`**
- **`ProMechBeamorientIntegerGet()`**
- **`ProMechBeamorientIntegerSet()`**
- **`ProMechBeamorientVectorGet()`**
- **`ProMechBeamorientVectorSet()`**

Functions Superseded:

- **`ProMechbeamorientDataGet()`**
- **`ProMechbeamorientDataSet()`**
- **`ProMechbeamorientdataTypeGet()`**
- **`ProMechbeamorientdataTypeSet()`**
- **`ProMechbeamorientdataAngleGet()`**
- **`ProMechbeamorientdataAngleSet()`**
- **`ProMechbeamorientdataVectorGet()`**
- **`ProMechbeamorientdataVectorSet()`**
- **`ProMechbeamorientdataFree()`**

The function `ProMechbeamorientDataGet()` provides access to the data structure containing the properties of the beam orientation. Use the function `ProMechbeamorientDataSet()` to set the properties of the beam orientation data. The functions `ProMechbeamorientDataGet()` and `ProMechbeamorientDataSet()` have been deprecated. Use the functions `ProMechBeamorientIntegerGet()` and `ProMechBeamorientIntegerSet()` instead.

The function `ProMechbeamorientDescriptionGet()` returns the description of the beam orientation. Use the function `ProMechbeamorientDescriptionSet()` to set the description of the beam orientation.

The functions `ProMechBeamorientExpressionGet/Set`, `ProMechBeamorientIntegerGet/Set`, and `ProMechBeamorientVectorGet/Set` use the enumerated type `ProMechBeamorientPropertyType` to define the beam orientation property type.

The values are as follows:

```
typedef enum
{
 PRO_MECH_BEAM_ORIENT_OFFSET_TYPE = 0, /* ProMechBeamOrientType (int)
 */

 PRO_MECH_BEAM_ORIENT_ANGLE = 1, /* ProMechExpression */

 PRO_MECH_BEAM_ORIENT_OFFSET = 2 /* ProMechVector (3)
 [Dx Dy Dz]
 */
}
ProMechBeamorientPropertyType;
```

The function `ProMechBeamorientExpressionGet()` gets the value for the defined beam orientation property type. If an expression is defined, the output value is calculated using `ProMathExpressionEvaluate()`. Use the function `ProMechBeamorientExpressionSet()` to set the value for the beam orientation property type. For the functions `ProMechBeamorientExpressionGet/Set`, the only enumerated value allowed is `PRO_MECH_BEAM_ORIENT_ANGLE`. You can get and set the angle of the beam orientation.

The function `ProMechBeamorientIntegerGet()` gets the integer of the specified beam orientation property type. Use the function `ProMechBeamorientIntegerSet()` to set an integer value for the specified beam orientation property type. For the functions `ProMechBeamorientIntegerGet/Set`, the only enumerated value allowed is `PRO_MECH_BEAM_ORIENT_OFFSET_TYPE`.

`PRO_MECH_BEAM_ORIENT_OFFSET_TYPE` returns the handle to `ProMechBeamOrientType`. You can specify the type of orientation using the enumerated type `ProMechBeamOrientType`.

The types of orientations are as follows:

- `PRO_MECH_BEAM_ORIENT_OFFSET_SHAPE_ORIGIN`— Specifies the point of origin of the beam shape coordinate system.
- `PRO_MECH_BEAM_ORIENT_OFFSET_CENTROID`— Specifies the origin of the principal coordinate system which is at the centroid of the section. For general sections and all standard sections, it is coincident with `PRO_MECH_BEAM_ORIENT_OFFSET_SHAPE_ORIGIN`.

- 
- `PRO_MECH_BEAM_ORIENT_OFFSET_SHEAR_CENTER`— Specifies the point on a beam section about which the section rotates under deflection.

The function `ProMechBeamorientVectorGet()` returns the Creo Simulate vector handle `ProMechVector`. Use the function `ProMechBeamorientVectorSet()` to set the handle to `ProMechVector`. The functions `ProMechVectorComponentGet/Set` provide read and write access to the individual vector components of the specified beam orientation property type. For more information about handling vector components, see [Creo Simulate Vector Functions on page 1864](#).

For the functions `ProMechBeamorientVectorGet/Set`, the only enumerated value allowed is `PRO_MECH_BEAM_ORIENT_OFFSET`. For example, you can get/set the direction of the beam vector.

The function `ProMechBeamorientVectorGet()` automatically allocates the memory for the Creo Simulate vector handle. Use the function `ProMechVectorFree()` to free the memory.

The function `ProMechbeamorientdataTypeGet()` returns the type of the orientation specified for the Creo Simulate beam orientation item. Use the function `ProMechbeamorientdataTypeSet()` to set the type of orientation. The functions `ProMechbeamorientdataTypeGet()` and `ProMechbeamorientdataTypeSet()` have been deprecated. Use the enumerated type `ProMechBeamOrientType` instead.

The function `ProMechbeamorientdataAngleGet()` returns the angle of the beam orientation. Use the function `ProMechbeamorientdataAngleSet()` to set the angle of the beam orientation. The functions `ProMechbeamorientdataAngleGet()` and `ProMechbeamorientdataAngleSet()` have been deprecated. Use the functions `ProMechBeamorientExpressionGet()` and `ProMechBeamorientExpressionSet()` instead.

The function `ProMechbeamorientdataVectorGet()` returns the direction of the beam vector. Use the function `ProMechbeamorientdataVectorSet()` to set the direction of the beam vector. The functions `ProMechbeamorientdataVectorGet()` and `ProMechbeamorientdataVectorSet()` have been deprecated. Use the functions `ProMechBeamorientVectorGet()` and `ProMechBeamorientVectorSet()` instead.

Use the function `ProMechbeamorientdataFree()` to free the memory allocated to the beam orientation data structure. The function `ProMechbeamorientdataFree()` has been deprecated.

---

## Beam Releases

The beam releases specify the degrees of freedom you want to release for a beam end or beam ends. Beam releases determine the degrees of freedom that do not participate in a connection at the end of a beam. You can specify beam releases for both straight and curved beams.

The beam releases data structure contains a combination of the six degrees of freedom relative to the beam's local axes, that is, translation in X, Y, and Z and rotation in X, Y, and Z.

The functions described in this section provide read and write access to the data and contents of the Creo Simulate beam releases data structure. Beam releases use the `ProType` field in the `ProMechItem` structure as `PRO_SIMULATION_BEAM_RELEASE`.

Functions Introduced:

- **ProMechbeamreleasedataAlloc()**
- **ProMechbeamreleaseDataGet()**
- **ProMechbeamreleaseDataSet()**
- **ProMechbeamreleaseDescriptionGet()**
- **ProMechbeamreleaseDescriptionSet()**
- **ProMechbeamreleasedataRotationflagsGet()**
- **ProMechbeamreleasedataRotationflagsSet()**
- **ProMechbeamreleasedataTranslationflagsGet()**
- **ProMechbeamreleasedataTranslationflagsSet()**
- **ProMechbeamreleasedataFree()**

The function `ProMechbeamreleasedataAlloc()` allocates the memory for the beam release data handle.

The function `ProMechbeamreleaseDataGet()` provides access to the data structure containing the properties of the beam release item.

The translation and rotation flags correspond to translation or rotation about the X, Y, and Z directions. Set the value of each flag to `PRO_B_TRUE`, to indicate that the beam is not constrained in the specified direction. Set the value to `PRO_B_FALSE` to indicate that the beam is constrained in the specified direction.

The function `ProMechbeamreleasedataFree()` releases the memory assigned to the beam release data handle.

---

## Creo Simulate Spring Items

A spring connects two points or a point to the ground in the specified model. It provides the stiffness that you specify at the location on the model where you place it. The stiffness can be translational (force per unit length) or torsional (torque). The force generated by the spring is proportional to the amount of displacement that occurs. The functions described in this section enable you to access the data and contents of the Creo Simulate spring items. Springs use the `ProType` field in the `ProMechitem` structure as `PRO_SIMULATION_SPRING`.

Functions Introduced:

- **ProMechspringReferencesGet()**
- **ProMechspringReferencesSet()**
- **ProMechspringTypeGet()**
- **ProMechspringAdvanceddataGet()**
- **ProMechspringAdvanceddataSet()**
- **ProMechspringGrounddataGet()**
- **ProMechspringGrounddataSet()**
- **ProMechspringSimpledataGet()**
- **ProMechspringSimpledataSet()**
- **ProMechsimplespringdataAlloc()**
- **ProMechsimplespringdataTorsionalstiffnessGet()**
- **ProMechsimplespringdataTorsionalstiffnessSet()**
- **ProMechsimplespringdataExtensionalstiffnessValueGet()**
- **ProMechsimplespringdataExtensionalstiffnessValueSet()**
- **ProMechsimplespringdataFree()**
- **ProMechadvancedspringdataAlloc()**
- **ProMechadvancedspringdataPropertiesGet()**
- **ProMechadvancedspringdataPropertiesSet()**
- **ProMechadvancedspringdataRotationGet()**
- **ProMechadvancedspringdataRotationSet()**
- **ProMechadvancedspringdataYdirectionGet()**
- **ProMechadvancedspringdataYdirectionSet()**
- **ProMechadvancedspringdataFree()**
- **ProMechgroundspringdataAlloc()**
- **ProMechgroundspringdataCsysGet()**

- **ProMechgroundspringdataCsysSet()**
- **ProMechgroundspringdataPropertiesGet()**
- **ProMechgroundspringdataPropertiesSet()**
- **ProMechgroundspringdataFree()**

The function `ProMechspringReferencesGet()` returns the geometrical references specified while modeling the spring. The references define the location of the spring on the model. Use the function

`ProMechspringReferencesSet()` to set the geometrical references for the spring.

The function `ProMechspringTypeGet()` returns the type of the specified spring. The output argument *Type* has one of the following values:

- **PRO\_MECH\_SPRING\_SIMPLE**—Specifies a simple spring. This type of spring connects two points, two vertices, a point to an edge, a point to a surface, a point to a pattern of points, a point to a single point feature. The extensional and torsional stiffness properties will be defined for this spring.

Use the function `ProMechspringSimpledataGet()` to provide access to the data structure containing the simple spring data. Use the function `ProMechspringSimpledataSet()` to modify the data structure containing the simple spring data.

- **PRO\_MECH\_SPRING\_GROUND**—Specifies a To Ground spring. This type of spring connects a point, a single point feature, or a single pattern of points to ground. The spring stiffness properties and the orientation are defined for this spring.

A separate properties object can be defined for this type of spring.

Use the function `ProMechspringGrounddataGet()` to provide access to the data structure containing the ground spring data. Use the function `ProMechspringGrounddataSet()` to modify the data structure containing the ground spring data.

- **PRO\_MECH\_SPRING\_ADVANCED**—Specifies an Advanced spring. This type of spring connects two points, a point to an edge, a point to a surface, a point to a pattern of points, or a point to a single point feature. The stiffness properties, orientation properties, and an additional rotation are defined for this spring. Use the function `ProMechspringAdvanceddataGet()` to provide access to the data structure containing the advanced spring data. Use the function `ProMechspringAdvanceddataSet()` to modify the data structure containing the advanced spring data.

Extensional stiffness of a spring resists the stretching or compression of the spring. The extensional stiffness of the spring is of constant stiffness or is defined by a force-deflection curve. The function

---

`ProMechsinglespringdataExtensionalstiffnessValueGet()` returns the extensional stiffness of the spring. Use the function `ProMechsinglespringdataExtensionalstiffnessValueSet()` to set the extensional stiffness for the spring.

---

 **Note**

Note: The functions

`ProMechsinglespringdataExtensionalstiffnessGet()` and `ProMechsinglespringdataExtensionalstiffnessSet()` have been deprecated. Use the functions

`ProMechsinglespringdataExtensionalstiffnessValueGet()` and

`ProMechsinglespringdataExtensionalstiffnessValueSet()` instead.

---

## Creo Simulate Spring Property Items

The functions described in this section provide access to the data and contents of the Creo Simulate spring property items. Spring properties use the `ProType` field in the `ProMechitem` structure as `PRO_SIMULATION_SPRING_PROPS`.

Functions Introduced:

- **`ProMechspringpropsDescriptionGet()`**
- **`ProMechspringpropsDescriptionSet()`**
- **`ProMechSpringpropsBooleanGet()`**
- **`ProMechSpringpropsBooleanSet()`**
- **`ProMechSpringpropsMatrixGet()`**
- **`ProMechSpringpropsMatrixSet()`**
- **`ProMechSpringpropsVectorGet()`**
- **`ProMechSpringpropsVectorSet()`**

Functions Superseded:

- **`ProMechspringpropsdataAlloc()`**
- **`ProMechspringpropsDataGet()`**
- **`ProMechspringpropsDataSet()`**
- **`ProMechspringpropsdataDampingcoefficientsGet()`**
- **`ProMechspringpropsdataDampingcoefficientsSet()`**
- **`ProMechspringpropsdataExtensionalcoefficientsGet()`**

- **ProMechspringpropsdataExtensionalcoefficientsSet()**
- **ProMechspringpropsdataTorsionalcoefficientsGet()**
- **ProMechspringpropsdataTorsionalcoefficientsSet()**
- **ProMechspringpropsdataCouplingcoefficientsGet()**
- **ProMechspringpropsdataCouplingcoefficientsSet()**
- **ProMechspringpropsdataAutocouplingGet()**
- **ProMechspringpropsdataAutocouplingSet()**
- **ProMechspringpropsdataFree()**

The function `ProMechspringpropsDataGet()` provides access to the data structure containing the Spring Properties data. The function `ProMechspringpropsDataGet()` has been deprecated. Use either `ProMechspringpropsMatrixGet()` or `ProMechspringpropsVectorGet()` instead.

The functions listed above provide read and write access to the definition of the spring properties. You can access the name, description, extensional, torsional and coupling stiffness, and the damping coefficients for the spring properties.

The function `ProMechspringpropsDescriptionGet()` returns the description for the spring property. Use the function `ProMechspringpropsDescriptionSet()` to set the description for the spring property.

The functions `ProMechSpringpropsBooleanGet/Set`, `ProMechSpringpropsMatrixGet/Set`, and `ProMechSpringpropsVectorGet/Set` use the enumerated type `ProMechSpringpropsPropertyType` to define the spring property type.

The enumerated type `ProMechSpringpropsPropertyType` has the following values:

- `PRO_MECH_SPRINGPROPS_EXTENSIONAL`
- `PRO_MECH_SPRINGPROPS_TORSIONAL`
- `PRO_MECH_SPRINGPROPS_COUPLING`
- `PRO_MECH_SPRINGPROPS_DAMPING`
- `PRO_MECH_SPRINGPROPS_AUTOCOUPLING`

The function `ProMechSpringpropsBooleanGet()` gets the Boolean value for the autocoupling option. Use the function `ProMechSpringpropsBooleanSet()` to set the Boolean value for the autocoupling option.

The function `ProMechSpringpropsMatrixGet()` returns the Creo Simulate matrix handle `ProMechMatrix`. Use the function `ProMechSpringpropsMatrixSet()` to set the handle to `ProMechMatrix`. The functions `ProMechMatrixComponentGet/Set`

---

provide read and write access to the individual matrix components. For more information about handling matrix components, see [Creo Simulate Matrix Functions on page 1864](#).

The output matrix gets the following values depending on the spring property type:

- Extensional coefficients (Kxx,Kyy,Kzz,Kxy,Kxz,Kyz)
- Torsional coefficients (Txx,Tyy,Tzz,Txy,Txz,Tyz)
- Coupling coefficients (KTxx, KTxy, KTxz, KTyx, KTyx, KTyx, KTzx, KTzy, KTzz)

The function `ProMechSpringpropsMatrixGet()` automatically allocates memory for the Creo Simulate matrix handle. Use the function `ProMechMatrixFree()` to free the assigned memory.

The function `ProMechSpringpropsVectorGet()` returns the Creo Simulate vector handle `ProMechVector`. Use the function `ProMechSpringpropsVectorSet()` to set the handle to `ProMechVector`. The functions `ProMechVectorComponentGet/Set` provide read and write access to the individual vector components. For more information about handling vector components, see [Creo Simulate Vector Functions on page 1864](#). The vector returns the damping coefficients (Cxx, Cyy, Czz) as output. The function `ProMechSpringpropsVectorGet()` automatically allocates the memory for the Creo Simulate vector handle. Use the function `ProMechVectorFree()` to free the memory.

## Creo Simulate Mass Items

A mass is an idealization that you can use to represent a concentrated mass without a specified shape. The mass of an object determines how that object resists translation and rotation. You can also add mass that is distributed over features such as curves, edges, or surfaces.

The functions described in this section provide access to the data and contents of the Creo Simulate mass items. Masses use the `ProType` field in the `ProMechitem` structure as `PRO_SIMULATION_MASS`.

Functions Introduced:

- **`ProMechmassDistributionGet()`**
- **`ProMechmassDistributionSet()`**
- **`ProMechmassReferencesGet()`**
- **`ProMechmassReferencesSet()`**
- **`ProMechmassTypeGet()`**
- **`ProMechmassSimplifieddataGet()`**
- **`ProMechmassSimplifieddataSet()`**

- 
- **ProMechmassAdvanceddataGet()**
  - **ProMechmassAdvanceddataSet()**
  - **ProMechmassComponentdataGet()**
  - **ProMechmassComponentpointdataSet()**
  - **ProMechmassComponentdistributeddataSet()**
  - **ProMechsimplemassdataAlloc()**
  - **ProMechsimplemassdataMassGet()**
  - **ProMechsimplemassdataMassSet()**
  - **ProMechsimplemassdataFree()**
  - **ProMechadvancedmassdataAlloc()**
  - **ProMechadvancedmassdataCsysGet()**
  - **ProMechadvancedmassdataCsysSet()**
  - **ProMechadvancedmassdataPropertiesGet()**
  - **ProMechadvancedmassdataPropertiesSet()**
  - **ProMechadvancedmassdataFree()**
  - **ProMechcomponentmassdataAlloc()**
  - **ProMechcomponentmassdataComponentGet()**
  - **ProMechcomponentmassdataComponentSet()**
  - **ProMechcomponentmassdataFree()**

The function `ProMechmassDistributionGet()` returns the types of masses that can be applied to curves, surfaces, and edges in FEM Mode.

The output argument *type* can have the following values:

- `PRO_MECH_MASS_DISTR_AT_POINT`—Specifies that the mass is added to a point, vertex, multiple single points, point features, and point patterns.
- `PRO_MECH_MASS_DISTR_TOTAL`—Specifies the total distribution of mass along a surface or curve.
- `PRO_MECH_MASS_DISTR_PER_UNIT`—Specifies the distribution of mass along a curve or surface per unit length or per unit area respectively.

Use the function `ProMechmassDistributionSet()` to set the types of masses that can be applied to curves, surfaces, and edges in FEM Mode.

The function `ProMechmassReferencesGet()` returns the mass reference objects. The references can be either curves, edges, or surfaces. Use the function `ProMechmassReferencesSet()` to set the mass reference objects.

The function `ProMechmassTypeGet()` returns the types of masses defined for a point or vertex. The output argument *type* can have one of the following values:

- 
- `PRO_MECH_MASS_SIMPLE`—Specifies a simple mass type. Specify an integer as the mass value and points, single point, multiple single points, point features, point patterns, edges, curves, or surfaces as the reference for the simple mass type. Use the function `ProMechmassSimpledataGet()` to access the simple mass data structure. Use the function `ProMechmassSimpledataSet()` to modify the simple mass data structure.
  - `PRO_MECH_MASS_ADVANCED`—Specifies the advanced mass type. Specify the coordinate system and the mass property object for a single point, multiple single points, point features, and point patterns. Use the function `ProMechmassAdvanceddataGet()` to access the advanced mass data structure. Use the function `ProMechmassAdvanceddataSet()` to modify the advanced mass data structure.
  - `PRO_MECH_MASS_COMP_AT_POINT`—Specifies the component mass data for a part or subassembly of an assembly. For this type of mass, the mass definition is specified using the component's mass, moment of inertia, and center of gravity. This mass type can be created using points, edges or curves, or Surfaces as the reference. Use the function `ProMechmassComponentdataGet()` to access the component mass data structure. Use the function `ProMechmassComponentpointdataSet()` to modify the component at point mass data structure.
  - This mass type is applicable only for the assembly mode.
  - `PRO_MECH_MASS_COMP_DISTRIBUTED`—Specifies the component distributed mass data for a part or subassembly of an assembly. For this type of mass, only the component's mass is used to specify the mass definition. This mass type can be created using points, edges or curves, or surfaces as the reference. Use the function `ProMechmassComponentdataGet()` to access the component mass data structure. Use the function `ProMechmassComponentdistributeddataSet()` to modify the component distributed mass data structure.
  - This mass type is applicable only for the assembly mode.

The function `ProMechsimplemassdataAlloc()` allocates memory for a simple mass data structure.

The function `ProMechsimplemassdataMassGet()` returns the value of the mass for a simple mass data and the function `ProMechsimplemassdataMassSet()` sets the value of the mass for a simple mass data.

The function `ProMechadvancedmassdataAlloc()` allocates memory for the advanced mass data structure.

---

The function `ProMechadvancedmassdataCsysGet()` returns the reference co-ordinate system for the advanced mass data and the function `ProMechadvancedmassdataCsysSet()` sets the reference co-ordinate system for the advanced mass data.

The function `ProMechadvancedmassdataPropertiesGet()` returns the mass property for the advanced mass data.

The function `ProMechadvancedmassdataPropertiesSet()` sets the mass property for the advanced mass data.

The function `ProMechcomponentmassdataAlloc()` allocates memory for the component mass data structure.

The function `ProMechcomponentmassdataComponentGet()` specifies a reference for the component mass data. You can specify only one datum point or vertex as reference for the mass type `PRO_MECH_MASS_COMP_AT_POINT`. You can specify points, edges, curves, or surfaces as reference for the mass type `PRO_MECH_MASS_COMP_DISTRIBUTED`.

The function `ProMechcomponentmassdataComponentSet()` sets the reference type for the component mass data.

## Creo Simulate Mass Properties

The functions described in this section provide read and write access to the data and contents of the Creo Simulate property items. Mass properties use the `ProType` field in the `ProMechitem` structure as `PRO_SIMULATION_MASS_PROPS`.

Functions Introduced:

- **`ProMechmasspropsDescriptionGet()`**
- **`ProMechmasspropsDescriptionSet()`**
- **`ProMechMasspropsExpressionGet()`**
- **`ProMechMasspropsExpressionSet()`**
- **`ProMechMasspropsMatrixGet()`**
- **`ProMechMasspropsMatrixSet()`**

Functions Superseded:

- **`ProMechmasspropsMassGet()`**
- **`ProMechmasspropsMassSet()`**
- **`ProMechmasspropsMomentsGet()`**
- **`ProMechmasspropsMomentsSet()`**

---

The function `ProMechmasspropsDescriptionGet()` returns the description for the mass property. Use the function `ProMechmasspropsmassSet()` to set the description for the mass property.

The function `ProMechmasspropsMassGet()` returns the value of the mass specified for the mass properties object. Use the function `ProMechmasspropsMassSet()` to set the value of the mass. The functions `ProMechmasspropsMassGet()` and `ProMechmasspropsMassSet()` have been deprecated. Use the functions `ProMechMasspropsExpressionGet()` and `ProMechMasspropsExpressionSet()` instead.

The function `ProMechmasspropsMomentsGet()` returns the moment of inertia about each mass element's center of gravity with respect to the axes and principal planes of the WCS. The moment of inertia is returned in the form of a matrix. Use the function `ProMechmasspropsMomentsSet()` to set the moment of inertia matrix. The functions `ProMechmasspropsMomentsGet()` and `ProMechmasspropsMomentsSet()` have been deprecated. Use the functions `ProMechMasspropsMatrixGet()` and `ProMechMasspropsMatrixSet()` instead.

The functions `ProMechMasspropsExpressionGet()` and `ProMechMasspropsExpressionSet()` use the enumerated type `ProMechMasspropsPropertyType`. The values are:

- `PRO_MECH_MASSPROPS_MASS`
- `PRO_MECH_MASSPROPS_MOMENTS`

The function `ProMechMasspropsExpressionGet()` gets the value of the defined mass property object. If an expression is defined, the output value can be calculated using `ProMathExpressionEvaluate()`. Use the function `ProMechMasspropsExpressionSet()` to set the value for the mass property object.

The function `ProMechMasspropsMatrixGet()` returns the Creo Simulate matrix handle `ProMechMatrix`. Use the function `ProMechMasspropsMatrixSet()` to set the handle to `ProMechMatrix`. The functions `ProMechMatrixComponentGet/Set` provide read and write access to the individual matrix components. For more information about handling matrix components, see [Creo Simulate Vector Functions on page 1864](#).

## Creo Simulate Material Assignment

The functions described in this section allow you to assign materials to the 2D and 3D models. Material assignment uses the `ProType` field in the `ProMechitem` structure as `PRO_SIMULATION_MATL_ASSIGN`.

Functions referring to the material assignment elements use the structure `ProMechMatlAssignData` which is defined as:

```
typedef struct pro_matlassign_data
{
 int matl_id;
 int matl_orient_id;
}
ProMatlassignData;
```

## Accessing ProMechmatlassign

Functions Introduced:

- **ProMechmatlassignReferencesGet()**
- **ProMechmatlassignReferencesSet()**
- **ProMechmatlassignDataGet()**
- **ProMechmatlassignDataSet()**

The function `ProMechmatlassignReferencesGet()` returns the model references for material assignment. Use the function `ProMechmatlassignReferencesSet()` to set the model references for material assignment.

The function `ProMechmatlassignDataGet()` provides access to the data structure containing the properties of the material assignment item. Use the function `ProMechmatlassignDataSet()` to set the data structure containing the properties of the material assignment item.

## Material Assignment Data

Functions Introduced:

- **ProMechmecttempdataAlloc()**
- **ProMechmatlassigndataFree()**
- **ProMechmatlassigndataMaterialidGet()**
- **ProMechmatlassigndataMaterialidSet()**
- **ProMechmatlassigndataMaterialorientidGet()**
- **ProMechmatlassigndataMaterialorientidSet()**

The function `ProMechmecttempdataAlloc()` allocates the memory for a Creo Simulate material assignment data handle.

The function `ProMechmatlassigndataFree()` releases the memory assigned to the Creo Simulate material assignment data handle.

The function `ProMechmatlassigndataMaterialidGet()` returns the material id defined for the model references. Use the function `ProMechmatlassigndataMaterialidSet()` to set the material id for the model references.

---

The function `ProMechmatlassigndataMaterialorientidGet()` returns the material orientation id of the model references. Use the function `ProMechmatlassigndataMaterialorientidSet()` to set the material orientation id for the model references.

## Material Orientations

The functions described in this section specify material orientation for surfaces, volumes, shells, solids, 2D solids, and 2D plates. These functions provide read and write access to the data and contents of Creo Simulate material orientation objects. Material orientations use the `ProType` field in the `ProMechitem` structure as `PRO_SIMULATION_MATL_ORIENT`.

Functions Introduced:

- **`ProMechmaterialorientdataAlloc()`**
- **`ProMechmaterialorientDataGet()`**
- **`ProMechmaterialorientDataSet()`**
- **`ProMechmaterialorientDescriptionGet()`**
- **`ProMechmaterialorientDescriptionSet()`**
- **`ProMechmaterialorientdataObjecttypeGet()`**
- **`ProMechmaterialorientdataObjecttypeSet()`**
- **`ProMechmaterialorientdataCsysdataGet()`**
- **`ProMechmaterialorientdataCsysdataSet()`**
- **`ProMechmaterialorientdataProjectiondataGet()`**
- **`ProMechmaterialorientdataProjectiondataSet()`**
- **`ProMechmaterialorientdataRotationGet()`**
- **`ProMechmaterialorientdataRotationSet()`**
- **`ProMechmaterialorientdataSurfacerotationGet()`**
- **`ProMechmaterialorientdataSurfacerotationSet()`**
- **`ProMechmaterialorientdataTypeGet()`**
- **`ProMechmaterialorientdataSurfacerotationUnset()`**
- **`ProMechmaterialorientdataFirstdirectionSet()`**
- **`ProMechmaterialorientdataSeconddirectionSet()`**
- **`ProMechmaterialorientdataFree()`**
- **`ProMechmaterialorientcsysAlloc()`**
- **`ProMechmaterialorientcsysCsysGet()`**
- **`ProMechmaterialorientcsysCsysSet()`**

- **ProMechmaterialorientcsysProjectiontypeGet()**
- **ProMechmaterialorientcsysProjectiontypeSet()**
- **ProMechmaterialorientcsysXaxisGet()**
- **ProMechmaterialorientcsysXaxisSet()**
- **ProMechmaterialorientcsysYaxisGet()**
- **ProMechmaterialorientcsysYaxisSet()**
- **ProMechmaterialorientcsysZaxisGet()**
- **ProMechmaterialorientcsysZaxisSet()**
- **ProMechmaterialorientcsysFree()**
- **ProMechmaterialorientprojAlloc()**
- **ProMechmaterialorientprojPointsGet()**
- **ProMechmaterialorientprojPointsSet()**
- **ProMechmaterialorientprojTypeGet()**
- **ProMechmaterialorientprojXyzvectorGet()**
- **ProMechmaterialorientprojXyzvectorSet()**
- **ProMechmaterialorientprojFree()**

The function `ProMechMaterialorientDataGet()` provides access to the data structure containing the properties of the material orientation item. Use the function `ProMechmaterialorientDataSet()` to set the data structure containing the properties of the material orientation item.

The function `ProMechmaterialorientDescriptionGet()` returns the description of the material orientation. Use the function `ProMechmaterialorientDescriptionSet()` to set the description of the material orientation.

The function `ProMechmaterialorientdataObjecttypeGet()` returns the type of object to which the material orientation is applied. The types of object are:

- `PRO_MECH_MATLORI_MODEL`—Specifies a model.
- `PRO_MECH_MATLORI_SURFACE`—Specifies a surface.

Use the function `ProMechmaterialorientdataObjecttypeSet()` to set the type of object.

The function `ProMechmaterialorientReferencesGet()` returns the geometric references specified for the material orientation object.

---

The function `ProMechmaterialorientdataCsysdataGet()` returns a handle to the data structure containing the coordinate system data for the material orientation. Use the function

`ProMechmaterialorientdataCsysdataSet()` to set the coordinate system data for the material orientation.

The function `ProMechmaterialorientdataTypeGet()` returns the type of the material direction. The types are as follows:

- `PRO_MECH_MATLORI_COORD_SYSTEM`—Specifies that the material orientation direction is determined by the reference coordinate system.
- `PRO_MECH_MATLORI_1_DIR`—Specifies that the material orientation direction is determined by the first parametric direction of the material. Use the function `ProMechmaterialorientdataFirstdirectionSet()` to set the first direction of the material as the orientation type.
- `PRO_MECH_MATLORI_2_DIR`—Specifies that the material orientation direction is determined by the second parametric direction of the material. Use the function `ProMechmaterialorientdataSeconddirectionSet()` to set the second direction of the material as the orientation type.
- `PRO_MECH_MATLORI_PROJ_VECTOR`—Specifies that the material orientation direction is determined by the projection vector.

The function `ProMechmaterialorientdataProjectiondataGet()` returns the structure containing the projection data for the material orientation. Use the function

`ProMechmaterialorientdataProjectiondataSet()` to set the projection data for the material orientation.

The function `ProMechmaterialorientdataRotationGet()` returns additional rotations about one or more material directions only if the material orientation type is `PRO_MECH_MATLORI_MODEL`. Use the function `ProMechmaterialorientdataRotationSet()` to set the additional rotations about one or more material directions only if the material orientation type is `PRO_MECH_MATLORI_MODEL`.

The function `ProMechmaterialorientdataSurfacerotationGet()` returns the rotation angle for the material orientation if the orientation type is `PRO_MECH_MATLORI_SURFACE`.

Use the function

`ProMechmaterialorientdataSurfacerotationSet()` to set the rotation angle for the material orientation if the orientation type is `PRO_MECH_MATLORI_SURFACE`.

---

Use the function

`ProMechmaterialorientdataSurfacerotationUnset()` removes the rotation angle for the material orientation if the orientation type is `PRO_MECH_MATLORI_SURFACE`.

The function `ProMechmaterialorientprojTypeGet()` returns the type of projection assigned to the material orientation. The types of materials are:

- `PRO_MECH_MATLORI_PROJ_XYZ`—Specifies the values for the X, Y, and Z components to define the projection vector for the material orientation. Use the function `ProMechmaterialorientprojXyzvectorGet()` to access the projection vector. Use the function `ProMechmaterialorientprojXyzvectorSet()` to set the projection vector for the material orientation.
- `PRO_MECH_MATLORI_PROJ_POINTS`—Specifies the two points used to define the projection vector for the material orientation. Use the function `ProMechmaterialorientprojPointsGet()` to access the two points. Use the function `ProMechmaterialorientprojPointsSet()` to set the two points used for projection.

The function `ProMechmaterialorientcsysCsysGet()` returns the coordinate system used to specify the material directions. Use the function `ProMechmaterialorientcsysCsysSet()` to set the coordinate system for the material directions.

The function `ProMechmaterialorientcsysProjectiontypeGet()` returns the projection vector for the material orientation object. The valid projection types are as follows:

- `PRO_MECH_MATLORI_CSYS_PROJ_CLOSEST`—Specifies the material Direction 1 through a series of calculations.
- `PRO_MECH_MATLORI_CSYS_PROJ_X`—Specifies that the material direction 1 is along the direction of the X axis of the referenced coordinate system projected onto the surface.

Use the function

`ProMechmaterialorientcsysProjectiontypeSet()` to set the projection type for the material orientation data.

The function `ProMechmaterialorientcsysXaxisGet()` returns the material direction to which the x-axis of the coordinate system is mapped. Use the function `ProMechmaterialorientcsysXaxisSet()` to set the material direction to which the x-axis of the coordinate system is mapped.

The function `ProMechmaterialorientcsysYaxisGet()` returns the material direction to which the y-axis of the coordinate system is mapped. Use the function `ProMechmaterialorientcsysYaxisSet()` to set the material direction to which the y-axis of the coordinate system is mapped.

---

The function `ProMechmaterialorientcsysZaxisGet()` returns the material direction to which the z-axis of the coordinate system is mapped. Use the function `ProMechmaterialorientcsysZaxisSet()` to set the material direction to which the z-axis of the coordinate system is mapped.

## Example 4: Creating Material Orientations Referencing a Selected Coordinate System

The sample code in the file `PTMechExMatOrient.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_mech_examples/pt_mech_ex_src` shows how to create a new material orientation item in the current model, referencing a selected coordinate system.

## Creo Simulate Shells

Shells are used to model a thin layer of a defined thickness for a specified part. If the part is relatively thin compared to its length and width, use of shell modeling is more efficient.

The functions described in this section provide read and write access to the data and contents of the Creo Simulate shell objects. Shells use the `ProType` field in the `ProMechitem` structure as `PRO_SIMULATION_SHELL`.

Functions Introduced:

- **ProMechshellTypeGet()**
- **ProMechshellMaterialGet()**
- **ProMechshellMaterialIdGet()**
- **ProMechshellMaterialIdSet()**
- **ProMechshellReferencesGet()**
- **ProMechshellReferencesSet()**
- **ProMechshellSimpledataGet()**
- **ProMechshellSimpledataSet()**
- **ProMechshellAdvanceddataGet()**
- **ProMechshellAdvanceddataSet()**
- **ProMechshellsimpleAlloc()**
- **ProMechshellsimpleThicknessGet()**
- **ProMechshellsimpleThicknessSet()**
- **ProMechshellsimpleFree()**
- **ProMechshelladvancedAlloc()**
- **ProMechshelladvancedMaterialorientGet()**

- **ProMechshelladvancedMaterialorientSet()**
- **ProMechshelladvancedShellpropsGet()**
- **ProMechshelladvancedShellpropsSet()**
- **ProMechshelladvancedFree()**

The function `ProMechshellTypeGet()` returns the shell types. You can define the following types of shells:

- **PRO\_MECH\_SHELL\_SIMPLE**—Specifies a simple shell of uniform thickness. Use the function `ProMechshellSimplesdataGet()` to access the data structure for the simple shell. Use the function `ProMechshellSimplesdataSet()` to modify the data structure for the simple shell.
- **PRO\_MECH\_SHELL\_ADVANCED**—Specifies an advanced shell that uses specified shell properties. Use the function `ProMechshellAdvanceddataGet()` to access the data structure for the advanced shells. Use the function `ProMechshellAdvanceddataSet()` to modify the data structure for the advanced shell.

The function `ProMechshellMaterialGet()` returns the material defined for the shell.

Use the function `ProMechshellMaterialIdSet()` to set the material id for the shell.

The function `ProMechshellReferencesGet()` returns the surfaces associated with the shell. Use the function `ProMechshellReferencesSet()` to set the references for the shell.

The function `ProMechshellsimpleThicknessGet()` returns the value of the thickness for the shell. Use the function `ProMechshellsimpleThicknessSet()` to set value of the thickness of the shell.

The function `ProMechshelladvancedMaterialorientGet()` returns the material orientations assigned to the advanced shell. Use the function `ProMechshelladvancedMaterialorientSet()` to set the material orientation for the advanced shell.

The function `ProMechshelladvancedShellpropsGet()` returns the shell properties associated with the model. Use the function `ProMechshelladvancedShellpropsSet()` to set the shell properties associated with the model.

---

## Shell Properties

Shell properties are used to create shells that are not homogeneous, or to create shells that are comprised of several layers. A shell property can be assigned to a face, region, or datum surface.

The functions described in this section provide read and write access to data and contents of the Creo Simulate shell property objects. Shell properties use the `ProType` field in the `ProMechitem` structure as `PRO_SIMULATION_SHELL_PROPS`.

Functions Introduced:

- **ProMechshellpropsTypeGet()**
- **ProMechshellpropsDescriptionGet()**
- **ProMechshellpropsDescriptionSet()**
- **ProMechshellpropsHomogeneousdataGet()**
- **ProMechshellpropsHomogeneousdataSet()**
- **ProMechshellpropsLaminatelayupdataGet()**
- **ProMechshellpropsLaminatelayupdataSet()**
- **ProMechshellpropsLaminatetestiffdataGet()**
- **ProMechshellpropsLaminatetestiffdataSet()**
- **ProMechshlprophomogeneousAlloc()**
- **ProMechshlprophomogeneousThicknessGet()**
- **ProMechshlprophomogeneousThicknessSet()**
- **ProMechshlprophomogeneousFree()**
- **ProMechshlproplaminatetestiffAlloc()**
- **ProMechshlproplaminatetestiffAppliedstressGet()**
- **ProMechshlproplaminatetestiffAppliedstressSet()**
- **ProMechshlproplaminatetestiffBendingstiffnessGet()**
- **ProMechshlproplaminatetestiffBendingstiffnessSet()**
- **ProMechshlproplaminatetestiffCouplingstiffnessGet()**
- **ProMechshlproplaminatetestiffCouplingstiffnessSet()**
- **ProMechshlproplaminatetestiffExtensionalstiffnessGet()**
- **ProMechshlproplaminatetestiffExtensionalstiffnessSet()**
- **ProMechshlproplaminatetestiffIntertiaperunitareaGet()**
- **ProMechshlproplaminatetestiffIntertiaperunitareaSet()**
- **ProMechshlproplaminatetestiffMassperunitareaGet()**

- 
- **ProMechshlproplaminatetestiffMassperunitareaSet()**
  - **ProMechshlproplaminatetestiffTansverseshearGet()**
  - **ProMechshlproplaminatetestiffTansverseshearSet()**
  - **ProMechshlproplaminatetestiffThermalresforceGet()**
  - **ProMechshlproplaminatetestiffThermalresforceSet()**
  - **ProMechshlproplaminatetestiffThermalresmomentGet()**
  - **ProMechshlproplaminatetestiffThermalresmomentSet()**
  - **ProMechshlproplaminatetestiffFree()**
  - **ProMechstresscalldataAlloc()**
  - **ProMechstresscalldataCzGet()**
  - **ProMechstresscalldataCzSet()**
  - **ProMechstresscalldataMaterialIdGet()**
  - **ProMechstresscalldataMaterialIdSet()**
  - **ProMechstresscalldataPlyorientationGet()**
  - **ProMechstresscalldataPlyorientationSet()**
  - **ProMechstresscalldataFree()**
  - **ProMechstresscalldataProarrayFree()**
  - **ProMechstiffmatrixEntry11Get()**
  - **ProMechstiffmatrixEntry11Set()**
  - **ProMechstiffmatrixEntry12Get()**
  - **ProMechstiffmatrixEntry12Set()**
  - **ProMechstiffmatrixEntry16Get()**
  - **ProMechstiffmatrixEntry16Set()**
  - **ProMechstiffmatrixEntry22Get()**
  - **ProMechstiffmatrixEntry22Set()**
  - **ProMechstiffmatrixEntry26Get()**
  - **ProMechstiffmatrixEntry26Set()**
  - **ProMechstiffmatrixEntry66Get()**
  - **ProMechstiffmatrixEntry66Set()**
  - **ProMechstiffmatrixFree()**
  - **ProMechtransverseshearEntry44Get()**
  - **ProMechtransverseshearEntry44Set()**
  - **ProMechtransverseshearEntry45Get()**

- 
- **ProMechtransverseshearEntry45Set()**
  - **ProMechtransverseshearEntry55Get()**
  - **ProMechtransverseshearEntry55Set()**
  - **ProMechtransverseshearFree()**
  - **ProMechthermalrescoeffEntry11Get()**
  - **ProMechthermalrescoeffEntry11Set()**
  - **ProMechthermalrescoeffEntry12Get()**
  - **ProMechthermalrescoeffEntry12Set()**
  - **ProMechthermalrescoeffEntry22Get()**
  - **ProMechthermalrescoeffEntry22Set()**
  - **ProMechthermalrescoeffFree()**
  - **ProMechshlproplaminatelayupAlloc()**
  - **ProMechshlproplaminatelayupLayersGet()**
  - **ProMechshlproplaminatelayupLayersSet()**
  - **ProMechshlproplaminatelayupTypeGet()**
  - **ProMechshlproplaminatelayupTypeSet()**
  - **ProMechshlproplaminatelayupFree()**
  - **ProMechshlproplamlayuplayerMaterialIdGet()**
  - **ProMechshlproplamlayuplayerMaterialIdSet()**
  - **ProMechshlproplamlayuplayerNumberGet()**
  - **ProMechshlproplamlayuplayerNumberSet()**
  - **ProMechshlproplamlayuplayerOrientationGet()**
  - **ProMechshlproplamlayuplayerOrientationSet()**
  - **ProMechshlproplamlayuplayerThicknessGet()**
  - **ProMechshlproplamlayuplayerThicknessSet()**
  - **ProMechshlproplamlayuplayerShellpropsGet()**
  - **ProMechshlproplamlayuplayerShellpropsSet()**
  - **ProMechshlproplamlayuplayerFree()**
  - **ProMechshlproplamlayuplayerProarrayFree()**

The function `ProMechshellpropsTypeGet()` returns the type of properties that have been defined for the shell. The types of shell properties are:

- **PRO\_MECH\_SHLPROP\_HOMOGENEOUS**—Assigned to homogenous shells. A homogeneous shell consists of a single material whose properties do not vary through the thickness of the shell. Use the function

---

`ProMechshellpropsHomogeneousdataGet()` to access the data structure for homogeneous shell property. Use the function `ProMechshellpropsHomogeneousdataSet()` to set the homogeneous shell property.

- `PRO_MECH_SHLPROP_LAMINATE_STIFFNESS`—Assigned to laminate shells to specify their degree of stiffness. Laminate shells consists of one or more materials whose properties may vary through the thickness of the shell. Use the function `ProMechshellpropsLaminatestiffdataGet()` to access the data structure for the laminate stiffness shell property. Use the function `ProMechshellpropsLaminatestiffdataSet()` to set the laminate stiffness shell property.
- `PRO_MECH_SHLPROP_LAMINATE_LAYUP`—Assigned to laminate shells to define them as layers of shells. Use the function `ProMechshellpropsLaminatelayupdataGet()` to access the data structure for the laminate layup shell property. Use the function `ProMechshellpropsLaminatelayupdataSet()` to set the laminate layup shell property.

The function `ProMechshellpropsDescriptionGet()` returns the description for the shell properties. Use the function `ProMechshellpropsDescriptionSet()` to modify the description for the shell properties.

The function `ProMechshlprophomogeneousThicknessGet()` returns the shell thickness defined for shells. Use the function `ProMechshlprophomogeneousThicknessSet()` to set the thickness for the shell properties.

The function `ProMechshlproplaminatestiffAppliedstressGet()` returns the calculation of stresses and strains for the laminate stiffness shell property type. The resultant array contains the shell "Top" location and the shell "Bottom" location. The values specified in these areas are used to calculate the stresses and strains for the corresponding areas. Use the function `ProMechshlproplaminatestiffAppliedstressSet()` to set the value of the stress and strain in the calculation array.

The function `ProMechstresscalcddataCzGet()` returns the distance from the midsurface of the shell at which the stresses and strains for the laminate shell is calculated. The Cz is defined relative to material direction 3 of the material orientation assigned to the shell. Use the function `ProMechstresscalcddataCzSet()` to set the Cz value used to calculate the stress and strain.

The function `ProMechstresscalcddataMaterialIdGet()` returns the material specified at the CZ location. Use the function `ProMechstresscalcddataMaterialIdSet()` to set the material id.

---

The function `ProMechstresscalcddataPlyorientationGet()` returns the orientation of the ply material. The ply orientation angle is measured as a counter-clockwise rotation from material direction 1 about material direction 3. Use the function `ProMechstresscalcddataPlyorientationSet()` to set the orientation of the ply material.

The function

`ProMechshlproplaminatetestiffBendingstiffnessGet()` returns the shell bending stiffness matrix. Use the function `ProMechshlproplaminatetestiffBendingstiffnessSet()` to set the shell bending stiffness matrix.

The function

`ProMechshlproplaminatetestiffCouplingstiffnessGet()` returns the shell coupling stiffness matrix. Use the function `ProMechshlproplaminatetestiffCouplingstiffnessSet()` to set the shell coupling stiffness matrix.

The function

`ProMechshlproplaminatetestiffExtensionalstiffnessGet()` returns the shell extensional stiffness matrix. Use the function `ProMechshlproplaminatetestiffExtensionalstiffnessSet()` to set the shell extensional stiffness matrix.

The functions `ProMechstiffmatrixEntry11Get()`, `ProMechstiffmatrixEntry12Get()`, `ProMechstiffmatrixEntry16Get()`, `ProMechstiffmatrixEntry22Get()`, `ProMechstiffmatrixEntry26Get()`, and `ProMechstiffmatrixEntry66Get()` provide access the elements of the stiffness matrix.

Use the functions `ProMechstiffmatrixEntry11Set()`, `ProMechstiffmatrixEntry12Set()`, `ProMechstiffmatrixEntry16Set()`, `ProMechstiffmatrixEntry22Set()`, `ProMechstiffmatrixEntry26Set()`, and `ProMechstiffmatrixEntry66Set()` to modify the elements of the stiffness matrix.

The function

`ProMechshlproplaminatetestiffIntertiaperunitareaGet()` returns the rotary inertia per unit area for the laminate stiffness properties. Use the function `ProMechshlproplaminatetestiffIntertiaperunitareaSet()` to set the inertia per unit area for the laminate stiffness properties.

---

The function

`ProMechshlproplaminatetestiffMassperunitareaGet()` returns the mass per unit area for the laminate stiffness properties. Use the function `ProMechshlproplaminatetestiffMassperunitareaSet()` to set the mass per unit area for the laminate stiffness properties.

The function `ProMechshlproplaminatetestiffTansverseshearGet()` returns the transverse shear stiffness for the laminate shell. Use the function `ProMechshlproplaminatetestiffTansverseshearSet()` to set the transverse shear stiffness for the laminate shell.

The functions `ProMechtransverseshearEntry44Get()`, `ProMechtransverseshearEntry45Get()`, and `ProMechtransverseshearEntry55Get()` provide access to the elements 44, 45, and 55 of the transverse shear matrix. Use the functions `ProMechtransverseshearEntry44Set()`, `ProMechtransverseshearEntry45Set()`, and `ProMechtransverseshearEntry55Set()` to set the elements 44, 45, and 55 of the transverse shear matrix.

The functions

`ProMechshlproplaminatetestiffThermalresforceGet()` and `ProMechshlproplaminatetestiffThermalresmomentGet()` return the thermal resultant coefficients for the laminate shell. The thermal coefficients are specified as Force and Moment. Use the functions `ProMechshlproplaminatetestiffThermalresforceSet()` and `ProMechshlproplaminatetestiffThermalresmomentSet()` to set the thermal resultant coefficients for the laminate shell.

The functions `ProMechthermalrescoeffEntry11Get()`, `ProMechthermalrescoeffEntry12Get()`, and `ProMechthermalrescoeffEntry22Get()` provide access to the elements 11, 12, and 22 of the thermal resultant coefficient matrix. Use the functions `ProMechthermalrescoeffEntry11Set()`, `ProMechthermalrescoeffEntry12Set()`, and `ProMechthermalrescoeffEntry22Set()` to set the elements 11, 12, and 22 of the thermal resultant coefficient matrix.

The function `ProMechshlproplaminatelayupLayersGet()` returns an array of layers, or plies, stacked on each other to form the laminate. Use the function `ProMechshlproplaminatelayupLayersSet()` to set the layers assigned to the laminate shell properties.

The function `ProMechshlproplaminatelayupTypeGet()` returns the layer repetition pattern for the laminate layup type shells. The types of repetition patterns are:

- `PRO_MECH_LAMLAYUP_SYMMETRIC`—Specifies that the layers are repeated in reverse order.

- `PRO_MECH_LAMLAYUP_ANTISYMMETRIC`—Specifies that the layers are repeated in reverse order, and the orientation is also changed.
- `PRO_MECH_LAMLAYUP_NEITHER`—Specifies that the layers are not repeated.

Use the function `ProMechshlproplamlayupTypeSet()` to set the type of laminate layup shell properties.

The function `ProMechshlproplamlayuplayerMaterialIdGet()` returns the name of the material assigned to the specified layer. Use the function `ProMechshlproplamlayuplayerMaterialIdSet()` to set the id of the specified laminate layer.

The function `ProMechshlproplamlayuplayerNumberGet()` returns the number of times a particular layer is repeated for the laminate. Use the function `ProMechshlproplamlayuplayerNumberSet()` to set the number for the laminate layup layer.

The function `ProMechshlproplamlayuplayerOrientationGet()` returns the orientation of the specified layer of the laminate. Use the function `ProMechshlproplamlayuplayerOrientationSet()` to set the orientation of the specified layer of the laminate.

The function `ProMechshlproplamlayuplayerThicknessGet()` returns the thickness of the specified layer of the laminate. Use the function `ProMechshlproplamlayuplayerThicknessSet()` to set the thickness of the specified layer of the laminate.

The function `ProMechshlproplamlayuplayerShellpropsGet()` returns the shell properties for the specified laminate layer. Use the function `ProMechshlproplamlayuplayerShellpropsSet()` to set the shell properties.

## Shell Pairs

The shell pairs are created based on the surfaces belonging to a part. The shell pairs are compressed to a mid surface or set of mid surfaces and shell elements are assigned to it.

The functions described in this section provide read and write access to the data and contents of the Creo Simulate shell pair objects. Shell pairs use the `ProType` field in the `ProMechitem` structure as `PRO_SIMULATION_SHELL_PAIR`.

Functions Introduced:

- **`ProMechshlpairrefsAlloc()`**
- **`ProMechshellpairMaterialIdGet()`**
- **`ProMechshellpairMaterialIdSet()`**
- **`ProMechshellpairMaterialOrientIdGet()`**

- **ProMechshellpairMaterialOrientIdSet()**
- **ProMechshellpairReferencesGet()**
- **ProMechshellpairReferencesSet()**
- **ProMechshlpairrefsTypeGet()**
- **ProMechshlpairrefsTypeSet()**
- **ProMechshlpairrefsPlacementtypeGet()**
- **ProMechshlpairrefsPlacementtypeSet()**
- **ProMechshlpairrefsBottomreferencesGet()**
- **ProMechshlpairrefsBottomreferencesSet()**
- **ProMechshlpairrefsTopreferencesGet()**
- **ProMechshlpairrefsTopreferencesSet()**
- **ProMechshlpairrefsSelectedplacementGet()**
- **ProMechshlpairrefsSelectedplacementSet()**
- **ProMechshlpairrefsExtendAdjacentSurfacesGet()**
- **ProMechshlpairrefsExtendAdjacentSurfacesSet()**
- **ProMechshlpairrefsFree()**

The function `ProMechshellpairMaterialIdGet()` returns the material used to create the shell pair. Use the function `ProMechshellpairMaterialIdSet()` to set the material id of the shell pair.

The function `ProMechshellpairReferencesGet()` returns the geometric references for the shell pair item. Use the function `ProMechshellpairReferencesSet()` to set the geometric references for the shell pair item.

The function `ProMechshlpairrefsTypeGet()` returns the type of shell pair references. The types of shell pairs are:

- **PRO\_MECH\_SHELL\_PAIR\_CONSTANT**—Specifies a shell pair with constant thickness. All opposing surfaces parallel to each other and equidistant from the opposing surface for a constant-thickness shell pair.
- **PRO\_MECH\_SHELL\_PAIR\_VARIABLE**—Specifies a variable thickness shell pair. Both opposing surfaces are neither parallel nor concentric for a variable thickness shell pair.

---

 **Note**

From Creo Parametric onwards, the shell type `PRO_MECH_SHELL_PAIR_VARIABLE` is also supported in the Native mode of Creo Simulate .

---

- `PRO_MECH_SHELL_PAIR_MULTI_CONSTANT`—Specifies a shell pair with multiple pairs of surfaces. For a pair of surfaces, each surface is parallel to and equidistant from the opposing surface. However, the distance between the surfaces for each of the multiple pairs may vary.

---

 **Note**

From Creo Parametric onwards, the thickness type `PRO_MECH_SHELL_PAIR_MULTI_CONSTANT` has been deprecated and the function `ProMechshlpairrefsTypeSet ()` will return an error type `PRO_TK_UNSUPPORTED`.

---

Use the function `ProMechshlpairrefsTypeSet ()` to set the type of shell pair references.

The functions `ProMechshlpairrefsTopreferencesGet ()` and `ProMechshlpairrefsBottomreferencesGet ()` provide access to the top and bottom references for the shell pair. This should be defined for all shell pair types. Use the functions `ProMechshlpairrefsBottomreferencesSet ()` and `ProMechshlpairrefsTopreferencesSet ()` to set the top and bottom references for the shell pair.

The function `ProMechshlpairrefsPlacemnttypeGet ()` returns the placement of shell pair. The types of placement references are as follows:

- `PRO_MECH_SHELL_PAIR_PLACEMENT_TOP`—Specifies that the placement uses the top surface of the surface pair.
- `PRO_MECH_SHELL_PAIR_PLACEMENT_BOTTOM`— Specifies that the placement uses the bottom surface of the surface pair.
- `PRO_MECH_SHELL_PAIR_PLACEMENT_MIDDLE`— Specifies that the placement uses the mid surface of the surface pair.
- — Specifies that the placement uses an arbitrary selected surface, which can be a datum surface.

Use the function `ProMechshlpairrefsPlacemnttypeSet ()` to set the placement type of the shell pair.

---

Use the function `ProMechshlpairrefsSelectedplacementGet()` to access the data structure containing the selected surface. Use the function `ProMechshlpairrefsSelectedplacementSet()` to set the surface for the placement reference of type `SELECTED`.

Use the function

`ProMechshlpairrefsExtendAdjacentSurfacesGet()` to retrieve the value of the flag that indicates whether the adjacent surfaces in a shell pair will be extended during meshing or not. For a mixed model, you can set this flag to extend surfaces adjacent to the top and bottom surfaces of the shell pair by using the function `ProMechshlpairrefsExtendAdjacentSurfacesSet()`. However, this is possible only if the angle between the shell pair surfaces and their adjacent surfaces is less than the value specified by the configuration option.

---

 **Note**

For a midsurface model, Creo Simulate extends the adjacent surfaces regardless of the value of `sim_extend_surf_max_angle`. The default value of `sim_extend_surf_max_angle` is 30 degrees.

You must initialize the Creo Simulate environment to use these functions. For shell pairs defined in Pro/ENGINEER Mechanica 4.0 and earlier, this flag is set to 1 by default.

---

Use the function `ProMechshlpairrefsFree()` to free the simple shell data handle in Creo Simulate .

## Interfaces

Interfaces, also called connections, are used to connect surfaces. When you create an interface in Creo Simulate , specify how Creo Simulate will treat the connected surfaces during meshing and analysis. Interfaces use the `ProType` field in the `ProMechitem` structure as `PRO_SIMULATION_INTERFACE`.

Functions Introduced:

- **`ProMechinterfaceTypeGet()`**
- **`ProMechinterfaceReferencesGet()`**
- **`ProMechinterfaceReferencesSet()`**
- **`ProMechinterfacebonddataAlloc()`**
- **`ProMechinterfaceBonddataGet()`**
- **`ProMechinterfaceBonddataSet()`**
- **`ProMechinterfacebonddataFree()`**

- **ProMechinterfacefreedataAlloc()**
- **ProMechinterfaceFreedataGet()**
- **ProMechinterfaceFreedataSet()**
- **ProMechinterfacefreedataFree()**
- **ProMechinterfacecontactdataAlloc()**
- **ProMechinterfaceContactdataGet()**
- **ProMechinterfaceContactdataSet()**
- **ProMechinterfacecontactdataFree()**
- **ProMechinterfacethrresistdataAlloc()**
- **ProMechinterfaceThrresistdataGet()**
- **ProMechinterfaceThrresistdataSet()**
- **ProMechinterfacethrresistdataFree()**

The function `ProMechinterfaceTypeGet()` returns the type of interface used to connect surfaces. The types of interfaces are:

- **Structural**—Specifies the default for the interfaces created between the geometry in a structural model for meshing and running.
  - `PRO_MECH_INTERFACE_BOND_STRUCT`—Specifies that the contacting surfaces as bonded. This means that matching nodes on contacting surfaces merge.
  - `PRO_MECH_INTERFACE_CONTACT_STRUCT`—Specifies an interface between components when you want the components to have the freedom to remain separate from each other, and also when you want the components to transfer forces between them when they touch, or come into contact with each other.
  - `PRO_MECH_INTERFACE_FREE_STRUCT`—Specifies two surfaces as contacting, but does not merge the nodes. Meshes on the contacting surfaces are identical, and matching nodes are coincident.
- **Thermal**—Specifies the default for the interfaces created between the geometry in a thermal model for meshing and running.
  - `PRO_MECH_INTERFACE_BOND_THERM`—Specifies that coincident geometry is bonded.
  - `PRO_MECH_INTERFACE_FREE_THERM`—Specifies that no geometry in the assembly is merged.
  - `PRO_MECH_INTERFACE_RESIST_THERM`—Specify this interface type to create a thermal resistance interfaces at run-time.

---

The function `ProMechinterfaceReferencesGet()` returns the geometric entities selected to create the interface. Use the function `ProMechinterfaceReferencesSet()` to set the geometric entities selected to create the interface.

The function `ProMechinterfacebonddataAlloc()` allocates memory for the Creo Simulate bonded interface data.

The function `ProMechinterfaceBonddataGet()` provides access to the bonded interface data. The function returns whether the specified bonded interface should use links between pairs of nodes.

Use the function `ProMechinterfaceBonddataSet()` to assign the bonded interface data to the Creo Simulate item.

Use the function `ProMechinterfacebonddataFree()` to free the memory of the bonded interface data.

The function `ProMechinterfacefreedataAlloc()` allocates memory for the Creo Simulate free interface data structure.

The function `ProMechinterfaceFreedataGet()` provides access to the free interface data. The function returns a flag that indicates whether the meshes generated on the surfaces of the interface are coincident or not. Use the function `ProMechinterfaceFreedataSet()` to assign the free interface data to the Creo Simulate item.

The function `ProMechinterfacecontactdataAlloc()` allocates memory for the Creo Simulate contact interface data structure.

The function `ProMechinterfaceContactdataGet()` provides access to the properties of the contact interface data. Use the function `ProMechinterfaceContactdataSet()` to assign the contact interface data to the Creo Simulate item.

The function `ProMechinterfacethrresistdataAlloc()` allocates memory for the Creo Simulate thermal resistance interface data structure.

The function `ProMechinterfaceThrresistdataGet()` provides access to the thermal resistance interface data. Use the function `ProMechinterfaceThrresistdataSet()` to assign the thermal resistance interface data to the Creo Simulate item.

## Bonded Interface

Functions Introduced:

- **`ProMechbondinterfacedataMergenodesGet()`**
- **`ProMechbondinterfacedataMergenodesSet()`**

---

The function `ProMechbondinterfacedataMergenodesGet()` specifies if coincident nodes of components or surfaces touching each other are merged during meshing. Use the function `ProMechbondinterfacedataMergenodesSet()` to set whether coincident nodes for bonded interface should merge.

## Contact Interface

Functions Introduced:

- **`ProMechcontactinterfacedataSeparationdistanceExprGet()`**
- **`ProMechcontactinterfacedataSeparationdistanceExprSet()`**
- **`ProMechcontactinterfacedataAnglebetweensurfacesExprGet()`**
- **`ProMechcontactinterfacedataAnglebetweensurfacesExprSet()`**
- **`ProMechcontactinterfacedataCheckonlyplanarGet()`**
- **`ProMechcontactinterfacedataCheckonlyplanarSet()`**
- **`ProMechcontactinterfacedataSlippageGet()`**
- **`ProMechcontactinterfacedataSlippageSet()`**
- **`ProMechcontactinterfacedataCoefffrictionGet()`**
- **`ProMechcontactinterfacedataCoefffrictionSet()`**
- **`ProMechcontactinterfacedataSplitsurfacesGet()`**
- **`ProMechcontactinterfacedataSplitsurfacesSet()`**
- **`ProMechcontactinterfacedataCompatiblemeshGet()`**
- **`ProMechcontactinterfacedataCompatiblemeshSet()`**
- **`ProMechcontactinterfacedataFrictionSet()`**
- **`ProMechcontactinterfacedataFrictionGet()`**
- **`ProMechcontactinterfacedataDynamicCoefffrictionSet()`**
- **`ProMechcontactinterfacedataDynamicCoefffrictionGet()`**
- **`ProMechcontactinterfacedataDynamicCoeffSameAsStaticSet()`**
- **`ProMechcontactinterfacedataDynamicCoeffSameAsStaticGet()`**
- **`ProMechcontactinterfacedataUseSelectionFilterTolSet()`**
- **`ProMechcontactinterfacedataUseSelectionFilterTolGet()`**

To create a contact interface between two components of an assembly, with the reference type as component-component, specify the selection filter tolerance criteria. You can specify the selection filter tolerance criteria using the following functions.

---

Use the function

`roMechcontactinterfacedataSeparationdistanceExprGet()` to retrieve the separation distance. Separation distance is the distance between the surface pairs that you want to use to define a contact interface. This separation distance is the limit beyond which a contact interface cannot be created. If the distance between the surfaces of two components is smaller than the separation distance, the surfaces are used for creation of the contact interface.

The separation distance is returned as an expression of type `ProMechExpression`.

---

 **Note**

The function

`ProMechcontactinterfacedataSeparationdistanceExprGet()` supersedes the function `ProMechcontactinterfacedataSeparationdistanceGet()`.

---

The function

`ProMechcontactinterfacedataSeparationdistanceExprSet()` sets the separation distance. Specify this distance as an expression of type `ProMechExpression`.

---

 **Note**

The function

`ProMechcontactinterfacedataSeparationdistanceExprSet()` supersedes the function `ProMechcontactinterfacedataSeparationdistanceSet()`.

---

The function

`ProMechcontactinterfacedataAnglebetweensurfacesExprGet()` returns the angle between planar surfaces while creating contact interface. This angle is returned as an expression of type `ProMechExpression`.

---

 **Note**

The function

`ProMechcontactinterfacedataAnglebetweensurfacesExprGet()` supersedes the function `ProMechcontactinterfacedataAnglebetweensurfacesGet()`.

---

---

The function

`ProMechcontactinterfacedataAnglebetweensurfacesExprSet()` sets the angle between surfaces while creating contact interface. Specify this angle as an expression of type `ProMechExpression`.

---

 **Note**

The function

`ProMechcontactinterfacedataAnglebetweensurfacesExprSet()` supersedes the function

`ProMechcontactinterfacedataAnglebetweensurfacesSet()`.

---

The function

`ProMechcontactinterfacedataCheckonlyplanarGet()` returns a true if the contact is created between planar surfaces in a component-component type interface.

Use the function

`ProMechcontactinterfacedataCheckonlyplanarSet()` to create contacts only between planar surfaces.

The properties of the contact interface are as follows:

Use the function `ProMechcontactinterfacedataFrictionSet()` to set the type of the friction at the contact interface, between the pairs of nodes, using the enumerated type `ProMechInterfaceFrictionType`. The valid values are:

- `PRO_MECH_INTERFACE_FRICTION_INFINITE`—Specifies that infinite friction exists at the contact interface that is, the two components or surfaces cannot slide relative to each other.
- `PRO_MECH_INTERFACE_FRICTION_FINITE`—Specifies that finite friction exists at the contact interface that is, that is, the two components or surfaces are able to slide relative to each other.

Use the function `ProMechcontactinterfacedataFrictionGet()` to obtain the type of friction present at the contact interface.

The function `ProMechcontactinterfacedataSlippageGet()` returns true if slippage has occurred in the contact region during the analysis. Use the function `ProMechcontactinterfacedataSlippageSet()` to check for slippage in the contact area during analysis.

The function `ProMechcontactinterfacedataCoefffrictionGet()` returns the coefficient of friction used to calculate the slippage in the contact region during analysis. Use the function

---

`ProMechcontactinterfacedataCoefffrictionSet()` to set the coefficient of friction for computing the slippage. Specify a positive value as the coefficient of friction.

The function `ProMechcontactinterfacedataSplitsurfacesGet()` returns true if you split the surface shared by the volumes used to define the interface.

Use the function

`ProMechcontactinterfacedataSplitsurfacesSet()` to specify whether the interface should split surfaces.

The function `ProMechcontactinterfacedataCompatiblemeshGet()` specifies if a compatible mesh is created when components in the assembly are touching.

Use the function

`ProMechcontactinterfacedataCompatiblemeshSet()` to create geometrically-consistent node locations when the mesh for the surfaces of your interface is generated.

Use the function

`ProMechcontactinterfacedataDynamicCoefffrictionSet()` to set the dynamic coefficient of friction for the contact interface. The dynamic coefficient of friction prevents the axis surfaces from moving freely against each other which slows down the motion.

### Note

Set a value less than or equal to the value of static coefficient of friction for this interface.

---

Use the function

`ProMechcontactinterfacedataDynamicCoefffrictionGet()` to obtain the dynamic coefficient of friction for the specified contact interface data. Use the function `ProMathExpressionEvaluate()` to evaluate the dynamic coefficient of friction.

Use the function

`ProMechcontactinterfacedataDynamicCoeffSameAsStaticSet()` to set the dynamic coefficient of friction same as the static coefficient of friction. Pass the value `PRO_B_TRUE` to set the dynamic coefficient of friction same as static coefficient of friction.

Use the function

`ProMechcontactinterfacedataDynamicCoeffSameAsStaticGet()` to identify whether the dynamic coefficient of friction is same as the static coefficient of friction. This function returns the value `PRO_B_TRUE` if the dynamic and static coefficient of friction possess the same value.

---

Use the function

`ProMechcontactinterfacedataUseSelectionFilterTolSet()` to set the selection filter tolerance between contact surfaces. Pass the value `PRO_B_TRUE` to switch on the selection filter tolerances.

Use the function

`ProMechcontactinterfacedataUseSelectionFilterTolGet()` to identify whether the specified contact interface uses the selection filter tolerances between the contact surfaces. This function returns the value `PRO_B_TRUE` if the contact surfaces use the selection filter tolerances.

## Thermal Resistance Interface

Functions Introduced:

- **`ProMechthrrresistinterfacedataConductivityGet()`**
- **`ProMechthrrresistinterfacedataConductivitySet()`**

The function `ProMechthrrresistinterfacedataConductivityGet()` returns the heat transfer coefficient for the interface. The heat transfer coefficient is the heat that passes through the interface per unit time per unit area when the temperature difference between opposite interface surfaces is one unit.

Use the function

`ProMechthrrresistinterfacedataConductivitySet()` to set the heat transfer coefficient for the interface. Specify a positive number as the heat transfer coefficient.

## Free Interface

Functions Introduced:

- **`ProMechfreeinterfacedataSplitsurfacesGet()`**
- **`ProMechfreeinterfacedataSplitsurfacesSet()`**

The function `ProMechfreeinterfacedataSplitsurfacesGet()` returns true if you split the surface shared by the volumes used to define the free interface.

The function `ProMechfreeinterfacedataSplitsurfacesSet()` to specify whether the free interface should split surfaces.

## Gaps

A gap is a nonlinear element, used to model connection between points, edges and curves, or surfaces in your model by connecting two nodes in separated geometries. Gaps use the `ProType` field in the `ProMechitem` structure as `PRO_SIMULATION_GAP`.

---

Functions Introduced:

- **ProMechgapTypeGet()**
- **ProMechgapReferencesGet()**
- **ProMechgapReferencesSet()**
- **ProMechgapSimplifiedataGet()**
- **ProMechgapSimplifiedataSet()**
- **ProMechsimplegapdataAlloc()**
- **ProMechsimplegapdataFree()**
- **ProMechsimplegapdataYdirectionGet()**
- **ProMechsimplegapdataYdirectionSet()**
- **ProMechsimplegapdataDistributiontypeGet()**
- **ProMechsimplegapdataDistributiontypeSet()**
- **ProMechsimplegapdataAxialstiffnessGet()**
- **ProMechsimplegapdataAxialstiffnessSet()**
- **ProMechsimplegapdataTransversestiffnessGet()**
- **ProMechsimplegapdataTransversestiffnessSet()**
- **ProMechsimplegapdataClearanceGet()**
- **ProMechsimplegapdataClearanceSet()**

The function `ProMechgapTypeGet ()` returns the type of gap for the specified Creo Simulate Gap.

The function `ProMechgapReferencesGet ()` returns the geometric entities of the model that are selected to create the gap. Use the function `ProMechgapReferencesSet ()` to set the valid geometric references for the specified gap.

The function `ProMechgapSimplifiedataGet ()` returns the data structure for the Creo Simulate gap data. The Creo Simulate gap data structure defines the y-direction and the stiffness properties of the gap. Use the function `ProMechgapSimplifiedataSet ()` to set the Creo Simulate gap data structure.

The function `ProMechsimplegapdataAlloc ()` allocates memory for the Creo Simulate gap data structure.

`ProMechsimplegapdataYdirectionGet ()` returns the orientation of the XY-plane of the gap. Use the function `ProMechsimplegapdataYdirectionSet ()` to set the Y-direction of the gap data.

The function `ProMechsimplegapdataDistributiontypeGet ()` returns the method used to calculate the axial and transverse stiffnesses for the gap data. The types of distribution are as follows:

- `PRO_MECH_GAP_DISTR_TOTAL`—Specifies the sum of stiffness of all the contact elements.
- `PRO_MECH_GAP_DISTR_PER_UNIT`—Specifies that the stiffness value is calculated using the area of the first selected surface.

Use the function `ProMechsimplegapdataDistributiontypeSet()` to set the distribution type for the gap data.

The function `ProMechsimplegapdataAxialstiffnessGet()` returns the axial stiffness for the gap. The axial stiffness defines a stiffness or spring factor. Use the function `ProMechsimplegapdataAxialstiffnessSet()` to set the axial stiffness for the gap.

The function `ProMechsimplegapdataTransversestiffnessGet()` returns the transverse stiffness for the gap. The transverse stiffness defines the elastic stiffness of the material. Use the function `ProMechsimplegapdataTransversestiffnessSet()` to set the transverse stiffness of the gap.

The function `ProMechsimplegapdataClearanceGet()` returns the distance between two nodes at which the axial and transverse stiffnesses are active due to displacement during analysis. Use the function `ProMechsimplegapdataClearanceSet()` to set the clearance for the gap data.

## Mesh Control

Mesh controls define the characteristics of a mesh. Mesh controls specify the minimum or maximum size of the elements, the distribution of nodes along edges, hard points and hard curves, mesh ID numbering, mesh ID offsets, and the displacement coordinate system. The functions described in this section provide access to the data and contents of the Creo Simulate mesh control objects. Mesh controls use the `ProType` field in the `ProMechitem` structure as `PRO_SIMULATION_MESH_CNTRL`.

Functions Introduced:

- **`ProMechmeshcntrlTypeGet()`**
- **`ProMechmeshcntrlAutogemedgedistrdataGet()`**
- **`ProMechmeshcntrlAutogemedgedistrdataSet()`**
- **`ProMechmeshcntrlAutogemminedgedataGet()`**
- **`ProMechmeshcntrlAutogemminedgedataSet()`**
- **`ProMechmeshcntrlAutogemelemsizedataGet()`**
- **`ProMechmeshcntrlAutogemelemsizedataSet()`**
- **`ProMechmeshcntrlAutogemedgelencrvdataGet()`**

- 
- **ProMechmeshcntrlAutogemedgelencrvdataSet()**
  - **ProMechmeshcntrlEdgedistrdataGet()**
  - **ProMechmeshcntrlEdgedistrdataSet()**
  - **ProMechmeshcntrlElemsizedataGet()**
  - **ProMechmeshcntrlElemsizedataSet()**
  - **ProMechmeshcntrlShellcsysGet()**
  - **ProMechmeshcntrlShellcsysSet()**
  - **ProMechmeshcntrlHardpointGet()**
  - **ProMechmeshcntrlHardpointSet()**
  - **ProMechmeshcntrlHardcurveSet()**
  - **ProMechmeshcntrlIdsoffsetGet()**
  - **ProMechmeshcntrlIdsoffsetSet()**
  - **ProMechmeshcntrlNumberingGet()**
  - **ProMechmeshcntrlNumberingSet()**
  - **ProMechmeshcntrlSuppressGet()**
  - **ProMechmeshcntrlSuppressSet()**
  - **ProMechmcautogemsuppressTypeGet()**
  - **ProMechmcautogemsuppressTypeSet()**
  - **ProMechmeshcntrlAutogemsuppressGet()**
  - **ProMechmeshcntrlAutogemsuppressSet()**
  - **ProMechmeshcntrlAutogemisolateexcludedataGet()**
  - **ProMechmeshcntrlAutogemisolateexcludedataSet()**
  - **ProMechmeshcntrlReferencesGet()**
  - **ProMechmeshcntrlReferencesSet()**
  - **ProMechmcautogemHardpointSet()**
  - **ProMechmcautogemHardcurveSet()**

The function `ProMechmeshcntrlTypeGet()` returns the type of mesh control. The types of mesh controls are:

- `PRO_MECH_MC_AGEM_EDGE_DISTR`—Specifies the edge distribution data for AutoGEM. Use the function `ProMechmeshcntrlAutogemedgedistrdataGet()` to access the AutoGEM edge distribution data for the mesh control item. Use the function `ProMechmeshcntrlAutogemedgedistrdataSet()` to modify the AutoGEM edge distribution data for the mesh control item.

---

 **Note**

If you are creating a new mesh control using this type of data, you should assign the model as a reference using the function `ProMechmeshcntrlReferencesSet()`.

---

- **PRO\_MECH\_MC\_AGE\_MIN\_EDGE**—Specifies the minimum edge and face angles for AutoGEM. Use the function `ProMechmeshcntrlAutogemminedgeGet()` to access the AutoGEM minimum edge data for the mesh control item. Use the function `ProMechmeshcntrlAutogemminedgeset()` to modify the AutoGEM minimum edge data for the mesh control item.

---

 **Note**

If you are creating a new mesh control using this type of data, you should assign the model as a reference using the function `ProMechmeshcntrlReferencesSet()`.

---

- **PRO\_MECH\_MC\_AGE\_MAX\_ELEMENT\_SIZE**—Specifies the maximum element size for the AutoGEM mesh. Use the function `ProMechmeshcntrlAutogemelemsizeGet()` to access the AutoGEM maximum element data for the mesh control item. Use the function `ProMechmeshcntrlAutogemelemsizeset()` to modify the AutoGEM maximum element data for the mesh control item.

---

 **Note**

If you are creating a new mesh control using this type of data, you should assign the model as a reference using the function `ProMechmeshcntrlReferencesSet()`.

---

- **PRO\_MECH\_MC\_AGE\_EDGE\_LEN\_CRV**—Specifies the ratio of edge lengths of mesh elements adjacent to concave surfaces to the radius of curvature of the concave surfaces. Use the function `ProMechmeshcntrlAutogemedgelencrvGet()` to access the edge length by curvature data for the mesh control item. Use the function `ProMechmeshcntrlAutogemedgelencrvset()` to set the edge length by curvature ratio.

- 
- **PRO\_MECH\_MC\_EDGE\_DISTRIBUTION**—Specifies the number of nodes on one or more edges of the curves in the model. Use the function `ProMechmeshcntrlEdgedistrdataGet()` to access the edge distribution data for the mesh control item. Use the function `ProMechmeshcntrlEdgedistrdataSet()` to set the edge distribution data.

---

 **Note**

If you are creating a new mesh control using this type of data, you should assign the model as a reference using the function `ProMechmeshcntrlReferencesSet()`.

---

- **PRO\_MECH\_MC\_DISPL\_CSYS**—Specifies the displacement coordinate system used for displaying results for nodes associated with points, edges, curves, or surfaces.
- **PRO\_MECH\_MC\_MAX\_ELEMENT\_SIZE**—Specifies the maximum element size for the mesh. Use the function `ProMechmeshcntrlElemsizedataGet()` to access the maximum element size data for the mesh control item. Use the function `ProMechmeshcntrlElemsizedataSet()` to set the maximum element size for the mesh.

---

 **Note**

If you are creating a new mesh control using this type of data, you should assign the model as a reference using the function `ProMechmeshcntrlReferencesSet()`.

---

- **PRO\_MECH\_MC\_MIN\_ELEMENT\_SIZE**—Specifies the minimum element size for the mesh. Use the function `ProMechmeshcntrlElemsizedataGet()` to access the minimum element size data for the mesh control item. Use the function `ProMechmeshcntrlElemsizedataSet()` to set the maximum element size for the mesh.
- **PRO\_MECH\_MC\_SHELL\_CSYS**—Specifies the coordinate system used for displaying results for nodes associated with shell or quilt surfaces. Use the function `ProMechmeshcntrlShellcsysGet()` to access the shell coordinate system for the mesh control item. Use the function `ProMechmeshcntrlShellcsysSet()` to set the shell coordinate system for the mesh control item.

- 
- **PRO\_MECH\_MC\_HARD\_POINT**—Specifies a datum point that is defined as a hard point. Use the function `ProMechmeshcntrlHardpointGet()` to access the hard point data for the mesh control item. Use the function `ProMechmeshcntrlHardpointSet()` to set the hard point data for the mesh control item.
  - **PRO\_MECH\_MC\_HARD\_CURVE**—Specifies a datum curve that is defined as a hard curve. This type has no data, only references. Use the function `ProMechmeshcntrlHardcurveSet()` to set the mesh control item to be of the type hard curve. The reference for the item will be used for the control.
  - **PRO\_MECH\_MC\_IDS\_OFFSET**—Specifies the offset for the node IDs and element IDs for a component. Use the function `ProMechmeshcntrlIdsoffsetGet()` to access the offset data for the mesh control item. Use the function `ProMechmeshcntrlIdsoffsetSet()` to set the offset data.
  - **PRO\_MECH\_MC\_MESH\_NUMBERING**—Specifies a node and an element ID range for a component. Use the function `ProMechmeshcntrlNumberingGet()` to access the numbering data for the mesh control item. Use the function `ProMechmeshcntrlNumberingSet()` to set the numbering data for the mesh control item.
  - **PRO\_MECH\_MC\_SUPPRESS**—Specifies the components that must be ignored while applying the mesh control to the assembly level. Use the function `ProMechmeshcntrlSuppressGet()` to access the suppress data for the mesh control item. Use the function `ProMechmeshcntrlSuppressSet()` to set the suppress data for the mesh control item.
  - **PRO\_MECH\_MC\_AGE\_M\_SUPPRESS**—Specifies the type of AutoGEM controls that you want the mesh generator to ignore at the assembly level. Use the function `ProMechmcautogemsuppressTypeGet()` to access the types of AutoGEM control suppressed by this AutoGEM control data. Use the function `ProMechmcautogemsuppressTypeSet()` to set the type of AutoGEM control suppressed by this AutoGEM control data.

The functions `ProMechmeshcntrlAutogemsuppressGet()` and `ProMechmeshcntrlAutogemsuppressSet()` access and set the suppress data for the AutoGEM control items.

These functions support only the following AGEM mesh control types:

- **PRO\_MECH\_MC\_AGE\_M\_EDGE\_DISTR**
- **PRO\_MECH\_MC\_AGE\_M\_MIN\_EDGE**
- **PRO\_MECH\_MC\_AGE\_M\_ISOLATE\_EXCLUDE**

- 
- `PRO_MECH_MC_AGEM_MAX_ELEMENT_SIZE`
  - `PRO_MECH_MC_AGEM_EDGE_LEN_CRV`
  - `PRO_MECH_MC_AGEM_HARD_POINT`
  - `PRO_MECH_MC_AGEM_HARD_CURVE`
  - `PRO_MECH_MC_ALL`
  - `PRO_MECH_MC_AGEM_ISOLATE_EXCLUDE`—Specifies points, edges, curves, and surfaces from the model to isolate during analysis. The function `ProMechmeshcntrlAutogemisolateexcludedataGet()` returns the list of entities that AutoGEM can detect and isolate using mesh refinement. Use the function `ProMechmeshcntrlAutogemisolateexcludedataSet()` to set the entities for AutoGEM isolation using mesh refinement.
  - `PRO_MECH_MC_AGEM_HARD_POINT`—Specifies points, point features, or point patterns on the model to guide the AutoGEM mesh creation process. This control type has only references and no data associated with it. Use the function `ProMechmcautogemHardpointSet()` to set the AutoGEM mesh control item as hard point.
  - `PRO_MECH_MC_AGEM_HARD_CURVE`—Specifies the datum curves on the model to guide the AutoGEM mesh creation process. This control type has only references and no data associated with it. Use the function `ProMechmcautogemHardcurveSet()` to set the AutoGEM mesh control item as hard curve.
  - `PRO_MECH_MC_ALL`—Specifies all the types of mesh controls.

---

 **Note**

If you are creating a new mesh control using this type of data, you should assign the model as a reference using the function `ProMechmeshcntrlReferencesSet()`.

---

The function `ProMechmeshcntrlReferencesGet()` returns the references for each of the mesh control type. Use the function `ProMechmeshcntrlReferencesSet()` to set the references used by the mesh control item.

## Accessing AutoGEM Edge Distribution and Minimum Edge Mesh Control Data

The functions described in this section provide access to the data for the AutoGEM edge distribution Mesh Control.

---

Functions Introduced:

- **ProMechmcautogemedgedistrAlloc()**
- **ProMechmcautogemedgedistrNodesGet()**
- **ProMechmcautogemedgedistrNodesSet()**
- **ProMechmcautogemedgedistrRatioGet()**
- **ProMechmcautogemedgedistrRatioSet()**
- **ProMechmcautogemedgedistrStrictGet()**
- **ProMechmcautogemedgedistrStrictSet()**
- **ProMechmcautogemedgedistrFree()**
- **ProMechmcautogemminedgeAlloc()**
- **ProMechmcautogemminedgeEdgesGet()**
- **ProMechmcautogemminedgeEdgesSet()**
- **ProMechmcautogemminedgeLengthGet()**
- **ProMechmcautogemminedgeLengthSet()**
- **ProMechmcautogemminedgeFree()**

The function `ProMechmcautogemedgedistrNodesGet()` returns the number of nodes distributed along the selected edge. Use the function `ProMechmcautogemedgedistrNodesSet()` to set the number of nodes.

The function `ProMechmcautogemedgedistrRatioGet()` returns the aspect ratio defined while creating and editing elements. The aspect ratio is defined as the ratio of a length to the width of any surface in the model. Use the function `ProMechmcautogemedgedistrRatioSet()` to set the aspect ratio for the AutoGEM edge distribution mesh control data.

The function `ProMechmcautogemedgedistrStrictGet()` returns the value `true`, if the aspect ratio is within the maximum allowable range while creating and editing elements. Use the function `ProMechmcautogemedgedistrStrictSet()` to set the aspect ratio within the maximum allowable range.

Use the function `ProMechmcautogemedgedistrFree()` to free the memory containing the AutoGEM edge distribution data structure.

The function `ProMechmcautogemminedgeEdgesGet()` specifies the number of edges in a model for the AutoGEM minimum edge data. Use the function `ProMechmcautogemminedgeEdgesSet()` to set the number of edges.

The function `ProMechmcautogemminedgeLengthGet()` specifies the minimum length of any edge in the model. Use the function `ProMechmcautogemminedgeLengthSet()` to specify the minimum length of the edge for the AutoGEM min edge mesh control data.

---

Use the function `ProMechmcautogemmedgelenedgeFree()` to free the memory containing the AutoGEM minimum edge data structure.

## Accessing the AutoGEM Edge Length by Curvature Mesh Control Data

The functions described in this section enable you to create a denser element mesh adjacent to areas such as curves, fillets, and holes, that are likely to have high stress, using the edge length by curve ratio.

- **`ProMechmcautogemmedgelenrcvAlloc()`**
- **`ProMechmcautogemmedgelenrcvRatioGet()`**
- **`ProMechmcautogemmedgelenrcvRatioSet()`**
- **`ProMechmcautogemmedgelenrcvIgnoreRadiusGet()`**
- **`ProMechmcautogemmedgelenrcvIgnoreRadiusSet()`**
- **`ProMechmcautogemmedgelenrcvMinradiusGet()`**
- **`ProMechmcautogemmedgelenrcvMinradiusSet()`**
- **`ProMechmcautogemmedgelenrcvFree()`**

The function `ProMechmcautogemmedgelenrcvAlloc()` allocates memory for the Creo Simulate mesh control edge length by curvature data handle.

The function `ProMechmcautogemmedgelenrcvRatioGet()` returns the ratio of the expected edge lengths of mesh elements to the radius of the concave surface. Use the function `ProMechmcautogemmedgelenrcvRatioSet()` to set this ratio. Specify the ratio as a positive real number.

The function `ProMechmcautogemmedgelenrcvMinradiusGet()` returns the cut-off value for the radius of curvature below which the AutoGEM mesh control data will not be applied. Use the function `ProMechmcautogemmedgelenrcvMinradiusSet()` to set the cut-off value for the radius of curvature. This value can be specified in the current units of the model or as a percentage of the model size.

`ProMechmcautogemmedgelenrcvIgnoreRadiusGet()` returns true, if the curves having a radius of curvature lower than the cut-off value must be ignored by the AutoGEM mesh control data. Use the function `ProMechmcautogemmedgelenrcvIgnoreRadiusSet()` to specify whether to ignore curves having a radius of curvature lower than the cut-off value.

Use the function `ProMechmcautogemmedgelenrcvFree()` to free the memory containing the edge length by curvature mesh control data structure.

---

## Accessing the AutoGEM Maximum Element Size Mesh Control Data

The functions described in this section enable you to control the size of the elements created by the mesh generator for components, volumes, surfaces, edges, or curves.

Functions Introduced:

- **ProMechmcautogemelemsizeAlloc()**
- **ProMechmcautogemelemsizeSizeGet()**
- **ProMechmcautogemelemsizeSizeSet()**
- **ProMechmcautogemelemsizeFree()**

The function `ProMechmcautogemelemsizeAlloc()` allocates memory for the AutoGEM maximum element size mesh control data.

The function `ProMechmcautogemelemsizeSizeGet()` returns the maximum element size in the mesh. Use the function `ProMechmcautogemelemsizeSizeSet()` to set the element size.

Use the function `ProMechmcautogemelemsizeFree()` to free the memory containing the maximum element size mesh control data structure.

## Accessing Edge Distribution Mesh Control Data

The functions described in this section provide access to the edge distribution mesh control data.

Functions Introduced:

- **ProMechmcedgedistrAlloc()**
- **ProMechmcedgedistrNodesGet()**
- **ProMechmcedgedistrNodesSet()**
- **ProMechmcedgedistrRatioGet()**
- **ProMechmcedgedistrRatioSet()**
- **ProMechmcedgedistrStrictGet()**
- **ProMechmcedgedistrStrictSet()**
- **ProMechmcedgedistrFree()**

The function `ProMechmcedgedistrNodesGet()` returns the minimum number of nodes that are distributed along the selected edge or curve. Use the function `ProMechmcedgedistrNodesSet()` to set the number of nodes for the mesh control data.

---

The function `ProMechmcedgedistrRatioGet()` returns the ratio of the first interval on the edge or curve to the last interval on the edge or curve. Use the function `ProMechmcedgedistrRatioSet()` to set the ratio for the mesh control data.

The function `ProMechmcedgedistrStrictGet()` returns a boolean flag indicating whether the number of nodes must be used exactly. Use the function `ProMechmcedgedistrStrictSet()` to set the maximum allowable nodes for the mesh control data.

## Accessing AutoGEM Isolation Data

The functions in this section provide access to the entities that AutoGEM can detect and isolate using mesh refinement.

Functions Introduced:

- **`ProMechmcautogemisolateexcludeAlloc()`**
- **`ProMechmcautogemisolateexcludeExcludeGet()`**
- **`ProMechmcautogemisolateexcludeExcludeSet()`**
- **`ProMechmcautogemisolateexcludeFree()`**
- **`ProMechmcautogemisolateexcludeShellIsolMaxSizeGet()`**
- **`ProMechmcautogemisolateexcludeShellIsolTypeGet()`**
- **`ProMechmcautogemisolateexcludeSolidIsolMaxSizeGet()`**
- **`ProMechmcautogemisolateexcludeSolidIsolTypeGet()`**
- **`ProMechmcautogemisolateexcludeShellIsolMaxSizeSet()`**
- **`ProMechmcautogemisolateexcludeShellIsolTypeSet()`**
- **`ProMechmcautogemisolateexcludeSolidIsolMaxSizeSet()`**
- **`ProMechmcautogemisolateexcludeSolidIsolTypeSet()`**

The function `ProMechmcautogemisolateexcludeExcludeGet()` returns the value of the exclude boolean for the AutoGEM isolation for exclusion mesh control data. Use the function `ProMechmcautogemisolateexcludeExcludeSet()` to set the value of the exclude boolean for the AutoGEM isolation for exclusion mesh control data.

The function `ProMechmcautogemisolateexcludeShellIsolMaxSizeGet()` returns the value of maximum element size of isolation of shells for the AutoGEM isolation for exclusion mesh control data. Use the function `ProMechmcautogemisolateexcludeShellIsolMaxSizeSet()` to set the value of maximum element size of isolation of shells for the AutoGEM isolation.

---

The function

`ProMechmcautogemisolateexcludeShellIsolTypeGet()` returns the value of shell isolation type for the AutoGEM isolation for exclusion mesh control data. Use the function `ProMechmcautogemisolateexcludeShellIsolTypeSet()` to set the value of shell isolation type for the AutoGEM isolation for exclusion mesh control data.

The function

`ProMechmcautogemisolateexcludeSolidIsolMaxSizeGet()` returns the value of maximum element size of isolation of solids for the AutoGEM isolation for exclusion mesh control data. Use the function `ProMechmcautogemisolateexcludeSolidIsolMaxSizeSet()` to set the maximum element size of isolation of solids for the AutoGEM isolation.

The function

`ProMechmcautogemisolateexcludeSolidIsolTypeGet()` returns the value of solid isolation type for the AutoGEM isolation for exclusion mesh control data. Use the function `ProMechmcautogemisolateexcludeSolidIsolTypeSet()` to set the value of the solid isolation type for the AutoGEM isolation.

## Accessing the Displacement Coordinate System Data

The functions described in this section provide read and write access to the displacement coordinate system control data.

Functions Introduced:

- **`ProMechmcdisplacementcsysAlloc()`**
- **`ProMechmcdisplacementcsysCsysGet()`**
- **`ProMechmcdisplacementcsysCsysSet()`**
- **`ProMechmcdisplacementcsysFree()`**

The function `ProMechmcdisplacementcsysCsysGet()` returns the coordinate system used to display the results for the nodes associated with points, edges, curves, or surfaces.

The function `ProMechmcdisplacementcsysCsysSet()` sets the coordinate system for the mesh control data.

## Accessing the Mesh Control Element Size Data

Functions Introduced:

- **`ProMechmcelemsizeSizeGet()`**

- 
- **ProMechmcelemsizeSizeSet()**
  - **ProMechmcelemsizeFree()**

The function `ProMechmcelemsizeSizeGet()` returns the size of the elements for the mesh control data. Use the function `ProMechmcelemsizeSizeSet()` to set the size of the elements for the mesh control data.

## Accessing the Mesh Control Shell Coordinate System Data

Functions Introduced:

- **ProMechmshellcsysCsysGet()**
- **ProMechmshellcsysCsysSet()**
- **ProMechmshellcsysDirectionGet()**
- **ProMechmshellcsysDirectionSet()**
- **ProMechmshellcsysFree()**

The function `ProMechmshellcsysCsysGet()` returns the coordinate system specified for the mesh control data. Use the function `ProMechmshellcsysCsysSet()` to set the coordinate system specified for the mesh control data.

The function `ProMechmshellcsysDirectionGet()` returns the positive direction along the x, y, and z axis. Use the function `ProMechmshellcsysDirectionSet()` to set the positive direction along the x, y, and z axis.

## Accessing the Mesh Control Hard Point Data

Functions Introduced:

- **ProMechmchardpntNodeGet()**
- **ProMechmchardpntNodeSet()**
- **ProMechmchardpntFree()**

The function `ProMechmchardpntNodeGet()` returns the id of the node that is defined as a hard point. Use the function `ProMechmchardpntNodeSet()` to set the id of the node for the mesh control data.

## Accessing the Mesh Control ID Offset Data

Functions Introduced:

- **ProMechmcidsoffsetOffsetGet()**

- 
- **ProMechmcidoffsetOffsetSet()**
  - **ProMechmcidoffsetFree()**

The function `ProMechmcidoffsetOffsetGet()` returns a positive integer value to be added to the IDs of each node, element, and local mesh entity. Use the function `ProMechmcidoffsetOffsetSet()` to set the offset value for the mesh control data.

## Accessing the Mesh Control Numbering Data

Functions Introduced:

- **ProMechmcnumberingFirstGet()**
- **ProMechmcnumberingFirstSet()**
- **ProMechmcnumberingIncrementGet()**
- **ProMechmcnumberingIncrementSet()**
- **ProMechmcnumberingLastGet()**
- **ProMechmcnumberingLastSet()**
- **ProMechmcnumberingFree()**

The function `ProMechmcnumberingFirstGet()` returns the first ID for the nodes, elements, and local mesh entities. Use the function `ProMechmcnumberingFirstSet()` to set the first value of the mesh control data.

The function `ProMechmcnumberingIncrementGet()` returns the increment id for the nodes, elements, and local mesh entities. Use the function `ProMechmcnumberingIncrementSet()` to set the increment value for the mesh control data.

The function `ProMechmcnumberingLastGet()` returns the last ID for the nodes, elements, and local mesh entities. Use the function `ProMechmcnumberingLastSet()` to set the last value for the mesh control data.

## Accessing the Suppressed Mesh Control Data

Functions Introduced:

- **ProMechmcsuppressTypeGet()**
- **ProMechmcsuppressTypeSet()**
- **ProMechmcsuppressFree()**

The function `ProMechmcsuppressTypeGet()` returns the type of mesh control data that should be suppressed. Use the function `ProMechmcsuppressTypeSet()` to set the type of data to be suppressed.

---

## Welds

Welds are used to bridge gaps that are formed during shell compression between plates that have been mated because they touch or overlap. Welds use the `ProType` field in the `ProMechItem` structure as `PRO_SIMULATION_WELD`.

Functions Introduced:

- **ProMechweldReferencesGet()**
- **ProMechweldReferencesSet()**
- **ProMechweldTypeGet()**
- **ProMechweldperimeterAlloc()**
- **ProMechweldPerimeterdataGet()**
- **ProMechweldPerimeterdataSet()**
- **ProMechweldperimeterEdgesGet()**
- **ProMechweldperimeterEdgesSet()**
- **ProMechweldperimeterFree()**
- **ProMechweldedgeAlloc()**
- **ProMechweldedgeEdgeGet()**
- **ProMechweldedgeEdgeSet()**
- **ProMechweldedgeThicknessGet()**
- **ProMechweldedgeThicknessSet()**
- **ProMechweldedgeMaterialidGet()**
- **ProMechweldedgeMaterialidSet()**
- **ProMechweldedgeFree()**
- **ProMechweldedgeProarrayFree()**
- **ProMechweldspotAlloc()**
- **ProMechweldSpotdataGet()**
- **ProMechweldSpotdataSet()**
- **ProMechweldspotPointsGet()**
- **ProMechweldspotPntsSet()**
- **ProMechweldspotDiameterGet()**
- **ProMechweldspotDiameterSet()**
- **ProMechweldspotMaterialIdGet()**
- **ProMechweldspotMaterialIdSet()**
- **ProMechweldspotFree()**
- **ProMechweldendSet()**

- 
- **ProMechweldEnddataGet()**
  - **ProMechweldEnddataSet()**
  - **ProMechweldendAlloc()**
  - **ProMechweldendTypeGet()**
  - **ProMechweldendTypeSet()**
  - **ProMechweldendExtendAdjacentSurfacesGet()**
  - **ProMechweldendExtendAdjacentSurfacesSet()**
  - **ProMechweldendFree()**
  - **ProMechweldFeaturedataGet()**
  - **ProMechweldFeaturedataSet()**
  - **ProMechweldfeatureAlloc()**
  - **ProMechweldfeatureMaterialidGet()**
  - **ProMechweldfeatureOverrideflagGet()**
  - **ProMechweldfeatureThicknessGet()**
  - **ProMechweldedgeMaterialidSet()**
  - **ProMechweldfeatureOverrideflagSet()**
  - **ProMechweldfeatureThicknessSet()**
  - **ProMechweldfeatureFree()**

The function `ProMechweldReferencesGet()` returns the geometric entities selected to create the weld. Use the function `ProMechweldReferencesSet()` to set the references for the specified weld.

The function `ProMechweldTypeGet()` returns the type of weld used to connect the gaps. The types of weld are:

- **PRO\_MECH\_WELD\_PERIMETER**—Specifies a perimeter weld. Perimeter welds are used to connect parallel plates along the perimeter of one of the plates in an assembly model.
- **PRO\_MECH\_WELD\_END**—Specifies an end weld. End welds are used to connect plates in assembly models.
- **PRO\_MECH\_WELD\_SPOT**—Specifies a spot weld. Spot welds are used to connect two parallel surfaces at the specified datum point.
- **PRO\_MECH\_WELD\_FEAT**—Specifies a Weld Feature. This weld connection can be used to select Fillet and Groove types of weld connections for inclusion in a mid-surface compressed model.

---

The function `ProMechweldPerimeterdataGet()` provides access to the perimeter weld data structure. Use the function `ProMechweldPerimeterdataSet()` to set the perimeter weld data structure.

Use the function `ProMechweldperimeterFree()` to free the memory contained in the perimeter weld data structure.

The function `ProMechweldperimeterEdgesGet()` returns the perimeter edges of the top plate to be connected to the base plate. Use the function `ProMechweldperimeterEdgesSet()` to set the perimeter edges in the perimeter weld data.

The function `ProMechweldedgeEdgeGet()` returns the id of the edge selected to create the perimeter weld. Use the function `ProMechweldedgeEdgeSet()` to set the id of the edge.

The function `ProMechweldedgeThicknessGet()` returns the thickness of the weld on the selected edge in the perimeter weld. Use the function `ProMechweldedgeThicknessSet()` to set the thickness of the weld edge data.

The function `ProMechweldedgeMaterialidGet()` returns the type of material used in shell elements created on the Perimeter Weld surfaces.

Use the function `ProMechweldedgeMaterialidSet()` to select the material for the shell elements created on the Perimeter Weld surfaces. Specify the material ID as the input parameter of this function. In addition to the materials already present in the model, the input can be the material ID of one of the following surfaces:

- `PRO_MECH_WELD_MTL_BASE`—Specifies the base surface to which the weld extends.
- `PRO_MECH_WELD_MTL_DOUBLER`—Specifies the doubler surface on which the Perimeter weld is placed.

The functions `ProMechweldedgeFree()` and `ProMechweldedgeProarrayFree()` free the memory containing the edge data structure.

The function `ProMechweldperimeterFree()` frees the memory containing the data structure for the perimeter weld.

The function `ProMechweldSpotdataGet()` provides access to the spot weld data structure. Use the function `ProMechweldSpotdataSet()` to assign data to the spot weld data structure.

The function `ProMechweldspotPointsGet()` returns the datum points at which the spot weld is located. Use the function `ProMechweldspotPntsSet()` to set the points for the spot weld data.

---

The function `ProMechweldspotDiameterGet()` returns the diameter for the spot weld. Use the function `ProMechweldspotDiameterSet()` to set the diameter for the spot weld data.

The function `ProMechweldspotMaterialIdGet()` returns the material for the spot weld. Use the function `ProMechweldspotMaterialIdSet()` to set the material for the spot weld.

Use the function `ProMechweldspotFree()` to free the memory contained in the spot weld data structure.

Use the function `ProMechweldendSet()` to set the weld to be an end weld.

The function `ProMechweldEnddataGet()` returns the end weld data structure.

Use the function `ProMechweldendAlloc()` to allocate memory for the end weld data handle.

Use the method `ProMechweldEnddataSet()` to set the end weld data structure.

The function `ProMechweldendTypeGet()` returns the type of end weld defined between different surfaces. The valid types of end welds are:

- `PRO_MECH_WELD_END_SINGLE_TO_SINGLE`—Specifies a weld defined between a side surface and a shell or shell paired surface.
- `PRO_MECH_WELD_END_MANY_TO_SINGLE`—Specifies a weld defined from a solid surface to a solid surface.
- `PRO_MECH_WELD_END_SINGLE_TO_MANY`—Specifies a weld surface defined from a solid surface to a shell surface.

Use the function `ProMechweldendTypeSet()` to set the type of end welds.

The function `ProMechweldendExtendAdjacentSurfacesGet()` specifies whether or not surfaces adjacent to the selected source surface will be extended to the target surface to create the weld. Use the function `ProMechweldendExtendAdjacentSurfacesSet()` to control the placement of the weld on the extension of the adjacent surfaces.

Use the function `ProMechweldendFree()` to free the memory of the end weld data structure.

The function `ProMechweldFeaturedataGet()` returns the Weld Feature data structure.

Use the function `ProMechweldfeatureAlloc()` to allocate memory for the Weld Feature data structure.

Use the function `ProMechweldFeaturedataSet()` to set the Weld Feature data structure.

---

The function `ProMechweldfeatureOverrideflagGet()` specifies if the material and thickness properties that will be applied to the shell idealizations resulting from the weld definitions are inherited from the Weld Feature or not.

Specify the input value of the function

`ProMechweldfeatureOverrideflagSet()` as `true` to specify the properties for the shell idealizations. Specify the value as `false` to inherit the properties from the Weld Feature.

You can use the following functions to access and modify the material property and thickness of the Weld Feature only if you specify the input value as `true` for the function `ProMechweldfeatureOverrideflagSet()` or you select the option **Override Weld Feature Settings** from the Creo Simulate user interface.

The function `ProMechweldfeatureMaterialidGet()` returns the material type used for the Weld Feature. Use the function `ProMechweldfeatureMaterialidSet()` to set the material for the shell idealizations. Specify the material ID as the input parameter of this function.

The function `ProMechweldfeatureThicknessGet()` returns the thickness of the Weld Feature. Use the function

`ProMechweldfeatureThicknessSet()` to set the thickness of the shell idealizations.

Use the function `ProMechweldfeatureFree()` to free the memory contained in the Weld Feature data structure.

## Creo Simulate Features

Functions Introduced:

- **ProMechFeaturePromote()**

The function `ProMechFeaturePromote()` promotes the specified Creo Simulate feature making it accessible in Creo Parametric. The promoted feature however cannot be transferred back to Creo Simulate .

## Validating New and Modified Simulation Objects

You can check the validity of simulation objects that are created new or modified. During validation, an error object is created or updated with error, warning, and information messages.

Functions Introduced:

- **ProMechitemValidate()**
- **ProMecherrobjDataGet()**
- **ProMecherrobjMessageGet()**

---

The function `ProMechItemValidate()` validates the specified Creo Simulate item and returns an error object that collects the error, warning, and information messages. The function sets the error checking mode, validates the Creo Simulate item, resets the error checking mode, and returns the error object.

The error, warning and information messages are given by the enumerated type `ProMechErrobjType`, which has the following values:

- `PRO_MECH_ERROBJ_ERROR`
- `PRO_MECH_ERROBJ_WARNING`
- `PRO_MECH_ERROBJ_INFO`

The function `ProMecherrobjDataGet()` returns the number of events of an error object for the given `ProMechErrobjType`. To get the event message at a given index in an error object, you can use the function `ProMecherrobjMessageGet()`.

## Creo Simulate: Geometry

### Creo Simulate: Geometry

In Creo Parametric, when analysis is performed on a model (in either FEM or Native), the geometry that is seen on the screen is processed to create the Creo Simulate Geometry. This special temporary geometry is more suitable for analysis than the standard Creo Parametric geometry.

### Introduction

Creo Simulate Geometry differs from that of standard Creo Parametric geometry in several ways.

- Creo Simulate geometry provides a non-manifold representation of assembly models.

#### Non-manifold geometry

---

In assemblies, when two parts are mated, there exist two surfaces where the parts are mated, each of which does not know the existence of the other.

For analysis applications (particularly in meshing), you want the geometry to have only one surface in this mated area

- Creo Simulate geometry provides mid-surface geometry for models which have shells defined.

### Mid-surface geometry

- Creo Simulate geometry provides volume and surface region information.

### “Tagged” region

Without access to the Creo Simulate geometry, it is difficult to use the information on volume and surface region.

The Creo Simulate geometry identifies which surfaces are "duplicated" at the boundaries within the solid. This makes it easy for external applications to re-create the non-manifold solid.

- Creo Simulate Geometry model is devoid of the undesirable features (from the point of view of analysis) present in the Creo Parametric model such as
  - Small, localized misalignments in the geometry
  - Cusps
  - Very small sliver surfaces

## Obtaining Creo Simulate Geometry from Creo TOOLKIT

Creo Parametric represents the top level access to Creo Simulate geometry as an opaque handle called `ProMechModel`. The `ProMechModel` handle is generated upon request and can be accessed until it is freed by the application.

There are several modes which can be used to generate the model and its geometry:

- `PRO_MECH_MODEL_SOLID` signifies solid surfaces only. Shells will be ignored.
- `PRO_MECH_MODEL_SHELL` signifies shell-compressed surfaces. Non shell-compressed surfaces will not be included.
- `PRO_MECH_MODEL_MIXED` signifies both solid and shell-compressed surfaces.
- `PRO_MECH_MODEL_BOUNDARY` signifies shell surfaces occurring on the solid boundary.
- `PRO_MECH_MODEL_QUILT` signifies shell surfaces on quilts. This option requires that quilts be specified as additional entities to be processed.
- `PRO_MECH_MODEL_BAR` signifies bars on given datum curves. This option requires that curves be specified as additional entities to be processed.

It is not always necessary to have a Creo Simulate license to generate the Creo Simulate geometry. However, some situations do require the license:

- Use of the options `PRO_MECH_MODEL_SHELL`, `PRO_MECH_MODEL_MIXED` and `PRO_MECH_MODEL_BOUNDARY` is not permitted unless Creo Simulate is active. Please see the description for `ProMechanicsIsActive()` in the section [Accessing Creo Simulate Items on page 1825](#).
- If any component of the model contains surface or volume region feature, Creo Simulate must be active to access the geometry of these regions.

Functions Introduced:

- **`ProMechmodeldataAlloc()`**

- **ProMechmodeldataTypeSet()**
- **ProMechmodeldataEntitiesSet()**
- **ProMechmodeldataPreserveidsSet()**
- **ProMechmodeldataMergeCoincSolidEdgesSet()**
- **ProMechmodelGet()**
- **ProMechmodelFree()**
- **ProMechmodeldataFree()**

Use the function `ProMechmodeldataAlloc()` to allocate an input data structure for generation of Creo Simulate geometry.

Use the function `ProMechmodeldataTypeSet()` to assign the type of model to be generated.

Use the function `ProMechmodeldataEntitiesSet()` to assign the additional datum points, quilts, and curves to be included in the geometric processing.

Use the function `ProMechmodeldataPreserveidsSet()` to set the preservation of IDs. In the event of the "Preserve IDs" flag being set, Creo Simulate tries to preserve the IDs of surfaces and edges in Creo Simulate geometry between different calls to `ProMechmodelGet()`. This happens even if the original geometry of the model has changed slightly, but the success of this attempt to preserve geometry IDs is not always guaranteed.

Use the function `ProMechmodeldataMergeCoincSolidEdgesSet()` to set the flag that determines whether coincident solid edges will be merged. By default, the flag is `PRO_B_FALSE`, that is, the solid edges will not be merged.

Use the function `ProMechmodelGet()` to obtain the root handle of a Creo Simulate geometry model. The input arguments of this function are:

- *solid*—signifies the root solid model (part or assembly).
- *data*—signifies the options for the generation of geometry.

The output arguments are as follows:

- *mech\_model* signifies the root handle of the generated geometry.
- *status* signifies the status of generation and can have the following values:
  - `PRO_MECH_MODEL_SUCCESS` signifies success.
  - `PRO_MECH_MODEL_GENERAL_FAILURE` signifies general failure.
  - `PRO_MECH_MODEL_USER_INTERRUPT` signifies that the user interrupted the process before it completed.
  - `PRO_MECH_MODEL_SHELL_NO_PAIRS` signifies that no shell pairs were defined (for options that used shell compression).

- 
- `PRO_MECH_MODEL_SHELL_SOME_PAIRS` signifies that some paired and some unpaired surfaces exist.(for options that used shell compression).

Use the function `ProMechmodeldataFree()` to free a data handle used for generation of a Creo Simulate geometry model. Use the function `ProMechmodelFree()` to free a Creo Simulate model handle. This invalidates all geometric entities obtained from this handle.

## Accessing the ProMechModel

Functions Introduced:

- **`ProMechmodelMdlGet()`**
- **`ProMechmodelSolidVisit()`**
- **`ProMechmodelPointVisit()`**
- **`ProMechmodelCurveVisit()`**
- **`ProMechmodelToleranceGet()`**

The function `ProMechmodelMdlGet()` can be used to obtain the root solid model used for generation of this Creo Simulate model.

The function `ProMechmodelSolidVisit()` visits the solid volumes that make up a Creo Simulate geometry model.

The function `ProMechmodelPointVisit()` visits the datum points that are included in a Creo Simulate geometry model.

---

### **Note**

only datum points that have Creo Simulate items referencing them will be included unless you pass the additional points as input from `ProMechmodeldataEntitiesSet()`.

---

The function `ProMechmodelCurveVisit()` visits the composite curves that are included in a Creo Simulate geometry model.

---

### **Note**

only datum points that have Creo Simulate items referencing them will be included unless you pass the additional points as input from `ProMechmodeldataEntitiesSet()`.

---

Use the function `ProMechmodelToleranceGet()` to obtain the overall tolerance or epsilon value used for the preparation of the Creo Simulate geometry.

---

## Accessing the ProMechSolid

An opaque handle called a `ProMechSolid` represents a solid volume member of the model (typically, an assembly member).

Functions Introduced:

- **`ProMechsolidVisitAction()`**
- **`ProMechsolidFilterAction()`**
- **`ProMechsolidIdGet()`**
- **`ProMechsolidModelGet()`**
- **`ProMechsolidTypeGet()`**
- **`ProMechsolidAsmcomppathGet()`**
- **`ProMechsolidSurfaceVisit()`**
- **`ProMechsolidEdgeVisit()`**
- **`ProMechsolidVertexVisit()`**

The function types `ProMechsolidVisitAction()` and `ProMechsolidFilterAction()` are used as arguments to functions that visit `ProMechSolid` objects.

Use the function `ProMechsolidIdGet()` to obtain the ID of the solid volume. This ID is an index in the array of generated solid volumes and is not persistent among different calls to `ProMechmodelCreate()`.

Use the function `ProMechsolidModelGet()` to obtain the root Creo Simulate geometry model for this solid model.

Use the function `ProMechsolidTypeGet()` to obtain the solid volume type.

Use the function `ProMechsolidAsmcomppathGet()` to obtain the assembly component path from the top level assembly to this solid.

Use the function `ProMechsolidSurfaceVisit()` to visit the surfaces that are included in a given solid volume.

Use the function `ProMechsolidEdgeVisit()` to visit the edges that are included in a given solid volume.

Use the function `ProMechsolidVertexVisit()` to visit the vertices that are included in a given solid volume.

## Accessing Creo Simulate ProMechSurface

An opaque handle called a `ProMechSurface` represents a Creo Simulate geometry surface. A surface can be of the following types:

- `PRO_MECH_FACE_SOLID`—A solid surface

- 
- `PRO_MECH_FACE_SHELL`—A shell (mid-plane) surface
  - `PRO_MECH_FACE_SIDE`—A shell side surface
  - `PRO_MECH_FACE_SHELL_QLT`—A quilt surface
  - `PRO_MECH_FACE_BOUNDARY`—A solid boundary surface
  - `PRO_MECH_FACE_PERIM_WELD`—A generated surface for a perimeter weld object

Functions Introduced:

- **`ProMechsurfaceVisitAction()`**
- **`ProMechsurfaceFilterAction()`**
- **`ProMechsurfaceIdGet()`**
- **`ProMechsurfaceOwnerGet()`**
- **`ProMechsurfaceTypeGet()`**
- **`ProMechsurfaceContourVisit()`**
- **`ProMechsurfaceEdgeVisit()`**
- **`ProMechsurfaceVertexVisit()`**
- **`ProMechsurfaceIncontactfacesGet()`**
- **`ProMechsurfaceAncestorsGet()`**

The function types `ProMechsurfaceVisitAction()` and `ProMechsurfaceFilterAction()` are used as arguments to functions that visit `ProMechSurface` objects.

Use the function `ProMechsurfaceIdGet()` to obtain the surface ID of the surface.

#### **Note**

This ID is not persistent and is not related to the Creo Parametric surface ID.

---

Use the function `ProMechsurfaceOwnerGet()` to obtain the owner `ProMechsolid` of the surface.

Use the function `ProMechsurfaceTypeGet()` to obtain the type of surface.

Use the function `ProMechsurfaceContourVisit()` to visit the contours that are included in a given surface.

Use the function `ProMechsurfaceEdgeVisit()` to visit the edges that are included in a given surface.

Use the function `ProMechsurfaceVertexVisit()` to visit vertices that are included in a given surface.

---

Use the function `ProMechsurfaceAncestorsGet()` to obtain the ancestor surfaces for the given surface. These are the actual Creo Parametric geometry surfaces used to construct this Creo Simulate surface.

## Geometry Evaluation of ProMechSurface

For information about how Creo TOOLKIT represents surface geometry, see the section on [Core: 3D Geometry on page 177](#) and the appendix, [Element Trees: References on page 807](#).

Functions Introduced:

- **ProMechsurfaceParamEval()**
- **ProMechsurfaceUvpntVerify()**
- **ProMechsurfaceTessellationGet()**
- **ProMechsurfaceDataGet()**
- **ProMechsurfaceToNURBS()**
- **ProMechsurfaceTransformGet()**
- **ProMechsurfaceThicknessEval()**

Use the function `ProMechsurfaceParamEval()` to find the corresponding UV point on the Creo Simulate geometry surface on the basis of the XYZ point.

Use the function `ProMechsurfaceUvpntVerify()` to verify whether the specified UV point lies within the boundaries of the Creo Simulate surface.

Use the function `ProMechsurfaceTessellationGet()` to calculate the tessellation for the provided Creo Simulate surface.

Use the function `ProMechsurfaceDataGet()` to obtain the geometric representation of the surface.

Use the function `ProMechsurfaceToNURBS()` to obtain the NURBS representation of the Creo Simulate surface.

Use the function `ProMechsurfaceTransformGet()` to obtain UV transform between the two surfaces in contact.

Use the function `ProMechsurfaceThicknessEval()` to obtain the thickness of the shell Creo Simulate surface at the given UV point.

## Accessing ProMechContour

An opaque handle called a `ProMechContour` represents a contour member of the model. See the section on [Core: 3D Geometry on page 177](#) for a discussion of contours.

Functions Introduced:

- **ProMechcontourVisitAction()**
- **ProMechcontourFilterAction()**
- **ProMechcontourIdGet()**
- **ProMechcontourSurfaceGet()**
- **ProMechcontourTraversalGet()**
- **ProMechcontourEdgeVisit()**
- **ProMechcontourUvpntVerify()**
- **ProMechcontourAreaEval()**
- **ProMechcontourContainingContourGet()**

The function types `ProMechcontourVisitAction()` and `ProMechcontourFilterAction()` are used as arguments to functions that visit `ProMechContour` objects.

Use the function `ProMechcontourIdGet()` to obtain the ID for a given contour. This ID is unique within the surface that owns the contour.

Use the function `ProMechcontourSurfaceGet()` to obtain the surface that contains the contour.

Use the function `ProMechcontourTraversalGet()` to obtain the contour traversal.

Use the function `ProMechcontourEdgeVisit()` to visit the edges that make up a contour.

Use the function `ProMechcontourUvpntVerify()` to verify whether the specified UV point lies within the given Creo Simulate contour.

Use the function `ProMechcontourAreaEval()` to find the surface area inside the given outer contour, accounting for internal voids.

The function `ProMechcontourContainingContourGet()` returns the containing contour for a Creo Simulate contour object.

## Accessing ProMechEdge

An opaque handle called a `ProMechEdge` represents an edge member of the model.

Functions Introduced:

- **ProMechedgeVisitAction()**
- **ProMechedgeFilterAction()**
- **ProMechedgeIdGet()**
- **ProMechedgeOwnerGet()**

- 
- **ProMechEdgeSurfaceVisit()**
  - **ProMechEdgeContourVisit()**
  - **ProMechEdgeEndpointsGet()**
  - **ProMechEdgeIncontactEdgesGet()**
  - **ProMechEdgeAncestorsGet()**

The function types `ProMechEdgeVisitAction()` and `ProMechEdgeFilterAction()` are used as arguments to functions that visit `ProMechEdge` objects.

Use the function `ProMechEdgeIdGet()` to obtain the ID of the given edge.

#### **Note**

This ID is not persistent and is not related to the Creo Parametric edge ID.

---

Use the function `ProMechEdgeOwnerGet()` to obtain the owner `ProMechSolid` of the given edge.

Use the function `ProMechEdgeSurfaceVisit()` to visit the surfaces that share this edge.

Use the function `ProMechEdgeContourVisit()` to visit the contours that contain this edge.

Use the function `ProMechEdgeEndpointsGet()` to obtain the endpoints of the given edge.

Use the function `ProMechEdgeIncontactEdgesGet()` to obtain the list of edges that are in contact with the given edge.

Use the function `ProMechEdgeAncestorsGet()` to obtain the ancestor edges for the given edge. These are the actual Creo Parametric geometry edges used to construct this Creo Simulate edge.

## **Geometry Evaluation of ProMechEdge**

For information about how Creo TOOLKIT represents edge geometry, see the section on [Core: 3D Geometry on page 177](#) and the appendix, [Element Trees: References on page 807](#).

Functions Introduced:

- **ProMechEdgeUvdataEval()**
- **ProMechEdgeXyzdataEval()**
- **ProMechEdgeParamEval()**

- **ProMechedgeLengthEval()**
- **ProMechedgeLengthT1T2Eval()**
- **ProMechedgeParamByLengthEval()**
- **ProMechedgeTessellationGet()**
- **ProMechedgeDataGet()**
- **ProMechedgeToNURBS()**
- **ProMechedgeDirectionGet()**
- **ProMechedgeReldirGet()**

Use the function `ProMechedgeUvdataEval()` to evaluate the Creo Simulate edge in the UV space of the given surface.

Use the function `ProMechedgeXyzdataEval()` to evaluate the Creo Simulate edge parameter point in XYZ space.

Use the function `ProMechedgeParamEval()` to find the corresponding normalized parameter on the Creo Simulate edge by XYZ point.

Use the function `ProMechedgeLengthEval()` to obtain the length of the edge.

Use the function `ProMechedgeLengthT1T2Eval()` to find the length of the Creo Simulate edge between the given parameters.

Use the function `ProMechedgeParamByLengthEval()` to find the parameter of the point located at the given length from the given parameter.

Use the function `ProMechedgeTessellationGet()` to get the edge tessellation for the Creo Simulate edges.

Use the function `ProMechedgeToNURBS()` to obtain the NURBs representation of the Creo Simulate edge.

Use the function `ProMechedgeReldirGet()` to obtain the relative direction of two Creo Simulate edges in contact.

Use the function `ProMechedgeDataGet()` to obtain the geometric representation of the edge.

Use the function `ProMechedgeDirectionGet()` to obtain the edge direction with respect to the given contour.

## Accessing ProMechVertex

An opaque handle called a `ProMechVertex` represents a vertex member of the model.

Functions Introduced:

- **ProMechvertexVisitAction()**

- **ProMechvertexFilterAction()**
- **ProMechvertexIdGet()**
- **ProMechvertexOwnerGet()**
- **ProMechvertexPointGet()**
- **ProMechvertexSurfaceVisit()**
- **ProMechvertexEdgeVisit()**
- **ProMechvertexIncontactverticesGet()**

The function types `ProMechvertexVisitAction()` and `ProMechvertexFilterAction()` are used as arguments to functions that visit `ProMechVertex` objects.

Use the function `ProMechvertexIdGet()` to obtain the ID of the given vertex.

Use the function `ProMechvertexOwnerGet()` to obtain the volume that owns this vertex.

Use the function `ProMechvertexPointGet()` to obtain the coordinate point for a given vertex.

Use the function `ProMechvertexSurfaceVisit()` to visit the surfaces that include this vertex.

Use the function `ProMechvertexEdgeVisit()` to visit the edges that contain this vertex.

Use the function `ProMechvertexIncontactverticesGet()` to obtain the list of vertices that are in contact with the given vertex.

## Accessing ProMechPoint

An opaque handle called a `ProMechPoint` represents a datum point member of the model. By default, the Creo Simulate geometry will include only those points which have Creo Simulate loads or other items referencing them; you can generate additional points by including them as inputs to `ProMechmodeldataEntitiesSet()`.

Functions Introduced:

- **ProMechpointVisitAction()**
- **ProMechpointFilterAction()**
- **ProMechpointIdGet()**
- **ProMechpointOwnerGet()**
- **ProMechpointPointGet()**
- **ProMechpointPlacementtypeGet()**

- 
- **ProMechpointPlacementsurfaceGet()**
  - **ProMechpointPlacementedgeGet()**
  - **ProMechpointPlacementvertexGet()**
  - **ProMechpointAncestorsGet()**

The function types `ProMechpointVisitAction()` and `ProMechpointFilterAction()` are used as arguments to functions that visit `ProMechPoint` objects.

Use the function `ProMechpointIdGet()` to obtain the ID of the point.

#### **Note**

This ID is not persistent and is not related to the Creo Parametric point ID.

---

Use the function `ProMechpointOwnerGet()` to obtain the owner model of the given point.

Use the function `ProMechpointPointGet()` to obtain the coordinates of the point.

Use the function `ProMechpointPlacementtypeGet()` to obtain the placement type for the point. Following are list of possible placement types:

- `PRO_MECH_PNT_FREE` signifies that the point is not attached to a solid or shell.
- `PRO_MECH_PNT_FACE` signifies that the point lies on a `ProMechSurface`.
- `PRO_MECH_PNT_EDGE` signifies that the point lies on a `ProMechEdge`.
- `PRO_MECH_PNT_VERTEX` signifies that the point lies on a `ProMechVertex`.

Use the function `ProMechpointPlacementsurfaceGet()` to obtain the placement surface, if the placement type is `PRO_MECH_POINT_FACE`.

Use the function `ProMechpointPlacementedgeGet()` to obtain the placement edge, if placement type is `PRO_MECH_POINT_EDGE`.

Use the function `ProMechpointPlacementvertexGet()` to obtain the placement vertex, if the placement type is `PRO_MECH_POINT_VERTEX`.

Use the function `ProMechpointAncestorsGet()` to obtain the ancestor points for the given point. These are the actual Creo Parametric geometry points used to construct this Creo Simulate point.

---

## Accessing ProMechCompositeCurve

An opaque handle called a `ProMechCompositeCurve` represents a composite curve member of the model. By default, the Creo Simulate geometry will include only those curves which have Creo Simulate loads or other items referencing them. You can generate additional curves by including them as inputs to `ProMechmodeldataEntitiesSet()`.

Functions Introduced:

- **`ProMechcompositecurveVisitAction()`**
- **`ProMechcompositecurveFilterAction()`**
- **`ProMechcompositecurveIdGet()`**
- **`ProMechcompositecurveOwnerGet()`**
- **`ProMechcompositecurveCurveVisit()`**
- **`ProMechcompositecurveAncestorsGet()`**

The function types `ProMechcompositecurveVisitAction()` and `ProMechcompositecurveFilterAction()` are used as arguments to functions that visit `ProMechCompositeCurve` objects.

Use the function `ProMechcompositecurveIdGet()` to obtain the ID of the composite curve.

### Note

This ID is not persistent and is not related to the Creo Parametric composite curve ID.

---

Use the function `ProMechcompositecurveOwnerGet()` to obtain the owner model of the composite curve.

Use the function `ProMechcompositecurveCurveVisit()` to visit the curves that make up this composite curve.

Use the function `ProMechcompositecurveAncestorsGet()` to obtain the ancestor curves for the given curve. These are the actual Creo Parametric geometry curves used to construct this Creo Simulate curve.

## Accessing ProMechCurve

An opaque handle called a `ProMechCurve` represents a curve member of the model. A curve is always the child of a composite curve.

Functions Introduced:

- **`ProMechcurveVisitAction()`**

- **ProMechcurveFilterAction()**
- **ProMechcurveTypeGet()**
- **ProMechcurveEdgeGet()**
- **ProMechcurveParentGet()**
- **ProMechcurveParamGet()**
- **ProMechcurveEndpointsGet()**
- **ProMechcurveAncestorsGet()**

The function types `ProMechcurveVisitAction()` and `ProMechcurveFilterAction()` are used as arguments to functions that visit `ProMechCurve` objects.

Use the function `ProMechcurveTypeGet()` to obtain the curve's type. Curves may be of the following types:

- `PRO_MECH_SEGMENT_FREE`
- `PRO_MECH_SEGMENT_ON_EDGE`

Use the function `ProMechcurveEdgeGet()` to obtain the edge, if the curve type is `PRO_MECH_CURVE_EDGE`.

Use the function `ProMechcurveParentGet()` to obtain the parent composite curve for this curve.

Use the function `ProMechcurveParamGet()` to obtain the parameter along the parent composite curve at which this curve begins.

Use the function `ProMechcurveEndpointsGet()` to obtain the endpoints of the curve.

Use the function `ProMechcurveAncestorsGet()` to obtain the ancestor curves for the specified Creo Simulate curve. The ancestor curves are the actual Creo Parametric geometry curves used to construct the Creo Simulate curve.

## Geometry Evaluation of ProMechCurves

For information about how Creo TOOLKIT represents curve geometry, see the section on [Core: 3D Geometry on page 177](#) and the appendix, [Element Trees: References on page 807](#).

Functions Introduced:

- **ProMechcurveXyzdataEval()**
- **ProMechcurveParamEval()**
- **ProMechcurveLengthEval()**
- **ProMechcurveLengthT1T2Eval()**
- **ProMechcurveParamByLengthEval()**

- 
- **ProMechcurveDataGet()**
  - **ProMechcurveToNURBS()**

Use the function `ProMechcurveXyzdataEval()` evaluates the Creo Simulate curve parameter point in the XYZ point.

Use the function `ProMechcurveParamEval()` to find the corresponding normalized parameter on the Creo Simulate curve by XYZ point.

Use the function `ProMechcurveLengthEval()` to obtain the length of the curve.

Use the function `ProMechcurveLengthT1T2Eval()` to find the length of the Creo Simulate curve between the given parameters.

Use the function `ProMechcurveParamByLengthEval()` to find the parameter of the point located at the given length from the given parameter.

Use the function `ProMechcurveDataGet()` to obtain the geometric representation of the edge.

Use the function `ProMechcurveToNURBS()` to obtain the NURBS representation of the Creo Simulate curve.

## To Create a Surface Region Feature

This section describes the use the header file `ProSurfReg.h` to create a surface region feature programmatically. The section [Element Trees: Principles of Feature Creation on page 771](#) provides the necessary background for creating features; we recommend you read that material first.

---

### Note

The Surface Region feature is available and can be regenerated only in the Creo Simulate environment.

---

The following figure shows the element tree for the Surface Region feature.

The Surface Region feature element tree contains no non-standard element types. The following table describes special information about the elements in this tree.

| Element ID                      | Value                                                                                                                                                                                                                                                                                                                            |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_FEATURE_TYPE              | PRO_FEAT_SPLIT_SURF                                                                                                                                                                                                                                                                                                              |
| PRO_E_STD_FEATURE_NAME          | Specifies the name of the Surface Region feature. The default value is “Surface Region”. This element is optional.                                                                                                                                                                                                               |
| PRO_E_SURFREG_SPLITTING_OPTION  | Specifies the method to define the surface contour. Valid values are:<br><br>PRO_SURFREG_SKETCH—Split the surface using a sketch.<br><br>PRO_SURFREG_CHAIN—Split the surface using a chain.                                                                                                                                      |
| PRO_E_STD_SECTION               | Specifies a 2D section or a sketched section. Refer to the section <a href="#">Creating Features Containing Sections on page 1004</a> for details on how to create features that contain sketched sections.<br><br>Refer to the section <a href="#">Creating Section Models on page 987</a> for details on creating 2D sections. |
| PRO_E_STD_CURVE_COLLECTION_APPL | Specifies a collection of selected curves or edges or both to copy.                                                                                                                                                                                                                                                              |
| PRO_E_STD_SURF_COLLECTION_APPL  | Specifies a collection of selected surfaces to copy.                                                                                                                                                                                                                                                                             |

# Creo Simulate: Finite Element Modeling (FEM)

## Creo Simulate: Finite Element Modeling (FEM)

This section contains descriptions of the Creo TOOLKIT functions that support Creo Parametric Finite Element Modeling (FEM).

### Overview

The Finite Element Modeling (FEM) functions in this section are designed to give you access to data generated by the Pro/MESH module of Creo Parametric. You can do the following:

- Export a Pro/MESH output file to disk.

### Exporting an FEA Mesh

Function Introduced:

- **ProFemmeshExport()**

The function `ProFemmeshExport()` generates the Finite Element Mesh based on the given parameters, and exports it to the specified file.

The function uses the data structure `ProFemmeshData`, which is defined as follows:

```
typedef struct pro_femmesh_data
{
 ProFemmeshType mesh_type;
 ProFemshellmeshType shell_type;
 int num_quilts;
 ProFemquiltref * pro_quilt_ref_arr;
 ProFemanalysisType analysis;
 ProFemelemshapeType elem_shape;
 ProFemsolverType solver;
 ProFemcsysref csys_ref;
 int num_aux_csys;
 ProFemcsysref * aux_csys_ref_arr;
} ProFemmeshData;
```

The `pro_femmesh_data` fields are as follows:

- `mesh_type`—The mesh type. The possible values are as follows:
  - `PRO_FEM_SOLID_MESH`—Mesh solid parts using tetrahedral solid mesh elements.

- 
- PRO\_FEM\_SHELL\_MESH—Shell mesh using triangular or quadrangular mesh elements. This type is designed for meshing surfaces.
  - PRO\_FEM\_MIXED\_MESH—Mesh models with a mixture of shell and tetrahedral mesh elements.
  - PRO\_FEM\_QUILT\_MESH—A mesh for any simple or advanced shell idealizations created for quilt surfaces.
  - PRO\_FEM\_BOUNDARY\_MESH—A shell mesh of triangular or quadrilateral elements on the model's exterior surfaces.
  - PRO\_FEM\_BAR\_MESH—A bar mesh for one dimensional idealizations.
  - shell\_type—The type of shell element. This field is ignored for a solid mesh. The possible values are as follows:
    - PRO\_FEM\_TRIANGLE
    - PRO\_FEM\_QUADRANGLE
  - num\_quilts—The quilt identifier.
  - pro\_quilt\_ref\_arr—An array of references of quilt surfaces in the assembly.
  - analysis—The analysis type. The possible values are as follows:
    - PRO\_FEM\_ANALYSIS\_STRUCTURAL—Structural analysis, including stress, strain, thermal stress, and displacement.
    - PRO\_FEM\_ANALYSIS\_MODAL—Modal analysis, including the constraint sets applied to the model.
    - PRO\_FEM\_ANALYSIS\_THERMAL—Thermal analysis, including temperature, heat flux, and heat gradient.
  - elem\_shape—The type of element to be used for the solver.
    - PRO\_FEM\_MIDPNT\_LINEAR—Linear elements are used for the analysis. This includes corner nodes, straight edges, and planar faces.
    - PRO\_FEM\_MIDPNT\_PARABOLIC—Parabolic elements are used for the analysis.
    - PRO\_FEM\_MIDPNT\_PARABOLIC\_FIXED—The excessively curved edges of solid and shell mesh parabolic elements are slightly straightened and then used for analysis.

The number of nodes that are as follows:

|             |                             |
|-------------|-----------------------------|
| Tetrahedron | PRO_FEA_LINEAR: 4 nodes     |
|             | PRO_FEA_PARABOLIC: 10 nodes |
| Triangle    | PRO_FEA_LINEAR: 3 nodes     |
|             | PRO_FEA_PARABOLIC: 6 nodes  |
| Quadrangle  | PRO_FEA_LINEAR: 4 nodes     |
|             | PRO_FEA_PARABOLIC: 8 nodes  |

- `solver`—The type of solver used for analysis. The possible values are:
  - `PRO_FEM_FEAS_ANSYS`—Specifies an ANSYS solver.
  - `PRO_FEM_FEAS_NASTRAN`—Specifies a NASTRAN solver.
  - `PRO_FEM_FEAS_NEUTRAL`—Specifies other solvers that support the FEM Neutral file format for analysis.
- `csys_ref`—An array of geometric references.
- `num_aux_csys`—Additional coordinate system to be included in the analysis.
- `aux_csys_ref_arr`—An array of geometric references for the auxiliary coordinate system.

#### Note

Prior to calling this function, the model (`pro_solid`) should be displayed in the graphics window.

The input arguments of this function are as follows:

- `pro_solid`—The handle of a Creo Parametric model (part or assembly).
- `p_mesh_data`—The pointer to the data structure containing the mesh generation parameters.
- `file_name`—The file name to export mesh to.

This function supersedes the function `pro_export_fea_mesh()`

## Mechanism Design: Mechanism Features

### Mechanism Design: Mechanism Features

This section describes the programmatic creation of mechanism modeling entities such as springs and dampers as Creo Parametric features.

---

The section also explains for to add motor features such as, servo motors, forces motors, and so on.

We recommend you read the section, [Overview of Feature Creation on page 771](#) in the section, [Element Trees: Principles of Feature Creation on page 771](#). It provides the necessary background for creating features using Creo TOOLKIT.

## Mechanism Spring Feature

A spring generates a translational or rotational spring force in a mechanism. It produces a linear spring force when stretched or compressed, and a torsion force when rotated. The magnitude of the spring force is directly proportional to the amount of displacement from the position of equilibrium.

Springs are created as Creo Parametric features and their values are stored as valid Creo Parametric parameters.

## Feature Element Tree for the Mechanism Spring Feature

The element tree for the Mechanism Spring feature is documented in the header file, `ProDamperFeat.h`. The following figure demonstrates the structure of the feature element tree.

## Feature Element Tree for Mechanism Spring

```
PRO_E_FEATURE_TREE
|
|--PRO_E_STD_FEATURE_NAME
|
|--PRO_E_SPRING_DAMPER_TYPE
|
|--PRO_E_SPRING_DAMPER_REF
|
|--PRO_E_SPRING_K
|
|--PRO_E_SPRING_U
|
|--PRO_E_SPRING_DIAMETER
|
|--PRO_E_SPRING_USE_DIAMETER
|
|--PRO_E_SPRING_ATTACH_POINTS
|
|--PRO_E_SPRING_ATTACH_REF
|
|--PRO_E_SPRING_FLIP_U_ANGLE
```

The following list details special information about the elements in the feature element tree:

- PRO\_E\_STD\_FEAT\_NAME—Specifies the name of the mechanism spring feature.
- PRO\_E\_SPRING\_DAMPER\_TYPE—Specifies the mechanism spring feature type. It can have the following values:
  - PRO\_SPRING\_DAMPER\_FORCE—Specifies an extension or compression spring.
  - PRO\_SPRING\_DAMPER\_TORQUE—Specifies a torsion spring.
- PRO\_E\_SPRING\_DAMPER\_REF—Specifies the spring placement references. For an extension spring or compression spring, you can select the translational axis or two points on two different bodies as the placement references. For a torsion spring, you can select the rotational axis as the placement reference.
- PRO\_E\_SPRING\_K—Specifies the value for the stiffness coefficient of the spring.
- PRO\_E\_SPRING\_U—Specifies the value for the unstretched length of the spring.

- `PRO_E_SPRING_DIAMETER`—Specifies the value for the spring icon diameter for an extension spring.
- `PRO_E_SPRING_USE_DIAMETER`—Specifies the **Adjust Icon Diameter** option (available in the Creo Parametric user interface) that allows you to change the value of the spring icon diameter. This element is not available by default. It takes the following values:
  - `PRO_SPRING_USE_DIAMETER_NO`
  - `PRO_SPRING_USE_DIAMETER_YES`
- `PRO_E_SPRING_ATTACH_POINTS`—Specifies the attachment points for the two ends of a torsion spring. The attachment points can be of the following types:
  - `PRO_SPRING_USE_MOTION_AXIS_ZERO`—Specifies the JAS (Joint Axis Set) option, where the attachment references are automatically populated with the selected JAS references.
  - `PRO_SPRING_CUSTOM_ATTACHMENT_POINTS`—Specifies custom attachment references where you can specify two attachment references such as datum planes, datum points, and vertices. The vector between each attachment reference and the selected rotational axis is automatically calculated. By default, the greatest angle between the two vectors is defined as the spring angle. On selecting both the attachment references, the unstretched value of the torsion spring is automatically updated according to the current angle between the two vectors.
- `PRO_E_SPRING_ATTACH_REF`—Specifies the actual attachment references for the torsion spring depending upon the attachment type set for the element `PRO_E_SPRING_ATTACH_POINTS`.
- `PRO_E_SPRING_FLIP_U_ANGLE`—Specifies the option to flip the direction of the current angle between the attachment references for a torsion spring.

## Mechanism Damper Feature

A damper generates a force that removes energy from a moving mechanism and dampens its motion. The damper force is always proportional to the magnitude of velocity of the entity on which you are applying the damper, and acts in the direction opposite to movement.

Dampers are created as Creo Parametric features and their values are stored as valid Creo Parametric parameters.

---

## Feature Element Tree for the Mechanism Damper Feature

The element tree for the Mechanism Damper feature is documented in the header file, `ProDamperFeat.h`. The following figure demonstrates the structure of the feature element tree.

### Feature Element Tree for Mechanism Damper

The following list details special information about the elements in the feature element tree:

- `PRO_E_STD_FEAT_NAME`—Specifies the name of the mechanism damper feature.
- `PRO_E_SPRING_DAMPER_TYPE`—Specifies the mechanism damper feature type. It can have the following values:
  - `PRO_SPRING_DAMPER_FORCE`—Specifies an extension damper or compression damper.
  - `PRO_SPRING_DAMPER_TORQUE`—Specifies a torsion damper.
- `PRO_E_SPRING_DAMPER_REF`—Specifies the damper placement references. For an extension damper or compression damper, you can select the translational or slot axis, or two points on two different bodies as the placement references. For a torsion damper, you can select the rotational axis as the placement reference.
- `PRO_E_DMP_CVAL`—Specifies the value for the damping coefficient.

## Mechanism Belt Feature

A belt is treated as a connection connecting all the pulley bodies. The belt provides the same angular velocity to all pulleys connected by it.

Belts are created as Creo Parametric features and their values are stored as valid Creo Parametric parameters.

## Feature Element Tree for the Mechanism Belt Feature

The element tree for the Mechanism Belt feature is documented in the header file, `ProBeltFeat.h`. The following figure demonstrates the structure of the feature element tree.

### Feature Element Tree for Mechanism Belt

```
PRO_E_FEATURE_TREE
|
|--PRO_E_FEATURE_TYPE
|--PRO_E_STD_FEATURE_NAME
|
|--PRO_E_BELT_PULLEYS
| |
| |--PRO_E_BELT_PULLEY_RECORD
| |--PRO_E_BELT_PULLEY_SEL
| |--PRO_E_BELT_PULLEY_WRAP_SIDE
| |--PRO_E_BELT_PULLEY_DIAMETER
| |--PRO_E_BELT_PULLEY_DIAM_COINCIDENT
| |--PRO_E_BELT_PULLEY_CONN_NUM
| |--PRO_E_BELT_PULLEY_FLIP_CONN_BODIES
| |--PRO_E_BELT_PULLEY_NUM_WRAPS
|
|--PRO_E_BELT_PLANE
|
|--PRO_E_BELT_DEFINE_CUSTOM_U_LENGTH
|--PRO_E_BELT_UNSTRETCHED_LENGTH
|--PRO_E_BELT_STIFFNESS_COEFF
```

The following list details special information about the elements in the feature element tree:

- `PRO_E_FEATURE_TYPE`—Specifies the feature type.
- `PRO_E_STD_FEATURE_NAME`—Specifies the name of the mechanism belt feature.
- `PRO_E_BELT_PULLEYS`—Specifies an array of pulley bodies of the type `PRO_E_BELT_PULLEY_RECORD` which consists of the following elements:
  - `PRO_E_BELT_PULLEY_SEL`—Specifies the geometric reference selected as the pulley body. It can be a cylindrical surface, a circular curve

---

or edge, or a PIN or Cylinder connection. You must define at least two pulley bodies for the belt.

Creo Parametric automatically selects both the sides of the cylindrical surface or the circular curve or edge so that the pulley is complete. In case of a cylindrical or circular reference, the pulley's axis of rotation is automatically detected by detecting a PIN or Cylinder connection aligned to the theoretical axis of the geometric reference and perpendicular to the belt plane. If such a connection does not exist, the reference is considered invalid. In case of a connection reference, the rotation axis of the selected connection is used as the pulley axis.

- `PRO_E_BELT_PULLEY_WRAP_SIDE`—Specifies the pulley wrapping direction. It can be left (-1) or right (+1) and relative to the previous pulley. You can flip the belt to the other contact point detected between the belt and the pulley.
- `PRO_E_BELT_PULLEY_DIAMETER`—Specifies the pulley diameter. A cylindrical curve with the specified diameter is displayed around the selected pulley reference and on the belt plane. The pulley diameter is coincident with the pulley reference by default, except in case of connection references.
- `PRO_E_BELT_PULLEY_DIAM_COINCIDENT`—Indicates if the pulley diameter is coincident with the pulley reference. This element is set to `PRO_B_TRUE`, which means the pulley diameter is set to the value `Coincident` by default for non-connection references.
- `PRO_E_BELT_PULLEY_CONN_NUM`—Specifies the number of the PIN or Cylinder connection selected as the pulley reference from the available valid connections. One of the bodies that defines the connection is considered the pulley body, while the other body connected to it is considered the carrier body.
- `PRO_E_BELT_PULLEY_FLIP_CONN_BODIES`—Specifies the option to flip between the pulley and carrier bodies, in case of connection references. This option is not available in case of geometric references.
- `PRO_E_BELT_PULLEY_NUM_WRAPS`—Specifies the number of full wraps around the currently selected pulley. The wraps are considered as not overlapping and are not displayed in the 3D icon for the belt. The number of wraps affects the belt length. In case of open ended belts, the number of wraps influences the motion extent of the connected bodies.
- `PRO_E_BELT_PLANE`—Specifies the planar surface or datum plane that defines the belt plane. The plane should be perpendicular to the rotation axis of the first pulley. This element is optional. If the belt plane is not specified, it is detected based on the selected pulley references as follows:

- Cylindrical surfaces—If a cylindrical surface is used as the pulley reference, the perpendicular plane positioned in the center of the cylindrical surface (for the first pulley in case of multiple pulleys) is used as the belt plane
- Circular edge or curve—If a circular edge or curve is used as the pulley reference, the plane for the corresponding edge or curve (for the first pulley in case of multiple pulleys) is used as the belt plane.
- PIN/Cylinder connections—In case of connection references, the internal orange body zero point (for the first pulley in case of multiple pulleys) is used as the belt plane.
- PRO\_E\_BELT\_DEFINE\_CUSTOM\_U\_LENGTH—Identifies if the unstretched belt length can be specified by the user, or if it is system-defined. The length is system-defined by default.
- PRO\_E\_BELT\_UNSTRETCHED\_LENGTH—Specifies the value for the unstretched belt length. The system-defined length is calculated based on the pulley references and their specified diameters. When the user enters a desired belt length, Creo Parametric tries to reconnect the assembly according to the specified belt length. If the reconnect operation fails, the belt length reverts to the previously entered value.
- PRO\_E\_BELT\_STIFFNESS\_COEFF—Specifies the belt stiffness coefficient value.

## Mechanism 3D Contact Feature

3D contacts are connections between a group of surfaces selected from two parts. These connections are similar to cams, joints, gears, and belts. Depending on the surfaces selected, 3D contacts can be of the following types:

- Sphere to Sphere (point contact)
- Sphere to Planar surface (point contact)
- Cylinder to Cylinder (line contact)
- Cylinder to Planar surface (line contact)
- Sphere to Cylinder (point contact)
- Toroid to Plane (point contact)

3D Contacts are created as Creo Parametric features and their values are stored as Creo Parametric feature parameters.

---

## Feature Element Tree for the Mechanism 3D Contact Feature

The element tree for the Mechanism 3D Contact feature is documented in the header file, ProContact3dFeat.h. The following figure demonstrates the structure of the feature element tree.

 **Note**

From Pro/ENGINEER Wildfire 5.0 onwards, the feature element tree for the 3D Contact feature has been updated. 3D Contact features created using the old tree are represented in the new tree format. You will need to rebuild your existing Pro/TOOLKIT applications according to the new element tree.

---

The following list details special information about the elements in the feature element tree:

- `PRO_E_FEATURE_TYPE`—Specifies the feature type.
- `PRO_E_STD_FEATURE_NAME`—Specifies the name of the mechanism 3D contact feature.
- `PRO_E_C3D_MAT_OPTION1`—Specifies the material type for the first contact part. The material type is given by the enumerated type `ProC3dMaterialType` that takes the following values:
  - `PRO_C3D_MAT_DEFAULT`—Specifies the material properties of the participating contact part. This is the default type. If this type is set, the elements `PRO_E_C3D_POISSON1`, `PRO_E_C3D_YOUNG1`, and `PRO_E_C3D_DAMPING1` are not available for modification and are set by default.
  - `PRO_C3D_MAT_SEL_MAT`—Allows you to select a material type from the list of materials used in the assembly or from the material library directory. If this type is set, the elements `PRO_E_C3D_POISSON1`, `PRO_E_C3D_YOUNG1`, and `PRO_E_C3D_DAMPING1` are not available for modification and are set as per the selected material.
  - `PRO_C3D_MAT_USE_VALS`—Allows you to specify the values for the material properties. The elements `PRO_E_C3D_POISSON1`, `PRO_E_C3D_YOUNG1`, and `PRO_E_C3D_DAMPING1` are available and can be set as required.
- `PRO_E_C3D_REF1_RECS`—Specifies an array of selected surface references belonging to the first part that is used in the 3D contact. You can select multiple surfaces having a common center, equal diameter and a common edge. The surface reference is of type `PRO_E_C3D_REF_REC` and consists of the following elements:
  - `PRO_E_C3D_REF`—Specifies the selected surface reference. The reference can be a spherical, cylindrical, toroidal, or planar surface, or a vertex. If you select a vertex from the first part as one of the references, a sphere is displayed around the vertex and the vertex is considered as a

- 
- sphere in the 3D contact. If the first reference is a vertex, specify the value for the vertex radius using the element `PRO_E_C3D_VERT_RAD`. The first surface determines the second part that can be selected for the connection.
- `PRO_E_C3D_REF_FULL_GEOM`—Specifies whether a complete surface or a segment of the surface is selected. This option is specified by the enumerated type `ProC3dFullGeomFlag` and has the following values:
    - ◆ `PRO_C3D_FULL_GEOM`—Specifies that a complete surface has been selected for the 3D contact.
    - ◆ `PRO_C3D_PARTIAL_GEOM`—Specifies that a segment of a cylinder, sphere, or toroid has been selected for the 3D contact.
  - `PRO_E_C3D_REF_FLIP`—Specifies if the direction for the 3D contact is flipped. The value for this element is `PRO_B_FALSE` by default which means the contact direction is not flipped and the surface direction is used. This element is applicable only if you use quilt surfaces to create the 3D contacts.
  - `PRO_E_C3D_MAT_NAME1`—Specifies the name of the material type selected for the first contact part. This element can be set only if the element `PRO_E_C3D_MAT_OPTION1` is set to `PRO_C3D_MAT_SEL_MAT`.
  - `PRO_E_C3D_POISSON1`—Specifies the value for Poisson's ratio for the first contact part.
  - `PRO_E_C3D_YOUNG1`—Specifies the value for Young's modulus for the first contact part.
  - `PRO_E_C3D_DAMPING1`—Specifies the value for the damping coefficient for the first contact part.
  - `PRO_E_C3D_MAT_OPTION2`—Specifies the material type for the second contact part. Refer to the description of the element `PRO_E_C3D_MAT_OPTION1` for the material types that you can select.
  - `PRO_E_C3D_REF2_RECS`—Specifies an array of selected surface references of the type `PRO_E_C3D_REF_REC` from the second part that is used in the 3D contact. Refer to the description of the element `PRO_E_C3D_REF1_RECS` for information on the options that can be set for each surface reference. If you select a vertex from the second part as one of the references, a sphere is displayed around the vertex and the vertex is considered as a sphere in the 3D contact. If the second reference is a vertex, the `PRO_E_C3D_VERT_RAD` element becomes available for you to specify the value for the vertex radius.
  - `PRO_E_C3D_MAT_NAME2`—Specifies the name of the material type selected for the second contact part. This element can be set only if the element `PRO_E_C3D_MAT_OPTION2` is set to `PRO_C3D_MAT_SEL_MAT`.

- 
- `PRO_E_C3D_POISSON2`—Specifies the value for Poisson’s ratio for the second contact part.
  - `PRO_E_C3D_YOUNG2`—Specifies the value for Young’s modulus for the second contact part.
  - `PRO_E_C3D_DAMPING2`—Specifies the value for the damping coefficient for the second contact part.
  - `PRO_E_C3D_VERT_RAD`—Specifies the value for the vertex radius if a vertex is selected as one the references.
  - `PRO_E_C3D_FRICTION`—Identifies if friction will be used in the contact calculation. This element is set to `PRO_B_FALSE` by default which means no friction.
  - `PRO_E_C3D_STATIC_FRIC_COEF`—Specifies the value for the static friction coefficient.
  - `PRO_E_C3D_KINEM_FRIC_COEF`—Specifies the value for the kinematic friction coefficient.

## Mechanism Motor Features

The Mechanism Motor element tree enables you to add servo and force motors.

Use servo motors to impose a particular motion on a mechanism. Servo motors cause a specific type of motion to occur between two bodies in a single degree of freedom. Add servo motors to your model to prepare it for analysis.

Use force motors to impose a particular load on a mechanism. A force motor causes motion by applying a force in a single degree of freedom along a translational, rotational, or slot axis.

## Feature Element Tree for the Mechanism Motor Feature

The element tree for the Mechanism Motor feature is documented in the header file, `ProMotorFeat.h`. The following figure demonstrates the structure of the feature element tree.

| PRO_E_MOTOR_UD_EXPR            | PRO_VALUE_TYPE_WSTRING | Specifies a user-defined expression.                                                                                                                                    |
| PRO_E_MOTOR_UD_DOM_TYPE        | PRO_VALUE_TYPE_INT     | Specifies the type of domain for the expression using the enumerated data type ProMotorUExprDomain Type.                                                                |
| PRO_E_MOTOR_UD_DOM_LOWER_BOUND | PRO_VALUE_TYPE_DOUBLE  | Specifies the value for lower bound.                                                                                                                                    |

| Element ID                     | Data Type              | Description                                                                                                                                                                                                     |
|--------------------------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRO_E_MOTOR_UD_DOM_UPPER_BOUND | PRO_VALUE_TYPE_DOUBLE  | Specifies the value for upper bound.                                                                                                                                                                            |
| PRO_E_MOTOR_CUST_LOAD_NAME     | PRO_VALUE_TYPE_WSTRING | <p>This element is applicable only for force motors when the element PRO_E_MOTOR_FUNC_TYPE is set to PRO_MOTOR_CUSTOM_LOAD.</p> <p>Specifies the name of the custom file that has pre-defined custom loads.</p> |

## Event-driven Programming: Notifications

Notifications allow your Creo TOOLKIT application to detect certain types of events in Creo Parametric and provide that your own function is called before or after each such event. Creo Parametric notifies your Creo TOOLKIT application of these events.

### Using Notify

Functions Introduced:

- **ProNotificationSet()**
- **ProNotificationUnset()**

The function `ProNotificationSet()` sets up a notification by specifying the type of event and the pointer to the callback function. The event is specified as a value of the enumerated type `ProNotifyType`. The argument for the callback function has the type `ProFunction`; for consistency, each callback function returns a `ProError` status, even in cases where the status is ignored by Creo Parametric. The callback functions have different arguments, so each callback type has its own typedef that defines its arguments and their types. When calling `ProNotificationSet()`, you must cast the callback function pointer to `ProFunction`.

---

### **Note**

- If you call `ProNotificationSet()` more than once with the same event type, the existing callback is overwritten with the one supplied in the later call.
- When notifications are set in Creo TOOLKIT applications, every time an event is triggered, notification messages are added to the trail files. From Creo Parametric 2.0 M210 onward, a new environment variable `PROTK_LOG_DISABLE` enables you to disable this behavior. When set to `true`, the notifications messages are not added to the trail files.

---

To cancel a notification, call `ProNotificationUnset()`.

## Notification Types

The notification events in Creo Parametric fall into the following classes:

### File Management Events

Notifications to all of the file management operations in Creo Parametric, such as save, retrieve, copy, rename and so on.

---

### **Note**

From Creo Parametric 3.0 onward, some callback functions and events for notifications have been deprecated, and will be obsolete in future releases. Refer to the header files `ProMdl.h` and `ProNotify.h` for more information.

---

The possible file management notifications fall into the following subclasses:

### Pre-file Management Events

Your callback function is called before the file management event. It is called only for models that are the explicit objects of the file management operation. For example, it is not called when a part is saved as a result of saving a parent assembly.

If the Creo Parametric user initiated the event, the callback is called before the prompt asking the user for the name of the Creo Parametric models on which to act.

The callback function can optionally write output arguments that determine the Creo Parametric models on which the event will operate. In this case, Creo Parametric will not prompt the user.

The callback function can, by returning an error status, cancel the file management event altogether.

## Pre-file Management Events

| Event type             | Callback typedef          | Include file |
|------------------------|---------------------------|--------------|
| PRO_MODEL_FILE_OPEN_OK | ProModelFileOpenOKAction  | ProNotify.h  |
| PRO_MODEL_SAVE_PRE     | ProModelSavePreAction     | ProMdl.h     |
| PRO_MODEL_COPY_PRE     | ProModelCopyPreAction     | ProMdl.h     |
| PRO_MODEL_RENAME_PRE   | ProModelRenamePreAction   | ProMdl.h     |
| PRO_MODEL_RETRIEVE_PRE | ProModelRetrievePreAction | ProMdl.h     |
| PRO_MDL_ERASE_PRE      | ProMdlErasePreAction      | ProMdl.h     |
| PRO_MODEL_PURGE_PRE    | ProModelPurgePreAction    | ProMdl.h     |
| PRO_MDL_DELETE_PRE     | ProMdlDeletePreAction     | ProMdl.h     |
| PRO_MODEL_CREATE_PRE   | ProModelCreatePreAction   | ProMdl.h     |
| PRO_MODEL_START        | ProModelStartAction       | ProMdl.h     |
| PRO_CHECKIN_UI_PRE     | ProCheckinUIPreAction     | ProNotify.h  |
| PRO_MODEL_SAVE_PRE_ALL | ProModelSavePreAllAction  | ProMdl.h     |

The callback function `ProModelRetrievePreAction` gets called only when you click **File ► Open** button in the Creo Parametric user interface. Retrieval of the models by dragging or by double clicking in browser window results in the not triggering the call back. Once set, this notification blocks the Creo Parametric's standard **File ► Open** event. Hence, you must substitute the blocked event with your own event through this function.

## Pre-All File Management Events

Your callback function is called before all file management events on models, even if those models were not explicitly specified by the user. For example, if you save an assembly, the callback function is also called for any modified parts that will be saved as a result of that action.

| Event type             | Callback typedef         | Include file |
|------------------------|--------------------------|--------------|
| PRO_MODEL_SAVE_PRE_ALL | ProModelSavePreAllAction | ProMdl.h     |

---

## Post-file Management Events

Your callback function is called after the file management operation, and is given input arguments that show which models were the subject of the operation. Like a pre-file management callback, it is called only for models that are the explicit objects of the file management operation.

## Post-file Management Events

| Event type                | Callback typedef                | Include file |
|---------------------------|---------------------------------|--------------|
| PRO_MODEL_SAVE_POST       | ProModelSavePostAction          | ProMdl.h     |
| PRO_MODEL_COPY_POST       | ProModelCopyPostAction          | ProMdl.h     |
| PRO_MODEL_RENAME_POST     | ProModelRenamePostAction        | ProMdl.h     |
| PRO_MODEL_ERASE_POST      | ProModelErasePostAction         | ProMdl.h     |
| PRO_MODEL_RETRIEVE_POST   | ProModelRetrievePostAction      | ProMdl.h     |
| PRO_MODEL_PURGE_POST      | ProModelPurgePostAction         | ProMdl.h     |
| PRO_MODEL_DELETE_POST     | ProModelDeletePostAction        | ProMdl.h     |
| PRO_MODEL_CREATE_POST     | ProModelCreatePostAction        | ProMdl.h     |
| PRO_UDF_LIB_COMPLETE_POST | ProUdfLibraryCompletePostAction | ProUdf.h     |

## Post All File Management Events

Your callback function is called for all file management events on models, even if those models were not explicitly specified by the user. For example, if you save an assembly, the callback function is also called for any modified parts that are saved as a result of that action.

## Post All File Management Events

| Event type                  | Callback typedef              | Include file |
|-----------------------------|-------------------------------|--------------|
| PRO_MODEL_SAVE_POST_ALL     | ProModelSavePostAllAction     | ProMdl.h     |
| PRO_MODEL_COPY_POST_ALL     | ProModelCopyPostAllAction     | ProMdl.h     |
| PRO_MODEL_ERASE_POST_ALL    | ProModelErasePostAllAction    | ProMdl.h     |
| PRO_MODEL_RETRIEVE_POST_ALL | ProModelRetrievePostAllAction | ProMdl.h     |
| PRO_MODEL_DELETE_POST_ALL   | ProModelDeletePostAllAction   | ProMdl.h     |

---

## File Management Failure Events

Your callback function is called after a file management operation that failed. The function is called with arguments that show the type of file management operation that failed, the models it was operating on, and the type of error encountered (in the form of a `ProError` value).

---

### Note

From Creo Parametric 3.0 onward, some callback functions and events for notifications have been deprecated. Refer to the header files `ProMdl.h` and `ProNotify.h` for more information.

---

## File Management Failed Events

| Event type                          | Callback typedef                       | Include file             |
|-------------------------------------|----------------------------------------|--------------------------|
| <code>PRO_MODEL_DBMS_FAILURE</code> | <code>ProModelDbmsFailureAction</code> | <code>ProMdl.h</code>    |
| <code>PRO_MDL_CREATE_CANCEL</code>  | <code>ProMdlCreateCancelAction</code>  | <code>ProNotify.h</code> |

## Model and Feature Modification Events

Notifications that signal a change to the content of the model. They often include both pre- and post-notifications of change events and include operations on features, solids, parameters and dimensions. See the section [Notes on Regeneration Events on page 1979](#) for more information.

Use the notification types `PRO_FEATURE_REROUTE_PRE` and `PRO_FEATURE_REROUTE_POST` to trap the command **Feature Reroute** in parts or assemblies. Use notification types `PRO_FEATURE_REPLACE_PRE` and `PRO_FEATURE_REPLACE_POST` to trap replacement of assembly components performed in assembly mode with the command **Component, Adv Utils, Replace**.

The notification types `PRO_ASMCOMP_ACTIVATE_PRE` and `PRO_ASMCOMP_ACTIVATE_POST` are called before and after an assembly component is activated within the context of an assembly in Creo Parametric using the right mouse button **Activate**. The notification types provide the path to the currently active component, allowing applications to understand the context of an action in the assembly.

## Notes on Regeneration Events

Notifications which trigger before or after feature regeneration should be used carefully, because your callback function is being called while the regeneration of a solid is in progress. This section describes some of the important information you should keep in mind when using notification for model events.

At the start of model regeneration, Creo Parametric discards all data structures that describe geometry, although the geometry items themselves are retained (to preserve the integer identifiers). This means that although you can still traverse the features (using `ProSolidFeatVisit()`) and the geometry items in a feature (using `ProFeatureGeomitemVisit()`), geometry items belonging to features not yet regenerated will have no corresponding OHandles. Therefore, functions such as `ProSurfaceInit()` and `ProEdgeInit()` will not work. If you analyze the geometry of the features already regenerated, you will see it as unmodified by the features still to be regenerated.

It is dangerous to attempt modifications to the model or file management operations during a regeneration notification function.

## Model Modification Events

| Event type                  | Callback typedef             | Include file   |
|-----------------------------|------------------------------|----------------|
| PRO_DIM_MODIFY_VALUE_PRE    | ProDimModifyValuePreAction   | ProDimension.h |
| PRO_FEATURE_CREATE_PRE      | ProFeatureCreatePreAction    | ProFeature.h   |
| PRO_FEATURE_CREATE_POST     | ProFeatureCreatePostAction   | ProFeature.h   |
| PRO_FEATURE_COPY_POST       | ProFeatureCopyPostAction     | ProFeature.h   |
| PRO_FEATURE_DELETE_PRE      | ProFeatureDeletePreAction    | ProFeature.h   |
| PRO_FEATURE_DELETE_POST     | ProFeatureDeletePostAction   | ProFeature.h   |
| PRO_FEATURE_SUPPRESS_PRE    | ProFeatureSuppressPreAction  | ProFeature.h   |
| PRO_FEATURE_SUPPRESS_POST   | ProFeatureSuppressPostAction | ProFeature.h   |
| PRO_FEATURE_REDEFINE_PRE    | ProFeatureRedefinePreAction  | ProFeature.h   |
| PRO_FEATURE_REDEFINE_POST   | ProFeatureRedefinePostAction | ProFeature.h   |
| PRO_FEATURE_REGEN_PRE       | ProFeatureRegenPreAction     | ProFeature.h   |
| PRO_FEATURE_REGEN_POST      | ProFeatureRegenPostAction    | ProFeature.h   |
| PRO_FEATURE_REGEN_FAILURE   | ProFeatureRegenFailureAction | ProFeature.h   |
| PRO_FEATURE_NEEDS_REGEN_GET | ProFeatureNeedsRegenGet      | ProFeature.h   |
| PRO_FEATURE_REROUTE_PRE     | ProFeatureReroutePreAc       | ProFeature.h   |

| Event type                             | Callback typedef                       | Include file   |
|----------------------------------------|----------------------------------------|----------------|
|                                        | tion                                   |                |
| PRO_FEATURE_REROUTE_POST               | ProFeatureReroutePostAction            | ProFeature.h   |
| PRO_FEATURE_REPLACE_PRE                | ProFeatureReplacePreAction             | ProFeature.h   |
| PRO_FEATURE_REPLACE_POST               | ProFeatureReplacePostAction            | ProFeature.h   |
| PRO_FEATURE_RESUME_PRE                 | ProFeatureResumePreAction              | ProFeature.h   |
| PRO_FEATURE_RESUME_POST                | ProFeatureResumePostAction             | ProFeature.h   |
| PRO_GROUP_UNGROUP_PRE                  | ProGroupUngroupPreAction               | ProGroup.h     |
| PRO_GROUP_UNGROUP_POST                 | ProGroupUngroupPostAction              | ProGroup.h     |
| PRO_PARAM_MODIFY_W_UNITS_PRE           | ProParameterCreateWithUnitsPreAction   | ProParameter.h |
| PRO_PARAM_CREATE_POST                  | ProParameterCreatePostAction           | ProParameter.h |
| PRO_PARAM_MODIFY_W_UNITS_PRE           | ProParameterModifyWithUnitsPreAction   | ProParameter.h |
| PRO_PARAM_MODIFY_W_UNITS_POST          | ProParameterModifyWithUnitsPostAction  | ProParameter.h |
| PRO_PARAM_DELETE_PRE                   | ProParameterDeletePreAction            | ProParameter.h |
| PRO_PARAM_DELETE_W_UNITS_POST          | ProParameterDeleteWithUnitsPostAction  | ProParameter.h |
| PRO_SOLID_REGEN_PRE                    | ProSolidRegeneratePreAction            | ProSolid.h     |
| PRO_SOLID_REGEN_POST                   | ProSolidRegeneratePostAction           | ProSolid.h     |
| PRO_SOLID_UNIT_CONVERT_PRE             | ProSolidUnitConvertPreAction           | ProNotify.h    |
| PRO_SOLID_UNIT_CONVERT_POST            | ProSolidUnitConvertPostAction          | ProNotify.h    |
| PRO_SOLID_PRINC_SYS_UNITS_RENAMED_POST | ProSolidPrincSysUnitsRenamedPostAction | ProNotify.h    |
| PRO_DWGTABLE_ROW_DELETE_PRE            | ProDwgtableRowDeletePreAction          | ProNotify.h    |
| PRO_DWGTABLE_ROW_DELETE_POST           | ProDwgtableRowDeletePostAction         | ProNotify.h    |
| PRO_DWGTABLE_DELETE_PRE                | ProDwgtableDeletePreAction             | ProNotify.h    |
| PRO_DWGTABLE_DELETE_POST               | ProDwgtableDeletePostAction            | ProNotify.h    |

---

## Context Change Events

Notifications called after events that change details in the current Creo Parametric context. They allow your application to leverage the details of these changes as needed.

## Session Context Events

| Event type                   | Callback typedef               | Include file   |
|------------------------------|--------------------------------|----------------|
| PRO_DIRECTORY_CHANGE_POST    | ProDirectoryChangePostAction   | ProNotify.h    |
| PRO_WINDOW_CHANGE_POST       | ProWindowChangePostAction      | ProNotify.h    |
| PRO_POPUPMENU_CREATE_POST    | ProPopupmenuCreatePostAction   | ProPopupmenu.h |
| PRO_POPUPMENU_DESTROY_PRE    | ProPopupmenuDestroyPreAction   | ProPopupmenu.h |
| PRO_WINDOW_VACATE_PRE        | ProWindowVacatePreAction       | ProWindows.h   |
| PRO_WINDOW_OCCUPY_POST       | ProWindowOccupyPostAction      | ProWindows.h   |
| PRO_WINDOW_OCCUPY_MODEL_POST | ProWindowOccupyModelPostAction | ProWindows.h   |
| PRO_GLOBAL_INTERF_CALC_POST  | ProGlobalInterfCalcPostAction  | ProNotify.h    |
| PRO_ASMCOMP_ACTIVATE_PRE     | ProAsmcompActivatePreAction    | ProNotify.h    |
| PRO_ASMCOMP_ACTIVATE_POST    | ProAsmcompActivatePostAction   | ProNotify.h    |

## Graphics Events

| Event type           | Callback typedef        | Include file |
|----------------------|-------------------------|--------------|
| PRO_MDL_DISPLAY_PRE  | ProMdlDisplayPreAction  | ProMdl.h     |
| PRO_MDL_DISPLAY_POST | ProMdlDisplayPostAction | ProMdl.h     |

## Graphics Events

Notifications before and after the repainting of the current Creo Parametric window. This enables you to overlay your own graphics over the window and ensure that they get refreshed when the Creo Parametric window is repainted, for any reason.

---

### **Note**

These notifications will be called many times; for this reason, your callback routine should be as optimized as possible to avoid performance penalties. For other techniques that may be used to draw graphics, which will repaint with the Creo Parametric window, refer to the section on Display Lists. Refer to the [User Interface: Basic Graphics on page 494](#) section for details.

---

## NC Output Events

| Event type        | Callback typedef       | Include file |
|-------------------|------------------------|--------------|
| PRO_NCSEQ_CL_POST | ProNcseqClPostAction   | ProNotify.h  |
| PRO_OPER_CL_POST  | ProMfgoperClPostAction | ProNotify.h  |

## NC Output Events

Notification of the output from Creo NC of an operation CL data file, or an Creo NC sequence CL data file. This enables you to perform your own post-processing on these files. The callback functions are called with arguments that provide the name of the file created.

## CL Command Events

| Event type              | Callback typedef         | Include file |
|-------------------------|--------------------------|--------------|
| PRO_NCL_COMMAND_EXPAND  | ProClCommandExpandAction | ProClCmd.h   |
| PRO_NCL_COMMAND_GET_LOC | ProClCommandGetLocAction | ProClCmd.h   |

## CL Command Events

Notifications that give you the ability to create auxiliary NC sequences with programmatically created CL commands.

## Mold Layout Events

Notifications that are invoked before entering a corresponding Mold Layout dialog.

---

## Mold Layout UI Events

| Event type                | Callback typedef            | Include file |
|---------------------------|-----------------------------|--------------|
| PRO_RMDT_CREATE_IMM_PRE   | ProRmdtCreateImmPreAction   | ProRmdt.h    |
| PRO_RMDT_BOUND_BOX_PRE    | ProRmdtBoundingBoxPreAction | ProRmdt.h    |
| PRO_RMDT_CAV_LAYOUT_PRE   | ProRmdtCavLayoutPreAction   | ProRmdt.h    |
| PRO_RMDT_CREATE_WP_PRE    | ProRmdtCreateWpPreAction    | ProRmdt.h    |
| PRO_RMDT_MATERIAL_PRE     | ProRmdtMaterialPreAction    | ProRmdt.h    |
| PRO_RMDT_MBASE_SELECT_PRE | ProRmdtMBaseSelectPreAction | ProRmdt.h    |

## Selection Events

Notifications are invoked when there is a change in selection. Creo TOOLKIT application checks how the selection was changed by comparing the current selection buffer with the previous selection that was cached.

## Selection Buffer Events

| Event type                | Callback typedef            | Include file   |
|---------------------------|-----------------------------|----------------|
| PRO_SELBUFFER_CHANGE_POST | ProSelbufferChangePosAction | ProSelbuffer.h |

## Weld Events

| Event type                    | Callback typedef                | Include file |
|-------------------------------|---------------------------------|--------------|
| PRO_DRAWING_WELD_SYMPATH_GET  | ProDrawingWeldSympathGetAction  | ProNotify.h  |
| PRO_DRAWING_WELD_GROUPIDS_GET | ProDrawingWeldGroupidsGetAction | ProNotify.h  |
| PRO_DRAWING_WELD_SYMTXT_GET   | ProDrawingWeldSymtextGetAction  | ProNotify.h  |

## Weld Events

Notifications that give you the ability to customize the results generated by Creo Parametric when gathering info for weld operations.

---

# Event-driven Programming: External Objects

This describes the Creo TOOLKIT functions that enable you to create and manipulate external objects.

## Summary of External Objects

External objects are objects created by an application that is external to Creo Parametric. Although these objects can be displayed and selected within a Creo Parametric session, they can not be independently created by Creo Parametric. Using Creo TOOLKIT functions, you can define and manipulate external objects, which are then stored in a model database.

---

### Note

External objects are limited to text and wireframe entities. In addition, external objects can be created for parts and assemblies only. That is, external objects can be stored in a part or assembly database only.

---

In a Creo TOOLKIT application, an external object is defined by a `ProExtobj` object. This `DHandle` identifies an external object in the Creo Parametric database, which contains the following information for the object:

- Object class—A class of external objects is a group that contains objects with similar characteristics. All external objects must belong to a class. Object class is contained in the `ProExtobjClass` object.
- Object data—The object data contains information about the display and selection of an external object. Object data is contained in the `ProWExtobjdata` object.
- Object parameters—External objects can own parameters. You can use the `ProParameter` API to get, set, and modify external object parameters.
- Object references—External objects can reference any Creo Parametric object. This functionality is useful when changes to Creo Parametric objects need to instigate changes in the external objects. The changes are communicated back to your Creo TOOLKIT application via the callback functions.
- Callback functions—Creo TOOLKIT enables you to specify callback functions for a class of external objects. These functions are called whenever the external object owner or reference is deleted, suppressed, or modified. In this manner, the appearance and behavior of your external objects can depend on the object owner or reference.

---

## External Objects and Object Classes

This section describes the Creo TOOLKIT functions that relate to the creation and manipulation of external objects and object classes. Note that this description does not address the display or selection of the external object. For more information on this topic, see [External Object Data on page 1987](#).

### Creating External Object Classes

Functions Introduced:

- **ProExtobjClassCreate()**
- **ProExtobjClassDelete()**

Every external object must belong to a class. The concept of a “class” enables you to group together external objects that exhibit similar characteristics. In addition, classes permit multiple applications to create external objects without conflict.

The `ProExtobjClass` object contains the name and type of an external object class. PTC recommends that you supply a class name unique to your application. The type of the class is an integer that should vary among the different classes.

To register an external object class, pass a completed `ProExtobjClass` object to the function `ProExtobjClassCreate()`. To unregister a class, call the function `ProExtobjClassDelete()`.

### Creating External Objects

Functions Introduced:

- **ProExtobjCreate()**
- **ProExtobjDelete()**
- **ProExtobjClassGet()**

After the object class is registered, you can create the external object by calling the function `ProExtobjCreate()`. This function requires as input the object class and owner of the external object. (Currently, the owner of the external object can be a part or an assembly only.) As output, this function gives a pointer to the handle of the newly created external object.

When the external object is created, it is assigned an integer identifier that is persistent from session to session. The external object is saved as part of the model database and will be available when the model is retrieved next.

To delete an external object, call the function `ProExtobjDelete()`. This function requires as input both the object to be deleted and the class to which it belongs. To determine the class of an external object, call the function `ProExtobjClassGet()`.

---

## External Object Owners

Functions Introduced:

- **ProExtobjOwnerobjGet()**
- **ProExtobjOwnerobjSet()**

The owner of an external object is set during the call to `ProExtobjCreate()`. For example, the “owner” would be the part or assembly where the external object resides.

To determine the owner of an external object, call the function `ProExtobjOwnerobjGet()`. To change the owner, call the function `ProExtobjOwnerobjSet()`.

## Recycling External Object Identifiers

Functions Introduced:

- **ProExtobjReusableSet()**
- **ProExtobjReusableGet()**
- **ProExtobjReusableClear()**

By default, the identifier of an external object is not “recycled.” When you delete an external object, its identifier is not freed for reuse by external objects that are subsequently created.

You can override this default behavior using the function `ProExtobjReusableSet()`. This function enables external object identifiers to be recycled. To determine whether external object identifiers are set to be recyclable, call the function `ProExtobjReusableGet()`. To reset to the default behavior (no recycling), call the function `ProExtobjReusableClear()`.

## External Object Parameters

As with features and models, external objects can also have user-defined parameters. Although you can specify parameters for an external object, there is no method to retrieve these parameters interactively in Creo Parametric. Therefore, external object parameters are a way to store information in the Creo Parametric model that is not accessible to end-users.

You can convert a `ProExtobj` object to a `ProModelitem` object by casting. See the [Parameter Objects on page 216](#) section for more information.

## External Types and Identifiers for External Objects

Functions Introduced:

- **ProExtobjExttypeSet()**

- 
- **ProExtobjExttypeGet()**
  - **ProExtobjExtidSet()**
  - **ProExtobjExtidGet()**

`ProExtobj` is a `DHandle` that contains the type, identifier, and owner of an external object. This information identifies the external object in the Creo Parametric database.

Some applications might require additional type and identifier information to be assigned to external objects. That is, the type and identifier may need to be independent of those assigned within Creo Parametric.

The function `ProExtobjExttypeSet()` sets an external type for an external object. The function `ProExtobjExttypeGet()` obtains the external type for the specified external object.

The function `ProExtobjExtidSet()` sets an external integer identifier for the specified external object. To get the external identifier for a given external object, call the function `ProExtobjExtidGet()`.

## Visiting External Objects

Function Introduced:

- **ProExtobjVisit()**

Using the traversal functions for external objects, you can visit each external object in turn, and perform some action or filtration on it. The function `ProExtobjVisit()` specifies action and filter functions of type `ProExtobjVisitAction()` and `ProExtobjFilterAction()`, respectively.

## External Object Data

Simply creating an external object does not allow the object to be displayed or selected in Creo Parametric. For this, you must supply external object data that is used, stored, and retrieved by Creo Parametric. The data is removed from the model database when the external object is deleted.

External object data is described by the opaque workspace handle `ProWExtobjdata`. The functions required to initialize and modify this object are specific to the type of data being created. That is, creating display data requires one set of functions, whereas creating selection data requires another.

Once you have created a `ProWExtobjdata` object, the manipulation of the external object data is independent of its contents: the functions required to add or remove data are the same for both display and selection data.

The following sections describe the Creo TOOLKIT functions that relate to external object data. The sections are as follows:

- 
- [Display Data for External Objects on page 1988](#)
  - [Selection Data for External Objects on page 1991](#)
  - [Manipulating External Object Data on page 1993](#)

## Display Data for External Objects

Display data gives information to Creo Parametric about how the external object is to appear in the model window. This data must include the color, scale, line type, and transformation of the external object. In addition, display data can include settings that override the user's ability to zoom and spin the external object.

Note that setting display data does not result in the external object being displayed. To see the object, you must repaint the model window using the function `ProWindowRepaint()`.

### Allocating Display Data

Function Introduced:

- **`ProDispdatAlloc()`**

For display data, the workspace handle `ProWExtobjdata` is allocated using the function `ProDispdatAlloc()`. Because the other Creo TOOLKIT display data functions require `ProWExtobjdata` as input, you must call `ProDispdatAlloc()` before calling the other functions in this section.

The input for `ProDispdatAlloc()` is the address of a `ProWExtobjdata` object that you declare in your application. You must set this `ProWExtobjdata` object to `NULL` before passing its address to `ProDispdatAlloc()`.

### Creating the External Object Entity

Functions Introduced:

- **`ProDispdatEntsSet()`**
- **`ProDispdatEntsGet()`**
- **`ProDispdatEntsWithColorSet()`**

External objects are currently limited to text and wireframe entities. You can specify the entities to be displayed by creating an array of `ProCurvedata` objects that contain that necessary information. `ProCurvedata` is a union of specific entity structures, such as line, arrow, arc, circle, spline, and text. Note that when you specify the entities in the `ProCurvedata` array, the coordinate system used is the default model coordinate system.

---

After you have created the array of `ProCurvedata` objects, you can add entities to the display data by calling the function `ProDispdatEntsSet()`. Note that `ProDispdatEntsSet()` supports only `PRO_ENT_LINE` and `PRO_ENT_ARC` entities. However, you can draw polygons as multiple lines, and circles as arcs of extent  $2\pi$ .

To obtain the entities that make up an external object, call the function `ProDispdatEntsGet()`.

The function `ProDispdatEntsWithColorSet()` sets the display data for a list of entities and the color for each entity. The entities that are supported are:

- `PRO_ENT_LINE`
- `PRO_ENT_ARC`

The entities are specified in the local coordinates of the external object. Use the function `ProDispdatTrfSet()` to transform the local coordinates to model coordinates.

[Example 1: Creating an External Object on page 1998](#) shows how to specify an external object that is composed of line segments.

## Transformation of the External Object

Functions Introduced:

- **`ProDispdatTrfSet()`**
- **`ProDispdatTrfGet()`**
- **`ProExtobjScreentrifGet()`**

To perform a coordinate transformation on an external object, you must set the transformation matrix within the associated display data. To do this, call the function `ProDispdatTrfSet()` and pass the transformation matrix as an input argument. To obtain the transformation matrix contained in a particular set of display data, call the function `ProDispdatTrfGet()`.

[Example 1: Creating an External Object on page 1998](#) implements a transformation from default coordinates to a coordinate system that is dependent on the orientation of a selected surface.

### Note

Even if you do not want to transform your external object from the default coordinate system, you must specify a transformation matrix. In this case, pass the identity matrix to `ProDispdatTrfSet()`. If you omit this step, your external object will not be displayed.

---

---

To obtain the complete transformation of an object from external object coordinates (default coordinates) to screen coordinates, call the function `ProExtobjScreentrfGet()`.

---

 **Note**

In the assembly mode, `ProExtobjScreentrfGet()` is applicable for external objects owned only by the top assembly model. Use the function `ProDispdatTrfGet()` to retrieve the transformation of external objects in sub-models in the assembly mode. In the part mode, `ProExtobjScreentrfGet()` is applicable for all objects.

---

## External Object Display Properties

Functions Introduced:

- **`ProDispdatPropsSet()`**
- **`ProDispdatPropsGet()`**

By default, when users spin or zoom in on a model, external objects are subjected to the same spin and zoom scale as the model. In addition, by default external objects are always displayed, even if the owner or reference objects are suppressed. Setting external object display properties within display data enables you to change these default behaviors.

The `ProExtobjDispprops` object is an enumerated type that contains the possible settings for display properties. To set any of these properties within display data, create a `ProExtobjDispprops` array that contains your settings and pass this array to the function `ProDispdatPropsSet()`. To determine the display settings for specified display data, call the function `ProDispdatPropsGet()`.

The settings contained in `ProExtobjDispprops` are as follows:

- `PRO_EXTOBJ_ZOOM_INVARIANT`—Sets the external object to be invariant with the zoom scale or magnification of the model. The object appears the same size at all times.
- `PRO_EXTOBJ_SPIN_INVARIANT`—Set the external object to be invariant with the spin or orientation of the model. The object has the same orientation at all times.
- `PRO_EXTOBJ_BLANKED`—Blank the display of the external object. This setting is useful if you want to suppress the external object when the reference or owner objects are suppressed.

---

## External Object Color

Functions Introduced:

- **ProDispdatColorGet()**
- **ProDispdatColorSet()**

The enumerated type `ProColortype` specifies the colors available for external objects. To set the object color within display data, call the function `ProDispdatColorSet()`. To determine the color in the specified display data, use `ProDispdatColorGet()`.

## Line Styles for External Objects

Functions Introduced:

- **ProDispdatLinestyleSet()**
- **ProDispdatLinestyleGet()**

The enumerated type `ProLinestyle` specifies the line styles available for external objects. To set the object line style within the display data, call the function `ProDispdatLinestyleSet()`. To determine the line style in the specified display data, use `ProDispdatLinestyleGet()`.

## External Object Scale

Functions Introduced:

- **ProDispdatScaleSet()**
- **ProDispdatScaleGet()**

To vary the size of your external object without altering the entities themselves, you must specify an object scale factor as part of the display data. To set the scale factor, call the function `ProDispdatScaleSet()`. To determine the scale factor in the specified display data, use `ProDispdatScaleGet()`.

[Example 1: Creating an External Object on page 1998](#) shows how to set the scale of an object to be dependent on the size of the owner object.

## Selection Data for External Objects

Functions Introduced:

- **ProSeldatAlloc()**
- **ProSeldatSelboxesSet()**
- **ProSeldatSelboxesGet()**

You can select external objects using the Creo TOOLKIT selection function `ProSelect()`, with the selection option `ext_obj`. For this selection to be possible, however, you must designate a set of “hot spots,” or selection boxes for

---

the object. These selection boxes indicate locations in which mouse selections will cause the external object to be selected. Selection boxes are specified as part of the external object selection data.

The function `ProSeldataAlloc()` allocates selection data in preparation for the specification of the selection boxes.

A selection box is defined by the pair of points contained in a `ProSelbox` object. The coordinates of the points are specified in the external object's coordinate system (the default coordinates). The line between the points forms the diagonal of the selection box; the edges of the box lie parallel to the coordinate axes of the external object. To set the selection boxes within the selection data, call the function `ProSeldataSelboxesSet()` and pass as input a pointer to a list of `ProSelbox` objects. This enables your external object to have more than one associated selection box.

#### Note

PTC recommends that the size and arrangement of the selection boxes be dependent on the size and shape of the external object. If the external object is compact and uniformly distributed in all coordinate directions, one selection box will probably suffice.

However, if the external object is distributed nonuniformly, or is interfering with other objects, you must designate more specific locations at which selection should occur.

---

To obtain the list of selection boxes in a given selection data, call the function `ProSeldataSelboxesGet()`.

The `ProSelect()` function returns an array of `ProSelection` objects. To obtain a `ProExtobj` object from a `ProSelection` object, call the function `ProSelectionModelitemGet()` and cast the output `ProModelitem` directly into `ProExtobj`. (`ProExtobj` and `ProModelitem` are DHandles with identical declarations.)

## Selecting the Node from the External Application Tree

The tree created by an external application (SPEOS tree) is similar to the Creo Parametric model tree. Each node of this tree represents an external object that has been created by the application. The external objects could be different types of entities, such as, light sources, light sensors, and so on.

Functions Introduced:

- **`ProSelectExternalhighlightRegister()`**
- **`ProSelectExternalselectionRecord()`**

---

The function `ProSelectExternalhighlightRegister()` registers the call back functions when you select or deselect a node in the user tree or an object in the graphics window. The notification function `ProSelectionStartNotify()` is called when the function `ProSelect()` is activated. It notifies the application about entering `ProSelect()`. The call back function `ProSelectionExtHighlightAct()` is called when you select or deselect an external object. The TOOLKIT application will highlight the external object or remove the highlight according to the selection. On clicking a tree node, the application creates a `ProSelection` object and uses the function `ProSelectExternalselectionRecord()` to pass it to `ProSelect()`. The input arguments of this function are:

- *selection*—Specifies the selection object created by an external application.
- *action*—Specifies the type of selection. The valid values are:
  - `PRO_SELECT_OVERRIDE`—For unmodified selection
  - `PRO_SELECT_TOGGLE`—For CTRL modified selection.

The function `ProSelectionEndNotify()` notifies the application on exiting the function `ProSelect()`.

## Manipulating External Object Data

Functions Introduced:

- **`ProExtobjdataAdd()`**
- **`ProExtobjdataSet()`**
- **`ProExtobjdataGet()`**
- **`ProExtobjdataRemove()`**
- **`ProExtobjdataFree()`**

The previous two sections describe how to create and modify external object data. In the case of both display and selection data, the data creation process results in the opaque workspace handle `ProWExtobjdata`. The functions in this section enable you to manipulate how the external object data relates to the object itself.

To add new data to an external object, pass the data handle `ProWExtobjdata` to the function `ProExtobjdataAdd()`. To set the contents of existing object data, call the function `ProExtobjdataSet()`.

The function `ProExtobjdataGet()` obtains the handle for the display or selection data associated with an external object. To specify which type of data you want to retrieve, pass to this function one of the values in the enumerated type `ProExtobjdataType`. The declaration is as follows:

```
typedef enum
{
 PRO_EXTOBJDAT_DISPLAY,
 PRO_EXTOBJDAT_SELBOX
}
```

---

```
} ProExtobjdataType;
```

To remove data from an external object, use the function `ProExtobjdataRemove()`. To free the memory occupied by external object data, call the function `ProExtobjdataFree()`.

## External Object References

You can use external object references to make external objects dependent on model geometry. For example, consider an external object that is modeled as the outward-pointing normal of a surface. Defining the surface as a reference enables the external object to behave appropriately when the surface is modified, deleted, or suppressed.

In general, an external object can reference any of the geometry that belongs to its owner. In addition, if the owner belongs to an assembly, the external object can also reference the geometry of other assembly components, provided that you supply a valid component path.

---

### Note

Setting up the references for an external object does not fully define the dependency between the object and the reference. You must also specify the callback function to be called when some action is taken on the reference.

---

## Creating External Object References

Functions Introduced:

- **ProExtobjRefAlloc()**
- **ProExtobjRefFree()**
- **ProExtobjRefselectionSet()**
- **ProExtobjRefselectionGet()**
- **ProExtobjReftypeSet()**
- **ProExtobjReftypeGet()**
- **ProExtobjRefAdd()**
- **ProExtobjRefRemove()**

The `ProWExtobjRef` object is an opaque workspace handle that defines an external object reference. To allocate the memory for a new external object reference, call the function `ProExtobjRefAlloc()`. To free the memory occupied by an object reference, call the function `ProExtobjRefFree()`.

---

If you have the `ProSelection` object that corresponds to your intended reference geometry, you can set this `ProSelection` to be the reference by calling the function `ProExtobjRefselectionSet()`. To obtain the `ProSelection` object for a specified reference, use `ProExtobjRefselectionGet()`.

You might need to use “reference types” to differentiate among the references of an external object. To set a reference type, call the function `ProExtobjReftypeSet()`. To obtain the reference type of the specified reference, call the function `ProExtobjReftypeGet()`.

Once you have set the `ProSelection` and the reference type for an external object reference, you must add the reference to the external object using the function `ProExtobjRefAdd()`. To remove a reference from an external object, use `ProExtobjRefRemove()`.

## Visiting External Object References

Function Introduced:

- **`ProExtobjRefVisit()`**

Using the traversal functions for external object references, you can visit each external object reference in turn, and perform some action or filtration on it. The function `ProExtobjRefVisit()` specifies action and filter functions of type `ProExtobjRefVisitAction()` and `ProExtobjRefFilterAction()`, respectively.

## Callbacks for External Objects

Functions Introduced:

- **`ProExtobjCBAct()`**
- **`ProExtobjCBEnable()`**
- **`ProExtobjCallbacksSet()`**

External objects are associated with their owners and the references that you specify. Currently, the callbacks mechanism for external objects enables you to receive notification when the reference is deleted, modified, or suppressed. Your callback function can respond in a manner appropriate for the action taken on the reference.

The `ProExtobjCallbacks` object is a structure that specifies the callback functions for each action on the external object's owner or reference. Each callback function is specified by a function pointer of type `ProExtobjCBAct`.

When you create an external object class, you should also fill in a `ProExtobjCallbacks` object for that class. To set the callbacks for the class, call the `ProExtobjCallbacksSet()` function.

- Currently, the only supported callbacks for external objects are for deletion, modification, and suppression.
- You cannot use a callback for an external object that references a Creo Parametric feature (and not some geometry of it).

The `ProExtobjCallbacks` data structure is defined as follows:

```
typedef struct
{
 int enabled_cbs;
 ProExtobjCBAAct display_CB; /* not yet
implemented */
 ProExtobjCBAAct select_CB; /* not yet
implemented */
 ProExtobjCBAAct owner_modify_CB; /* not yet
implemented */
 ProExtobjCBAAct owner_suppress_CB; /* not yet
implemented */
 ProExtobjCBAAct owner_delete_CB; /* not yet
implemented */
 ProExtobjCBAAct ref_modify_CB;
 ProExtobjCBAAct ref_suppress_CB;
 ProExtobjCBAAct ref_delete_CB;
} ProExtobjCallbacks;
```

The first field, `enabled_cbs`, is a flag that enables and disables the callback functions. Set each of the other fields in the structure to the name of the callback function appropriate for each action. To enable or disable the callback functions for a particular action and object class, call the function `ProExtobjCBEnable()`.

As shown in the previous structure, the external objects callbacks are implemented only for cases where the reference is modified, suppressed, or deleted. For this reason, you must exercise caution when enabling callbacks using `ProExtobjCBEnable()`. One of the inputs of the function is an action bitmask that specifies which callback actions are to be enabled. The action bitmask is composed of members of the enumerated type `ProExtobjAction`. The values of the enumerated type are as follows:

```
typedef enum
{
 PRO_EO_ALT_DISPLAY = (1 << 6),
 /* alternate display --
 not implemented */
 PRO_EO_ALT_SELECT = (1 << 7),
 /* alternate selection --
 not implemented */
 PRO_EO_ACT_OWN_MODIF = (1 << 9),
```

```

/* not implemented */
PRO_EO_ACT_OWN_SUPPR = (1 << 10),
/* not implemented */
PRO_EO_ACT_OWN_DELETE = (1 << 11),
/* not implemented */
PRO_EO_ACT_REF_MODIF = (1 << 13),
PRO_EO_ACT_REF_SUPPR = (1 << 14),
PRO_EO_ACT_REF_DELETE = (1 << 15)
} ProExtobjAction;

```

The action bitmask must not contain any callback actions that are not supported. Given the comments in the `ProExtobjCallbacks` structure, the only allowed callback actions are `PRO_EO_ACT_REF_MODIF`, `PRO_EO_ACT_REF_SUPPR`, and `PRO_EO_ACT_REF_DELETE`.

The following table describes the actions given in the `ProExtobjCallbacks` data structure.

| Callback Type     | When it is Triggered                                                                |
|-------------------|-------------------------------------------------------------------------------------|
| display_CB        | The external object is displayed. Currently, this is not implemented.               |
| select_CB         | The external object is selected. Currently, this is not implemented.                |
| owner_modify_CB   | The owner of the external object is modified. Currently, this is not implemented.   |
| owner_suppress_CB | The owner of the external object is suppressed. Currently, this is not implemented. |
| owner_delete_CB   | The owner of the external object is deleted. Currently, this is not implemented.    |
| ref_modify_CB     | The reference of the external object is modified.                                   |
| ref_suppress_CB   | The reference of the external object is suppressed.                                 |
| ref_delete_CB     | The reference of the external object is deleted.                                    |

## Warning Mechanism for External Objects

Functions Introduced:

- **ProExtobjClassWarningEnable()**
- **ProExtobjClassWarningDisable()**
- **ProExtobjWarningEnable()**
- **ProExtobjWarningDisable()**

When users perform some action on the references of an external object, you might want to display a warning message to ask users to confirm the action. Creo TOOLKIT includes functions that implement such warnings, either for all external objects in a class or for individual external objects. For example, if a user attempts to delete a feature whose geometry is referenced by a class of external objects, the

---

Creo TOOLKIT warning mechanism, if enabled, would open a warning window that states the potential problem. The users would pick Yes to continue with the deletion, or No to abort the deletion.

To enable the warnings for a class of external objects, call the function `ProExtobjClassWarningEnable()`. Note that all external objects that belong to the class will inherit the enabled warning if they are created subsequent to the call to `ProExtobjClassWarningEnable()`.

The input arguments to `ProExtobjClassWarningEnable()` are the class object `ProExtobjClass` and an action bitmask composed of members of the enumerated type `ProExtobjAction` (described in the section [Callbacks for External Objects on page 1995](#)). The action bitmask specifies for which actions the warning is to be displayed. Currently, the only supported actions are `PRO_EO_ACT_REF_SUPPR` (suppression of the reference) and `PRO_EO_ACT_REF_DELETE` (deletion of the reference).

To have the warnings displayed for both reference suppression and deletion, the call to `ProExtobjClassWarningEnable()` would appear as follows:

```
ProExtobjClassWarningEnable (&User_arrow_class,
PRO_EO_ACT_REF_SUPPR|PRO_EO_ACT_REF_DELETE);
```

In this call, `User_arrow_class` is declared as a `ProExtobjClass` (an external object class).

To disable the warnings for a class of external objects, call `ProExtobjClassWarningDisable()`. Note that all external objects that belong to the class will inherit the disabled warning if they are created subsequent to the call to the function `ProExtobjClassWarningDisable()`.

To enable warnings for a single external object (not the entire class), call the function `ProExtobjWarningEnable()`. This function is similar to `ProExtobjClassWarningEnable()` except the first argument for `ProExtobjWarningEnable()` is a pointer to a `ProExtobj` object. To disable the warnings for a single external object, call the function `ProExtobjWarningDisable()`.

## Example 1: Creating an External Object

The sample code in the file `UgExtobjCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_extobj` shows how to create an external object at a location specified by the user. The external object is a green arrow that is aligned with the normal to a selected surface.

---

 **Note**

For the sake of simplicity, the example does not implement selection data.

---

## Event-driven Programming: Toolkit-Based Analysis

This section describes the functions that enable you to create analysis and analysis feature objects in a Creo Parametric solid.

### Overview

Creo Behavioral Modeling allows the creation of two types of objects in a Creo Parametric solid:

- Analysis
- Analysis Feature

In Creo Parametric you can create an analysis using the commands under the **Analysis** tab. Analyses show the results of certain standard types of measurement or calculation, for example, curvature of an edge or surface, or the center of gravity of a solid. Users can name an analysis and store it in the solid, along with the references to the geometry items it analyses. The analysis is then reevaluated automatically upon each model regeneration, and can be queried at any time using the **Analysis** command. Such an analysis is stored separately from the features and geometry items in the solid.

An analysis feature is a feature that uses an analysis to determine the values of its feature parameters and the shape of its geometry items. An analysis feature is a variety of datum feature and is created using the Creo Parametric **Datum** command. An example of the use of an analysis feature is the creation of a coordinate system datum at the center of gravity of a solid, aligned with its axes of inertia. Another example is a pair of datum points at the closest points of two parts in an assembly.

Creo TOOLKIT analysis functions allow definition of analyses and analysis features whose computations are performed by callback functions provided by the Creo TOOLKIT application. This means that Creo TOOLKIT can be used to make analysis computations, and determine feature geometry, in ways not native to Creo Parametric. We refer to the analyses and analysis features defined by Creo TOOLKIT as toolkit-based; this stresses the fact that the computations could be performed by a separate Creo TOOLKIT application.

Creo TOOLKIT users should practice using standard Creo Parametric analyses and analysis features before studying toolkit-based analyses.

---

The functions and data structures specific to toolkit-based analysis features are declared in the header file `ProAnalysis.h`.

## Interactive Creation of Toolkit-Based Analysis

If a Creo TOOLKIT application registers a Toolkit-Based Analysis type, the **Analysis** menu on the Creo Parametric toolbar contains an extra button labeled **Toolkit-Based**. Click this button to see the **Toolkit-Based** dialog box.

The selector at the top of the dialog box shows the types of external analysis registered by the Creo TOOLKIT application.

When you have chosen the type, click the **Analysis** UI button; this calls the Creo TOOLKIT callback, which prompts the user for the information needed by the analysis. When you have answered all the prompts, click **Compute**.

**Compute** performs the analysis and displays the resulting text, if any, in the text area of the dialog box. It may also display some graphics.

When you have clicked **Compute**, you may also click **Info**, which displays the output text in an information window.

The **Saved Analyses** and **Close** buttons behave as for standard analyses.

## Interactive Creation of Toolkit-Based Analysis Feature

In Creo Parametric, under the **Analysis** tab, in the **Manage** group, select the **Analysis** command. This displays the Creo Parametric **ANALYSIS** dialog box, which leads the user through the definition of the elements of the analysis feature. If a Creo TOOLKIT application is running and has registered at least one type of toolkit-based analysis, there will be an additional button labeled **Toolkit-Based** in the Type section.

Set the name of the analysis first, set the type to Toolkit-Based Analysis, and continue to the next step, which is called “Definition”. The **Toolkit-Based** dialog box appears. This behaves exactly as for an external analysis, until you click the **Close** button. It then returns to the **ANALYSIS** dialog box, to allow you to continue specifying the feature elements.

The remaining elements are Result Params and Result Datums. These behave exactly as for standard analysis features, except that the parameters and datums are defined by the Creo TOOLKIT application. One or other may be absent if the toolkit-based analysis defines no parameters or no datums.

---

## Storage of Toolkit-Based Analysis Feature in Creo Parametric

A toolkit-based analysis feature is stored in Creo Parametric in exactly the same way as any other feature. It appears in the model tree as a feature of type **Analysis**, and all the regular **Feature** commands can be used on it.

The references to existing geometry that the feature needs to calculate its own parameters and geometry are given to Creo Parametric by the Creo TOOLKIT application in the form of `ProSelection` structures. Creo Parametric stores these references, using the standard method for storing feature references. This means that the Creo TOOLKIT application does not need to store this information, and that the feature automatically has the correct behavior for the following Creo Parametric functions:

- Feature Regeneration—Creo Parametric knows from the feature references what other features it depends on, and therefore whether the features needs to be included in a particular regeneration.
- Rerouting Features
- Patterning Features

The Creo TOOLKIT application may also give Creo Parametric the values of any variables that control the geometry, and Creo Parametric stores them as feature dimensions in the new feature. The Creo TOOLKIT application can then read the current dimension values when recomputing the feature geometry. This means the feature correctly responds to dimension changes as a result of, for example, being driven by a relation.

The Creo TOOLKIT application must store as external data any information about toolkit-based analysis features that is not stored as either geometry references or dimensions.

## Registering a Toolkit-Based Analysis with Creo Parametric

Function Introduced:

- **ProAnalysisTypeRegister()**

The function `ProAnalysisTypeRegister()` registers a toolkit-based analysis with Creo Parametric by specifying its type name and the set of callback functions to be used when creating it and performing the computation. Call this function in `user_initialize()`.

---

If called correctly, both the **Analysis** command and the **ANALYSIS** dialog box used in creating an analysis feature will include the button **Toolkit-Based** as the analysis type. Refer to the sections [Interactive Creation of Toolkit-Based Analysis on page 2000](#) and [Interactive Creation of Toolkit-Based Analysis Feature on page 2000](#) for more information on creating these objects.

## Analysis Callbacks

When registering a Toolkit-Based Analysis type, callbacks must be provided for each of the following 13 types:

- `ui`
- `dims`
- `infoalloc`
- `infofree`
- `compcheck`
- `compute`
- `display`
- `output`
- `savecheck`
- `infosave`
- `inforetrieve`
- `infocopy`
- `result`

Each callback is passed an argument of the `ProAnalysis` type, which is an opaque handle and identifies the analysis information stored by Creo Parametric.

The following table explains when the callbacks are called, and how each one should be used.

When Creo Parametric creates a toolkit-based analysis or analysis feature:

| Callback               | Description                                                                                                                                                                                                                     |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>infoalloc</code> | Allocate memory for the Creo TOOLKIT application information about the toolkit-based analysis.                                                                                                                                  |
| <code>ui</code>        | Creo TOOLKIT prompts the user for inputs that define the analysisfor example, select a surface datum point on which to position a csys.                                                                                         |
| <code>compcheck</code> | Tell Creo Parametric whether the computation can be performed. If the Creo TOOLKIT application cannot perform the computation (for example, because input data is unavailable), it returns an error and the regeneration fails. |
| <code>compute</code>   | Perform the analysis computation and store the                                                                                                                                                                                  |

| Callback | Description                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          | results in memory.                                                                                                                                                                                                                                                                                                                                                                                                 |
| display  | Display graphics showing the computation result.                                                                                                                                                                                                                                                                                                                                                                   |
| output   | Pass a set of text lines to Creo Parametric for display in the <b>ANALYSIS</b> dialog box to show the result of the computation.                                                                                                                                                                                                                                                                                   |
| infocopy | Copy the application information from an existing analysis to a new one. Call <code>infocopy</code> during creation because of the way in which Creo Parametric handles feature creation.                                                                                                                                                                                                                          |
| dims     | Creo TOOLKIT gives Creo Parametric a list of double values needed to calculate the geometry. Creo Parametric stores these as model dimensions.                                                                                                                                                                                                                                                                     |
| result   | Creo TOOLKIT gives Creo Parametric a description of the feature parameters and geometry items that result from the computation of the analysis. Creo Parametric may also call this callback when it needs to know only the number and names of parameters and datums; an example is when the user selects <b>Feature Info</b> . For more details, refer to the section <a href="#">Results Data on page 2004</a> . |

When the Creo Parametric user saves the analysis to the solid:

| Callback  | Description                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| savecheck | Tell Creo Parametric whether the description of the analysis can be saved.                                                                                                                                                                                                                                                                                                                                             |
| infosave  | Give Creo Parametric a list of geometry items referenced by the analysis. Creo Parametric stores these using its own internal mechanism for storing references. The references appear in the model as feature references, and are used to determine the relationship of the feature to other features, and therefore when the feature needs to be regenerated.<br><br>OR<br><br>Store any other data as external data. |

When the Creo Parametric user retrieves a solid containing analyses:

| Callback     | Description                                                                                                                                                                                                                                                                            |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| inforetrieve | Creo Parametric provides an array of <code>ProSelection</code> objects representing the geometry references it stored with the analysis. (This means that the Creo TOOLKIT application does not need to save these references between sessionsCreo Parametric uses its own mechanism.) |

When the Creo Parametric user leaves the **ANALYSIS** dialog box without saving the new analysis, or erases a solid containing a toolkit-based analysis:

| Callback | Description                                                                                     |
|----------|-------------------------------------------------------------------------------------------------|
| infofree | The Creo TOOLKIT application frees the memory used by its internal description of the analysis. |

Many of the callbacks will be called during other commands in Creo Parametric whenever the toolkit-based analysis or analysis feature is affected.

## Creo Toolkit Analysis Information

Functions Introduced:

- **ProAnalysisInfoGet()**
- **ProAnalysisInfoSet()**
- **ProAnalysisTypeGet()**

The Creo TOOLKIT application must keep its own description of the analysis in memory in order to perform the computation. This memory is allocated, filled, and freed in the callbacks provided, as described in the section [Analysis Callbacks on page 2002](#).

The callback-calling sequence may vary depending upon exactly what the Creo Parametric user does. This means Creo TOOLKIT applications should not use global variables to pass the “current” analysis from one callback to another.

Instead of such variables, Creo Parametric can store a pointer to the Creo TOOLKIT data stored inside the `ProAnalysis` object. Use function `ProAnalysisTypeGet()` to return the type of a specified analysis. The `infoalloc` callback should end with a call to `ProAnalysisInfoSet()`, which gives Creo Parametric the pointer to the new description. Every other callback that needs to use this data should call `ProAnalysisInfoGet()` to get a pointer to the application data for the analysis object, rather than assume this by context.

Creo Parametric cannot access the user data, nor can it provide general storage of this data in the Creo Parametric file when the solid is saved. As explained in the section [Analysis Callbacks on page 2002](#) earlier, the callbacks `infosave` and `inforetrieve` respectively give to Creo Parametric, and return after retrieval, geometry references contained in the information; double values can be stored as dimensions. Note that any other information the application needs to store should be saved and retrieved inside `infosave` and `inforetrieve` using Creo TOOLKIT external data.

## Results Data

This section describes in more detail the data given to Creo Parametric by the Creo TOOLKIT application as the output from the results callback.

The output consists of two arrays, one for the feature parameters, the other for the feature geometry. Each of these is a `ProArray` allocated by Creo Parametric before calling the callback.

The structure for a feature parameter is:

```
typedef struct analysis_param
{
 ProName name;
 ProBoolean create;
 ProLine description;
 ProParamvalue *values;
} ProAnalysisParameter;
```

The name is that of the feature parameter that will be created. The `create` flag shows the default setting of the **Create** option for the parameter in the **ANALYSIS** dialog box. The description appears alongside the parameter in the **ANALYSIS** dialog box. The array of values should have only a single item in it in the current release. The structure `ProParamvalue` is the same one used for accessing user parameters through the functions in `ProParameter.h` and `ProParamvalue.h`. The value type must be “double” in the current release.

The structure for a geometry item is:

```
typedef struct analysis_geom
{
 ProName name;
 ProBoolean create;
 ProAnalysisEntityType type;
 ProAnalysisEntity *shapes;
} ProAnalysisGeomitem;
```

The name is given to the resulting datum (NOT to the feature), but with a numerical suffix to ensure that the name is unique in the Creo Parametric model. The `create` flag is exactly as for parameters.

The entity type is an enum which is a subset of the object types in `ProType`. The types supported by this release are:

|                       |                 |
|-----------------------|-----------------|
| PRO_ANALYSIS_CURVE    | Curve           |
| PRO_ANALYSIS_CSYS     | Coord csys      |
| PRO_ANALYSIS_POINT    | Datum point     |
| PRO_ANALYSIS_COMP_CRV | Composite curve |
| PRO_ANALYSIS_SURFACE  | Surface         |

Array “shapes” contains any number of geometric entities of the same type. The union that represents an entity shape is:

```
typedef union
{
 ProAnalysisSrfData *surface;
 ProQuiltdata *quilt;
 ProCurvedata *curve;
 ProCsysdata csys;
```

---

```
} ProAnalysisEntity;
```

The fields in this union all have types that are generic geometry types in Creo TOOLKIT, and are declared in the appropriate headers: `ProSurfacedata.h`, `ProQuiltdata.h`, `ProCurvedata.h`, `ProCsysdata.h`, `ProEdgedata.h`. The first three fields, although they are pointers, are not opaque: in spawn mode or asynchronous mode they point to memory in the Creo TOOLKIT process, not in the Creo Parametric process. It is recommended that you build these structures using the functions in the corresponding header files, for example, `ProCurvedataAlloc()`, `ProLinedataInit()`, and so on.

## ProAnalysisSrfData Structure

The `ProAnalysisSrfData` structure is used to define a datum surface from a toolkit-based analysis feature. This structure consists of:

```
typedef struct ProAnalysisSrfData
{
 ProEdgedata *edge_data;
 ProSurfacedata *pro_surface;
} ProAnalysisSrfData;
```

The `ProSurfacedata*` structure contains the surface shape, parameters, and a populated `ProContourdata` structure referencing the boundary edges. The `ProEdgedata*` member should be a `ProArray` of edge geometric data whose ids are referenced by the contour data in the surface data structure.

Function Introduced:

- **ProAnalysisSrfDataAlloc()**

The function `ProAnalysisSrfDataAlloc()` allocates the `ProAnalysisSrfData` data structure.

### Example 1: Offset Coordinate System Datum

The sample code in the file `UgExtAnalysisSurfcsys.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_ext_analysis` shows a Creo TOOLKIT application that defines a toolkit-based analysis that builds a coordinate system datum at an offset from a surface point. The Z axis can be an inward or an outward normal to the surface, the X and Y axes are aligned with the UV mesh lines in the surface, and the origin can be offset in the Z direction. The offset value is stored as a feature dimension.

## Analysis Attributes

Functions Introduced:

- **ProAnalysisAttrSet()**
- **ProAnalysisAttrIsSet()**

---

These functions allow you to get and set certain attributes on a toolkit-based analysis. The only attribute defined in the current release is `PROANALYSIS_COMPUTE_OFF`. If this is set, the compute and result callbacks will not be called during regeneration of the model. If the toolkit-based analysis belongs to a feature, the geometry of the feature will be frozen until the `PROANALYSIS_COMPUTE_OFF` is unset again. If the feature geometry includes a surface curve, the 3D location of the curve will be recalculated during regeneration in accordance with the existing UV curves definition but using the new geometry of the surface. This means the curve remains in the surface even if the surface moves while `COMPUTE_OFF` is `TRUE`.

Use the `PROANALYSIS_COMPUTE_OFF` attribute to temporarily turn off the toolkit-based analysis to save time when making other changes to the model.

## Visiting Saved Toolkit-Based Analyses

Functions Introduced:

- **ProSolidAnalysisVisit()**
- **ProAnalysisNameGet()**

The function `ProSolidAnalysisVisit()` visits a saved toolkit-based analysis in a part or assembly. It does not visit standard saved analyses, nor toolkit-based analyses in features.

The function `ProAnalysisNameGet()` provides the name under which a toolkit-based analysis is saved.

## Visiting Toolkit-Based Analyses Features

Functions Introduced:

- **ProFeatureAnalysisGet()**

To visit analyses in analysis features, use `ProSolidFeatureVisit()`, filter for features whose type is `PRO_FEAT_ANALYSIS`, and call `ProFeatureAnalysisGet()` on each feature.

## Using the Model without Creo Toolkit

If a model contains external analyses or external analysis features of a type defined by a Creo TOOLKIT application, and that model is retrieved into Creo Parametric while the Creo TOOLKIT application is not running, Creo Parametric will not attempt to recompute those analyses during regeneration. Saved toolkit-based analyses will retain their old values, and toolkit-based analysis features will have their geometry frozen.

---

If a Creo TOOLKIT application is terminated during a Creo Parametric session, any toolkit-based analysis types it registered will be automatically deregistered, and any analyses that use those types will be frozen.

## Event-driven Programming: Foreign Datum Curves

This describes the Creo TOOLKIT functions that enable you to create foreign datum curves.

### Foreign Datum Curves

In Creo TOOLKIT, you create foreign datum curves using the feature creation techniques described in the section [Element Trees: Principles of Feature Creation on page 771](#). The header file `ProForeignCurve.h` contains the element tree structure and a table that maps each element to an element identifier, value type, and valid values.

The following figure shows the element tree structure for foreign datum curve creation. Note that all elements are required.

### Element Tree for Foreign Datum Curve

As the element tree implies, foreign datum curve creation requires that you provide the feature type, curve type, curve class, reference coordinate system, data used in the analytical representation of the curve, and curve continuity. Creo Parametric uses this information, together with an evaluation function, to create an internal representation of the curve.

---

## Providing an Evaluation Function

Function Introduced:

- **ProForeignCurveEvalFunction()**

In addition to building the element tree for your datum curve feature, you must provide its analytical representation to Creo Parametric. This representation is made available to Creo Parametric in a special function called an evaluator, or evaluation function.

The evaluation function must contain parameterized equations for the X, Y, and Z coordinates of points that define the curve. If  $C(X,Y,Z)$  is a function representing the curve in three-dimensional space, you can represent the parameterized equations for each coordinate as follows:

$$\begin{aligned}X &= f(t) \\Y &= g(t) \\Z &= h(t)\end{aligned}$$

In these equations, the parameter  $t$  ranges from 0 to 1 over the extent of the curve. For example, a parametric representation of a circle of radius  $R$  lying in the XY-plane, whose center coincides with the origin, is as follows:

$$\begin{aligned}X &= R \cdot \cos(2 \cdot \text{PI} \cdot t); \\Y &= R \cdot \sin(2 \cdot \text{PI} \cdot t); \\Z &= 0;\end{aligned}$$

In these equations,  $\text{PI} = 3.14159$ .

Creo TOOLKIT provides the prototype for the evaluation function. The syntax is as follows:

```
typedef ProError (*ProForeignCurveEvalFunction)
(
 ProName class, /* input */
 wchar_t *data_string, /* input */
 ProSelection csys, /* input */
 double curve_param, /* input */
 ProVector xyz_point, /* output */
 ProVector deriv1, /* output */
 ProVector deriv2 /* output */
);
```

The function arguments are as follows:

- *class*—Identifies the type of curves generated by the evaluation function.
- *data\_string*—The flag that controls specific attributes of the curve.
- *csys*—The reference coordinate system with respect to which the curve geometry is defined. Pass it to the evaluation function as a `ProSelection` object.
- *curve\_param*—The parameter value at which the X, Y, and Z coordinates, as well as the first and second derivatives, will be evaluated.

- *xyz\_point*—The X, Y, and Z coordinates at the value of *curve\_param*.
- *deriv1*—The values of the first derivatives of X, Y, and Z with respect to the parameter, at the value of *curve\_param*.
- *deriv2*—The values of the second derivatives of X, Y, and Z with respect to the parameter, at the value of *curve\_param*.

All arguments are passed to the evaluation function by Creo Parametric, based on the values you provide for the elements in the element tree.

A single evaluation function can be used to create a number of curve variations within a given class. The parameterized curve equations typically contain constants whose values control the shape, size, location, and orientation of the curve. You can write the evaluation function such that, depending on the value of the *data\_string* argument, different values of those constants will be used to calculate the location of points on the curve.

## Curve Continuity

Curve continuity, in a sense, defines the smoothness of intersections between the ends of the foreign curve and other geometry in the model. It also defines the continuity of three-dimensional geometry created from the curve, such as a swept surface. First-order continuity implies that the first derivatives of two adjoining curve segments are equal at the point at which the curves join. Second-order continuity is similarly defined. Depending on the curve continuity you want, the evaluator function needs to contain first and second derivatives of the parameterized curve equations.

You specify the curve continuity using the `PRO_E_CURVE_CONTINUITY` element in the element tree. The valid values, contained in the enumerated type `ProForeignCrvCont`, are as follows:

- `PRO_FOREIGN_CURVE_CALC_XYZ`
- `PRO_FOREIGN_CURVE_CALC_XYZ_1_DER`
- `PRO_FOREIGN_CURVE_CALC_XYZ_1_AND_2_DER`

These values correspond to zeroth-, first-, and second-order continuity, respectively. If you use the value `PRO_FOREIGN_CURVE_CALC_XYZ`, Creo Parametric passes `NULL` for *deriv1* and *deriv2* to the evaluation function. Similarly, if you use the value `PRO_FOREIGN_CURVE_CALC_XYZ_1_DER`, Creo Parametric passes `NULL` for *deriv2* to the evaluation function. Therefore, you should check for `NULL` values of *deriv1* and *deriv2* in your evaluation function before trying to assign derivative values to them.

Creo Parametric calls your evaluation function multiple times for a series of values of the curve parameter, ranging from 0 to 1. The function outputs the following information:

- X, Y, and Z coordinates of the curve at the specified parameter value

- 
- Values of the first and second derivatives, as needed for the desired curve continuity

These values are then used by Creo Parametric to construct the curve.

## Binding the Evaluation Function to a Class

Function Introduced:

- **ProForeignCurveClassEvalSet()**

The evaluation function must be bound to a class. This is done with a call to the function `ProForeignCurveClassEvalSet()`. The function takes as arguments the class name and a pointer to the evaluation function. If you call `ProForeignCurveClassEvalSet()` and pass `NULL` for the evaluation function pointer, it unbinds a previously bound evaluation function from the class.

## Task Based Application Libraries

Applications created using the different Creo Parametric API products are interoperable. These products use Creo Parametric as the medium of interactions, eliminating the task of writing native -platform specific interactions between different programming languages.

## ProArgument and Argument Management

Use the data structure `ProArgument` to pass application data to and from tasks in other applications. The declaration for this structure is:

```
typedef struct pro_argument
{
 ProName label;
 ProValueData value;
} ProArgument;
```

The `ProValueData` structure supports the following argument types:

- Integer
- Double
- String (`char*`)
- String (`wchar_t*`)
- Boolean
- `ProSelection`
- `ProMatrix`

---

Do not use the value type `PRO_VALUE_TYPE_POINTER` (provided with this structure in order to support feature element tree values) when passing arguments between applications.

Functions Introduced:

- **ProArgumentByLabelGet()**
- **ProValuedataStringSet()**
- **ProValuedataWstringSet()**
- **ProValuedataTransformGet()**
- **ProValuedataTransformSet()**
- **ProArgumentProarrayFree()**

Use the function `ProArgumentByLabelGet()` to locate an argument within a `ProArray` of `ProArgument` structures passed between applications.

Use the function `ProValuedataStringSet()` to allocate and copy memory into the `ProValuedata` structure for a `char*` argument. Using this function ensures that `ProArgumentProarrayFree()` releases all memory in an arguments array.

Use the function `ProValuedataWstringSet()` to allocate and copy memory into the `ProValuedata` structure for a `wchar_t*` argument. Use this function to ensure that `ProArgumentProarrayFree()` releases all memory in an arguments array.

Use the function `ProValuedataTransformSet()` to allocate and copy memory into the `ProValuedata` structure for a `ProMatrix` argument. Use this function to ensure that `ProArgumentProarrayFree()` releases all memory in an arguments array.

Use the function `ProValuedataTransformGet()` to copy a `ProMatrix` value into a local variable. The matrix data is not directly accessible from the `double**` member of the `ProValuedata` structure.

Use the function `ProArgumentProarrayFree()` to completely free an array of `ProArgument` structures.

## Creating Creo TOOLKIT DLL Task Libraries

Functions that are intended to act as Creo TOOLKIT task library functions must have the same signature as `ProTkdllFunction()`:

```
typedef ProError (*ProTkdllFunction) (
 ProArgument* inputs, ProArgument** outputs);
```

---

Use the preprocessor macro `PRO_TK_DLL_EXPORT` with any function that must be accessible to external applications. This macro provides platform-specific instructions to the compiler to make the function visible to other external applications. This macro must be placed in the function prototype, if it exists, and in the function definition if the prototype does not exist.

Some platforms require externally visible symbols to be declared on the application link line.

## Memory Management in Task Library Functions

To avoid memory leaks or overwrites, the DLL functions must use proper memory management. The DLL function must:

- Ensure that the contents of the input `ProArgument` array are not freed. This is taken care of by the calling application and the Creo TOOLKIT communications code.
- Use the `ProValuedata*Set()` functions to assign values to the output `ProArgument` array. This allows the calling application to free the output array with `ProArgumentProarrayFree()`.

### Example 1: An Exported Toolkit Task Function

The sample code in the file `UgImportfeatCreate.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_featcreat`, function demonstrates how you can set up and implement a Creo TOOLKIT task function accessible from other Creo Parametric auxiliary applications. It uses the required signature and macro for task functions. It parses the input argument array to search for parameters required by the task.

## Launching Creo TOOLKIT DLL Functions

Functions Introduced:

- **`ProToolkitDllLoad()`**
- **`ProToolkitTaskExecute()`**
- **`ProToolkitDllUnload()`**
- **`ProToolkitDllIdGet()`**
- **`ProToolkitDllHandleGet()`**

Use the function `ProToolkitDllLoad()` to register and start a Creo TOOLKIT DLL. The input parameters of this function are similar to the fields of a registry file and are as follows:

- *app\_name*—The name of the application to initialize.
- *exec\_file*—The DLL file to load, including its full path.

- 
- *text\_dir*—The path to the application's message and UI text files.
  - *user\_display*—Set this parameter to `PRO_B_TRUE` if you want the interactive user to be able to see the application registered in the Creo Parametric User Interface and to see error messages if the application fails.

The function outputs a handle to the loaded DLL in the form of a `ProToolkitDllHandle`. If the function fails to load the DLL, the function outputs information describing the failure and the application's `user_initialize()` function is called.

Use the function `ProToolkitTaskExecute()` to call a properly designated function of the Creo TOOLKIT DLL library. You can pass arbitrary combinations of input arguments to the library function.

Use the function `ProToolkitDllUnload()` to shutdown a Creo TOOLKIT DLL previously loaded by `ProToolkitDllLoad()`. The application's `user_terminate()` function is called.

Use the function `ProToolkitDllIdGet()` to get a string representation of the DLL application. The string representation can be sent to other applications, which can use `ProToolkitDllHandleGet()` to obtain the Creo TOOLKIT DLL handle using this string representation. Pass `NULL` to the first argument of `ProToolkitDllIdGet()` to get the identifier for the calling application.

## Custom Creo TOOLKIT DLL Tasks for Creo Distributed Batch

You can create a customized Creo Distributed Batch task by providing a Creo TOOLKIT DLL to be run by the Creo Distributed Batch service. The steps required to create and deploy a custom DLL task for Creo Distributed Batch are as follows:

- Compose the Creo TOOLKIT DLL containing a function that meets the criteria for a custom DLL task function. Refer to the [Creating Creo TOOLKIT DLL Task Libraries on page 2012](#) section for the function signature. Use the standard Creo Distributed Batch arguments while coding the function. Refer to the [Coding a Custom DLL Task Function on page 2015](#) section for more information on the arguments.
- Create a DLL registry file for Creo Distributed Batch. Refer to the [Registry File for Custom DLL Tasks on page 2016](#) section for more information.
- Create a TTD (Task Type Definition) file specifying the Creo TOOLKIT DLL and the custom task function to be executed by the custom task. Refer to the [TTD File Format for Custom DLL Tasks on page 2017](#) section for more information.

---

## Coding a Custom DLL Task Function

Creo Distributed Batch provides the following input arguments to the custom DLL task function:

---

### Note

All the input arguments are of the widestring data type.

---

- `DBS_WORKING_DIRECTORY`—Specifies the full path of the working directory for the Creo Distributed Batch service. It stores all the `log`, `inf`, and output files generated during the execution of a custom task.
- `DBS_CURRENT_OBJECT_NAME`—Specifies the name of the object that will acted upon by the custom DLL task function.
- `DBS_CURRENT_OBJECT_TYPE`—Specifies the type of the object such as a 3D model, assembly, or drawing. The value of this argument will be a widestring containing an integer value of the type that matches with the values in the enumerated type `ProMdlType`.

Creo Distributed Batch supplies any additional input arguments and their values, if they are listed in a TTD file, as `<USER_DATA></USER_DATA>` tags within the `<TKFUNC></TKFUNC>` node. Each user data tag is supplied as an independent argument.

The custom DLL task function can influence the state of Creo Distributed Batch and the status of the task through one of the following output arguments. If an argument is not supplied, the current or default value is used.

---

### Note

All the output arguments are of the widestring data type.

---

- `DBS_CURRENT_OBJECT_NAME`—Specifies the name of the generated object. This output informs Creo Distributed Batch that a model with this name should be used for other TTD entries that follow.
- `DBS_CURRENT_OBJECT_TYPE`—Specifies the type of the generated object such as a 3D model, assembly, or drawing. The value of this argument will be a widestring containing an integer value of the type that matches with the values in the enumerated type `ProMdlType`. This output informs Creo Distributed Batch that a model of this type should be used for other TTD entries that follow.

- **DBS\_IGNORE\_FILE**—By default, the Creo Distributed Batch service returns any file generated in the working directory, except for report type files such as `log`, `inf` and `txt`. The names of the files specified by this output argument will not be included in the output returned to the client. You can return more than one argument of this type.
- **DBS\_OUTPUT\_FILE**—Some file types such as `log`, `inf` and `txt` are not transferred to the Creo Distributed Batch client by default. File names specified by this output argument indicate that a particular file such as `trail.txt` should be passed back to the client. This file is always returned even if Creo Distributed Batch ignores it. This argument is not required for files returned by default. You can return more than one argument of this type.
- **DBS\_OUTPUT\_DIRECTORY**—Specifies the output directory containing all files except ones such as trail files or log files that are ignored by Creo Distributed Batch. This optional argument is required only if the contents of the output directory are different from the input working directory.
- **DBS\_MESSAGE**—Specifies the user-visible message that will be printed in the log file generated by the custom DLL task function. This message is especially useful if the function returns an error.

In case of chained TTD tasks (described in the [TTD File Format for Custom DLL Tasks on page 2017](#) section), the output arguments generated by the first TTD containing the custom DLL task function are supplied as input arguments to the second TTD within the same file.

The custom DLL task function should return one of the following types of errors:

- **PRO\_TK\_NO\_ERROR**—Specifies that the task function executed successfully.
- **PRO\_TK\_BAD\_INPUTS**—Specifies that the task function was called with incorrect input arguments.

## Registry File for Custom DLL Tasks

Registering a custom Creo TOOLKIT DLL means providing information to the Creo Distributed Batch service about the files that form the DLL.

An example of the registry file is as follows:

```
name pt_userguide.dll
exec_file <creo_toolkit_loadpoint>/${<machine_type>}/obj/pt_
userguide.dll
text_dir <creo_toolkit_loadpoint>/protk_appls/pt_userguide/text
where:
<creo_toolkit_loadpoint> refers to the directory that forms the
loadpoint of Creo Parametric TOOLKIT under the Creo Parametric
installation.
<machine_type> refers to the type of machine on which Creo
Parametric is installed. For example x86e_win64.
```

---

The fields of the above registry file are described below:

- `name`—Specifies the name of the Creo TOOLKIT DLL to be used as the `dllname` attribute in the TTD file.
- `exec_file`—Specifies the full path to the DLL binary file on the service machine.
- `text_dir`—Specifies the directory containing language-specific directories that include the menu and message files used by the DLL.

The registry file must be named `dbatchs.dat`. The DLL registry file must be visible to the Creo Distributed Batch service on the service machine. To make it visible, place the `dbatchs.dat` file in the same location as the Creo Distributed Batch service executable `dbatchs.exe` available in the `<creo_loadpoint>\<datecode>\Common Files\$\<machine_type>\nms` directory. More than one custom DLL can be listed in a given `dbatchs.dat` file.

## TTD File Format for Custom DLL Tasks

TTD files serve as templates for all the common tasks that can be performed using Creo Distributed Batch. Refer to the Creo Distributed Batch Help for complete information about the nodes included in a TTD file.

For a custom DLL task, specify the name of the Creo TOOLKIT DLL as the `dllname` attribute and the function `ProToolkitTaskExecute()` that causes Creo Parametric to execute the task function as the `func` attribute within the `<TKFUNC></TKFUNC>` node in a TTD file. Specify the name of the custom DLL task function in the `<DLL_FUNCTION></DLL_FUNCTION>` tag within the `<TKFUNC></TKFUNC>` node. You can also include the required `<USER_DATA></USER_DATA>` tags within the `<TKFUNC></TKFUNC>` node.

Additionally, you can specify an existing Creo TOOLKIT function along with its input arguments and enumerated types within a `<TKFUNC></TKFUNC>` node. A TTD file containing multiple `<TKFUNC></TKFUNC>` nodes is called a chained TTD.

### Example 2: Chained TTD Task to convert a Creo Parametric model into a simplified representation in the VRML format

Following is an example of a TTD file for a custom DLL task function.

```
<TTD version="1.0" created_by="PTC">
 <DESCRIPTION>Load and call external DLL to change the
current model to simprep</DESCRIPTION>
 <DETAILS>Load an external Creo Parametric TOOLKIT DLL into the
Creo Parametric session</DETAILS>
 <SERVICE name="dbatchs"/>
 <TKFUNC func="ProToolkitTaskExecute"
 dllname="pt_userguide.dll">
 <DLL_FUNCTION>TestSimprepActivateTask</DLL_FUNCTION>
```

```

 <USER_DATA name="SIMP_REP">NO_B</USER_DATA>
 </TKFUNC>
 <!-- Export to VRML format -->
 <TKFUNC func="ProExportVRML">
 </TKFUNC>
</TTD>

```

In the above `simprep.ttd` file, the function `ProToolkitTaskExecute()` executes the custom task function `TestSimrepActivateTask` defined in `pt_userguide.dll`. The function `TestSimrepActivateTask` converts a Creo Parametric model into a simplified representation. The name of the simplified representation to be created must be specified in the `<USER_DATA></USER_DATA>` tag.

The activated simplified representation is converted into the VRML format by the second `<TKFUNC></TKFUNC>` node entry in the chained TTD task. This part of the execution is directly handled by Creo Distributed Batch.

The C language code for the custom task function `TestSimrepActivateTask` used in the `simprep.ttd` file is present in the sample code in the file `UgInterfaceExport.c` located at `<creo_toolkit_loadpoint>/protk_appls/pt_userguide/ptu_interface`.

## Launching Synchronous J-Link Applications

The functions described in this section allow Creo TOOLKIT API users to launch a synchronous J-Link application and call methods within it with user-specified arguments.

The ability to launch and control a J-Link application by a Creo TOOLKIT API enables:

- Code reuse through the ability to create J-Link libraries that can be called from Creo TOOLKIT or other APIs.
- Creation of platform independent library routines.

Functions Introduced:

- **ProJlinkApplicationStart()**
- **ProJlinkTaskExecute()**
- **ProJlinkApplicationStop()**

Use the function `ProJlinkApplicationStart()` to register and start a J-Link application. The input parameters of this function are similar to the fields of a registry file and are as follows:

- *app\_name*—Assigns a unique name to this J-Link application.

- *java\_app\_class*—Specifies the fully qualified class and package name of the Java class that contains the J-Link application's start and stop method.
- *java\_app\_start*—Specifies the start method of the program.
- *java\_app\_stop*—Specifies the stop method of the program.
- *java\_app\_add\_classpath*—Specifies the locations of packages and classes that can be loaded when running a Java program. Can be NULL, if not needed
- *text\_dir*—Specifies the application text path for menus and messages. Can be NULL if the application does not use menus or messages.
- *user\_display*—Specifies whether to display the application in the **Auxiliary Applications** dialog box in Creo Parametric.

The function provides the `ProJLinkAppHandle` handle to the J-Link application. If the start method throws an exception, the description of the exception is stored in the argument *startup\_exception*.

The function `ProJLinkTaskExecute()` calls a registered task in a J-Link application. The input parameters are:

- *handle*—Specifies the handle to the J-Link application.
- *task\_id*—Specifies the task to be executed. The J-Link application should register the task using the J-Link method `pfcSession.BaseSession.RegisterTask()`. Refer to J-Link documentation for more information on the `RegisterTask()` method.
- *input\_args*—Specifies the input arguments to be passed to the task.

The output of this function is an array of arguments of type `ProArgument`. These arguments are returned by the J-Link task method.

If the method throws an exception, the description of the exception is stored in the output argument *exception*.

The function `ProJLinkApplicationStop()` stops the J-Link application specified by the `ProJLinkAppHandle` application handle. The function activates the application's stop method.

If the stop method throws an exception, the description of the exception is stored in the output argument *exception*.

# Unicode Encoding

## Unicode Encoding

This section appendix describes how the new Unicode support used internally by Pro/ENGINEER from Wildfire 4.0 onward affects Creo TOOLKIT and its applications.

## Introduction to Unicode Encoding

UNICODE is an acronym for "Universal Character Encoded System". It is a unique character encoding scheme allowing characters from European, Greek, Arabic, Hebrew, Chinese, Japanese, Korean, Thai, Urdu, Hindi, and other world languages to be encoded in a single character set. This enables applications to simultaneously support text in multiple languages in their data files. Unicode encoding covers most of the letters, punctuation marks, and technical symbols commonly used in the English language that are not covered by the legacy encoding.

Unicode defines two mapping methods:

- UCS (Universal Character Set) encoding
- UTF (Unicode Transformation Format) encoding

For more information on Unicode Encoding, visit <http://unicode.org>.

Pro/ENGINEER Wildfire 4.0 onward, all string data in Pro/ENGINEER (previously stored in the legacy encoding format) is now stored in the Unicode encoding. Pro/ENGINEER Wildfire 4.0 uses the UCS-2 encoding on Windows platforms and UCS-4 encoding in UNIX environments for widestring data. It reads and writes character data using the multibyte UTF-8 encoding on all platforms. UTF-8 is an 8-bit, variable-length character encoding format that uses one to four bytes per character.

Some important terminology about string encoding related to Creo TOOLKIT that is used throughout this appendix is described as follows:

- “Unicode encoding” refers to the string and widestring encodings used by Pro/ENGINEER Wildfire 4.0 and later.
- “Legacy encoding” refers to the encoding used by Pro/ENGINEER Wildfire 3.0 and earlier. Depending on the language, this encoding is typically some version of an EUC encoding.
- “Native encoding” refers to the encoding used by the operating system in the language in which the system is running. This encoding is the same as legacy encoding in most cases.

- 
- “Multibyte string” refers to a character array representing a string in the C language. Because of the limited size of the character (a single byte), combinations of multiple bytes are used to represent characters outside the ASCII range.
  - “7-bit ASCII” refers to the character range 0x0 through 0x127. This range is shared between Unicode and non-Unicode encodings used by Creo Parametric. Thus, any data of this type is unchanged after transcoding.
  - “8-bit ASCII” refers to the character range 0x128 through 0x255. In many European native encodings, this range is used to represent European accented vowels and other letters. In Unicode, this range is not directly used. Therefore, 8-bit ASCII native strings are not equivalent in Unicode.
  - “Byte Order Mark” (BOM) refers to a string of three bytes U+FEFF (represented in C language strings by “\357\273\277”), and is placed on the top of a text file to indicate that the text is Unicode encoded. Unicode has designated the character U+FEFF as the BOM and reserved U+FFFE as an illegal character for UTF-8 encoding. Most of the text files generated by Creo Parametric are written with the BOM and Unicode encoding. Creo Parametric can accept a Unicode encoded text file with a BOM, or a legacy encoded text file without a BOM as the input.
  - “Transcoding” refers to the act of changing a string or widestring encoding from one encoding to another, for example, from platform native to Unicode or vice-versa. For some transcoding operations, there is a possibility of data loss, since characters from one encoding may not be supported in the target encoding.

## Unicode Encoding and Creo Toolkit

Pro/TOOLKIT applications running with Pro/ENGINEER Wildfire 4.0 and later must, by default, receive and send strings and widedstrings to Pro/ENGINEER in Unicode encoding. This is a change to the encoding previously received by applications in Wildfire 3.0 and earlier. Because the workstation operating system will not be running in Unicode and other languages, functions and libraries accessed by the Creo TOOLKIT application may not be Unicode aware, the Creo TOOLKIT application must deal with the change of encoding.

Make changes to the application to expect and accept Unicode strings and widedstrings when dealing with Creo Parametric data. At the external interfaces from the application to the operating system or third-party APIs, perform necessary transcoding operations to ensure that those other systems receive an expected encoding.

PTC recommends that all applications be evaluated for Unicode compliance regardless of their purpose or intended data. However, applications that would particularly be affected by Unicode encoding are as follows:

- 
- Any Creo TOOLKIT application expected to work with Creo Parametric in any language other than English.
  - Any Creo TOOLKIT application expecting Creo Parametric data in any language other than English (where strings from that data are transferred to and from Creo Parametric or any other source).

## Necessity of Unicode Compliance

It is strongly recommended that you make your existing Creo TOOLKIT applications Unicode-compliant for the following reasons:

- Applications that are not Unicode-compliant will be unable to reliably handle Creo Parametric data saved in the Unicode format with strings (notes, annotations, table, and so on) in multiple languages other than English. For example, a Creo Parametric drawing can now contain both German and Japanese notes. The Creo TOOLKIT application will not be able to read or modify those notes correctly without being Unicode compliant. This could result in data loss or corruption.
- Applications that do not consider the Unicode nature of Creo Parametric data may try to pass that data directly to the system or third-party APIs that do not recognize it correctly. This could cause data corruption or crashes.
- Applications that do not transcode non-Unicode data into Unicode before using the data as strings inside Creo Parametric models will generate corrupt and incorrect models.

## External Interface Handling

Creo TOOLKIT applications running in Unicode will need to create utilities around the interfaces between non-Unicode aware third-party APIs and interfaces. While PTC cannot directly provide such interfaces, this section discusses the considerations for creating such utilities by showing how one external API such as the C runtime library can be used from a Unicode environment.

Any C runtime library accepting `char*` or `wchar_t*` as input may be adversely affected by receiving Unicode data. Typically, it should be possible to create a simple wrapper for each C runtime interface used in the application, where the input string to the interface is expected to be in Unicode. The string should be transcoded before calling the system API. Examples of such C runtime functions are listed below (this is not an exhaustive list):

- `fopen()`
- `access()`, `_access()`
- `chdir()`, `readdir()`, `opendir()`

- 
- `chmod()`, `_chmod()`
  - `findfirst()`, `_findnext()`
  - `getcwd()`
  - `getenv()`
  - `open()`, `opendir()`
    - `fgetc()`
    - `fgets()`
    - `fputc()`
    - `fputs()`
    - `fread()`, `fwrite()`
    - `puts()`
  - `remove()`, `stat()`, `system()`, `tmpfile()`, `unlink()`

## Special External Interface: `printf()` and `scanf()` Functions

The `printf()` and `scanf()` family of C runtime functions are a special case of an external interface. The format string must be transcoded when these interfaces are called. The list of variable arguments passed to the functions may also contain string and widestring data that needs to be transcoded and modified in format. Because of the complexity of wrapping these C runtime functions, PTC has provided a standard Creo TOOLKIT function equivalent for each. These functions support all the format specifiers and modifiers supported by the C language specification.

Functions Introduced:

- **`ProTKPrintf()`**
- **`ProTKFprintf()`**
- **`ProTKSprintf()`**
- **`ProTKSnprintf()`**
- **`ProTKVprintf()`**
- **`ProTKVfprintf()`**
- **`ProTKVsprintf()`**
- **`ProTKVsnprintf()`**
- **`ProTKScanf()`**
- **`ProTKFscanf()`**
- **`ProTKSscanf()`**
- **`ProTKSnscanf()`**

- 
- **ProTKVscanf()**
  - **ProTKVfscanf()**
  - **ProTKVsscanf()**

The function `ProTKPrintf()` provides the Unicode equivalent to the C runtime function `printf()`. The number of characters returned by this function is sent to `stdout`. The output data is transcoded to the native encoding format, which may result in out-of-locale characters in the results.

The function `ProTKFprintf()` provides the Unicode equivalent to the C runtime function `fprintf()`. The number of characters returned by this function are copied into the file. This file will receive the data in the Unicode-encoded format.

The functions `ProTKSprintf()` and `ProTKSnprintf()` provide the Unicode equivalent to the C runtime functions `sprintf()` and `snprintf()` respectively. The number of characters returned by these functions are copied into the output buffer.

The function `ProTKScanf()` provides the Unicode equivalent to the C runtime function `scanf()`. This function parses the contents of the input from `stdin`. The output data in the string or character format is in Unicode encoding.

The function `ProTKFscanf()` provides the Unicode equivalent to the C runtime function `fscanf()`. This function parses the contents of the input from a file.

The functions `ProTKSscanf()` and `ProTKSnscanf()` provide the Unicode equivalent to the C runtime functions `sscanf()` and `snscanf()` respectively.

The Unicode equivalent of the C runtime functions `v*printf()` and `v*scanf()`, which take a variable arguments list instead of variable number of arguments, have also been provided in the form of `ProTKV*printf()` and `ProTKV*scanf()` functions.

## Special External Interface: Windows-runtime Functions

Win32 functions that take `char*` inputs are not Unicode compliant, and thus cannot be used with data directly obtained from Pro/ENGINEER Wildfire 4.0 and later. The simplest approach to using Windows runtime functions is to use the functions accepting `wchar_t*` inputs since these functions are Unicode compliant (Windows native encoding for `wchar_t*` is Unicode). For example, use the function `GetMessageW()` instead of `GetMessage()` or `GetMessageA()`.

## Special External Interface: Hardcoded Strings

Another example of an external interface is a hardcoded string. You should review all uses of hardcoded strings in your application and ensure that they fit the following categories:

- 
- They use only 7-bit ASCII characters or wide characters.
  - They use Unicode escape sequences.

8-bit ASCII or non-Unicode escape sequences in hardcoded strings do not work correctly unless you transcode the string into Unicode before sending it to Creo Parametric.

## Updating Older Applications

### Overview

This section appendix describes the tools that are available for updating applications from older versions to the current release of Creo TOOLKIT.

Creo TOOLKIT users are responsible for updating their applications from older versions to use the new Creo TOOLKIT functions. When you update the applications, use the functions that have been updated in the current release.

PTC provides tools that facilitate updating of your Creo TOOLKIT applications from older versions. However, in certain scenarios, the tools may not give expected results.

### Tools Available for Updating Applications

PTC provides the `mark_deprecated.pl` tool to update your applications from older versions to the current release. This perl script is located at `<creo_loadpoint>\<datecode>\Common Files\protoolkit\scripts`. The script parses directories and looks for files with extensions such as, `.c`, `.cxx`, and `.cpp`, which are the default extensions included in the script.

The script searches for deprecated symbols, such as, functions, structures, enumerated data types and so on, in these files. When it finds such symbols, the script inserts comments with recommendations of possible replacements. By default, the script uses the mapping table `protkmap.txt` provided at `<creo_loadpoint>\<datecode>\Common Files\protoolkit\scripts`.

The mapping table is based on DEPRECATED and SUCCESSORS tags specified in the Creo TOOLKIT header files. Some deprecated functions may not have direct replacement functions. In such cases, the script adds the comment AS APPROPRIATE.

---

The script options are listed when you run `mark_deprecated.pl` with no arguments, or with options `-h`, `-?` or `-help`.

---

 **Note**

The options may vary in future releases.

---

When you run the script, it saves a copy of the original files. However, PTC recommends that you back up all the files, before running the script.

The script generates two types of output. The outputs depend on the `-m` option.

For example, consider a file with the name `model.c`. It contains the following code:

```
void findMdlParam(ProMdl mdl) {
 ProMdlnameShortdata *modelList = NULL;
/* should we call ProMdlInit here?? */
 error = ProMdlDependenciesList (mdl, &modelList, &noOfModels);
 error = ProMdlCopy (mdl); // what to do? /*who knows? That's a question
 btkString errorStr = "\"ProMdlCopy (mdl)\" - error";
 PrintModelDependencies(modelList);
/*
 * This is long multiline comment, where some Pro/TK
 * calls like ProCollectionAlloc or ProCollectioninstrAlloc
 * can be found.
 */
 return;
}
```

If you specify the `-m` option, the original file is retained, and the output file with the name `<filename>_markup.c` is created. The comments recommending new symbols are inserted on separate lines in the output file. For the file `model.c`, the following output is generated in the file `model_markup.c`:

```
void findMdlParam(ProMdl mdl) {
 ProMdlnameShortdata *modelList = NULL;
/* should we call ProMdlInit here?? */
/* Deprecated_API_Used: Replace ProMdlInit with ProMdlnameInit */
 error = ProMdlDependenciesList (mdl, &modelList, &noOfModels);
/* Deprecated_API_Used: Replace ProMdlDependenciesList with
ProMdlDependenciesMdlnameList */
 error = ProMdlCopy (mdl); // what to do? /*who knows? That's a question
/* Deprecated_API_Used: Replace ProMdlCopy with ProMdlnameCopy */
 btkString errorStr = "\"ProMdlCopy (mdl)\" - error";
 PrintModelDependencies(modelList);
/*
 * This is long multiline comment, where I can also note some Pro/TK
```

```

 * calls like ProCollectionAlloc or ProCollectioninstrAlloc
** Deprecated_API_Used: Replace ProCollectionAlloc with
ProCrvcollectionAlloc, ProSrvcollectionAlloc **
** Deprecated_API_Used: Replace ProCollectioninstrAlloc with AS
APPROPRIATE **
 * can be found.
 */
 return;
}

```

If you do not specify the `-m` option, a copy of the original file is saved as `<filename>.c.orig`. The comments with recommendations are inserted in the original file. For example, the original file is saved as `model.c.orig`. The following output is generated in the file `model.c`:

```

void findMdlParam(ProMdl mdl) {
 ProMdlnameShortdata *modelList = NULL;
 /* should we call ** PROTK_DEPRECATED ProMdlInit ->
ProMdlnameInit ** ProMdlInit here?? */
 error = /* PROTK_DEPRECATED ProMdlDependenciesList ->
ProMdlDependenciesMdlnameList */
ProMdlDependenciesList (mdl, &modelList, &noOfModels);
 error = /* PROTK_DEPRECATED ProMdlCopy -> ProMdlnameCopy */ ProMdlCopy
(mdl);
 // what to do? /*who knows? That's a question
 btkString errorStr = "\"ProMdlCopy (mdl)\\" - error";
 PrintModelDependencies(modelList);
 /*
 * This is long multiline comment, where some Pro/TK
 * calls like ** PROTK_DEPRECATED ProCollectionAlloc ->
ProCrvcollectionAlloc,
ProSrvcollectionAlloc ** ProCollectionAlloc or ** PROTK_DEPRECATED->
AS APPROPRIATE ** ProCollectioninstrAlloc
 * can be found.
 */
 return;
}

```

## Migrating to Creo Object TOOLKIT C++

### Overview

This section appendix describes how to migrate to Creo Object TOOLKIT C++.

PTC introduced Creo Object TOOLKIT C++ as a part of its modernization plan and to improve productivity.

---

To enable users to smoothly migrate their existing Creo TOOLKIT applications, the Creo TOOLKIT APIWizard provides links to equivalent Creo Object TOOLKIT C++ methods.

Additionally, from Creo 3.0 onward, PTC provides a tool to facilitate migration of Creo TOOLKIT applications to Creo Object TOOLKIT C++.

Certain functional areas are not yet available in Creo Object TOOLKIT C++. In such cases, you can continue using the Creo TOOLKIT functions in Creo Object TOOLKIT C++ applications, as both the toolkits are compatible. Refer to the *Creo Object TOOLKIT C++ User's Guide* for more information.

## Migrating Applications Using Tools

PTC provides the `mark_otkmethod.pl` tool to help you migrate applications from Creo TOOLKIT to Creo Object TOOLKIT C++. This perl script is located at `<creo_loadpoint>\<datecode>\Common Files\protoolkit\scripts`. The script parses directories and looks for files with extensions such as, `.c`, `.cxx`, and `.cpp`, which are the default extensions included in the script.

The script searches for Creo TOOLKIT functions in these files. When it finds Creo TOOLKIT functions, the script inserts comments with recommendations of possible replacing Creo Object TOOLKIT C++ methods. By default, the script uses the mapping table `protk2otkmap.txt` provided at `<creo_loadpoint>\<datecode>\Common Files\protoolkit\scripts`.

The script options are listed when you run `mark_otkmethod.pl` with no arguments, or with options `-h`, `-?` or `-help`.

### Note

The options may vary in future releases.

---

When you run the script, it saves a copy of the original files. However, PTC recommends that you back up all the files, before running the script.

The script generates two types of outputs depending on the `-m` option. The `mark_otkmethod.pl` generates output similar to the `mark_deprecated.pl` script.

For example, consider a file `Xsection.c`. It contains the following code:

```
ProMessageDisplay(msgfil, "USER Pick the start plane");
status = ProSelect("face", 1, NULL, NULL, NULL, NULL, &sel, &n_sel);
if(status != PRO_TK_NO_ERROR || n_sel < 1)
 return(0);

ProSelectionModelitemGet(sel[0], &surface_modelitem);
```

---

```

 ProSurfaceInit(part, surface_modelitem.id, &surface);
 ProSurfaceTypeGet(surface, &stype);
 if(stype != PRO_SRF_PLANE)
return(0);

```

If you specify the `-m` option, the original file is retained, and the output file with the name `<filename>_markup.c` is created. The recommended Creo Object TOOLKIT C++ methods are inserted as comments on separate lines in the output file. In this example, for the file `Xsection.c`, the following output is generated in the file `Xsection_markup.c`:

```

 ProMessageDisplay(msgfil, "USER Pick the start plane");
/* Replace ProMessageDisplay with pfcSession::UIDisplayMessage /
 pfcSession::UIDisplayLocalizedMessage */

 status = ProSelect("face", 1, NULL, NULL, NULL, NULL, &sel, &n_sel);

/* Replace ProSelect with pfcBaseSession::Select */
 if(status != PRO_TK_NO_ERROR || n_sel < 1)
 return(0);

 ProSelectionModelitemGet(sel[0], &surface_modelitem);

/* Replace ProSelectionModelitemGet with pfcSelection::GetSelModel /
 pfcSelection::GetSelItem */
 ProSurfaceInit(part, surface_modelitem.id, &surface);
 ProSurfaceTypeGet(surface, &stype);
 if(stype != PRO_SRF_PLANE)
return(0);

```

If you do not specify the `-m` option, a copy of the original file is saved as `<filename>.c.orig`. The comments with recommendations are inserted in the original file. In this example, the original file `Xsection.c` is saved as `Xsection.c.orig`. The following output is generated in the file `Xsection.c`:

```

/* Replace ProMessageDisplay -> pfcSession::UIDisplayMessage /
 pfcSession::UIDisplayLocalizedMessage */
ProMessageDisplay(msgfil, "USER Pick the start plane");

status =/* Replace ProSelect -> pfcBaseSession::Select */
 ProSelect("face", 1, NULL, NULL, NULL, NULL, &sel, &n_sel);

 if(status != PRO_TK_NO_ERROR || n_sel < 1)
 return(0);

/* Replace ProSelectionModelitemGet -> pfcSelection::GetSelModel /

```

```

 pfcSelection::GetSelItem */
ProSelectionModelitemGet(sel[0], &surface_modelitem);

 ProSurfaceInit(part, surface_modelitem.id, &surface);
 ProSurfaceTypeGet(surface, &stype);
 if(stype != PRO_SRF_PLANE)
return(0);

```

## Migrating to the Multibody Environment

### Overview

This section appendix describes how to migrate to the Creo Parametric multibody environment.

PTC introduces multibody part design to improve design productivity, flexibility, and usability.

The existing Creo TOOLKIT application continues to work seamlessly for legacy models and models having a single body. However, you must upgrade to Creo Parametric 7.0.0.0 to use the multibody environment.

To support the multibody environment, Creo Parametric 7.0.0.0 is updated in the following aspects:

- New APIs are added
- Some existing APIs are deprecated and are superseded by new APIs
- Implementation of existing APIs is updated. No visible changes in Creo Toolkit APIs
- New element trees are added to support new multibody features
- Some existing element trees are updated.
- Some enumerated data types and their values are updated
- Existing structures are updated

To enable you to smoothly migrate your existing Creo TOOLKIT applications, the Creo TOOLKIT APIWizard provides the following APIs to support multibody:

Feature Name	API name
Body Operations	• ProSolidBodyCreate()     • ProSolidBodyDelete()     • ProSolidDefaultBodySet()     • ProSolidBodyConstructionSet()
Querying Body	• ProSolidBodiesCollect()

Feature Name	API name
	• ProSolidBodySurfaceVisit()     • ProSolidDefaultBodyGet()     • ProSolidBodyStateGet()     • ProSolidBodyIsConstruction()     • ProSolidBodyOutlineGet()     • ProSolidBodyFeaturesGet()     • ProGeomitemBodyGet()
Interference	• ProVolumeInterferenceBodiesGet()     • ProVolumeInterferenceDisplayForBody()
Material Properties	• ProSolidBodyMaterialSet()     • ProSolidBodyMaterialGet()     • ProSolidBodyMaterialGet()     • ProSolidBodyDensityGet()     • ProSolidBodyMassPropertyGet()
Sheetmetal	• ProSolidBodyIsSheetmetal()
Cross-Section	• ProXSectionExcludeCompGet()     • ProXSectionItemDataGet()     • ProXSectionItemFree()     • ProXSectionItemXhatchStyleGet()     • ProXSectionItemXhatchStyleSet()     • ProXSectionItemsArrFree()     • ProXSectionItemsCollect()     • ProXSectionOffsetCreate()

Feature Name	API name
	- ProXSectionPlanarCreate()    - ProXsecMdlnameAlloc()    - ProXsecMdlnameFree()    - ProXsecNewXhatchStyleCreateFromName()    - ProXsectionCompXhatchStyleGet()    - ProXsectionCompXhatchStyleSet()    - ProXsecMdlnameNameGet()    - ProXsecMdlnameNameSet()    - ProXsecMdlnameSolidOwnerGet()    - ProXsecMdlnameSolidOwnerGet()    - ProXsecMdlnameSolidOwnerSet()
Shrinkwrap options	ProShrinkwrapoptionIgnoreconstrbodiesSet()
UDF	ProUdfFileIsPreCreo7()

## Impact on Existing APIs

You must evaluate the need for using the new APIs based on the logic of your application. The following table lists the names of the existing APIs and respective superseding APIs.

Deprecated API	New API
ProSolidSurfaceVisit()	ProSolidBodiesCollect() ProSolidyBodySurfaceVisit()
ProPartToProIntfData()	ProPartToProInterfaceData() ProQuiltdataTypeGet() ProQuiltdataTypeSet()
ProXsecGeometryCollect()	ProXSectionItemsCollect() ProXSectionItemDataGet()
ProXsecPlanarWithoption	ProXSectionPlanarCreate()

Deprecated API	New API
sCreate ()	
ProXsecExcludeCompGet ()	ProXSectionExcludeCompGet ()
ProXsecCompXhatchStyleGet ()	ProXsectionCompXhatchStyleGet () ProXSectionItemXhatchStyleGet ()
ProXsecCompNewXhatchStyleGet ()	ProXsectionCompXhatchStyleGet () ProXSectionItemXhatchStyleGet ()
ProXsecCompXhatchStyleSet ()	ProXsectionCompXhatchStyleSet () ProXSectionItemXhatchStyleSet ()
ProXsecCompNewXhatchStyleSet ()	ProXsectionCompXhatchStyleSet () ProXSectionItemXhatchStyleSet ()
ProXsecCompNewXhatchStyleSetByName ()	ProXsecNewXhatchStyleCreateFromName () /ProXsectionCompXhatchStyleSet () ProXSectionItemXhatchStyleSet ()
ProXsecOffsetCreate ()	ProXSectionOffsetCreate ()
ProPartDensitySet ()	ProMaterialCurrentSet () ProMaterialPropertySet ()

**The following points are important to remember:**

- Check instances of deprecated API use.
- Modify code to use superseding APIs
- Test the updated application on legacy models and on multibody models.
- Some of the deprecated APIs work on multibody models if the special configuration option `allow_gmb_tkapi` is set to `yes`.

## User-Defined Features

With the introduction of bodies in Creo Parametric 7.0.0.0, the following occurs:

- 
- When creating a part, you can add body references to some features, such as to protrusion and cut features.
  - When creating an assembly, you cannot add body references.
  - UDFs created in an earlier release of Creo Parametric do not have body references.
  - UDFs created in an assembly in Creo Parametric 7.0.0.0 do not have body references.

For more information about how UDF placement is handled in Creo Parametric 7.0.0.0, refer to the section [Multibody support in UDF and Copy feature on page 169](#) in the [Core: Features on page 137](#) section.

## Update in API Implementation to Support Multibody

Implementation of some APIs is changed. To programmatically select bodies, pass the string `3d_body` to the API `ProSelect` to select bodies.

## Update in Existing Element Trees

Some existing features are affected due to the introduction of the multibody features such as creating or adding a body. The following header files are updated:

- `ProShell.h`
- `ProRib.h`
- `ProSmtDrvSurf.h`
- `ProExtrude.h`
- `ProRevolve.h`
- `ProSweep.h`
- `ProHole.h`
- `ProRound.h`
- `ProChamfer.h`
- `ProModifyRound.h`
- `ProModifyChamfer.h`
- `ProSmtShell.h`

### The following points are important to remember:

- Check if the affected features are created in the Creo TOOLKIT application.
- If you are working in the single body or legacy environment, then no action is required.

- 
- If you are working in the multibody environment, update the application code and use the updated element trees for the specific features.
  - If you are using an updated version of the Creo TOOLKIT application, perform subsequent testing for multibody models.

## New Element Trees for Supporting Multibody Features

To support multibody features, the following header files are added:

- `ProSplitBody.h`
- `ProBooleanBodies.h`
- `ProRemoveBody.h`
- `ProBodyCopy.h`
- `ProBodyOpts.h`

You can create multibody features using these new feature element trees based on the logic of your Creo TOOLKIT application.

## Update to Values of Enumerated Data Types

With the introduction of the multibody environment, the following enumerated values are impacted:

- `PRO_SURFCOLL_ALL_SOLID_SRFS` is deprecated

---

### Note

As a result, the functions `ProSrfcollectionRegenerate()`, `ProElementCollectionSet()`, and `ProSelbufferCollectionAdd()` return the error `PRO_TK_MULTIBODY_UNSUPPORTED` for multibody based models.

---

- The new enum values `PRO_SURFCOLL_BODY_SRFS` and `PRO_SURFCOLL_ALL_BODY_SRFS` are added.
- New enum value `PRO_LAYER_BODY` is added.

If the enum value `PRO_SURFCOLL_ALL_SOLID_SRFS` exists in your Creo TOOLKIT application code, then you need to update the code and test the legacy and multibody models.

## Impact on Existing Structures

`ProQuiltData` is updated with a new structure member to support multibody environment. As a result, the function `ProPartToIntfData()` is impacted.

# Creo Toolkit Registry File

## Registry File Fields

This appendix section describes how to use the Registry file to have a foreign program communicate with Creo Parametric.

The following table lists the fields in the registry file `creotk.dat` or `protk.dat`.

Field	Description
name	Assigns a unique name to the Creo TOOLKIT application. The name is used to identify the application if there is more than one. The name can be the product name and does not have to be the same as the executable name.   This field has a limit of <code>PRO_NAME_SIZE-1</code> wide characters (<code>wchar_t</code>).
startup	Specifies the method Creo Parametric should use to communicate with the Creo TOOLKIT application.   This field can take one of three values; <code>spawn</code>, <code>dll</code> or <code>java</code>.      • <code>spawn</code>— If the value is <code>spawn</code>, Creo Parametric starts the foreign program using interprocess communications.    • <code>dll</code>— If the value is <code>dll</code>, Creo Parametric loads the foreign program as a DLL.    • <code>java</code>— If the value is <code>java</code>, Creo Parametric starts the application as a J-Link class. Consult the <i>J-Link User's Guide</i> for more details.      The default value is <code>spawn</code>.
fail_tol	Specifies the action of Creo Parametric if the call to <code>user_initialize()</code> in the foreign program returns non-zero, or if the foreign program subsequently fails. If this is <code>TRUE</code>, Creo Parametric continues as normal. If this field is missing or is set to <code>FALSE</code>, Creo Parametric shuts down Creo Parametric and other foreign programs.
exec_file	Specifies the full path and name of the file produced by compiling and linking the Creo TOOLKIT application. In <code>DLL</code> mode, this is a dynamically linkable library; in <code>spawn</code> mode, it is a complete executable.   This field has a limit of <code>PRO_PATH_SIZE-1</code> wide characters (<code>wchar_t</code>).
text_dir	Specifies the full path name to text directory that contains the language-specific directories. The language-specific directories contain the message files, menu files, resource files and UI bitmaps in the language supported by the Creo TOOLKIT application. Please refer to the <a href="#">User Interface: Menus, Commands, and Popupmenus on page 320</a> and <a href="#">User Interface: Messages on page 305</a> sections for more information.   The <code>text_dir</code> does not need to include the trailing <code>/text</code>; it is added automatically by Creo Parametric.   The search priority for messages and menu files is as follows:

Field	Description
	1. Current working directory     2. <code>text_dir\text</code>     3. <code>&lt;creo_loadpoint&gt;\&lt;datecode&gt;\Common Files\&lt;machine_type&gt;\text</code>, where <code>&lt;machine_type&gt;</code> is the machine-specific subdirectory, such as, <code>i486_nt</code> or <code>x86e_win64</code>. Set the environment variable <code>PRO_MACHINE_TYPE</code> to define the type of machine on which Creo Parametric is installed.       The <code>text_dir</code> should be different from the Creo Parametric text tree. This field has a limit of <code>PRO_PATH_SIZE-1</code> wide characters (<code>wchar_t</code>).
<code>rbn_path</code>	Specifies the name of the ribbon file along with its path, which must be loaded when you open Creo Parametric. The location of the ribbon file is relative to the location of the text directory. The field <code>text_dir</code> specifies the path for the text directory. For example, if you want to specify a ribbon file <code>appl_rbn.rbn</code> placed at <code>text_dir/appl/appl_rbn.rbn</code>, specify <code>rbn_path</code> as <code>appl/appl_rbn.rbn</code>.   If the field is not specified, by default, the ribbon file with its location, <code>text_dir/toolkitribbonui.rbn</code> is used.
<code>delay_start</code>	If you set this to <code>TRUE</code>, Creo Parametric does not invoke the Creo TOOLKIT application as it starts up, but enables you to choose when to start the application. If this field is missing or is set to <code>FALSE</code>, the Creo TOOLKIT application starts automatically.
<code>description</code>	Acts as a help line for your auxiliary application. If you leave the cursor on an application in the Start/Stop GUI, Creo Parametric displays the description text (up to 80 characters). You can use non-ASCII characters, as in menu files.   To make the description appear in multiple languages, you must use separate <code>protk.dat</code> files in <code>&lt;hierarchy&gt;/&lt;platform&gt;/&lt;text&gt;/&lt;language&gt;</code>.
<code>allow_stop</code>	If you set this to <code>TRUE</code>, you can stop the application during the session. If this field is missing or is set to <code>FALSE</code>, you cannot stop the application, regardless of how it was started.
<code>end</code>	Indicates the end of the description of the Creo TOOLKIT application. It is possible to add further statements that define other foreign applications. All of these applications are initialized by Creo Parametric.

## Sample Registry Files

This section lists several examples that illustrate the various ways to have a foreign program communicate with Creo Parametric.

### Example 1

In this example, Creo Parametric spawns the foreign program, which runs on the same machine. The communication is via pipes (the default mode when the foreign program runs on the same machine as Creo Parametric).

---

File: protk.dat

[Start of file on next line]

```
name Product1
exec_file /home/protk/$<machine_type>/obj/frnpgm1
text_dir /home/protk
end
```

[End of file on previous line]

## Example 2

This example illustrates how to run multiple foreign programs, as specified in the protk.dat file.

File: protk.dat

[Start of file on next line]

```
name Product1
startup dll
exec_file /home/protk/$<machine_type>/obj/frnpgm1.dll
text_dir /home/protk
end
name Product2
startup spawn
exec_file /home/protk2/$<machine_type>/obj/frnpgm2
text_dir /home/protk2
end
```

[End of file on previous line]

# Creo Toolkit Library Types

## Overview

This section appendix describes the various libraries available in a Creo TOOLKIT installation.

The libraries available in a Creo TOOLKIT installation have been classified under:

- [Standard Libraries on page 2041](#)
- [Alternate Libraries on page 2041](#)

From Creo Parametric 4.0 F000 onward, the libraries listed in the following table are no longer supported and will not be available with the software. The New Library Name column provides a list of the equivalent libraries that are now available. Apart from the compatibility issues explained in the section [Version](#)

---

Compatibility: [Creo Parametric and Creo Parametric TOOLKIT on page 45](#), applications based on Creo Parametric 3.0 and previous releases will continue to run successfully with Creo Parametric 4.0.

Old Library Name	New Library Name
protk_dll.lib	protk_dll_NU.lib
protoolkit.lib	protoolkit_NU.lib
protk_dllmd.lib	protk_dllmd_NU.lib
protkmd.lib	protkmd_NU.lib

## Linking the Applications

Before you run an existing application in Creo Parametric 8.0, link it to the new libraries and the import libraries: `ucore.lib` and `udata.lib`. The new libraries do not link the application to the Unicode libraries but use `ucore.lib` and `udata.lib` at runtime to resolve the Unicode dependencies, which also reduces the size of the application. Since these libraries are import libraries, the application must resolve Unicode dependencies at runtime by loading the actual libraries `ucore64.dll` and `udata64.dll`. These DLLs are located at `<creo_load_point>/Common Files/<platform>/obj` and `<creo_load_point>/Common Files/<platform>/lib`.

In Creo Parametric 8.0.0.0 and later, the DLLs `ucore46.dll` and `udata46.dll` are not installed by default. If you need to load applications that are compiled prior to the Creo Parametric 7.0 release, you must install the DLLs separately. To download and install these DLLs separately, ensure that the **Legacy Toolkit Application Runtime** checkbox is selected while installing Creo Parametric. If you do not install these DLLs separately, your Creo TOOLKIT applications will not work.

---

### Note

If you have upgraded to the latest version of Creo, the DLLs are automatically updated and you do not need the old libraries.

---

---

### Note

Creo Parametric uses International Components for Unicode (ICU) for Unicode support. ICU is an open-source software. PTC is committed to use latest and most secure version of open source software, therefore PTC recommends that applications are re-linked with latest version of Creo.

---

---

For synchronous applications, the references to `ucore64.dll` and `udata64.dll` are resolved by Creo Parametric when the application is started.

For asynchronous applications, these references must be resolved by the application. For linking asynchronous applications, add the path where the dlls `ucore64.dll` and `udata64.dll` are located, that is `<creo_load_point>/Common Files/<platform>/lib` to the environment variable `PATH`.

All the sample makefiles available with Creo TOOLKIT use the new libraries. For instance, the sample example `make_examples` created for Creo TOOLKIT applications created for Creo TOOLKIT applications contains information on how to use `protk_dll_NU.lib`. The sample file is located at `<creo_toolkit_loadpoint>/<platform>/obj`.

## Standard Libraries

Most Creo TOOLKIT users will be able to use the standard Creo TOOLKIT libraries. These libraries are available on all platforms and are used by the majority of Creo TOOLKIT sample applications.

Library Name	Purpose
<code>protoolkit_NU.lib</code> <code>ucore.lib</code> <code>udata.lib</code>	Spawn mode library
<code>pt_asynchronous.lib</code>	Asynchronous mode library
<code>protk_dll_NU.lib</code> <code>ucore.lib</code> <code>udata.lib</code>	DLL mode library

## Alternate Libraries

Creo TOOLKIT offers alternate libraries that may be useful for applications compiled with `/MD` flag and built with `msvcrt.lib`. These libraries are similar to the standard Creo TOOLKIT libraries in content, but differ in using `msvcrt.lib` instead of `libcmt.lib`.

Library Name	Purpose
<code>protkmd_NU.lib</code>	Spawn mode library
<code>ptasyncmd.lib</code>	Asynchronous mode library
<code>protk_dllmd_NU.lib</code>	DLL mode library

The makefiles `make_install_md` and `make_async_md` build with these libraries.

### Note

Although /MD provides compatibility with multi-threaded components, Creo TOOLKIT calls must be made within a single thread. Creo Parametric does not respond to calls made from multiple threads. Extra threads may be created by applications only to do tasks which do not directly call Creo TOOLKIT functions.

---

## Creo Toolkit Sample Applications

### Installing Sample Applications

This section appendix describes the sample applications provided with Creo TOOLKIT.

When you install Creo TOOLKIT from the Creo Parametric CD, Creo TOOLKIT is installed under the loadpoint of Creo Parametric, that is, `<creo_loadpoint>\<datecode>\Common Files\protoolkit\protk_appls`. In Creo Parametric 6.0.0.0 and later, these sample applications are digitally signed. Refer to the [Fundamentals on page 30](#) section for more information on Installation of Creo TOOLKIT.

The Creo TOOLKIT directory contains all the headers, libraries, example applications, and documentation specific to Creo TOOLKIT. The following diagram illustrates the applications installed under the `protk_appls` directory after installation.

## Details on Sample Applications

The sample applications provided with Creo TOOLKIT are available in directories under the following path <creo\_loadpoint>\<datecode>\Common Files\protoolkit\protk\_appls.

## pt\_inst\_test

Location	Makefile
<creo_toolkit_loadpoint>/protk_appls/pt_install_test	make_install

The application `pt_inst_test` is used to check the Creo TOOLKIT Installation. It verifies the ProMenubar and custom user interface dialog box functions.

## pt\_inst\_cxx

Location	Makefile
<creo_toolkit_loadpoint>/protk_appls/pt_install_cxx	make_install_cxx

The application `pt_inst_cxx` is used to check the C++ version of the Creo TOOLKIT installation. It verifies the ProMenubar and custom user interface dialog box functions that use the C++ compiler and classes.

## pt\_inst\_test\_md

Location	Makefile
<creo_toolkit_loadpoint>/protk_appls/pt_install_test	make_install_md

The application `pt_inst_test_md` provides the version of the makefile for Windows platforms that uses MD libraries.

MD libraries are intended for building a DLL for Windows. Some Microsoft libraries must be linked with these libraries. For more information on MD libraries, refer to [Alternate Libraries on page 2041](#).

---

## pt\_autoaxis

Location	Makefile
<creo_toolkit_loadpoint>/protk_appls/pt_autoaxis	make_autoaxis

The sample application `pt_autoaxis` automatically creates axes on revolved surfaces if they don't already exist. It is intended for manufacturing engineers who receive a model with holes which were not made with standard Creo Parametric hole features. It covers functions for feature creation and geometry analysis.

## pt\_userguide

Location	Makefile
<creo_toolkit_loadpoint>/protk_appls/pt_userguide	make_userguide

The sample application `pt_userguide` consolidates examples that access the User Interface.

## pt\_examples

Location	Makefile
<creo_toolkit_loadpoint>/protk_appls/pt_examples	make_examples

The sample application `pt_examples` consists of Creo TOOLKIT application examples. It provides a user interface to access many areas of Creo TOOLKIT. This application covers Creo TOOLKIT functions and modules, including ProMenubar and ProMenu based UI functions. The directory `pt_examples` includes sub-directories containing useful utility functions.

## pt\_geardesign

Location	Makefile
<creo_toolkit_loadpoint>/protk_appls/pt_geardesign	make_geardesign

The sample application `pt_geardesign` provides the user interface to create gear models. This application covers feature creation using element trees and the custom user interface dialog box functions.

## pt\_async

Location	Makefile
<creo_toolkit_loadpoint>/protk_appls/pt_async	make_async

The sample application `pt_async` provides an example for the full asynchronous mode.

## pt\_async\_md

Location	Makefile
<creo_toolkit_loadpoint>/protk_appls/pt_async	make_async_md

The sample application `pt_async_md` provides an example for the asynchronous mode compilation of a DLL using MD libraries on Windows. The application requires two binaries, namely, `pt_async_md.dll`, and the wrapper executable `pt_async_md_wrapper.exe` which will load the DLL and invoke it. The application is identical to `pt_async` in all other respects. For more information on MD libraries, refer to [Alternate Libraries on page 2041](#).

---

## pt\_simple\_async

Location	Makefile
<creo_toolkit_loadpoint>/protk_appls/pt_simple_async	make_simple_async

The sample example `pt_simple_async` provides an example for the simple asynchronous mode.

## pt\_basic

Location	Makefile
<creo_toolkit_loadpoint>/protk_appls/pt_basic	make_basic

The sample application `pt_basic` provides the Creo TOOLKIT application template. It verifies the user interface, notifications, and the application setup.

## pt\_af\_examples

Location	Makefile
<creo_toolkit_loadpoint>/protk_appls/pt_af_examples	make_af_examples

The sample application `pt_af_examples` provides production examples using annotation features and annotations.

## pt\_udf\_examples

Location	Makefile
<creo_toolkit_loadpoint>/protk_appls/pt_udf_examples	make_udf_examples

The sample application `pt_udf_examples` demonstrates production examples using UDF placement capabilities. These include a flexible user interface for placing UDF libraries interactively, by reading the properties of the UDF library file.

## pt\_mech\_examples

Location	Makefile
<creo_toolkit_loadpoint>/protk_appls/pt_mech_examples	make_mech_examples

The sample application `pt_mech_examples` provides production examples using the ability to assign, create and modify Creo Simulate item properties.

---

# Advanced Licensing Options

## Advanced Licensing Options

This section describes the licensing requirements for advanced options in Creo TOOLKIT.

### Advance Licensing Options for Creo Toolkit

To use some of the functionality in Pro/TOOLKIT you must have advanced development license options.

For each TOOLKIT function that requires an advanced license, the Creo TOOLKIT header file entry includes a note specifying the development license requirement. This note is also visible in the APIWizard description page for the function. Advanced licenses are required in the following situations:

- To run a locked application, Creo Parametric requires the basic Creo TOOLKIT development option and any advanced toolkit options required by specific functions called by the application. If the application contains calls to such functions, Creo Parametric checks out the corresponding advanced license option on demand.
- To unlock an application, the unlock utility requires the basic Creo TOOLKIT development option and any advanced toolkit options required by specific functions called by the application. The utility will not hold any of the advanced options, as it does the basic Creo TOOLKIT development option, after unlock is completed.
- Creo Parametric does not require any of the Creo TOOLKIT licenses to run a properly unlocked application.

Applications are assigned requirements for advanced options based on whether the application is coded to use any functions requiring the advanced option. It does not matter if an application does not use the function requiring licensing during a particular invocation of the application. The licensing requirements are resolved the moment the application is started by or connects to Creo Parametric, not at the first time an advanced function is invoked.

For more information on how to unlock an application, refer to the section [Unlocking a Creo Toolkit Application on page 49](#).

---

# Pro/DEVELOP to Creo Toolkit Function Mapping

## Pro/DEVELOP to Creo Toolkit Function Mapping

This section appendix describes how to update legacy applications using Pro/DEVELOP functions with current Creo TOOLKIT functions.

From Creo Parametric 2.0 onward, the Pro/Develop functions are obsolete. The Pro/Develop header files and related support files will not be shipped with Creo Parametric in future. PTC recommends that you update applications that use Pro/Develop functions to use equivalent Creo TOOLKIT functions or Creo Object TOOLKIT C++ methods.

## The Relationship Between Creo Toolkit and Pro/DEVELOP

Creo TOOLKIT replaces and contains Pro/DEVELOP, the customization toolkit until Release 17 of Pro/ENGINEER. Creo TOOLKIT uses an Object-Oriented style.

### Creo Toolkit OHandles:

Creo TOOLKIT OHandles are equivalent to the type `Prohandle` used in Pro/DEVELOP. You can convert the handles between Creo TOOLKIT and Pro/DEVELOP simply by casting to the appropriate type. Creo TOOLKIT provides different OHandles for different object types where Pro/DEVELOP provided only a single generic handle; this provides for better type-checking during compilation. See [Converting from Pro/DEVELOP on page 2049](#) for more details.

## Converting from Pro/DEVELOP

You can convert functions from Pro/DEVELOP to Creo TOOLKIT, and also mix the two styles of functions.

## Using Pro/DEVELOP Applications with Creo Toolkit

Creo TOOLKIT replaces Pro/DEVELOP and provides most of the functionality that existed in Pro/DEVELOP. Existing Pro/DEVELOP applications will not become obsolete however, for the following reasons:

- Creo TOOLKIT inherits from Pro/DEVELOP the mechanisms by which the application C code is integrated into Creo Parametric. These mechanisms will continue to be used by Creo TOOLKIT for the indefinite future.

- 
- The complete library of Pro/DEVELOP functions is installed automatically along with the library of Creo TOOLKIT functions, and will be installed in this way from Release 2000i onwards.

Therefore, Pro/DEVELOP applications built using Release 17 will continue to work with Pro/ENGINEER Release 18 and later, without having to be recompiled and relinked. Using Creo TOOLKIT, you can recompile and relink Pro/DEVELOP applications developed using Release 17 without having to change the source code. These applications will continue to function as before.

However, you should plan to convert your applications to Creo TOOLKIT as soon as possible, even if you do not need to use any of the new functionality provided by Creo TOOLKIT. The conversion is desirable because Creo TOOLKIT provides more consistent and complete functionality, even in areas already well-covered by Pro/DEVELOP. In addition, PTC will give lower priority to requests for enhancements and maintenance to Pro/DEVELOP functions than to requests for equivalent Creo TOOLKIT functions, where they exist.

Thanks to the technology they share, you can use functions from both Creo TOOLKIT and Pro/DEVELOP within a single application. This means that:

- You can convert a Pro/DEVELOP application to use Creo TOOLKIT functions gradually.
- Pro/DEVELOP applications can use the new functionality provided by Creo TOOLKIT without the immediate need for a complete conversion.

A final reason for wanting to mix Pro/DEVELOP and Creo TOOLKIT functions is that not all of the Pro/DEVELOP functions have been replaced by equivalent Creo TOOLKIT functions.

## Techniques of Conversion and Mixing

Besides a difference in the conventions they use, Pro/DEVELOP and Creo TOOLKIT reference items in the Creo Parametric database in different ways. The following sections describe the technical points to consider when you convert from Pro/DEVELOP to Creo TOOLKIT, or when you mix both types of functions in a single application.

### Terminology

In general, the terminology used by Creo TOOLKIT is close to that of Pro/DEVELOP. The following table lists the most important terms that differ in meaning between the two toolkits.

Creo Toolkit	Pro/DEVELOP
Object	N/A
Model	Object
Solid (part or assembly)	Model
Surface	Face or surface

Creo Toolkit	Pro/DEVELOP
Component of an assembly	Member
Component path	Member identifier table (memb_id_tab)
External data	Generic application data

## General Functionality

To find the functions in Creo TOOLKIT that cover a particular area of functionality, scan the appendix in this user's guide, or use the Topical option in the Creo TOOLKIT browser. Beware of any difference in terminology from Pro/DEVELOP identified in the previous section.

If you want to find the Creo TOOLKIT equivalent of a particular Pro/DEVELOP function, refer to the table [Expandable Arrays on page 63](#). The table maps each Pro/DEVELOP function to the closest equivalent Creo TOOLKIT function (or functions).

In some functional areas, especially where Pro/DEVELOP provided good coverage, you can use the equivalent Creo TOOLKIT functions in an identical way, although the function names, return values, and sometimes the order of the arguments have been changed to conform to Creo TOOLKIT conventions.

For example, the following Pro/DEVELOP functions are almost exactly equivalent to the Creo TOOLKIT functions listed.

Pro/DEVELOP Function	Creo Toolkit Function
promenu_create()	ProMenuFileRegister()
promenu_expand()	ProMenuAuxfileRegister()
promenu_on_button()	ProMenubuttonActionSet()

Other functions require more care, however. For example, one of the conventions of Creo TOOLKIT is that the input arguments come before the output arguments.

In some areas of functionality, traditional Pro/DEVELOP techniques have been replaced in Creo TOOLKIT by techniques that are more general, flexible, and consistent with the techniques used within Creo Parametric. A good example is the visit functions, which replace two different Pro/DEVELOP techniques. For example:

Pro/DEVELOP Function	Creo Toolkit Equivalent
prodb_get_feature_ids()	ProSolidFeatVisit()
prodb_first_part_face(), prodb_next_part_face()	ProSolidBodySurfaceVisit()

It is possible to use the Creo TOOLKIT visit functions to create a utility that follows one of the Pro/DEVELOP styles. An example is shown in the section [Expandable Arrays on page 63](#).

---

Some areas of Creo TOOLKIT functionality reveal a more general, and more consistent, view of the contents of the Creo Parametric database than that familiar to users of Pro/DEVELOP, and therefore require a slightly deeper understanding. For example, Creo TOOLKIT does not contain exact equivalents of the following Pro/DEVELOP functions for traversing the components of an assembly:

- `prodb_first_member()`
- `prodb_next_member()`

Assembly components (called “members” in Pro/DEVELOP) are represented as features in the Creo Parametric database, so these two functions can be replaced by a call to `ProSolidFeatVisit()`, using `ProFeatureTypeGet()` to identify the features of type `PRO_FEAT_COMPONENT`. The feature identifier for an assembly component is identical to the member identifier used in Pro/DEVELOP.

In the same way, the following Pro/DEVELOP functions that find datum planes and datum curves are also replaced by more generic functions in Creo TOOLKIT:

- `prodb_first_datum()`
- `prodb_next_datum()`
- `prodb_get_datum_curves()`

Here, too, the first step is to traverse the features using `ProSolidFeatVisit()`. You can then traverse all the geometrical items in a feature using `ProFeatureGeomitemVisit()`. Datum planes are geometry items of type `PRO_SURFACE`, in features of type `PRO_FEAT_DATUM`; datum curves are geometry items of type `PRO_CURVE`, which can occur in features of many types.

This manual always explains the structure of the Creo Parametric database wherever necessary, without assuming any prior knowledge of the Pro/DEVELOP viewpoint. As shown in the previous examples, if you are converting a Pro/DEVELOP application that traverses Creo Parametric geometry, you should pay particular attention to the [Core: 3D Geometry on page 177](#) section appendix.

You can use Creo TOOLKIT functions to create utilities for the specific cases you need. Many such utilities are provided in the sample code located under the Creo TOOLKIT loadpoint.

Finally, Creo TOOLKIT covers whole new areas of functionality that were not supported at all by Pro/DEVELOP, such as the direct programmatic creation of features, including simple kinds of sketched features, datum planes, and manufacturing features. Some Pro/DEVELOP applications, especially those that create features using user-defined features (UDFs), and which customize Manufacturing, may therefore benefit from a complete redesign to take full advantage of Creo TOOLKIT.

---

## Registry Files

The Creo TOOLKIT registry file has the same format as the Pro/DEVELOP registry file. The search path used by Creo TOOLKIT to find the registry file is like that used by Pro/DEVELOP. However, the file name `prodev.dat` is now replaced by `creotk.dat` or `protk.dat`, and the configuration file option `prodevdat` is now either `creotkdat`, or `protkdat`, or `toolkit_registry_file`. To convert from Pro/DEVELOP to Creo TOOLKIT, simply substitute these names.

For an extended period, the search path for the Pro/DEVELOP registry file will continue to be used by Creo Parametric, in addition to the search path for Creo TOOLKIT. Therefore, you do not need to rename the Pro/DEVELOP registry file or configuration file option immediately.

## Menu and Message Files

Although the Pro/DEVELOP functions for accessing menus and messages have been replaced by close equivalents in Creo TOOLKIT, the menu and message files themselves retain exactly the same form and function. No conversion is necessary.

## Unlocking Your Application

The Creo TOOLKIT script for unlocking a finished application is named `protk_unlock`, but is otherwise identical to `prodev_unlock`.

## Application Program Structure

All the Pro/DEVELOP run modes are available in identical form in Creo TOOLKIT, and the structure of a Creo TOOLKIT application is the same as that of a Pro/DEVELOP application. Some of the core functions have been given new Creo TOOLKIT-style names for the sake of consistency, but are otherwise the same. The functions `user_initialize()` and `user_terminate()` remain identical in name and purpose.

## Handles and Data Types

Although Creo TOOLKIT is more rigorous than Pro/DEVELOP in the way it references objects in the Creo Parametric database, there are some close correspondences that simplify the task of mixing Pro/DEVELOP and Creo TOOLKIT functions.

As a general rule, database items referred to in Pro/DEVELOP by the type `Prohandle`, and referred to as OHandles (opaque handles) in Creo TOOLKIT, are pointers to the same Creo Parametric data structures. You can directly convert them by casting. The following table lists the most important examples.

Pro/DEVELOP Prohandle for the item type	Can be cast directly to the Creo Toolkit object
Object	ProMdl
Assembly	ProAssembly
Part	ProPart
Model (part or assembly)	ProSolid
Surface	ProSurface
Contour	ProContour
Edge	ProEdge
Curve	ProCurve
Datum quilt	ProQuilt
Point	ProPoint
Axis	ProAxis
Coordinate system	ProCsys

For database items that can be identified in Pro/DEVELOP by an integer identifier, that identifier is the same one generated by Creo TOOLKIT functions such as `ProSurfaceIdGet()` and `ProEdgeIdGet()`, and is the same one required as input to functions such as `ProSurfaceInit()`. It is also the value of the `id` field when one of these objects is represented as a `ProGeomitem`.

Converting a Pro/DEVELOP integer identifier to a Creo TOOLKIT OHandle can be done in two ways:

- Convert to a Prohandle within Pro/DEVELOP using `pro_element_info()`, then cast the resulting pointer.
- Use the identifier directly as the input to the appropriate `Pro*Init()` function.

The following diagrams show the possible conversion paths between Pro/DEVELOP and Creo TOOLKIT for database items.

The first diagram applies to objects of type Surface, Edge, Axis, Csys, Curve, Point, and Quilt. In each case, replace the asterisk (\*) with the appropriate name.

## Pro/DEVELOP Database Item Conversion Path

The exception to the previous diagram is that the Pro/DEVELOP function `pro_element_info()` is not supported for coordinate system datums.

A contour does not have an integer identifier in either Pro/DEVELOP or Creo TOOLKIT, but you can convert the Pro/DEVELOP Prohandle to ProContour and back by casting.

A view does not have an integer identifier in Creo TOOLKIT, but you can convert the Pro/DEVELOP Prohandle to ProView by casting.

A vertex is represented in Pro/DEVELOP as an edge (or a curve) and a value for the parameter `tof` of either 0 or 1. Creo TOOLKIT uses this technique in the ProSelection object, but for function inputs and in ProGeomitem it uses the specific types `PRO_EDGE_START` and `PRO_EDGE_END` (and `PRO_CRV_START` and `PRO_CRV_END` for datum curve ends). Because `PRO_EDGE_START` and `PRO_CRV_START` always refer to the end where `t = 0`, conversion is easy.

A feature is represented in Creo TOOLKIT by ProFeature, which is a DHandle, and therefore not equivalent to a Pro/DEVELOP Prohandle. The integer identifier still maps directly, however.

The following diagram applies to converting features.

## Feature Conversion

The following objects are DHandles, which are identical in form to ProModelitem and were identified only by an integer identifier in Pro/DEVELOP. They also inherit from ProModelitem, which means that, for example, ProSelectionModelitemGet() can be used to unpack them from a ProSelection object after calling ProSelect(). In each case, the id field in the object handle corresponds to the integer id used to identify these objects in Pro/DEVELOP.

- ProDimension
- ProGtol
- ProDtlnote
- ProDtlenity
- ProDtlsyminst
- ProDtlsymdef
- ProDtlgroup
- ProDgmitem
- ProNote

## Note

The objects `ProDtlNote` and `ProNote` refer to detail (drawing) notes, and notes respectively. They share the same value of the type field - `PRO_NOTE` - but they are distinguished by the type of their owning model.

The following diagram applies to Creo TOOLKIT objects `ProSolid`, `ProPart`, and `ProAssembly` when you map to Pro/DEVELOP parts and assemblies. For objects of type `ProMdl` that are not parts or assemblies, the integer identifiers are not applicable, but the rest of the diagram is correct.

### Pro/DEVELOP Part and Assembly Mapping

Many explicit data types from Pro/DEVELOP have been carried across into Creo TOOLKIT directly, and, although they generally have been given new names, they are directly compatible. In fact, the remaining Pro/DEVELOP include files now reference the new definitions in the Creo TOOLKIT include files.

Enumerated types have also been given new names for their values, and in some cases where Pro/DEVELOP used `#defined` values of an integer, Creo TOOLKIT provides an enum. However, the integer mapping of the values is retained in every case. Some examples of Pro/DEVELOP data types now defined in Creo TOOLKIT are shown in the following table.

Pro/DEVELOP	Creo Toolkit
Ptc_surf	ProSurfacedata
Ptc_curve	ProCurvedata
Pro_linestyle	ProLinestyle
pro_mode	ProMode
Pro_text_attributes	ProTextAttribute
int	ProMousebutton
int	ProDrawMode
int	ProColortype

For some items that have representations in both Creo TOOLKIT and Pro/DEVELOP, the data structures are not the same, and no direct conversion is possible. However, you can always convert by reducing such structures to their component data items. For example, to convert the Pro/DEVELOP representation of a parameter, `Pro_parameter_info`, to the Creo TOOLKIT `ProParameter` object, you can use functions such as `ProParameterInit()` and `ProParameterValueWithUnitsSet()`, using the fields in the Pro/DEVELOP structure as inputs. (In this case, it would probably be better to make a complete conversion to the Creo TOOLKIT functions, and thus avoid mixing these types in an application.)

A more complex example of this is the Pro/DEVELOP `Select3d` structure, whose Creo TOOLKIT counterpart is `ProSelection`. The following table explains the mapping by showing the fields of `Select3d` alongside the Creo TOOLKIT functions that extract the equivalent information from `ProSelection`.

Select3d Field	Creo Toolkit Read Access
sel_type	<code>ProSelectionModelitemGet()</code> , then read <code>modelitem.type</code> . See the note that follows this table.
selected_id	<code>ProSelectionModelitemGet()</code> , then read <code>modelitem.id</code> .
selected_ptr	<code>ProSelectionModelitemGet()</code> , then <code>Pro*Init()</code> , depending on the type.
select_pnt	<code>ProSelectionPoint3dGet()</code> .
sel_param	<code>ProSelectionUvParamGet()</code> .
sel_depth	<code>ProSelectionDepthGet()</code> .
part_ptr	<code>ProSelectionAsmcomppathGet()</code> , and

Select3d Field	Creo Toolkit Read Access
	ProAsmcomppathMdlGet().
assembly_ptr	ProSelectionAsmcomppathGet(), then read comppath.owner.
memb_num	ProSelectionAsmcomppathGet(), then read comppath.table_num.
memb_id_tab	ProSelectionAsmcomppathGet(), then read comppath.comp_id_tab.
view_ptr	ProSelectionViewGet().

### Note

The values of the Select3d field sel\_type do not map directly to values of ProType, used in ProModelitem. Do not convert these types by direct assignment. See the next table for the mapping.

This table also makes clear what data from Pro/DEVELOP you need to build a ProSelection object in Creo TOOLKIT, using the functions ProSelectionAlloc(), ProSelectionSet(), ProSelectionUvParamSet(), and ProSelectionVerify().

There was an anomaly in selecting datum points in Pro/DEVELOP that has been corrected in Creo TOOLKIT. The selected\_id is the identifier of the feature, and the datum point identifier is given by the field sel\_elem\_id. However, this does not carry over into Creo TOOLKIT—the ProModelitem identifier is the identifier of the datum point. (To get the feature, use the function ProGeomitemFeatureGet().)

The following table shows how the values of the sel\_type field in Select3d (and the corresponding pro\_select() option strings) map to values of ProType used in Creo TOOLKIT for ProModelitem and ProGeomitem objects used in Creo TOOLKIT as object handles that inherit from ProModelitem, such as ProGeomitem, ProDimension, ProGtol, ProDtlnote, and so forth.

pro_select() option	Select3d sel_type	ProType
point	SEL_3D_PNT	PRO_POINT
axis	SEL_3D_AXIS	PRO_AXIS
datum	SEL_3D_SRF	PRO_SURFACE
csys	SEL_3D_CSYS	PRO_CSYS
feature	SEL_3D_FEAT	PRO_FEATURE
edge	SEL_3D_EDG	PRO_EDGE
edge_end	SEL_3D_VERT	PRO_EDGE_START or PRO_EDGE_END
curve	SEL_3D_CURVE	PRO_CURVE
curve_end	SEL_CURVE_END	PRO_CRV_START or PRO_CRV_

pro_select() option	Select3d sel_type	ProType
		END
sldedge	SEL_3D_EDGE	PRO_EDGE
qltedge	SEL_3D_EDGE	PRO_EDGE
surface	SEL_3D_SRF	PRO_SURFACE
sldface	SEL_3D_SRF	PRO_SURFACE
qltface	SEL_3D_SRF	PRO_SURFACE
dtmqlt	SEL_3D_SRF_LIST	PRO_QUILT
part	SEL_3D_PART	PRO_PART
prt_or_asm	SEL_3D_PART	PRO_PART or PRO_ASSEMBLY
dimension	DTL_DIM	PRO_DIMENSION
ref_dim	DTL_REFDIM	PRO_REF_DIMENSION
gtol	DTL_GTOL	PRO_GTOL
dtl_symbol	DTL_SYMBOL	PRO_SYMBOL_INSTANCE
dwg_table	SEL_DWG_TABLE	PRO_DRAW_TABL
any_note	DTL_USER_NOTE	PRO_NOTE
note_3d	SEL_3D_NOTE	PRO_NOTE
dgm_obj	SEL_DGM_REF_OBJ	PRO_DIAGRAM_OBJECT
dgm_non_cable_wire	DTL_WIRE	PRO_DIAGRAM_WIRE
draft_ent	DTL_DRAFT_ENT	PRO_DRAFT_ENTITY
ext_obj	SEL_3D_EXT_OBJ	PRO_EXTOBJ
table_cell	SEL_TABLE_CELL	PRO_DRAW_TABLE_CELL

To minimize the need to convert between Select3d and ProSelection, follow these guidelines:

- If you need a Select3d as an input to a Pro/DEVELOP function, and the element referred to is to be selected interactively, use one of the Pro/DEVELOP select functions listed below instead of ProSelect() until you can convert the whole application.
  - pro\_select()
  - pro\_get\_selection()
  - pro\_set\_and\_get\_selection()
- If you need to use a Pro/DEVELOP function whose output is, or contains, a Select3d, try to process the output using Pro/DEVELOP functions instead of converting to a ProSelection object where possible. For example, use pro\_show\_select() instead of ProSelectionHighlight().

To help you maintain such mixtures, the online browser retains the description of the Pro/DEVELOP selection functions and Select3d that are, strictly speaking, superseded by Creo TOOLKIT.

However, PTC recommends that you retain your documentation for Pro/DEVELOP to use with Creo TOOLKIT.

## Equivalent Pro/DEVELOP Functions

The following table lists the functions that have equivalents in Creo TOOLKIT. If the Pro/DEVELOP function is not included in this list, the function retains the Pro/DEVELOP style in Creo TOOLKIT. For ease of use, the Pro/DEVELOP functions are presented by functional group.

Pro/DEVELOP Function	Equivalent Creo Toolkit Function
<b>Core Functions</b>	
<b>Synchronous Mode</b>	
pro_term()	ProEngineerEnd()
<b>Asynchronous Mode</b>	
prodev_start_proengineer()	ProEngineerStart()
prodev_set_interrupt_func()	Not supported in Creo TOOLKIT. It can be safely removed from applications which call it. For information on how to structure a full asynchronous mode application to accept Creo Parametric events, refer to the section <a href="#">Core: Asynchronous Mode on page 277</a> .
prodev_handle_interrupt()	ProEventProcess()
prodev_set_proe_term_func()	ProTermFuncSet()
user_proe_term_func()	ProTerminationAction()
prodev_get_proe_status()	ProEngineerStatusGet()
<b>User-Supplied Main</b>	
prodev_main()	ProToolkitMain()
<b>Menus</b>	
<b>Adding a Menu Button</b>	
promenu_create()	ProMenuFileRegister()
promenu_expand()	ProMenuAuxfileRegister()
promenu_on_button()	ProMenubuttonActionSet()
promenu_load_action()	ProMenubuttonGenactionSet()
<b>New Menus</b>	
promenu_action()	ProMenuProcess()
promenu_exit_up()	ProMenuDelete()
promenu_make()	ProMenuCreate()
promenu_no_exit()	ProMenuHold()
promenu_exit_action_up()	ProMenuDeleteWithStatus()
promenu_make_compound()	ProCompoundmenuCreate()
<b>Preempting Creo Parametric Commands</b>	
promenu_load_pre_func()	ProMenubuttonPreactionSet()
promenu_load_post_func()	ProMenubuttonPostactionSet()
<b>Manipulating Menus</b>	
promenu_set_item_location()	ProMenubuttonLocationSet()
promenu_set_item_visible()	ProMenubuttonVisibilitySet()
promenu_remove_item()	ProMenubuttonDelete()
<b>Data Menus</b>	
promenu_set_mode()	ProMenuModeSet()

promenu_set_data_mode()	ProMenuDatamodeSet()

## Geometry Traversal

### Overview

This section illustrates the relationships between faces, contours, and edges.

Note the following:

- A simple rectangular face has one contour and four edges.
- A contour will traverse a boundary such that the part face is always on the right-hand side (RHS). For an external contour, the direction of traversal is clockwise. For an internal contour, the direction of traversal is counterclockwise.
- If a part is extruded from a sketch that has a U-shaped cross section, there will be separate surfaces at each leg of the U-channel.
- If a part is extruded from a sketch that has a square-shaped cross section, and a slot feature is then cut into the part to make it look like a U-channel, there will be one surface across the legs of the U-channel. In other words, the original surface of the part is represented as one surface with a cut through it.
- Geometry traversal happens on body, solid surface and contour. For quilts, datum curves, edges, the geometry traversal will happen through a solid. To collect all the bodies in a specified solid, use the function `ProSolidBodiesCollect()`.

### To Walk Through the Geometry of a Block

1. Walk through the surfaces of a body, using `ProSolidBodySurfaceVisit()`.
2. Walk through the surfaces of a solid, using `ProSolidSurfaceVisit()`.
3. Walk through the contours of each surface, using `ProSurfaceContourVisit()`.
4. Walk through the edges of each contour, using `ProContourEdgeVisit()`.

---

## Geometry Terms

Consider the following definitions:

- surface—An ideal geometric representation, that is, an infinite plane.
- face—A trimmed surface. A face has one or more contours.
- contour—A closed loop on a face. A contour consists of multiple edges. A contour can belong to one face only.
- edge—The boundary of a trimmed surface.

An edge of a solid is the intersection of two surfaces. The edge belongs to those two surfaces, hence to two contours. An edge of a datum surface can be either the intersection of two datum surfaces, or the external boundary of the surface. If the edge is the intersection of two datum surfaces, it will belong to those two surfaces (hence, to two contours). If the edge is the external boundary of the datum surface, it will belong to that surface alone (hence, to a single contour).

Examples 1 through 5 show some sample parts and list the information about their surfaces, faces, contours, and edges.

### Example 1

This part has 6 faces.

- Face A has 1 contour and 4 edges.
- Edge E2 is the intersection of faces A and B.
- Edge E2 is a component of contours C1 and C2.

## Example 2

Face A has 2 contours and 6 edges.

## Example 3

This part was extruded from a rectangular cross section. The feature on the top was added later as an extruded protrusion in the shape of a semicircle.

- Face A has 1 contour and 6 edges.
- Face B has 2 contours and 8 edges.
- Face C has 1 contour and 4 edges.

#### Example 4

This part was extruded from a cross section identical to Face A. In the Sketcher, the top boundary was sketched with two lines and an arc. The sketch was then extruded to form the base part, as shown.

- Face A has 1 contour and 6 edges.
- Face B has 1 contour and 4 edges.
- Face C has 1 contour and 4 edges.
- Face D has 1 contour and 4 edges.

#### Example 5

This part was extruded from a rectangular cross section. The slot and hole features were added later.

- Face A has 1 contour and 8 edges.
- Face B has 3 contours and 10 edges.

---

# Geometry Representations

## Geometry Representations

This section appendix describes the geometry representations of the data structures defined in `ProGeomitem.h`. These structures are output by the geometry functions described in detail in the [Core: 3D Geometry on page 177](#) section.

## Domain of Evaluation

Surfaces and edges can be extended from their original domain as the user continues to add features to the model. For example, the user can add a feature such as a draft surface or local push, which requires the original surface to be extended outside its original domain.

When this occurs, you will find that the `uv` parameters of the surface have been extended. The `ProSurfacedata` data structure reflects the extension, and returns the updated values for the `u` and `v` extents.

Because the evaluator functions use the analytical surface (or curve) definition, they work for any parameter values. Thus, any surface (or curve) can be extended as needed. In addition, if you pass in parameters outside the current `uv` domain, the evaluator functions still return values for the parameters as requested.

If you are using the evaluators supplied by Creo TOOLKIT, you do not have to do anything. For surfaces, the evaluator functions work over this extended range of parameters. Your evaluator function for foreign datum surfaces is also expected to allow for extrapolation.

Edges are always parameterized between `0.0` and `1.0`. When surfaces are extended, new edges are created that have parameters in the range `0.0` to `1.0`.

If you develop your own evaluator functions, you must be aware that the domain of a surface can be extended, as with foreign datum surfaces.

## Surfaces

## Surface Data Structures

The surface structure contains data that describes the boundary of the surface, and a pointer to the primitive surface on which it lies. The primitive surface is a three-dimensional geometric surface parameterized by two variables ( $u$  and  $v$ ). The surface boundary consists of closed loops (contours) of edges. Each edge is attached to two surfaces, and each edge contains the  $u$  and  $v$  values of the portion of the boundary that it forms for both surfaces. Surface boundaries are traversed clockwise around the outside of a surface, so an edge has a direction in each surface with respect to the direction of traversal.

Other data found in the surface structure includes the rectangular extents of the two-dimensional domain, the three-dimensional surface, and a flag indicating whether the surface normal points towards the inside or outside of the part. The user data is intended for run-time use only, and this information is not stored with the surface.

This section describes the surface data structures. The data structures are listed in order of complexity. For ease of use, the alphabetical listing of the data structures is as follows:

- [Cone on page 2081](#)
- [Coons Patch on page 2084](#)
- [Cylinder on page 2080](#)
- [Cylindrical Spline Surface on page 2089](#)
- [Fillet Surface on page 2085](#)
- [Foreign Surface on page 2090](#)
- [General Surface of Revolution on page 2082](#)
- [NURBS Surface on page 2087](#)

- [Plane on page 2080](#)
- [Ruled Surface on page 2083](#)
- [Second Derivative Spline Surface on page 2087](#)
- [Spline Surface on page 2086](#)
- [Tabulated Cylinder on page 2084](#)
- [Torus on page 2082](#)

## Plane

### Plane

The plane entity consists of two perpendicular unit vectors ( $e1$  and  $e2$ ), the normal to the plane ( $e3$ ), and the origin of the plane.

#### Data Format:

$e1[3]$             Unit vector, in the  $u$  direction  
 $e2[3]$             Unit vector, in the  $v$  direction  
 $e3[3]$             Normal to the plane  
 $origin[3]$        Origin of the plane

#### Parameterization:

$(x, y, z) = u * e1 + v * e2 + origin$

## Cylinder

### Cylinder

The generating curve of a cylinder is a line, parallel to the axis, at a distance  $R$  from the axis. The radial distance of a point is constant, and the height of the point is  $v$ .

#### Data Format:

e1[3]            Unit vector, in the u direction  
e2[3]            Unit vector, in the v direction  
e3[3]            Normal to the plane  
origin[3]        Origin of the plane  
radius           Radius of the cylinder

#### Parameterization:

$$(x, y, z) = \text{radius} * [\cos(u) * e1 + \sin(u) * e2] + v * e3 + \text{origin}$$

#### Engineering Notes:

For the cylinder, cone, torus, and general surface of revolution, a local coordinate system is used that consists of three orthogonal unit vectors ( $e1$ ,  $e2$ , and  $e3$ ) and an origin. The curve lies in the plane of  $e1$  and  $e3$ , and is rotated in the direction from  $e1$  to  $e2$ . The  $u$  surface parameter determines the angle of rotation, and the  $v$  parameter determines the position of the point on the generating curve.

## Cone

### Cone

The generating curve of a cone is a line at an angle  $\alpha$  to the axis of revolution that intersects the axis at the origin. The  $v$  parameter is the height of the point along the axis, and the radial distance of the point is  $v * \tan(\alpha)$ .

#### Data Format:

e1[3]            Unit vector, in the u direction  
e2[3]            Unit vector, in the v direction  
e3[3]            Normal to the plane  
origin[3]        Origin of the cone  
 $\alpha$             Angle between the axis of the cone  
                 and the generating line

#### Parameterization:

$$(x, y, z) = v * \tan(\alpha) * [\cos(u) * e1 + \sin(u) * e2] + v * e3 + \text{origin}$$

## Torus

### Torus

The generating curve of a torus is an arc of radius  $R_2$  with its center at a distance  $R_1$  from the origin. The starting point of the generating arc is located at a distance  $R_1 + R_2$  from the origin, in the direction of the first vector of the local coordinate system. The radial distance of a point on the torus is  $R_1 + R_2 * \cos(v)$ , and the height of the point along the axis of revolution is  $R_2 * \sin(v)$ .

#### Data Format:

```
e1[3] Unit vector, in the u direction
e2[3] Unit vector, in the v direction
e3[3] Normal to the plane
origin[3] Origin of the torus
radius1 Distance from the center of the
 generating arc to the axis of
 revolution
radius2 Radius of the generating arc
```

#### Parameterization:

```
(x, y, z) = (R1 + R2 * cos(v)) * [cos(u) * e1 +
 sin(u) * e2] + R2 * sin(v) * e3 +
 origin
```

## General Surface of Revolution

### General Surface of Revolution

A general surface of revolution is created by rotating a curve entity, usually a spline, around an axis. The curve is evaluated at the normalized parameter  $v$ , and the resulting point is rotated around the axis through an angle  $u$ . The surface of revolution data structure consists of a local coordinate system and a curve structure.

#### Data Format:

```
e1[3] Unit vector, in the u direction
e2[3] Unit vector, in the v direction
e3[3] Normal to the plane
origin[3] Origin of the surface of revolution
curve Generating curve
```

#### Parameterization:

```
curve(v) = (c1, c2, c3) is a point on the curve.
(x, y, z) = [c1 * cos(u) - c2 * sin(u)] * e1 +
 [c1 * sin(u) + c2 * cos(u)] * e2 +
 c3 * e3 + origin
```

## Ruled Surface

### Ruled Surface

A ruled surface is the surface generated by interpolating linearly between corresponding points of two curve entities. The  $u$  coordinate is the normalized parameter at which both curves are evaluated, and the  $v$  coordinate is the linear parameter between the two points. The curves are not defined in the local coordinate system of the part, so the resulting point must be transformed by the local coordinate system of the surface.

#### Data Format:

```
e1[3] Unit vector, in the u direction
e2[3] Unit vector, in the v direction
e3[3] Normal to the plane
origin[3] Origin of the ruled surface
curve_1 First generating curve
curve_2 Second generating curve
```

#### Parameterization:

```
(x', y', z') is the point in local coordinates.
(x', y', z') = (1 - v) * C1(u) + v * C2(u)
(x, y, z) = x' * e1 + y' * e2 + z' * e3 + origin
```

## Tabulated Cylinder

### Tabulated Cylinder

A tabulated cylinder is calculated by projecting a curve linearly through space. The curve is evaluated at the  $u$  parameter, and the  $z$  coordinate is offset by the  $v$  parameter. The resulting point is expressed in local coordinates and must be transformed by the local coordinate system to be expressed in part coordinates.

#### Data Format:

e1[3] Unit vector, in the  $u$  direction  
e2[3] Unit vector, in the  $v$  direction  
e3[3] Normal to the plane  
origin[3] Origin of the tabulated cylinder  
curve Generating curve

#### Parameterization:

$(x', y', z')$  is the point in local coordinates.  
 $(x', y', z') = C(u) + (0, 0, v)$   
 $(x, y, z) = x' * e1 + y' * e2 + z' * e3 + \text{origin}$

## Coons Patch

### Coons Patch

A Coons patch is used to blend surfaces together. For example, you would use a Coons patch at a corner where three fillets (each of a different radius) meet.

#### Data Format:

le_curve	$u = 0$ boundary
ri_curve	$u = 1$ boundary
dn_curve	$v = 0$ boundary
up_curve	$v = 1$ boundary
point_matrix[2][2]	Corner points
uvder_matrix[2][2]	Corner mixed derivatives

## Fillet Surface

### Fillet Surface

A fillet surface is found where a round or a fillet is placed on a curved edge, or on an edge with non-constant arc radii. On a straight edge, a cylinder would be used to represent the fillet.

#### Data Format:

pnt_spline	$P(v)$ spline running along the $u = 0$ boundary
ctr_spline	$C(v)$ spline along the centers of the fillet arcs
tan_spline	$T(v)$ spline of unit tangents to the axis of the fillet arcs

#### Parameterization:

$$R(v) = P(v) - C(v)$$

$$(x, y, z) = C(v) + R(v) * \cos(u) + T(v) \times R(v) * \sin(u)$$

## Spline Surface

### Spline Surface

The parametric spline surface is a nonuniform bicubic spline surface that passes through a grid with tangent vectors given at each point. The grid is curvilinear in  $uv$  space. Use this for bicubic blending between corner points.

#### Data Format:

<code>u_par_arr[]</code>	Point parameters, in the $u$ direction, of size $Nu$
<code>v_par_arr[]</code>	Point parameters, in the $v$ direction, of size $Nv$
<code>point_arr[][3]</code>	Array of interpolant points, of size $Nu \times Nv$
<code>u_tan_arr[][3]</code>	Array of $u$ tangent vectors at interpolant points, of size $Nu \times Nv$
<code>v_tan_arr[][3]</code>	Array of $v$ tangent vectors at interpolant points, of size $Nu \times Nv$
<code>uvder_arr[][3]</code>	Array of mixed derivatives at interpolant points, of size $Nu \times Nv$

#### Engineering Notes:

- Allows for a unique  $3 \times 3$  polynomial around every patch.
- There is second order continuity across patch boundaries.
- The point and tangent vectors represent the ordering of an array of  $[i][j]$ , where  $u$  varies with  $i$ , and  $v$  varies with  $j$ . In walking through the `point_arr[][3]`, you will find that the innermost variable representing  $v(j)$  varies first.

## Second Derivative Spline Surface

The Second Derivative Spline Surface (`ProSpline2ndDersrfddata`) is a bicubic spline surface with possibility of altering the degree of boundary segments to accommodate corresponding curvature (2nd derivatives) conditions. Use this for bicubic blending with second degree derivatives along boundaries.

<code>u_par_arr[]</code>	Point parameters, in the u direction, of size Nu
<code>v_par_arr[]</code>	Point parameters, in the v direction, of size Nv
<code>point_arr[][3]</code>	Array of interpolant points, of size Nu x Nv
<code>u_tan_arr[][3]</code>	Array of u tangent vectors at interpolant points, of size Nu x Nv
<code>v_tan_arr[][3]</code>	Array of v tangent vectors at interpolant points, of size Nu x Nv
<code>uvder_arr[][3]</code>	Array of mixed derivatives at interpolant points, of size Nu x Nv
<code>(*u_der2_arrs[2])[3]</code>	2 Arrays of 2nd U derivatives along V boundaries interpolation points, size of Nv.
<code>(*v_der2_arrs[2])[3]</code>	2 Arrays of 3rd V derivatives along U boundaries interpolation points, size of Nu.
<code>(*uuv_der[2])[3]</code>	2 Arrays of uuv mixed derivatives along V boundaries interpolation points, size of Nv.
<code>(*vvu_der[2])[3]</code>	Arrays of vvu mixed derivatives along U boundaries interpolation points, size of Nv.
<code>der4[4][3] UUVV</code>	derivatives at the corners

Engineering notes:

- Each second degree derivatives array can be `NULL`. If it is defined then corresponding 3rd degree mixed derivatives should be defined.
- Each `der4` can be `NULL` and should be defined if 2nd degree derivatives are defined in both directions at the corresponding corner.

## NURBS Surface

The NURBS (nonuniform rational B-spline) surface is defined by basis functions (in u and v), expandable arrays of knots, weights, and control points.

## NURBS Surface

### Data Format:

deg[2] Degree of the basis functions (in u and v)

u\_par\_arr[] Array of knots on the parameter line u

v\_par\_arr[] Array of knots on the parameter line v

wghts[] Array of weights for rational NURBS, otherwise NULL

c\_point\_arr[][3] Array of control points

### Definition:

$$R(u,v) = \frac{\sum_{i=0}^{N1} \sum_{j=0}^{N2} C_{i,j} \times B_{i,k}(u) \times B_{j,l}(v)}{\sum_{i=0}^{N1} \sum_{j=0}^{N2} w_{i,j} \times B_{i,k}(u) \times B_{j,l}(v)}$$

k = degree in u

l = degree in v

N1 = (number of knots in u) - (degree in u) - 2

N2 = (number of knots in v) - (degree in v) - 2

B = basis function in u

B = basis function in v

w = weights

C = control points (x, y, z) \* w

### Engineering Notes:

The weights and f arrays represent matrices of size wghts[N1+1][N2+1] and c\_points\_arr[N1+1][N2+1]. Elements of the matrices are packed into arrays in row-major order.

---

## Cylindrical Spline Surface

The cylindrical spline surface is a nonuniform bicubic spline surface that passes through a grid with tangent vectors given at each point. The grid is curvilinear in modeling space.

### Cylindrical Spline Surface

#### Data Format:

```
e1[3] x' vector of the local coordinate system
e2[3] y' vector of the local coordinate system
e3[3] z' vector of the local coordinate system,
 which corresponds to the axis of revolution
 of the surface
origin[3] Origin of the local coordinate system
splsrfsf Spline surface data structure
```

#### The spline surface data structure contains the following fields:

```
u_par_arr[] Point parameters, in the
 u direction, of size Nu
v_par_arr[] Point parameters, in the
 v direction, of size Nv
point_arr[][3] Array of points, in cylindrical
 coordinates, of size Nu x Nv.
 The array components are as follows:
 point_arr[i][0] - Radius
 point_arr[i][1] - Theta
 point_arr[i][2] - Z
u_tan_arr[][3] Array of u tangent vectors.
 in cylindrical coordinates,
 of size Nu x Nv
v_tan_arr[][3] Array of v tangent vectors,
 in cylindrical coordinates,
 of size Nu x Nv
uvder_arr[][3] Array of mixed derivatives,
 in cylindrical coordinates,
 of size Nu x Nv
```

## Engineering Notes:

If the surface is represented in cylindrical coordinates ( $r, \theta, z$ ), the local coordinate system values ( $x', y', z'$ ) are interpreted as follows:

$$\begin{aligned}x' &= r \cos(\theta) \\y' &= r \sin(\theta) \\z' &= z\end{aligned}$$

A cylindrical spline surface can be obtained, for example, by creating a smooth rotational blend (shown in the figure on the previous page).

In some cases, you can replace a cylindrical spline surface with a surface such as a plane, cylinder, or cone. For example, in the figure, the cylindrical spline surface  $S_1$  was replaced with a cone

( $r_1 = r_2$ , and  $r_3 = r_4$  and  $r_1 \neq r_3$ ).

If a replacement cannot be done (such as for the surface  $S_0$  in the figure ( $r_a \neq r_b$  or  $r_c \neq r_d$ )), leave it as a cylindrical spline surface representation.

## Foreign Surface

The foreign surface consists of two perpendicular unit vectors ( $e_1$  and  $e_2$ ), the normal to the plane ( $e_3$ ), the origin of the plane and the foreign ID returned by the function `user_init_surf()`.

### Data Format:

<code>e1[3]</code>	Unit vector, in the u direction
<code>e2[3]</code>	Unit vector, in the v direction
<code>e3[3]</code>	Normal to the plane
<code>origin[3]</code>	Origin of the plane
<code>foreign_id</code>	Foreign ID returned by <code>user_init_surf()</code>

Parameterization is established by the Foreign Surface callback function `user_eval_surf()`.

## Edge and Curve Data Structures

The data structures are used to represent edges (line, arc, and spline) as well as the curves (line, arc, spline, and NURBS) within the surface data structures.

This section describes the edge and curve data structures, arranged in order of complexity. For ease of use, the alphabetical listing of the edge and curve data structures is as follows:

- [Arc on page 2091](#)
- [Line on page 2091](#)
- [NURBS on page 2087](#)
- [Spline on page 2092](#)
- [Ellipse on page 2093](#)

---

## Arc

The arc entity is defined by a plane in which the arc lies. The arc is centered at the origin, and is parameterized by the angle of rotation from the first plane unit vector in the direction of the second plane vector. The start and end angle parameters of the arc and the radius are also given. The direction of the arc is counterclockwise if the start angle is less than the end angle, otherwise it is clockwise.

### Data Format:

vector1[3]	First vector that defines the plane of the arc
vector2[3]	Second vector that defines the plane of the arc
origin[3]	Origin that defines the plane of the arc
start_angle	Angular parameter of the starting point
end_angle	Angular parameter of the ending point
radius	Radius of the arc.

### Parameterization:

$t'$  (the unnormalized parameter) is  
 $(1 - t) * \text{start\_angle} + t * \text{end\_angle}$   
 $(x, y, z) = \text{radius} * [\cos(t') * \text{vector1} + \sin(t') * \text{vector2}] + \text{origin}$

## Line

### Data Format:

end1[3]	Starting point of the line
end2[3]	Ending point of the line

### Parameterization:

$(x, y, z) = (1 - t) * \text{end1} + t * \text{end2}$

## NURBS

The NURBS (nonuniform rational B-spline) curve is defined by expandable arrays of knots, weights, and control points.

### Cubic NURBS Curve

#### Data Format:

degree                    Degree of the basis function  
params[]                 Array of knots  
weights[]                Array of weights for rational  
                             NURBS, otherwise NULL.  
c\_pnts[][3]             Array of control points

#### Definition:

$$R(t) = \frac{\sum_{i=0}^N C_i \times B_{i,k}(t)}{\sum_{i=0}^N w_i \times B_{i,k}(t)}$$

k = degree of basis function

N = (number of knots) - (degree) - 2

w = weights

C = control points (x, y, z) \* w

B = basis functions

By this equation, the number of control points equals N+1.

## Spline

The spline curve entity is a nonuniform cubic spline, defined by a series of three-dimensional points, tangent vectors at each point, and an array of unnormalized spline parameters at each point.

#### Data Format:

par\_arr[]                Array of spline parameters  
                             (t) at each point.  
pnt\_arr[][3]            Array of spline interpolant points  
tan\_arr[][3]            Array of tangent vectors at  
                             each point

#### Parameterization:

x, y, and z are a series of unique cubic functions, one per segment, fully determined by the starting and ending points, and tangents of each segment.

Let p\_min be the parameter of the first spline point, and p\_max be the parameter of the last spline point. Then, t', the unnormalized parameter, is t \* p\_max + (1-t) \* p\_min.

Locate the i<sup>th</sup> spline segment such that:

par\_arr[i] < t' < par\_arr[i+1]

(If t < 0 or t > +1, use the first or last segment.)

t0 = (t' - par\_arr[i]) / (par\_arr[i+1] - par\_arr[i])

---

```

t1 = (par_arr[i+1] - t') / (par_arr[i+1] - par_arr[i])
The coordinates of the points are then:
(x, y, z) = pnt_arr[i] * t1^2 * (1 + 2 * t0) +
 pnt_arr[i+1] * t0^2 * (1 + 2 * t1) +
 (par_arr[i+1] - par_arr[i]) * t0 * t1 *
 (tan_arr[i] * t1 - tan_arr[i+1] * t0)

```

## Ellipse

Ellipses in 3D geometry is split into two identical half-ellipses. The ellipse is defined by its major and minor axis radius values. Similar to arcs, elliptic segments are defined by a plane in which the ellipse lies, centered at the origin, and parameterized by the angle of rotation. The direction of the ellipse is counterclockwise if the start angle is less than the end angle, otherwise it is clockwise.

### Data Format:

```

center - Center point of the ellipse
major_axis_unit_vect - Direction for the X-axis of the ellipse
norm_axis_unit_vect - Direction for the Y-axis
major_len - The "radius" in the X-direction
minor_leng - The "radius" in the Y-direction
start_ang - The ellipse start angle
end_ang - The end angle for the ellipse

```

The y-axis can be found as a vector product of `norm_axis_unit_vect` on the `major_axis_unit_vect`. In actual examples, the `major_len` can be less than the `minor_len`.

### Parameterization:

```

t' (the unnormalized parameter) is
 (1 - t) * start_angle + t * end_angle
(x, y, z) = major_len * [cos(t') * vector1] +
 minor_len * [sin(t') * vector2] + origin

```

## Debugging Creo TOOLKIT

### Building a Creo TOOLKIT Application for Debugging

This section appendix describes how to debug Creo TOOLKIT applications.

---

The following tables list commonly used changes for sample makefiles that allow debugging of a Creo TOOLKIT application. Consult your compiler documentation for more information on the flags specified below and other debugging options.

On Windows

Compile Line Changes	Link Line Changes
Change CCFLAGS or CPPFLAGS to add /Od /Z7.	Change the /debug flag to /debug:full. Remove or comment the lines that delete \$(OBJ) after a successful build.

## Debugging Techniques

Depending on the type and implementation for your application, you can use one of the following debugging techniques:

- If your application is a DLL that creates user interface and notification callbacks to be used by the interactive user, refer to the following section on Debugging an Interactive DLL.
- If your application is a DLL that runs in batch mode (from `user_initialize()`), refer to [Debugging an Interactive DLL on page 2094](#).
- If your application is a spawn or asynchronous application, refer to [Debugging a Multiprocess Application on page 2096](#).

### Debugging an Interactive DLL

1. Start Creo Parametric with the DLL registered and loaded.
2. Use the debugger to attach to the process `xtop.exe`.
3. Set breakpoints in the callback functions that you wish to debug.

## Debugging\_a\_Batch\_Mode\_DLL

### Debugging\_a\_Batch\_Mode\_DLL

Debugging Without Setting Breakpoints Before Loading Code

The following steps outline the procedure to debug applications using a debugger such as `dbx` that does not allow breakpoints to be set before the code is loaded.

1. Setup a Creo Parametric `start` command that uses the debugger as follows:
  - a. Edit the `parametric.psf` file (or the related `psf` file for the given command).
  - b. In this file change the `RUN` line for `xtop`, to invoke the debugger first, as:

---

```
RUN="$PRO_DIRECTORY/bin/parametric1"
```

```
RUN="dbx $PRO_DIRECTORY/bin/parametric1"
```

2. Run the Creo Parametric `start` command. The debugger starts.
3. Set up a breakpoint that triggers when the DLL is loaded.

In dbx, enter `stop dlopen <DLL name>` For example, `stop dlopen pt_inst_test.dll`.

If you are using a graphical debugger such as Sun's Workshop, the same procedure is possible. Workshop allows a "CUSTOM" breakpoint using dbx syntax, such as `dlopenpt_inst_test.dll`.

4. Enter `run`. The program runs to the point of loading the DLL.
5. When the `dlopen` breakpoint is triggered, add a breakpoint to `user_initialize()`. At this point, the DLL is loaded and the `user_initialize()` function is in memory.

### Debugging With Breakpoints Set Before Loading Code

The following steps outline the procedure to debug applications using a debugger such as Microsoft Visual Studio that allows breakpoints to be set before the code is loaded.

1. Setup a Creo Parametric `start` command that uses the debugger as follows:
  - a. Edit the `parametric.psf` file (or the related `psf` file for the given command).
  - b. In this file, change the `RUN` line for `xtop`, to invoke the debugger first as:

```
RUN="%PRO_DIRECTORY%\%PRO_MACHINE_TYPE%\obj\
xtop.exe"
```

```
RUN=devenv
```

```
"%PRO_DIRECTORY%\%PRO_MACHINE_TYPE%\obj\
xtop.exe"
```

2. Run the Creo Parametric `start` command. The debugger starts.
3. Load the source file containing the functions into the debugger, and graphically set a breakpoint to the start of `user_initialize()`.
4. Run the program from the debugger User Interface. Even if the debugger indicates that no debugger information is available for `xtop.exe`, continue debugging.

When the DLL is loaded, the program will stop in the DLL's `user_initialize()`.

---

## Debugging Creo TOOLKIT DLLs on Windows

The Creo Parametric executable contains a default exception handler on Windows. This handler will catch and react to exceptions generated by a Creo TOOLKIT DLL by default.

To allow debugging on Windows without using the Creo Parametric exception handler, set the environment variable `ALLOW_MS_DEBUG` to `true` in the Control Panel.

Setting `ALLOW_MS_DEBUG` to `true` forces Creo Parametric executable not to execute the exception handler and thus the process will stop in the debugger on any exception. Alternatively, it is possible to set exception handling in the debugger to stop on the first occurrence of the exception, even for exceptions that are handled.

## Debugging a Multiprocess Application

### Debugging a Synchronous Spawn Mode Application

1. Start Creo Parametric with the application registered and started.
2. Use the debugger to attach to the application process, for example `pt_inst_test.exe`.
3. Set breakpoints in the callback functions that you wish to debug.

### Debugging a Synchronous Spawn Mode Application

1. Start Creo Parametric with the application registered and started.
2. Use the debugger to attach to the application process, for example `pt_inst_test.exe`.
3. Set breakpoints in the callback functions that you wish to debug.

### Debugging an Asynchronous Spawn Mode Application

1. Start the application from the debugger. Set a breakpoint to stop the application before the call to `ProEngineerStart()` or `ProEngineerConnect()`.
